yalnsour@pmu.edu.sa

Abstract: The healthcare sector in the Kingdom of Saudi Arabia (KSA) is currently going through a substantial reform aligned to the key objectives of Saudi Vision 2030, which basically emphasizes healthcare operations efficiency, supply chain excellence, waste management, and sustainable development. Healthcare institutions are facing undue inventory and waste-related concerns due to demand apprehension despite massive investments in healthcare infrastructure. AI and data analytics present influential possibilities to change healthcare supply chain management. To meet the need for healthcare, an efficient and robust supply chain system is required to meet the ever-growing demand that is increasingly becoming paramount. This study aims to investigate how AI and predictive analytics could help address the identified issues related to inventory management, waste reduction, and supply chain resilience.AI-based forecasting is supported by the use of statistical models, machine learning, software algorithms, and data mining methods as fundamental for predictive decisions. In the face of ever-rising research on artificial intelligence (AI) and predictive analytics, there is a need for healthcare supply chain management scholarly attention. This study intends to bridge the gap by developing a research framework and discussing sustainable healthcare supply chain performance in Saudi Arabia. A mixed methodological approach is considered in carrying out this study. Both quantitative and qualitative data are used in this study to achieve a broader understanding of this study, specifically in terms of AI-enabled forecasting. The authors intend to enhance the reliability, validity, and overall rigor in this research using a triangulation approach. The research findings provide practical evidence about the existing role of AI applications and their perceived impact on healthcare supply chains in the context of Saudi Arabia.

Keywords: Artificial intelligence, Predictive analytics, Demand forecasting, Healthcare supply chain, Sustainability management, Saudi Vision 2030

1. Introduction

The healthcare sector in the Kingdom of Saudi Arabia (KSA) is currently going through a substantial reform aligned to the key objectives of Saudi Vision 2030, which basically emphasizes healthcare operations efficiency, supply chain excellence, waste management, and sustainable development. According to the International Trade Administration, Saudi Arabia represents approximately 60% of total healthcare spending across the Gulf Cooperation Council (GCC) countries, which verifies this sector's strategic importance as well as the digital transformation as a priority for the Saudi government (2026). Healthcare supply chain management is essential to ensure uninterrupted availability of pharmaceuticals, medical devices, equipment, and other supplies. (Al Zaied et al., 2026). However, by implementing an AI-based forecasting approach, healthcare institutions can constantly improve their efficiency by improving supply chain performance. AI-based healthcare systems are transforming hospital logistics through demand forecasting, inventory management, and automation (Alshehri et al., 2025).

Healthcare institutions are facing excessive inventory stock and waste management issues due to demand uncertainty despite large investments in healthcare infrastructure (Ghamedi, 2025). The agility to respond to abruptly changing medical care demands and emergency situations requires incorporating an emerging digital technology-based healthcare system for accurate data analysis. This will help address key existing challenges across the sector for overstocking, inventory obsolescence, premature expiration, operating costs, and environmental issues arising from unnecessary waste and emissions. As a result, healthcare providers and regulators are increasingly seeking innovative techniques to improve supply chain performance while supporting sustainability objectives (Acharjya & Dash, 2025).

The emergence of Artificial Intelligence (AI) and advanced analytics technologies yields significant opportunities to transform healthcare supply chain management. AI-driven demand forecasting systems utilize machine learning algorithms, predictive analytics, and data processing in real-time to accurately assess future demand patterns and support preemptive decision-making (Al-Romeedy, 2026). The healthcare system integrating AI and data analytics from patient records helps to anticipate disease trends, seasonal demands, and consumption needs. This assists in waste reduction, stock shortages, and overall supply chain competence. This means AI-

based operations management in healthcare enables agile and resilient swift response to the changing market conditions (Tiwari, 2026).

