The chosen case company is a large, global organization employing approximately 100,000 people worldwide. The perspective is based on one small innovation team of seven employees. The team's primary responsibility was to explore and develop new manufacturing technologies with a focus on improving manufacturability and efficiency of future products. Their work was mainly incremental, with occasional involvement in external innovation initiatives.

Given the single-case design, future research could extend this work by examining multiple organisations or innovation units to enhance comparative understanding and improve transferability of the findings.

2.1 Data Collection

A major source of empirical data was nine months of work experience inside the company's innovation management team. During this time, the researcher was involved in daily activities, projects, meetings, and decision-making processes connected to innovation work. This provided access to internal challenges that would be difficult to capture externally, such as how innovation moved through the organization, who acted as gatekeepers, and how decisions were communicated.

This position made it possible to observe both formal and informal realities, including communication gaps, structural tensions, and cross-functional collaboration in practice. The observation period also covered increasing financial pressure, which ultimately led to the shutdown of the innovation team. These events supported identification of patterns and tensions within the innovation process at a structural level.

Attention was given to periods where innovation was postponed or reduced, including budget cuts and decision-making leading up to withdrawal of support. These observations helped identify conditions under which innovation was no longer perceived as sufficiently valuable during financial constraints.

To complement this, semi-structured interviews were conducted with employees across organisational levels, including innovation specialists, project managers, and leaders involved in strategic decisions. This was essential for understanding how innovation measurement was interpreted and used across the organisation.

Semi-structured interviews provided both structure and flexibility, ensuring comparability while allowing participants to share experiences not visible in formal documentation.

This observational material also functioned as a form of triangulation, supporting and contextualising the interview data within organisational governance and decision-making processes

2.2 Sampling Strategy

Interview participants were selected through purposeful sampling, meaning only employees directly connected to innovation work were included. The sample covered different organisational levels and perspectives on innovation measurement.

Participants were categorised into strategic, tactical, and operational levels. One participant worked with corporate innovation strategy, while another led a team expected to demonstrate measurable innovation value.

The focus was not the number of interviews but diversity of perspectives. A total of four in-depth interviews were conducted, which was considered sufficient given the high level of experience among participants and the emergence of recurring themes across accounts.

2.3 Data Analysis

After data collection, materials were organised and reviewed multiple times to identify initial patterns related to prioritisation, measurement, communication, and financial pressure.

Creswell's inductive coding approach was then applied, where meaningful data units were assigned initial codes and grouped into broader themes. Four key themes emerged:

- misalignment in innovation understanding
- innovation under financial and operational pressure
- tension between exploration and exploitation
- lack of structure and measurement in innovation processes and governance alignment

This approach enabled identification of inconsistencies both across organisational levels and between theory and practice.

To strengthen validity, data triangulation was used by combining interviews with nine months of observation, since the researcher was both participant and observer.

3. Innovation Theory Framework

As this study is an initial sample study of the field, a preliminary 'Snowball' literature review has been performed. The following overview synthesizes key theoretical perspectives on innovation and explains how these theories inform the conceptual framing and empirical research design of the authors work.

The selected theories collectively frame innovation as a multidimensional organizational capability influenced by structure, leadership, measurement systems, team dynamics, and external pressures. The literature highlights that innovation becomes particularly vulnerable during periods of constraint unless organizations possess clear strategic alignment and credible measurement practices. The empirical research design is therefore informed by these theoretical positions. Adams, Bessant and Phelps (2017) together with Björk, Frishammar and Sundström (2023) guide the investigation of innovation measurement quality, organizational alignment, and KPI practices. Acar, Tarakci and van Knippenberg (2019) inform the analysis of how constraints may simultaneously suppress and stimulate innovation under financial pressure. West et al. (2004; 2006) contribute a socio-organizational perspective emphasizing psychological climate, collaboration, and implementation challenges.

The empirical study therefore proposes semi-structured interviews with innovation managers, middle managers, operational employees, and executive leadership within a large organization experiencing financial or operational pressure. Observations of meetings, innovation processes, and decision-making structures would help identify how innovation is prioritized or deprioritized in practice. Document analysis of KPI systems, strategic reports, innovation frameworks, and budgeting processes would further support the investigation of how innovation becomes measurable, defensible, or marginalized during periods of constraint.

Together, the theoretical framework positions innovation measurement not as a neutral technical activity, but as a political and organizational mechanism shaping whether innovation survives during uncertainty.

However, all the authors agree on the importance and impeding necessity of performing innovation in organizations. This study on the contrary shows that even so, the innovation department in the case-organization analyzed here is fragile and subject to closure in times of crises. The various positions has been used to understand and explore the expressed perceptions of innovation in the case-study.

Table 1: Innovation Theory Overview.

Perception of Innovation	Theoretical Ideal / Definition	Organizational Premises	Challenges & Opportunities
Moeller, Stolla, and Doujak (2008)	Defined as a strategic, long-term organizational discipline in which innovation is embedded into management and business development processes rather than treated as isolated creativity.	Innovation requires intentional structures, managerial commitment, dedicated resources, and explicit strategies. Innovation must be organizationally legitimized and connected to long-term planning.	Structured incentives and organizational support can encourage innovation and continuity. However, overly rigid systems, excessive control, and bureaucratic processes may suppress experimentation and reduce innovative flexibility.
Acar, Tarakci, and van Knippenberg (2019)	Innovation is stimulated through productive constraints. Constraints are not necessarily barriers, but can increase focus, creativity, and problem-solving capability when managed constructively.	Organizations should create environments where limitations are strategically framed rather than avoided. Scarcity, deadlines, and restrictions can motivate teams to rethink assumptions and generate unconventional solutions.	Constraints may increase creativity, agility, and resource efficiency. However, excessive pressure, lack of psychological safety, or unrealistic constraints can reduce experimentation and discourage innovative risk-taking.
Adams, Bessant and Phelps (2017)	Innovation is a measurable organizational capability that must be assessed systematically across processes, culture, strategy, and outcomes rather than only through financial KPIs or product outputs.	Organizations need integrated innovation measurement systems aligned across departments and management levels. Innovation metrics should include learning processes, collaboration, capabilities, and long-term value creation.	Better measurement practices improve strategic alignment, accountability, and legitimacy of innovation investments. However, organizations often struggle with fragmented metrics, unclear ownership, and overreliance on short-term indicators.
Björk, Frishammar, and Sundström (2023)	Innovation measurement is a dynamic and contextual process requiring multiple complementary indicators rather than singular universal metrics.	Organizations should adopt flexible and multidimensional measurement systems adapted to strategic goals and innovation maturity.	Effective measurement can strengthen innovation performance and strategic prioritization. Poor measurement systems may distort innovation activities or create uncertainty regarding innovation value.
Bouncken, Aslam, Dragoi, Bogers and Kraus (2024)	Innovation is closely linked to entrepreneurial orientation and strategic adaptability.	Organizations require innovation strategies that support openness, collaboration, entrepreneurial thinking, and cross-functional integration.	Strong innovation strategies can enhance organizational performance and competitiveness. However, innovation may weaken if organizational strategy lacks alignment or measurable direction.
West, Sacramento and Fay (2006)	Innovation emerges through the interaction between creativity, team processes, and implementation capability.	Organizations need psychologically safe environments, collaborative work groups, supportive leadership, and sufficient autonomy for innovation implementation.	Moderate levels of challenge may stimulate innovation, while excessive demands or stress may reduce collaboration and implementation quality.
West et al. (2004)	Innovation is both a psychological and organizational phenomenon involving idea generation, implementation, and collective learning.	Organizations should foster participative leadership, interdisciplinary collaboration, trust, communication, and cultures supportive of experimentation.	Innovation benefits from collaborative and learning-oriented cultures. However, hierarchy and bureaucracy may inhibit creativity and implementation.