Adoption of AI technologies conforms to the national digital transformation agenda and the strategic priorities outlined in Saudi Vision 2030. The Saudi Data and Artificial Intelligence Authority (SDAIA) is carrying out new initiatives to promote AI-based demand forecasting for operations efficiency and waste management (Alshwaier and Abdullah, 2025). These efforts aim to accelerate the application of digital technologies across healthcare sectors to improve operational efficiency, promote innovation, and support sustainable economic development. Predictive decisions that are supported by AI provide strategic directions for healthcare supply chains. This will help in improving the quality of services while maintaining environmental sustainability. In addition, to prioritize social and economic sustainability (Thiyagarajan et al., 2026).

2. Problem Statement

The healthcare sector in Saudi Arabia is currently transforming to meet the growing demand due to an increasing population and urbanization. To meet the need for healthcare, an efficient and robust supply chain system is required to meet the ever-growing demand that is increasingly becoming paramount (Mani & Goniewicz, 2024; Al-Anezi, 2025; Saudi Vision 2030). Despite considerable investments in healthcare infrastructure and digital transformation initiatives, many healthcare organizations continue to rely on conventional demand forecasting and inventory monitoring that are often unable to accurately predict changing demand for medical supplies, pharmaceuticals, and healthcare equipment.

The use of inaccurate information or lack of accessibility to accurate data in real-time can be the main cause of inappropriate decisions resulting in oversupply or understocking pharmaceutical supply chains. Bwalya and Mutono-Mwanza (2025) emphasized that stock shortages and oversupply would undermine patient care and disrupt clinical operations. Likewise, Nair et al. exclaimed that rising procurement, storage, and logistics costs put additional financial pressure on healthcare institutions, while reducing overall operational capability (2024).

The ease of accessing precise data in real time is one of the core challenges in the context of healthcare used by staff, providers, suppliers, and logistics partners. The unavailability of reliable real-time data delays supply chains and hinders effective decision-making (Delgado et al., 2025). As a result of a lack of pre-defined data, the supply chain performance becomes reactive rather than predictive. To address this problem, AI-driven forecasting offers significant improvement in predictive decisions. This approach helps in forecast precision, inventory optimization, risk mitigation, and supply chain modification. The conceptual framework (Figure 1) illustrates the role of AI-driven demand forecasting in supporting operational efficiency, inventory optimization, and waste management to achieve healthcare supply chain management.

3. Research Objectives

In this study, researchers examine the role of decision-making in improving supply chain performance in Saudi Arabia's health sector, as this supports KSA’s Vision 2030. This research study aims to investigate how AI and predictive analytics could help address the identified issues related to inventory management, waste reduction, and supply chain resilience.

The main objectives of the research study are:

- Examining the influence of Artificial Intelligence in boosting healthcare supply chain efficiency in Saudi Arabia.
- Assessing the effectiveness of AI-based demand forecasting in lowering waste and fostering sustainability.
- Evaluating the impact of AI-enabled forecasting on inventory optimization and cost reduction.

4. Literature Review

Sustainable supply chain management is an essential part of the healthcare system. Recent academic literature and contemporary industry reports indicate that AI-driven demand forecasting can help bridge the gap identified in recent theoretical and empirical studies. This reveals that inventory optimization, operational efficiency, supply chain visibility, and waste management are core elements in improving sustainable healthcare supply chain performance.

4.1 Artificial Intelligence in Healthcare

In the recent academic literature, it is identified that AI is currently capable of replicating human cognitive capabilities, including learning, reasoning, problem-solving, and decision-making patterns (Ofosu-Ampong, 2024). The merging of AI in the healthcare system supports machine learning, deep learning, natural language, vision systems, expert systems, and decision support systems. AI contributes significantly to play a significant role in reshaping healthcare operations through advanced disease diagnosis. This leads to improved patient monitoring, clinical decision support, and more effective management of healthcare resources and operational processes (Aiwerioghene and Osuchukwu, 2025). It is evident from AI adoption, which is gaining extensive support under the charter of Saudi Vision 2030 and the National Strategy for Data and Artificial Intelligence (NSDAI). The academic literature clearly supports such proclamation by emphasizing digital transformation and technological innovation across the healthcare sector in Saudi Arabia (Mufleh et al., 2026). Healthcare institutions successively incorporate AI-based remedies to boost resource utilization, advance service quality, and grow healthcare openness. The widespread implementation of AI is now a strategic drive to further enhance the performance, agility, and sustainability of supply chain systems.

4.2 Predictive Analytics and Demand Forecasting in Healthcare

AI-based forecasting is supported by the use of statistical models, machine learning, software algorithms, and data mining methods as fundamental for predictive decisions (Aljohani, 2023). This plays a decisive role in forecasting demand, optimizing inventory levels, and supporting resource deployment for the healthcare supply chain management. However, clear and precise demand forecasting remains an essential challenge in effectively predicting the availability of critical medical supplies avoiding overstocking or undersupply. The use of predictive patterns in the healthcare supply chain employs innovative tactics by balancing stock, inventory, operations, and wastage. Big data analytics assist healthcare providers in making proactive decisions that improve both financial and operational outcomes by improving the inventory panorama and demand landscape (Al Khatib et al., 2024). In Saudi Arabia, the growing need for healthcare data and electronic health records brings new opportunities because of predictive analytics uses. The incorporation of predictive models supports healthcare organizations in improving their demand and supply fluctuations while contributing to sustainable supply chain management.

4.3 Healthcare Supply Chain Management and Sustainability

Worldwide, there is increasing demand for sustainability in the healthcare supply chain. This is shifting the paradigm by positioning technological innovation as a strategic priority for healthcare organizations. This leads to a rising requirement for sustainable supply chains even with geopolitical and pandemic disruptions. However, there are concerns about environmental degradation, excessive resource consumption, unnecessary waste, and process inefficiencies. It is affirmed that there is a need for a strategic drive to address the healthcare logistics challenges in the present Middle East political landscape, directly affecting Saudi Arabia's healthcare supply chain performance. Balancing economic performance and environmental sustainability to create social value is one of the key objectives of a sustainable healthcare supply chain. The quest is to reduce carbon footprints while optimizing resource usage and increasing operational efficiency in healthcare services (Nami et al., 2025). The literature review highlights similar ideas through expanding the role of digital technologies, particularly AI advocating sustainability in the healthcare supply chains.

4.4 Artificial Intelligence in Supply Chain Management

AI-based healthcare supply chain management is reshaping traditional SCM networks i.e., upstream and downstream supply chains. It is offering intelligent decision frameworks by driving a shift from reactive to proactive approaches. AI-based technologies influence substantial datasets from numerous supply chain stakeholders, including suppliers, distributors, healthcare institutions, and end users, to produce accurate forecasts and actionable insights (Vadaga et al., 2025). Champa and Segall stated that an AI-based forecasting system presents predictive performance by exposing hidden patterns in large datasets (2024). They further mentioned that it might not be possible to detect such patterns through conventional analytical methods. The literature review affirms that these AI capabilities can enable healthcare institutions to improve their inventory planning. It is also reassuring that it helps reduce the risk of stockouts and overstocking and enhances operational efficiency. The recent literature shows how AI incorporation in healthcare institutions leads to greater supply chain responsiveness and elasticity by backing in-time decision-making with dynamic responses to unexpected disruptions.

4.5 AI and Predictive Analytics in Healthcare Supply Chains

Academic research demonstrates how AI and data analytics back transformation in the healthcare supply chain management. Giachino et al. (2025) considered that data analytics help in predictive decisions enabling healthcare institutions to effectively forecast their demand and operational requirements. As mentioned by Rezaei (2025) that AI fortifies predictive capabilities through machine learning, pattern recognition, and automated decision-making processes. This means, technological innovation helps in enhanced performance gains through in business processes redesign (Khilji, 2026). Together, these technologies support more accurate, data-driven forecasting and contribute to the development of sustainable healthcare supply chains. AI-driven demand forecasting helps examine historical and real-time data to predict demand with greater accuracy (Khilji et al., 2026). However, AI-powered technologies are continuously advancing with new information, whereas healthcare needs are continuously evolving. The emerging systems use advanced algorithms to better understand market fluctuations and operational conditions to provide an enhanced forecasting performance (Alsehani, 2026).