3.1 Innovation as a Strategic Organizational Process and its Scalability

As a foundation for understanding innovation in large organizations, a range of theoretical perspectives were reviewed. (Moeller, Stolla, & Doujak, 2008) argue that innovation should be seen as a strategic, long-term organizational discipline - not as a random creative spark or occasional coincidence. According to them, innovation requires intentional structures: managerial commitment, dedicated resources, and explicit strategies for transforming ideas into value. However, they also point out that these very structures can sometimes work against innovation when managed poorly. In such cases, promising ideas may be overlooked, blocked, or simply never supported.

To illustrate this, the authors describe situations where following the established structure was actually harmful to innovation. They highlight exceptions—such as the well-known Apple example—where an idea owner bypassed the formal process and directly contacted Steve Jobs after being rejected by the system. Because the idea received approval at the top level, it ultimately influenced Apple's strategic direction. This example shows that formal innovation processes alone are not always sufficient; organizations also require a certain level of flexibility and leadership willingness to support unconventional or disruptive ideas.

Another important point raised by Moeller, Stolla and Doujak, is that innovation becomes significantly more complex as organizations grow. Scale introduces hierarchy, bureaucracy, compliance demands, and additional layers of decision-making. These factors can slow down innovation or shift it into a more controlled and risk-averse process. In this environment, incremental innovation tends to dominate, as it is easier to justify, measure, and integrate into standardized structures. At the same time, incremental innovation is often the first to be cut during financially difficult periods, as it lacks immediate or clearly visible payoff.

This view aligns with West et al. (2004), who emphasize the social side of innovation. As organizations grow, silo mentality, communication barriers, and conflicting priorities make collaboration more difficult. Even cross-functional teams, which are often popularized as innovation drivers, may struggle due to differences in language, expertise, and expectations. West et al. also highlight that psychological conditions, such as: trust, autonomy, shared ownership are just as crucial as structural settings.

Reviewing these two theoretical strands created a baseline for understanding innovation in large organizations. They supported the interpretation of observations from the case company by providing a reference point for identifying recurring barriers, delays, and misunderstandings in innovation work. These could then be related back to the structural and social factors described by the authors. Adding a measurement lens to this perspective made it possible to examine whether more appropriate or aligned innovation metrics could better support innovation within such complex systems.

3.2 Innovation Under Constraints: Budgeting, Prioritization and Financial Vulnerability

Although innovation is widely recognized as essential for long-term competitiveness, it is also highly vulnerable when companies face uncertainty and financial pressure under governance-driven prioritisation frameworks. Traditional corporate budgeting tools prioritize predictability, operational efficiency, and short-term financial outcomes—all of which conflict with the experimental and uncertain nature of innovation. To better understand different approaches to financing innovation, multiple theoretical perspectives were reviewed.

Denning (Forbes) argues that standard budgeting logic is fundamentally incompatible with innovation, as innovation often depends on iteration, learning, and uncertainty. Strict financial cycles typically leave little room for the unpredictable nature of innovative work. Similarly, literature from Harvard Business School suggests that although budgeting is essential for control, it often constrains experimentation and long-term exploration.

On the other hand, Acar, Tarakci, and van Knippenberg (2019) show that constraints can stimulate creativity, but only when supported by autonomy, intrinsic motivation, and psychological safety. In practice, however, constraints in large organizations more often result in reductions in staffing, time, or funding rather than supportive boundaries. As a result, organizations may unintentionally weaken their innovation capabilities precisely when long-term thinking is most needed.

Additionally, Christensen, Kaufman, and Shih (2010) add another dimension to this discussion. They argue that traditional financial tools (NPV, DCF, ROI, etc.) systematically undervalue innovation—especially disruptive innovation—because they are based on assumptions of predictability and stable markets. These tools were not designed for long-term or uncertain projects, yet they remain central to decision-making processes. This creates

a structural bias, where innovation may appear too risky, too slow, or too costly on paper, despite its potential long-term value.

Taken together, these theoretical perspectives supported the interpretation of both the interviews and the case company's situation. They made it possible to examine whether the quality of measurement could reduce the vulnerability of innovation under constraints—for example, by making value more visible, clarifying purpose, or strengthening alignment between innovation teams and upper management.

3.3 Complexity of Innovation Measurements

Since this paper focuses on the role of innovation measurement and its influence on outcomes, it was important to review theoretical work specifically addressing this area.

Despite the expertise of innovation management, many organizations still struggle to define what innovation measurement should actually capture. Because innovation is uncertain, long-term, and often quite risky, its outcomes are not always financially visible in early stages.

Björk, Frishammar, and Sundström (2023) describe this challenge clearly. They argue that companies often rely on output metrics (like number of new products, patents, or savings) while ignoring learning-based or capability-building indicators. When measurements focus only on visible results, innovation becomes reduced to something like a reporting tool—rather than a strategic process of exploration.

They further emphasize that innovation measurement must be strongly aligned with strategy and context. Without shared understanding across roles—executives, managers, innovation teams—measurement becomes misaligned, misunderstood, or even weaponized. When this happens, innovation appears either as a cost or a risk, making it easy to deprioritize during financial pressure.

Because this paper asks:

- "How does the quality of innovation measurement influence innovation outcomes in large organizations during periods of constraint?"

these theoretical perspectives are particularly relevant, as they help explain how measurement quality shapes innovation outcomes under conditions of uncertainty and financial pressure. They illustrate how misalignment in measurement systems can increase the vulnerability of innovation by affecting how it is interpreted, prioritised, and justified across organisational levels.

Taken together, the theories suggest that improving measurement quality is not only a matter of clarity, but may also strengthen the position of innovation during constrained periods by making its value more visible, supporting more informed decision-making, and improving alignment between strategic and operational levels.

These theoretical perspectives help explain why innovation—although very often celebrated across companies and strategically important—often becomes misunderstood, constrained, or deprioritized in large organizations. Strategic ambition, structural complexity, silos, inside politics, financial pressure, and measurement misalignment create a paradox: innovation is praised in theory but vulnerable in practice.

For this article, these theories support the methodological choices by providing a lens through which interview narratives and organizational observations can be interpreted. They make it possible to analyze not only "what happened" in the case company, but also why these dynamics might have occurred. Finally, they help position measurement as a potential lever for strengthening innovation resilience, improving communication between organizational levels, and supporting innovation in periods when it is most at risk.

4. Analysis

The analysis follows a qualitative approach inspired by Creswell, where interview data and observations were coded and grouped into themes. These themes reflect recurring patterns across organisational levels and allow for a structured understanding of how innovation is interpreted, practiced, and evaluated.

The insights developed in this chapter address the sub-questions and contribute to answering the main research question:

- How does the quality of innovation measurement influence innovation outcomes in large organisations during periods of constraint?

The following sections should be read in conjunction with Table 3, which summarises the key findings across organisational levels for each theme.

Table 2:Overview of Interview Insights Across Organisational Levels.