5. Research gap

In the face of ever-rising research on artificial intelligence (AI) and predictive analytics, there is a need for healthcare supply chain management scholarly attention. The identified gap can be filled by conducting more academic work toward understanding AI-driven demand forecasting. This study intends to bridge the gap by discussing sustainable healthcare supply chain performance in Saudi Arabia. The existing literature primarily emphasizes technological aspects for achieving accurate forecasting models and their impact on operational efficiency. However, this study is more focused on business process reformation towards the underlying mechanisms in AI-enabled forecasting for improved sustainability. This study in particular investigates how to develop empirical evidence regarding the mediating roles of AI-based systems. This study assesses inventory optimization, supply chain visibility, and resource utilization while translating forecasting capabilities into meaningful reductions in healthcare waste. To address the identified gap, the proposed conceptual model is graphically presented in Figure 1.

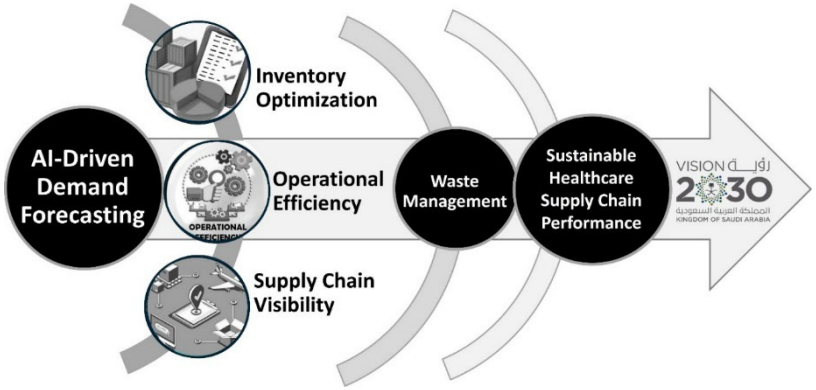

Figure 1: Proposed conceptual framework for sustainable healthcare supply chain performance (Authors, 2026)

6. Research Methodology

A mixed methodological approach is considered in carrying out this study. The AI-driven demand forecasting is studied to examine how technology plays an important role in enhancing healthcare operational efficiency and supply chain sustainability. A mixed method justifies the complex and multidimensional nature of healthcare supply chain management. The study examines operational processes in healthcare institutions across Saudi Arabia to identify key factors influencing the effective implementation of AI technologies. Both quantitative and qualitative data are used in this study to achieve a broader understanding of this study specifically in terms of AI-enabled forecasting. The current research aims at establishing the factors that can be used to promote better inventory management, efficient resource allocation, reduced waste, and supply chain resilience. This methodology will serve the triangulation methodology well as a way of validating the findings from this study. It is, therefore, critical for the researcher to validate his or her findings as valid, reliable, and robust. The findings will be useful as empirical evidence to both healthcare institutions and policymakers based on KSA Vision 2030.

6.1 Research Design

The research design uses a mixed-methods approach to investigate the impact of AI-driven demand forecasting on Saudi Arabia's healthcare supply chains. The study examines the multifaceted landscape of healthcare supply chain operations through empirical assessment of quantifiable supply chains performance. However, for an in-depth understanding of healthcare institutions. It is believed to examine both technological and managerial factors influencing effective AI implementation. Quantitative and qualitative research methods foster a comprehensive study of AI-based demand forecasting. The mixed approach is considered to help in this study to inspect the contribution of specified factors in supply chain optimization, decision-making effectiveness, and sustainability performance. Mixed-methods research is generally credited for its capability to create a complete understanding of the complex hypothesis through the combination of complementary forms of evidence (Bracio & Szarucki, 2020).