Theme	Strategic Manager	Middle Manager	Operational Manager	Innovation Manager
Misalignment in Innovation Understanding	"Another zone which is innovation… which can work independently."	Innovation seen as difficult to justify and as "extra work"	"We need to go sort of with the flow and shape our processes along the way."	"Some do, many don't." – On if people across organization understand what innovation means.
Innovation Under Financial Pressure	Innovation should be protected from short-term financial comparison	"I didn't have a business argument having a full team… that's how I made that decision."	Innovation not prioritised due to operational KPIs and workload	Innovation described as vulnerable and easily deprioritised
Exploration vs. Exploitation Tension	Focus on long-term growth and opportunity creation	Focus on short-term performance and delivery targets	"There are (processes)… but specifically innovation, there is not… we go with the flow."	Early-stage innovation lacks visibility and support
Lack of Structure, Governance, and Measurement	No clear system to evaluate innovation consistently	Unclear how innovation is measured or reported	No formal process; inconsistent approaches across teams	"You don't measure it… and that's the problem."

4.1 Misalignment in Innovation Understanding Across Organisational Levels

Innovation is not only a technical or procedural activity; it is shaped by people's assumptions, expectations, and mental models. The interviews and observations highlighted that innovation is not a shared concept. Instead, it carries different meanings, levels of importance, and perceived risks depending on one's position in the organisational hierarchy.

One of the clearest findings from the data is that the meaning of innovation shifts drastically across levels. There is no shared definition, no unified understanding of its purpose, and no common approach to carrying it out. This reflects how innovation responsibilities in large organisations are fragmented, leading to inconsistent expectations and competing priorities.

At the strategic level, innovation is framed as a driver of long-term growth and new opportunities. It is understood as an activity that should be protected in the budgeting process. This reflects innovation as a long-term investment that requires autonomy and protection from short-term pressures.

In contrast, middle management perspectives are more constrained. Innovation is acknowledged as relevant but is framed as an operational cost, especially during financially challenging periods. It is perceived as additional work and becomes difficult to justify when clear business arguments are required.

At the operational level, innovation is described as lacking a clear process, requiring teams to shape their approach as they go. It is often reframed as cost optimisation rather than strategic growth.

From the innovation management perspective, innovation work is described as vulnerable and often misunderstood across the organisation, with limited shared understanding between functions.

Observations further support these differences. At the operational level, innovation is typically understood as process improvement. Employees often see it as additional work rather than part of their core responsibilities, and it is not prioritised during periods of high workload. Innovation initiatives are also experienced as unclear due to inconsistent communication, shifting platforms, and undefined processes.

Overall, innovation is interpreted differently across organisational levels, leading to a fragmented understanding that directly influences how it is prioritised, supported, and evaluated.

4.2 Innovation Under Financial and Operational Pressure

Across interviews and observations, innovation consistently appears vulnerable in financial constraint and operational pressure.

At the middle management level, innovation is often deprioritised when resources are limited. It is seen as additional work that competes with delivery responsibilities and becomes difficult to justify when immediate results are required. This was evident in the closure of an innovation team following budget constraints, despite recognition of its value.

Operational teams are measured on delivery, cost, quality, and safety, with no formal indicators related to innovation. As a result, innovation is not prioritised in daily work, particularly when workloads are high.

Observations also showed that when financial pressure increased, innovation activities were among the first to be affected. Innovation projects were shut down without explanation, feedback, or evaluation. The teams involved were not informed about the reasoning behind these decisions, and no learning process followed.

This suggests that innovation is not sufficiently embedded in decision-making structures to withstand financial pressure. Instead, it is treated as a flexible activity that can be paused or removed when constraints arise.

4.3 Tension Between Exploration and Exploitation in Innovation Activities

A clear tension exists between long-term innovation activities and short-term priorities. At the strategic level, innovation is positioned as future-oriented and growth-driven. However, this perspective is not consistently translated into operational practice. Middle managers are structurally incentivised to focus on short-term performance, which creates a disconnect between long-term innovation ambitions and daily decision-making.

This tension is also visible in how innovation is evaluated. At higher organisational levels, innovation performance is associated with measurable outcomes such as signed agreements, external funding, and customer traction. These indicators focus on results that are close to market implementation.

At the same time, early-stage innovation activities such as experimentation, learning, and idea development are not systematically captured. As a result, only projects that reach a certain level of maturity become visible, while exploratory work remains unmeasured.

This creates a situation where innovation is expected to deliver long-term value but is primarily evaluated based on short-term, outcome-oriented criteria.

4.4 Lack of Structure, Governance, and Measurement in Innovation Processes

The analysis shows that the organisation lacks a coherent system for monitoring and measuring innovation. Interviews revealed that managers responsible for innovation could not identify consistent metrics used to evaluate performance. In several cases, they indicated uncertainty regarding how innovation was being measured, or whether it was measured at all.

Innovation work is often reported through informal updates, but these do not feed into a structured system. There is no shared definition of innovation performance, no consistent evaluation criteria, and no common reporting framework.

At the same time, different parts of the organisation use different approaches. Some areas rely on indicators such as signed projects, external funding, or customer agreements, while others have no formal measurement at all. This results in fragmented and inconsistent evaluation practices.

The absence of a shared innovation process further complicates measurement. Teams follow different methods or define their approach as they go, making it difficult to track progress or compare outcomes across projects.

Communication gaps reinforce this issue. Teams are often unaware of what is expected from them in terms of reporting, and management does not consistently communicate how innovation success is evaluated. This leads to situations where innovation work becomes invisible within the organisation.

In addition, information silos limit knowledge sharing. Teams do not consistently share progress or learnings, which results in duplicated work and fragmented insights.

Finally, ownership of innovation is unclear. No single function is responsible for defining KPIs, governing measurement processes, or ensuring accountability. Without ownership, measurement remains inconsistent and underdeveloped.

Overall, the lack of structure, clarity, and alignment makes it difficult for the organisation to measure innovation effectively. As a result, innovation activities remain difficult to evaluate, compare, and justify — particularly in periods of financial constraint.

5. Discussion

Based on the findings, the consequences of weak measurement practices became clear, enabling a direct answer to the research question:

How does the quality of innovation measurement influence innovation outcomes in large organisations during periods of constraint?

The analysis showed that innovation measurement cannot function effectively without foundational elements such as shared definitions, clear processes, communication structures, ownership, and strategic direction. When these are weak, measurement becomes fragmented or absent, negatively affecting innovation outcomes—especially during financially constrained periods.

5.1 A Lack of Innovation Outcomes or Reduced Output

During financial pressure, innovation is the first area to be cut because its metrics fail to demonstrate value beyond cost. Without defined performance indicators, teams cannot communicate their contribution or defend ongoing activities.

Early-stage projects are frequently shut down before reaching maturity—not due to lack of value, but due to inability to measure it.

Outcome: A reduced or empty innovation pipeline, fewer prototypes, fewer experiments, limited learning. In practice, this can result in no innovation outcomes during periods of constraint.

5.2 Low Innovation Performance

When innovation is not clearly measured or communicated, decision-makers cannot identify high-potential projects. Prioritisation becomes inconsistent and is often based on cost rather than strategic value or learning potential.

Outcome: Low innovation performance, misaligned priorities, and decisions focused on short-term savings rather than long-term value creation.

5.3 Decreased Organisational Innovation Capability

When measurement focuses on traditional KPIs such as cost optimisation rather than learning, progress, or capability-building, the organisation loses its ability to develop future innovation capacity. Without learning loops and experimentation, teams do not evolve.