The analysis of data sets from mixed methods provides support in the identified challenges associated with the combination of advanced forecasting systems. The research results from the mixed approach provide deeper insights into the mechanisms around AI technologies influencing decision-making processes. The approach helps in addressing research objectives to examine inventory management practices and sustainability initiatives in the healthcare supply chain management. This means the combination of qualitative and quantitative confirmation augments the strength of this study by capturing artificial intelligence measurable consequences and human intelligence critical experiences (Rana and Chimoriya, 2025).

6.2 Data Collection

This study employs a multi-source data collection approach during fieldwork to achieve the research objectives. The data collection methods comprise a survey, semi-structured interviews, and a systematic literature review of relevant literature. The mixed methods approach is helpful to achieve higher reliability and validity of the key findings. The approach accumulated evidence from both quantitative and qualitative means. However, the findings in this format strengthen robust findings about the role of Artificial Intelligence (AI)-driven demand forecasting in improving sustainability and operational efficiency within healthcare supply chains in Saudi Arabia.

6.3 Survey Data Collection

A structured questionnaire is developed to collect primary quantitative data in this study. The questionnaire was distributed to 10 healthcare institutions in Saudi Arabia, targeting 250 respondents. A total of 216 questionnaires were returned, of which 202 were deemed valid and suitable for analysis. Consequently, 202 responses were successfully recorded and processed, resulting in a valid response rate of 80.8%, which indicates a satisfactory survey completion rate. The gender ratio of respondents is 60% to 40% between Female and Male respectively. The survey is conducted based on research ethics and participants' consent to voluntarily take part. However, the majority of participants are among public and private hospitals, healthcare centers, pharmaceutical organizations, and supply chain service providers. The survey targets mainly those professionals involved in activities related to healthcare supply chain management. The categories of the respondents include supply chain managers, procurement managers, logistics coordinators, inventory managers, and healthcare administrators.

6.4 Semi-structured Interviews

The qualitative data is collected using the semi-structured interviews with key stakeholders involved in healthcare supply chain management. Participants are requested to take part voluntarily after confirming their consent. The voluntary participants include hospital administrators as well as supply chain managers, procurement professionals, healthcare policymakers, IT specialists, and experts in AI, BDA, and digital transformation. Qualitative data are collected through semi-structured interviews to better understand participants' backgrounds, expertise, and perspectives on adopting AI-driven forecasting systems.

6.5 Systematic Literature Review

A systematic literature review is conducted for secondary data analysis by examining contemporary academic literature, industry public reports, and policy-guided documents in addition to primary data collection. This method is valuable for reviewing studies focusing on AI, data analytics, healthcare supply chain management, demand forecasting, and sustainability. However, particular attention is paid to research relevant to Saudi Arabia's healthcare sector and to the objectives of Saudi Vision 2030. The mix of data sets from surveys, interviews, and the literature provides a comprehensive understanding of the effective role about AI-driven demand forecasting in developing sustainable, resilient, and efficient healthcare supply chains in Saudi Arabia.

6.6 Research Hypotheses

This study proposes five hypotheses, based on the literature review and research fieldwork in order to assess the impact of AI-based demand forecasting on the performance of the healthcare supply chain. These hypotheses provide a clear empirical framework for testing the study objectives using a mixed-methods methodology.

H1: *AI-driven demand forecasting has a positive impact the healthcare supply chain performs.*

H2: *Adopting AI helps improve inventory optimization.*

H3: *Forecasting with AI can greatly reduce waste in the healthcare supply chain.*

H4: *Using AI can make operations more cost-efficient.*

H5: *AI-based forecasting can strengthen the resilience of the healthcare supply chain.*

In the final stage of analysis, a triangulation is applied of data obtained from surveys, interviews, and literature review. This is beneficial to cross-verify research findings, reduce bias, and increase the validity and reliability of research conclusions. A thematic model is developed to map relationships between core variables based on above five research hypotheses, serving as the blueprint for data triangulation in this study.

7. Research Findings

In the final phase of this study, research key findings represent how the identified variables achieving the set objectives by examining the influence of AI inspiring Saudi Arabia's healthcare supply chain. The final result is practically reviewing the use of AI-based demand forecasting in reducing waste and fostering sustainability, while adequately assessing its impact on inventory optimization and cost reduction. The following table indicates an integrated comparative evaluation between quantitative and qualitative data analysis (Table 1).