Outcome: Weakened innovation capability, reduced skill development, and limited mechanisms for continuous improvement—ultimately reducing competitiveness.

5.4 Loss of Innovation Legitimacy

When innovation is evaluated mainly through cost metrics, it becomes perceived as a financial burden rather than a strategic investment. Motivation declines, and innovation loses influence in decision-making.

Outcome: Innovation is seen as non-essential, loses strategic importance, and struggles to justify its existence.

5.5 Explore: Exploit imbalance

Without frameworks distinguishing between Explore and Exploit activities, organisations tend to prioritise low-risk, short-term improvements.

Outcome: Incremental innovation dominates, while radical innovation is deprioritised, increasing organisational risk-aversion over time.

In summary, weak measurement practices shape innovation outcomes by reducing output, lowering performance, weakening capabilities, and shifting focus toward exploitation. During financial constraint, this makes innovation vulnerable and unable to demonstrate value or secure resources.

If innovation is not measured properly, organisations cannot expect strong or consistent outcomes.

6. Conclusions

Based on the findings from interviews, observations, and theory, which revealed weaknesses in innovation foundations, measurement systems, and outcomes, the following recommendations are proposed.

These aim to support the development of an innovation function that is understood, strategically prioritised, and able to demonstrate value—especially during financially constrained periods. The recommendations align with Strategyzer frameworks such as the Innovation Metrics Matrix and Explore–Exploit principles.

6.1 Strengthen Innovation Measurement Foundations

A shared and clearly understood measurement framework is essential for improving innovation performance. It ensures that innovation is seen as value creation rather than cost, and that outcomes are comparable across teams.

Distinguishing between Explore and Exploit activities is particularly important, as they differ in purpose and timelines. Early-stage initiatives should be measured using learning-based indicators rather than financial KPIs, to avoid premature termination of projects that have not yet matured.

6.2 Establish an Innovation Governance Structure

A clear governance structure is necessary to ensure consistent and transparent handling of innovation activities. A dedicated group or board can oversee initiatives, standardise evaluation criteria, and reduce reliance on subjective managerial decisions.

This becomes especially important during financial pressure, where structured governance enables more objective decision-making.

6.3 Involve Financial Stakeholders and Customers Early

Early involvement of financial stakeholders and customers strengthens alignment and reduces misunderstandings. It also allows organisations to apply more appropriate evaluation models, such as cost-to-learn or option-based value.

Training financial decision-makers in innovation logic can support more balanced and informed investment decisions.

6.4 Adapt Innovation Activities During Constraints

Innovation teams should be informed early about financial or structural changes. This allows them to adapt their scope instead of being shut down entirely.

Smaller-scale experiments, reduced-cost initiatives, and external funding options can maintain progress during constraints. Measurement expectations should also adjust accordingly, reflecting limited resources and exploratory conditions.

6.5 Clarify Innovation Structure and Definition

A shared definition of innovation is necessary to reduce confusion across the organisation. This includes clarifying what innovation includes, how it differs from optimisation, and where it applies.

Additionally, aligning tools, platforms, and processes reduces friction and improves participation. A coherent structure supports innovation as a stable strategic capability rather than a temporary function.

6.6 Strengthen Cross-organisational Alignment

Innovation should be integrated across organisational levels through shared platforms and transparent communication. This reduces silos, prevents duplication, and improves knowledge sharing.

Regular reviews, clear measurement logic, and accessible dashboards can improve alignment, transparency, and engagement.

These recommendations support the development of a more structured, measurable, and strategically anchored innovation system.

By improving measurement quality, organisations can better communicate value, align decision-making, and protect innovation during periods of uncertainty—strengthening long-term resilience and competitiveness.

Ethics Declaration

This study was conducted in accordance with general ethical research principles. The research did not require formal ethical approval, as it did not involve sensitive personal data, vulnerable populations, or interventions.

All participants were informed about the purpose of the study and participated voluntarily. No identifiable personal or organisational information has been disclosed. The case company remains anonymous, and all data has been handled with confidentiality and used solely for academic purposes.

AI Declaration

Artificial Intelligence (AI) tools, specifically ChatGPT, were used as a supportive tool in the preparation of this paper. The use of AI was limited to language refinement, including grammar correction, sentence restructuring, and improving clarity.

Abstract: The health sector, despite fundamental, is currently under significant pressure. The ageing of the population, combined with the growing prevalence of chronic diseases, has intensified burden on healthcare budgets. Simultaneously, the struggle with shortages of qualified professionals and limited resources create additional barriers to delivering effective care. Therefore, health systems face a dual challenge: they must improve efficiency to manage rising costs and ensure long-term sustainability; but also, they must maintain high standards of quality and equity to satisfy more informed, more demanding, and increasingly involved patients. To address these global pressures, the concept of e-Health has emerged, driven by the integration of electronic communication and information technologies into healthcare. Advances in digital tools have made health information and services more accessible worldwide, often at significantly lower costs, enabling improved healthcare delivery. Within e-Health, m-Health has gained prominence. By leveraging mobile technologies, m-Health has shifted the healthcare paradigm from a reactive model to a more proactive and preventive approach. The widespread adoption of smartphones and wearable devices allows individuals to monitor and manage their health anytime and anywhere, from using apps that track physical activity to devices that monitor vital signs in real time. The increasing use of healthcare-related mobile apps has led to the growth of its market, making it an attractive business for investors. A health app needs a sustainable business model that can generate revenue. Considering that most health apps are free, one of the most important and growing sources of revenue in the e-health market are in-app purchases (IAP). Despite the growing importance of IAP as a revenue source, few studies exist dedicated to this monetization mechanism. This study contributes to fill in this gap and aims to study the factors that explain the use of IAP as a revenue source. Applying probability models to a sample of health apps from Google Play and Apple App Stores, results show that IAP are positively correlated with the use of personal data for micro-segmentation. Also, the presence of IAP is an alternative to payment for downloading, but complementary to ads.

Keywords: In-app Purchases, App Monetization Models, e-Health, Mobile Apps, Apple App Store, Google Play Store

1. Introduction

The market for mobile health is experiencing a significant growth. Health apps market's expansion is attracting investors to an increasingly competitive industry, highlighting the need for a careful definition of the health app monetization model.

In the two largest app stores – Apple App Store and Google Play Store – most apps, health apps included, are available for free. Since many apps are available for free, how do developers monetize an app? A free app may potentiate the number of users, but the business model must generate revenue from other sources than payment for download.

There are several monetization models that can be enforced, individually or combined, considering the business strategic goals of the app developer, such as the freemium model, the in-app advertising model, the in-app purchases (IAP) model or the data monetization model (Antoja et al, 2019; Appel et al, 2020; Lee et al, 2021; Numminen et al, 2022; Ofulue and Benyoucef, 2022; Roma and Ragaglia, 2016; Tang, 2016).

Choosing from different revenue sources should take into consideration user´s experience and how the former will impact the latter (Cao et al, 2023; Ghose and Han, 2014). The balance between revenue goals and user's experience is crucial to provide utility and value, and to ensure the app will remain successful over time (Ji et al, 2019).

The study aims to answer the following research question: what factors explain the use of in-app purchases as a monetization mechanism for health apps? To do so, probability models were applied to a sample of 1,121 health apps marketed in the two major app stores in Portugal - the Apple App Store and the Google Play Store, to explain the use of IAP as source of revenue. The paper analyzes if and how alternative sources of revenue,

the category of the app and the app store where the app is made available impact the probability of using IAP as a monetization mechanism for health apps.