Table 1: Comparative Evaluation of Quantitative and Qualitative Data

Quantitative Results	Qualitative Evidence
Statistical relationships	Stakeholder experiences
Measured AI impacts	Practical implementation insights
Operational outcomes	Leadership and Organizational challenges
Sustainability indicators	Strategic perspectives
Performance metrics	Employee perceptions
Productivity improvements	User satisfaction narratives
Financial outcomes	Decision-making processes
Adoption rates	Barriers to adoption
Efficiency gains	Contextual explanations
Risk measurements	Risk perceptions and concerns
Innovation indicators	Innovation culture and practices
Customer satisfaction scores	Customer feedback and testimonials
Resource utilization metrics	Organizational capability assessments
Environmental, Social, Governance (ESG) scores	Sustainability narratives and commitments
Sustainability Indicators	Strategic Perspectives

The pairings in this mixed-method provides an effective mixed-methods comparative analysis by showing not only what happened (quantitative) but also why and how it happened (qualitative). This is followed by applying a triangulation, which has confirmed the strength of final results by satisfactory validity and credibility although the final outcome is delivering an inclusive understanding of how AI-driven demand forecasting contributes to sustainable healthcare supply chains in Saudi Arabia.

The collected data analysis further illustrates a total of 202 participants involved in this study with 23% from private hospital and healthcare centers and 24% from pharmaceutical companies followed by 18.5% from healthcare logistics. The voluntary participants are among Saudi Arabia's healthcare stakeholders with 47%

primary job responsibilities in supply chain, logistics and procurement. The majority of the participants work experience span lasts while 23.3% responses confirm that their organizations are almost fully implementing or at the pilot phase of implement of AI in their healthcare practices in contrast of 75.2% with no AI execution. From the data analysis it has been identified that 68% strongly agreed or agreed that their organizations are now actively integrating AI in their forecasting activities for predictive decision as graphically shown in the pie charts of Figure 2.

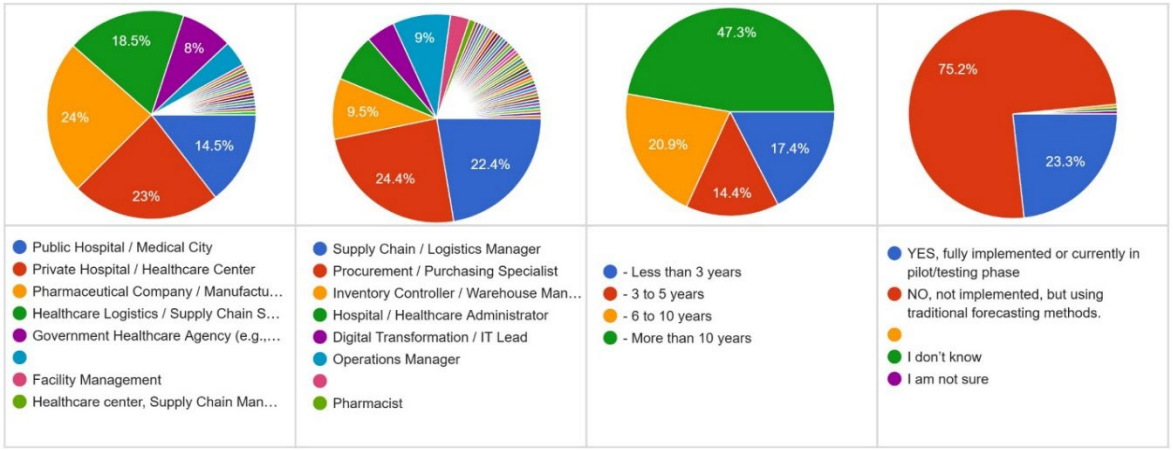

Figure 2: Data analysis for organizations' type, job role, years of experience, and AI integration (Authors, 2026)

In this study, researchers used mixed approach to test and validate research results. However, the quantitative analysis is conducted using data collected from 202 healthcare professionals in Saudi Arabia. The respondents were categorized into two groups: organizations that have already implemented AI-enabled demand forecasting (Adopters; n = 46-47) and organizations that have not yet implemented AI solutions (Non-Adopters; n = 149-150). The research outcomes ensure to support the empirical evidence regarding the efficacy of AI-based demand forecasting to improve the healthcare supply chain performance and sustainability.