This paper contributes to the existing literature on monetization models for health apps, focusing on the determinants of IAP, an increasingly important revenue source for health apps. Moreover, most studies on the app market in general, and the health app market in particular, use US data, but few studies analyze the European market. Thus, this paper adds to these latter studies by analyzing the case of the Portuguese health app market. This study can also bring new insights for health app developers and their decision on how to monetize an app in a context where health apps are increasingly capturing the interest of investors.

The remainder of the paper is organized as follows: section 2 presents prior research, establishing the state of the art; section 3 sets out the research methodology, namely the data collection, the variables used, and the econometric models employed; section 4 presents the results and their discussion, and section 5 concludes the paper.

2. Literature Review

In this rapidly changing environment driven by digital technologies, new ways of creating value among diverse actors emerge in innovative contexts such as multilateral markets. These innovations in monetization models are not exactly new inventions, but adaptations of existing traditional models for a new area such as the m-Health area (Antoja et al., 2019; Eurich and Mettler, 2017; Tidhar and Eisenhardt, 2020; Vimarlund, 2017).

Health apps have the potential to make the health sector more efficient and to create additional value for both citizens and health professionals. However, the developers of these health apps must configure their business models to capture the value created as a result of the complex relationships between the different stakeholders in healthcare delivery (Antoja et al., 2019; Ehret et al., 2013; Ehret and Wirtz, 2017; L. Guo et al., 2017; Kuziemsky and Vimarlund, 2018; Mettler and Eurich, 2012; Vial, 2019). Monetization is ethical when it aligns with patient welfare, protects privacy, and maintains transparency. It is useful because it enables innovation, reduces healthcare costs, and expands access — but only if implemented with strong ethical safeguards.

Health apps can adopt the following monetization strategies: (1) making the app available for free, (2) providing the paid app, (3) making the free and paid versions of the app available simultaneously, being given the user the opportunity to choose between versions - approach known as freemium. In the first strategy, app developers do not get revenue from downloading the app (since it is free), so revenue must come from other monetization mechanisms such as in-app ads or IAP. In the second strategy, app developers get revenue directly from the first day of sales (for each download of the app), and it is still possible to collect revenue from IAP (as for in-app ads, they are not common in paid apps) (Aydin and Silahtaroglu, 2021; Krishnan and Selvam, 2019; Lee et al., 2021; Liu et al., 2014).

For free apps, in-app ad revenue requires a large installed user base and the return from IAP requires continuous user engagement and conversion from users to in-app shoppers. For paid apps, the revenue from the download payment depends on an unstable influx of new users and the return from IAP is sometimes reduced due to the lower propensity of users to spend within a paid app (since, in their opinion, paying for the download sets up an economic substitute for IAP) (Aydin and Silahtaroglu, 2021; Ghose and Han, 2014; Krishnan and Selvam, 2019; Lee et al., 2021; Liu et al., 2014).

Finally, the freemium approach allows for different sources of revenue from both versions (and ultimately higher total revenues), but requires higher development-related costs, maintenance, and marketing of both versions. Additionally, even if the user base of any version stimulates the future demand of both versions (due to the phenomenon of social influence), there is still the danger of contemporary cannibalization, which will affect the current downloads of both versions (Arora et al., 2017; Aydin and Silahtaroglu, 2021; Hu, 2019; Krishnan and Selvam, 2019; Lee et al., 2021; Tidhar and Eisenhardt, 2020).

Most health and mobile apps are free, as shown by the dominance of free apps in the Apple App Store and Google Play Store. This widespread gratuity requires alternative revenue sources to sustain development. An app's success depends on diversifying monetization methods, and IAP remain one of the most common and effective strategies for generating income (Lee et al., 2021).

Free apps often monetize through indirect mechanisms such as IAP (Salehudin and Alpert, 2021). This shows an exponential growth trend in revenues from IAP, that will cause revenue from free apps, monetized through IAP, to outweigh revenue from paid apps.

Previous studies, such as Ghose and Han (2014), identified that the presence of in-app purchase option can influence ex-ante to potential app users, given that IAP represent additional features beyond the basic features of the app. According to Ghose and Han (2014), the in-app purchase option is very popular for app developers, as they expect to obtain, alternatively or in addition to immediate revenue from the download payment, additional revenue from these future IAP. This option is also popular among app users, given that the presence of IAP is an incentive to reduce the download price of the app, which transpires in the app demand that typically increases with the presence of the in-app purchase option.

IAP are, therefore, perceived as an economic substitute for payment for the app download. Hence, Ghose and Han (2014) alert that app users are less likely to spend on IAP in paid apps. Lee et al. (2021) add that users can, in the extreme, be pushed away by this upselling perspective, since they can consider the presence of in-app shopping options to explore them.

The specific case of IAP requires continuous engagement of users with the app and their conversion to consumers/buyers in the app. Given that the presence of these monetization mechanisms is visible to potential users on each app's web page in the app store, specifically at the time of the download decision, it is vital to achieve a delicate balance in defining these monetization mechanisms (payment for download and payment for IAP). On the one hand, the download price should be reduced, that is, there should be a discount on the price sufficient to trigger the downloads needed to compensate for this lost revenue. On the other hand, the (future) revenue from IAP must be high enough for developers to be able to recover lost revenue by offering (initially) a price discount on the download (Ghose and Han, 2014; Lee et al., 2021).

In this context of the app market, in which the vast majority of apps are moving away from direct monetization mechanisms (such as payment for download), app developers are betting on alternatives for indirect monetization, such as IAP, that enable, upon payment, the deletion of ads, the update to a 'full' version of the app or the acquisition of some additional/ special feature/ functionality for the app (Dinsmore et al., 2017; Salehudin and Alpert, 2021).

Shulman and Geng (2019) also highlight users tend to do their research on app download prices and that most of these potential consumers only discover in-app purchase prices later (after downloading the app). Achieving IAP is the result of ongoing or sporadic offers for updating which arise while using the app, and after prolonged exposure to an app, users are much more involved and likely to make an in-app purchase on impulse (Dinsmore et al., 2017; Shulman and Geng, 2019).

Numminen et al (2022), in their panel data study, for the US Apple App Store, of the effect of revenue model decisions for app revenues, found that, for gaming apps, a model that combines free downloads with the in-app purchase option leads to higher app revenues compared to a model where users only pay for downloading the app or to a model that combines paid downloads with the in-app purchase option.

There are benefits arising from monetizing via IAP since they do not face the drawbacks associated with the use of in-app ads. Users consider ads a source of costs as they are time consuming and distractive, represent extra costs from receiving ad-related traffic, and there are privacy costs linked to the customization of advertisement using personal data (Gao et al., 2022).

3. Methodology

3.1 Data and Variables

To study the determinants of IAP as a monetization source for health apps, a sample of 1,121 health apps was collected complying with the following criteria: mobile apps for Android or iOS systems, available in Portugal on Google Play Store or Apple App Store platforms and listed in the Top Free and Top Paid rankings, for the categories 'Health and Fitness' and 'Medical Care/Medicine'. These criteria followed those of related studies conducted on health apps (Antoja et al., 2019; Lee and Raghu, 2014; Liu et al., 2014). The sample has a cross-sectional nature. Table 1 exhibits the variables collected and available in the dataset and their description.