The descriptive statistics reveal a high level of agreement among AI adopters regarding the positive impact of AI-driven forecasting on healthcare supply chain performance. Supply Chain Resilience recorded the highest mean score as indicated in the results such as (M = 4.159, SD = 0.785), followed by Inventory Performance (M = 4.113, SD = 0.799), AI Integration (M = 4.051, SD = 0.753), Sustainability Performance (M = 4.014, SD = 0.786), and Cost Efficiency (M = 3.884, SD = 0.783).

The research findings indicate that healthcare institutions are required to implement AI to perceive substantial improvements in operational effectiveness and strategic responsiveness. Non-adopters expressed strong expectations about the benefits of AI adoption. The highest mean score is observed for Expected Inventory Benefits (M = 4.219, SD = 0.694), followed by Expected Strategic Benefits (M = 4.069, SD = 0.787). Organizational readiness was moderate (M = 3.488, SD = 0.872), while perceived barriers to AI adoption are also relatively high (M = 3.893, SD = 0.638). These findings indicate that although healthcare organizations recognize the advantages of AI, implementation challenges remain significant, this is shown in the following Table 2.

Table 2: Research survey results tabulated to calculate mean (M) and standard of deviation (SD)

Construct	N	Mean	SD
AI Integration	46	4.051	0.753
Inventory Performance	47	4.113	0.799
Sustainability Performance	46	4.014	0.786
Cost Efficiency	46	3.884	0.783
Resilience	46	4.159	0.785
Organizational Readiness	149	3.488	0.872

Construct	N	Mean	SD
Expected Inventory Benefits	149	4.219	0.694
Expected Strategic Benefits	149	4.069	0.787
AI Adoption Barriers	150	3.893	0.638

Source: Survey Results (202 respondents).

7.1 Reliability Analysis

Cronbach's Alpha was used to assess internal consistency among the study constructs. All values exceeded the recommended threshold of 0.70, indicating satisfactory reliability and measurement consistency. The highest reliability score was observed for Resilience/Strategic Alignment (α = 0.915), followed by Inventory Performance (α = 0.900), Expected Inventory Benefits (α = 0.896), and Expected Strategic Benefits (α = 0.871). The overall reliability results confirm that the questionnaire items effectively measured their intended constructs (Table 3).

Table 3: Research survey results tabulated to calculate mean (M) and standard of deviation (SD)

Construct	Cronbach's Alpha
AI Integration	0.847
Inventory Performance	0.900
Sustainability Performance	0.807
Cost Efficiency	0.794
Resilience / Strategic Alignment	0.915
Organizational Readiness	0.761
Expected Inventory Benefits	0.896
Expected Strategic Benefits	0.871
AI Adoption Barriers	0.711

All values > 0.70 indicate acceptable reliability.

7.2 Correlation Analysis

The correlation analysis demonstrates strong positive relationships among the principal variables. However, among AI adopters, AI Integration exhibited a strong correlation with:

- Inventory Performance (r = 0.748)
- Sustainability Performance (r = 0.663)
- Cost Efficiency (r = 0.745)
- Supply Chain Resilience (r = 0.747)

These findings indicate that higher levels of AI integration are associated with better inventory control, improved sustainability outcomes, lower operational costs, and stronger supply chain resilience. Similarly, among non-adopters, Organizational Readiness was positively related to Expected Inventory Benefits (r = 0.331) and Expected Strategic Benefits (r = 0.285), suggesting that organizations with stronger digital readiness are more likely to recognize the value of AI implementation.