Table 1: Variables description

Variable	Description
iap	Dummy variable that specifies whether the app has in-app purchases (IAP) = 0, if without IAP = 1, if with IAP
app store	Dummy variable that identifies the store where the app is marketed = 0, if Google Play Store = 1, if Apple App Store
category	Dummy variable that specifies the category of the app = 0, if Health and Fitness = 1, if Medical Care/Medicine
type	Dummy variable that identifies the type of app = 0, if Free = 1, if Paid
ads	Dummy variable that specifies whether the app has ads = 0, if without Ads = 1, if with Ads
advertising	Categorical variable that states if the app uses personal data for micro-segmentation/advertising purposes = 0, if No Use = 1, if Use = 2, if Doesn't Inform on the use
remuneration	Dummy variable that identifies if the app remunerates users = 0, if No = 1, if Yes

Note: the sample was collected on July 21, 2021.

The variable *iap* is the dependent variable in this study and its use is explained controlling for other variables such as the app store, the category of the health app, the existence of other revenue sources (free or paid app, in-app ads, or the use of data for micro-segmentation purposes), and the payment to users. Summary statistics of the variables collected in the sample are presented in Table 2.

Table 2: Descriptive statistics of the variables

Variable	Description	All Sample (N=1,121) Percent (a)	Apps without IAP (N=888) Percent (b)	Apps with IAP (N=233) Percent (c)
iap	= 0, if without IAP	79.21	--	--
	= 1, if with IAP	20.79	--	--
app store	= 0, if Google Play Store	59.05	58.90	59.66
	= 1, if Apple App Store	40.95	41.10	40.34
category	= 0, if Health and Fitness	35.06	33.67	40.34
	= 1, if Medical Care/Medicine	64.94	66.33	59.66
type	= 0, if Free	61.46	55.74	83.26
	= 1, if Paid	38.54	44.26	16.74
ads	= 0, if without Ads	81.71	87.16	60.94
	= 1, if with Ads	18.29	12.84	39.06
advertising	= 0, if No Use	3.30	4.05	0.43
	= 1, if Use	45.41	39.41	68.24
	= 2, if Doesn't Inform on the Use	51.29	56.53	31.33
remuneration	= 0, if No	98.84	98.76	99.14
	= 1, if Yes	1.16	1.24	0.86

In our sample of health apps (column (a)), the free download business model dominates, being the case for 61.46% of the apps. This feature of the sample reproduces the prevalent business model in the app market. Since most apps are available for free, developers must obtain revenue from other sources: 45.41% of these health apps discloses, in their privacy policy, the use of personal data for micro-segmentation purposes (51.29% of these apps do not inform on the use of data in their privacy policy, so one can only speculate on the use of the data and on why the information is missing on the privacy policy), over one fifth uses IAP as a monetization method, and 18.29% have in-app ads.

As for the app store where the apps are available, most health apps in the sample (59.05%) are from the Google Play Store and belong to the 'Medical Care/Medicine' app category (64.94%). Finally, only 1.16% of these health apps remunerate users.

Exploring the sub-samples of health apps (columns (b) and (c) of Table 2), it's clear that among the ones that monetize via IAP (column (c) of Table 2), a significant proportion (83.26%) are free apps. For the apps that do not monetize using IAP (column (b) of Table 2) that proportion falls to 55.74%. This suggests that IAP substitute revenue from payment for download. Other not surprising distinction between the sub-samples is the fact that in-app ads are present in 39.06% of the health apps that have IAP whereas only 12.84% of health apps that do not have IAP exhibit in-app ads. Moreover, while 68.24% of apps with IAP disclose the use of data for micro-segmentation purposes, for apps without IAP that is the case for only 39.41% of the apps. This implies that IAP, in-app ads options, and micro-segmentation complement as revenue sources of free apps.

An analysis by app store (Figure 1) reveals that the proportion of apps with and without IAP is quite similar in both the Google Play Store and the Apple App Store, where over 20% of the apps use IAP as a monetization mechanism.

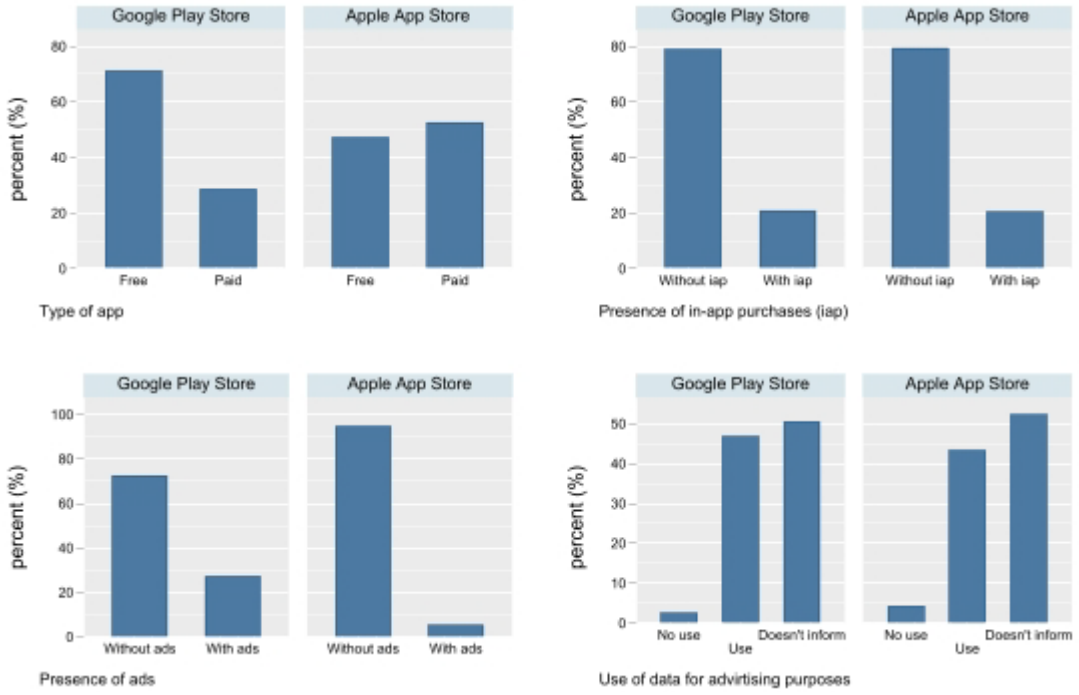

Figure 1: Monetization strategies of health apps, by app store
Source: Author's computations.

The major differences between app stores on the revenue sources occur on the type of app and on the presence of in-app ads. In effect, on the Google Play Store, more than 70% of health apps in the sample are free while in the Apple App Store less than half of the health apps are available for free. As previous studies have shown, Android users are more price sensitive than IOS users (Arora et al., 2017; Ghose and Han, 2014) and it explains why more apps are available for free in the Google Play Store. The presence of ads is significantly higher in the Google Play Store (27.30%) compared to the Apple App Store (5.20%). Also, the use of data for micro-segmentation/advertising purposes is slightly higher in the Google Play Store (46.83%) compared to the Apple App Store (43.36%).

3.2 Econometric Models

Due to the dichotomous nature of the dependent variable *iap*, probability or binary response models were applied in the econometric setup. Probit and logit models were used to model a nonlinear relationship between the dependent variable *iap* and the set of independent variables, making sure that the probability of an event occurring is between 0 and 1 (Gujarati and Porter, 2011). The significant difference between the two models is the cumulative distribution function considered. The probit model considers that the errors are normally distributed (the standard normal cumulative distribution function) while the logit model assumes a logistic distribution (the logistic function) (Cameron and Trivedi, 2008).

The estimation of both models is made by maximum likelihood and comparison of results is straightforward. To select the most appropriate model their log-likelihood were compared: the model that best fits the data is the one with the highest log likelihood.

Therefore, logit and probit regression models are used to establish how the independent variables explain the behaviour of the dependent variable (*iap*). Regression techniques allow us to understand the cause-effect relations, controlling for the other variables to be constant.

4. Results and Discussion

Estimations of both logit and probit models produce similar coefficients. Since probit models report higher log-likelihood values than logit models and, therefore, the goodness of fit is better for the probit models, this section will focus on the probit models' results. Moreover, for the purpose of interpretation, Table 3 exhibits the marginal effects of the independent variables on the dependent variable *iap*.

Table 3: Probit models' marginal effects (dependent variable: *iap*)

Table 3 displays the results for two models, (1) and (2), which differ in the number of observations used in the estimation. This difference is due to the variable used in each model to consider if the app uses data for micro-segmention/advertising purposes: *advertising* or *advertising_alt*. In model (1) the categorical variable *advertising* is included as a predictor: the variable equals 0 if the app does not use data for advertising purposes, equals 1 if the app uses data and equals 2 if the app does not inform on the use of data. When considering this categorical variable, the estimation uses 1121 observations. However, because there are 575 health apps that do not disclose on their privacy policy how they use the data collected for advertising purposes, this missing information was dropped, and a new dummy variable was created *advertising_*alt that equals 0 if the app does not use data for advertising purposes and that equals 1 otherwise. This latter variable is included as an alternative predictor to advertising in model (2) and this is the reason why model (2) is estimated using 546 observations. By doing so, the goodness of fit of the model improves.

In both models, the variable *app store* is statistically significant, and it positively influences the probability of a health app having IAP. All else equal, compared to an app marketed in the Google Play Store, being in the Apple App Store increases by 8.01 percentage points (p.p.) the probability of having IAP (model 1). This effect is enhanced if considered the specification adopted in model 2; indeed, ceteris paribus, being in the Apple App Store raises by 13.7 p.p. the probability of having IAP, compared to the Google Play Store. Differences in price sensitivity may explain why monetization mechanisms that imply a monetary payment are more common in the Apple App Store than in the Google Play Store (Ghose and Han, 2014; Roma et al., 2016).

Looking at the variables that are alternative sources of revenue, the variable *type* shows a negative and statistically significant impact on the probability of having IAP. The magnitude of the effect is alike is both models. Considering all else equal, being paid decreases by over 11 p.p. the probability of a health app having IAP. This seems to suggest that IAP and payment for download work as substitutes as monetization mechanisms. Since both mechanisms imply a direct spending of money, it is expected that users that pay for download the app are not keen to expend more money on IAP. Also, Garg and Telang (2013) argue that free apps have a higher volume of downloads, and, after download, app developers may extract revenues from IAP.

Contrary to payment for download, the use of ads and/or personal data for micro-segmention/advertising purposes work as revenue complements to IAP. Compared to an app without ads, having *ads* increases by over 22 p.p. the probability of using IAP to monetize an app, ceteris paribus. While IAP are an alternative revenue source, merely offering IAP does not guarantee revenue (to do so, users must purchase the available products/services). In this way, IAP don't have to be an alternative to ads but can be a complement in an in-app monetization model. Another important feature of IAP is that many of them are to remove ads, and this kind of IAP only makes sense in apps with ads.

The same positive and statistically significant effect is obtained for the *advertising* and *advertising_alt* variables: respectively, using data for micro-segmention/advertising purposes, compared to not using it, raises by 23 p.p. and by 25.9 p.p. the probability of including the IAP option in an app. Kollnig (2021) showed that apps, relying on IAP as a revenue source, harvest personal data. In fact, the use of personal data for micro-segmentation can boost revenue from IAP, because it facilitates customization, and increases the value of services offered.

Finally, compared to an app that does not remunerate users, the *remuneration* of users reduces the probability of using IAP as a revenue source by 14 p.p. (model (1)) or by 17.6 p.p (model (2)). Typically, remuneration is to compensate users for the use of their personal data (for example, selling it to third parties) or the engagement with the app (which may ensure active use of the app, and therefore the audience for ads).

5. Conclusion

This study shows that understanding health-app monetization models is essential for the development of digital health in Portugal. As m-Health tools become more common across both public and private healthcare, the way these apps generate revenue directly affects their accessibility, sustainability, and users' trust.

For Portuguese consumers, transparency about costs—whether direct, indirect, or hidden—is particularly important in a context marked by varying levels of digital-health literacy and strong concerns about personal-data use. For developers and startups, especially within Portugal's small but growing health-tech sector, choosing the right monetization strategy is a key factor for long-term viability.

Findings suggest that IAP are an alternative revenue source to price for download, but a complement to in-app ads. Furthermore, the choice for having IAP cannot be dissociated from the choice of platform where the health app is available for download.

The main limitation of this study is the lack of detailed information on the different types of IAP. Without distinguishing between purchases that remove ads, unlock features, or integrate external services, it is difficult to fully understand their impact on user behaviour and revenue generation. Addressing this gap would be especially valuable for Portugal, where evidence-based guidance on digital-health business models is still limited.

Future research that maps and evaluates specific IAP mechanisms would therefore contribute to more sustainable and user-centered monetization strategies, supporting Portugal's broader goals for digital transformation in health.

Abstract: This empirical study seeks to examine the role of content marketing and digital advertising within Cypriot small and medium-sized enterprises (SMEs) by essentially exploring the degree to which these businesses utilise digital marketing tools. In addition, it delves into the relevant challenges faced by these enterprises located in different regions in Cyprus and the outcomes gained of implementing such digital strategies. More specifically, this research highlights the significance of these advanced strategies in a rapidly evolving business landscape. A qualitative research method was applied interviewing owners and business executives via semi-structured in-depth interviews. The findings reveal that while the majority of the firms investigated by the research team have incorporated social media, email marketing, and search engine advertising into their strategies, a gap in strategic planning, budget allocation, and performance measurement is traced, respectively. Most of the them have focused on ad hoc tactics within their digital marketing endeavours, a fact that strategically showcases limitations with regard to their potential for sustained growth and competitiveness, especially when it comes to long-term goal achievement. However, interviewees underscored the considerable opportunities that effective content marketing and targeted advertising may provide with regard to customer loyalty, brand visibility, and sales. The study wraps up by recommending certain key structured digital marketing strategies, suggesting ways to improve training for social media managers, and pushing for better access to resources and analysis tools.