8. Discussion

The research study's final outcomes determine the effective role of AI in the healthcare supply chains. It verified that AI is already playing a crucial part in the transformation of healthcare SCM worldwide, including within

Saudi Arabia. The significant impact of AI is realized by many organizations across the board, although AI-Driven Demand forecasting can advance accuracy in predictive decisions, inventory optimization, and improved sustainability outcomes. The research results are consistent with other recent research studies covering the soaring value of data analytics and deep machine learning in contemporary healthcare operations productivity.

It is apparent from this study that advancement in accuracy prediction could be achieved through the incorporation of AI systems. This study contributes to rationalizing how AI and Predictive Analytics directly tackle the identified challenges in the problematic area by achieving the set objectives. The final findings acknowledged that traditional forecasting practices usually struggle to react with agility to vibrant healthcare supply chain situations in a volatile environment. AI-Driven demand forecasting actually adapts and keeps learning in a real-time approach from huge data analytics. As a result, healthcare supply chain performance can attain further enhancement in important day-to-day decisions regarding procurement, inventory control, and resource allocation.

AI-driven demand forecasting basically impacts substantially in terms of sustainability in SCM by reducing waste and supporting environmental objectives. However, to achieve such measures, the conceptual and pragmatic frameworks in this study validate how to achieve improvement by preventing excessive inventory accumulation and minimizing product expiration. At the same time, it is described that this way healthcare institutions can decrease their cost and, in contrast, they can improve their environmental impacts. These research results are pretty aligned with the sustainability goals highlighted in the Saudi Vision 2030. This study clearly contributes to the strategic drive for the digital transformation in healthcare supply chains. This leads to the successful consolidation of AI-based technologies for robust digital infrastructure development. The impactful data readiness further assists the responsive collaboration among healthcare providers, suppliers, technology vendors, and government agencies. This means that any organizations that are ready to confidently invest in such AI-driven capabilities are likely to succeed in their operational excellence and supply chain resilience.

9. Conclusion

This study examines the role of AI-driven demand forecasting in improving sustainability development and operational efficiency in healthcare supply chains in the context of KSA. The research results reveal that emerging digital technologies could play an influential role in improving forecasting, optimizing inventory, and reducing healthcare waste. This means it is helpful to have AI-based system in place to lower operations management costs while improving supply chain resilience. The research additionally reveals that AI-powered prediction provides pertinent support for sustainable healthcare supply chain practices by minimizing product expiration, improving resource utilization, and facilitating proactive decision-making. These benefits contribute directly to the healthcare transformation and sustainability objectives outlined in Saudi Vision 2030. It is revealed in this study that despite such identified advantages, there are still numerous challenges in the implementation of AI across the sector. The technological incorporation including AI-powered forecasting still remain challenging due to data integration issues, infrastructure limitations, workforce readiness, cybersecurity considerations, and organizational resistance to change. This means the identified issues require attention from senior levels to tackle these challenges. It is necessary, at the same time, to address the revealed challenges that require coordinated efforts among healthcare institutions, policymakers, technology providers, and regulatory authorities. This research study concludes by presenting a strategic drive in Saudi Arabia for AI-driven demand forecasting as an imminent opportunity for healthcare institutions to achieve efficient, resilient, and sustainable supply chains. The final findings ensure that investment in digital technologies, data governance frameworks, and AI capabilities would be indispensable to accomplish the long-term benefits of healthcare supply chain transformation while providing strong support for the broader goals of Saudi Vision 2030.

AI and Ethics Declaration: This study obtained ethical clearance from the relevant Institutional Ethics Committee whereas all activities are conducted respecting the approved ethical guidelines and standards. Artificial Intelligence (AI) tools were applied only for language editing, proofreading, and formatting support. However, it is declared here that no AI system was involved in the study design, data collection, data analysis, interpretation of results, or generation of research findings. The authors retain full responsibility for the study's content, analyses, conclusions, and originality, with the lead author assuming complete accountability for the integrity and accuracy of the manuscript.