Keywords: Digital Marketing, Content Marketing, Digital Advertising, SMEs, Cyprus

1. Introduction

In developing countries, SMEs contribute to 40% of the GDP (Thaha et al., 2021). Technology is advancing day by day, and these businesses have more opportunities (Lykourentzou et al., 2026; Petropoulos., 2025), especially through digital marketing. Digital marketing allows them to promote products and services in a timely, personalized and cost-effective way (Baines et al., 2013). Digital marketing also helps SMEs move from building brand awareness to making sales and better meeting customer needs. In this regard, their ability to learn and adapt is important for future growth (Pradhan et al., 2018). Two of the most prominent digital marketing practices are content marketing and paid digital advertising. Content marketing is based on the production of consistent and valuable content to raise brand awareness by using video blogs and social media (Cheung et al., 2020; Leung et al., 2022; Shahab et al., 2021; Stubb et al., 2019). The success of content marketing is based on the distribution of information through social media networks and search engine optimization (Feng et al., 2021; Cheng et al., 2020). On the other hand, digital advertising helps businesses reach their target audience by using measurable techniques to drive website traffic and raise brand awareness, while providing ongoing optimization to improve the return on investment (Apostolopoulos et a., 2025; Blake et al., 2015; Buhalis & Mamalakis, 2015; Goldfarb, 2014). However, for SMEs, especially in resource-constrained environments, it is important to make strategic decisions in terms of how to allocate budgets for organic content versus advertising (Kotler et al., 2021). Previous studies have investigated some aspects of SEO, SEM, and content-based engagement (Panchal et al., 2021; Ahmad et al., 2022), although limited research has been conducted to compare the long-term effect of content marketing versus the immediate gratification of advertising for SMEs. There is also limited research conducted while considering recent advances in AI-based personalization, user-generated content, influencer marketing, and video advertising.

This study aims to examine how SMEs can use content marketing and paid digital advertising, including PPC, to achieve maximum promotional impact. This will be achieved by studying their meanings, characteristics, and uses, as well as how SMEs select between them depending on their respective industries, audiences and subsequently, resources. The research will also seek to understand how SMEs may benefit from the integration of these strategies in order to increase their effectiveness, awareness, and loyalty, as well as how they may make the most of emerging digital marketing trends in different industries with different

audiences and resources. Moreover, it will seek to understand best practices in this regard in SMEs in Cyprus to increase their growth and competitiveness.

Specifically, this research seeks to answer the following questions. To what degree do SMEs practice content marketing and paid advertising strategies? What are the main obstacles SMEs encounter in applying these strategies? On top of that, which of these strategies, content marketing or paid advertising, is more effective in SMEs? Lastly, what are the best practices that Cypriot SMEs must consider to make their marketing strategies more effective? Lastly, the answers to these questions will provide recommendations to enhance the digital presence of Cypriot SMEs and make them more effective in their utilization of digital marketing tools.

2. Literature Review

The international literature has been interested in Content Marketing in SMEs (Feng et al., 2021; Ho et al., 2020). Content marketing is often described as “the strategic creation and distribution of valuable content to attract, engage and retain clearly defined audiences” (Holliman & Rowley, 2014). However, it is also differentiated as having a focus on trust and relationships rather than content use in more general terms (Mathew & Soliman, 2020). The interest in content marketing for SMEs comes in two forms: cost savings in media and brand assets that grow exponentially (Lou & Xie, 2021; Ahmad et al., 2017). The practical application for firms includes using various content forms (videos, blog posts, white papers, infographics, etc.) for raising brand awareness and stimulating demand (Tiago & Verissimo, 2014). Social platforms are central distribution rails which link content quality to visibility and engagement (Ho et al., 2020). Content marketing in SMEs involves valuable content and distribution, and in such cases, the importance of SEO and social media is particularly high (Feng et al., 2021). For high-performing content marketing, content formats need to be adapted to audience needs and consistency is also important (Shahab et al., 2021; Cheung et al., 2020). The development of a defined strategy and content alignment with the marketing funnel and measurement systems establish the foundation for content marketing success (Cheng et al., 2020; Lee et al., 2018). SMEs typically activate a strategy that includes search, social, display, and email (Simonetti & Bigne, 2024; Vitalis et al., 2023). Search engine marketing (SEM), integrating search engine optimization (SEO) and pay-per-click (PPC) strategies, has the potential to enhance visibility and attract high-intent traffic, as Lee (2018) observed. Combining SEO and PPC with content marketing have a competitive advantage and progressively greater benefits, according to Rohimi (2024). Furthermore, display inventory, encompassing banners and rich media content, enables ad networks to broaden their reach; however, the efficacy of banners hinges on their ability to initially capture audience attention, a point emphasized by Drèze and Hussherr (2003). Simonetti and Bigne (2024) also discovered that variations in format and the incorporation of motion elements can help with interaction.

Looking at different online marketing practices, social media ads promote awareness and consideration and are utilised mainly for their accurate targeting capabilities (Vitalis et al., 2023). Native marketing operates through various formats which function within editorial environments but businesses need to maintain transparency for preserving their audience's trust according to Manic (2015). Additionally, display and retargeting operations increase customer retention through high relevance but the practice of showing too many ads leads people to develop "ad blindness" which decreases their effectiveness and reduces their return on investment (Manchanda et al., 2006). Video ads can raise attention and intent when placement, duration, and relevance are well-optimized (Vaiciukynaite et al., 2017). Email serves as an essential CRM tool which helps businesses keep their customers but people tend to resist when they see direct persuasion messages; research shows that providing information through educational methods produces better results (Thomas et al., 2022; Campbell & Kirmani, 2000). Platform analytics (CTR, CPA) enable granular optimization (Kireyev et al., 2016). A multi-touch approach to customer journey analysis helps businesses understand their campaigns better because customers base their decisions on multiple touchpoints instead of single interactions (Kireyev et al., 2016). When considering the variety of platforms, YouTube can increase brand awareness among younger age groups, but it requires creative content that grabs attention, such as eye-catching thumbnails (Febriyantoro, 2020). TikTok can allow content to spread quickly through short videos, particularly for Gen Z (Dwinanda et al., 2022). Meta properties support engagement and measurable outcomes when content resonates and is well targeted (Sugeng & Chusjairi, 2022; Baek & Morimoto, 2012). Because organic reach has tightened on major platforms, paid support is often necessary to seed distribution, even for content that has potential to perform (Ho et al., 2020). The effectiveness of social media channels is improved through adaptation of content to the unique features of each platform and how users interact with them (Apostolopoulos et al., 2025; Lee et al., 2018; Mangold & Faulds, 2009).

3. Methodology

Given the study's aim, to understand how Cypriot SMEs perceive and apply content marketing and paid digital advertising, we adopted a qualitative research design. Qualitative inquiry privileges depth over breadth, seeking to surface meanings, interpretations, and lived experiences that are not easily reduced to numbers (Gittins et al., 2025). It is particularly suitable in the social sciences for interpreting human experience and context, which reflects to Dilthey's interpretive tradition (Makkreel, 2014). It has also been recommended for unpacking complex social, economic, and entrepreneurial environments (Neergaard & Ulhøi, 2007) and is well aligned to entrepreneurship scholarship exploring complex phenomena (Van Burg, 2022). Accordingly, a qualitative, interview-based approach was judged fit for purpose. We employed convenience sampling to facilitate access and cooperation (Moser & Korstjens, 2018), while ensuring participants were "information-rich cases" suitable for in-depth analysis (Patton, 2002). Inclusion criteria focused on owners or marketing-responsible staff within SMEs who were actively involved in digital promotion (content and/or ads). Targeted recruitment of participants sharing relevant roles and exposure supports deeper interpretation of the focal phenomenon (Makris et al, 2024).

The final sample comprised 14 SMEs operating across all districts of the Republic of Cyprus (Nicosia, Limassol, Larnaca, Paphos, Famagusta), spanning sectors such as food service, advertising, tourism services, apparel, wellness/medical, legal, IT, retail, real estate/hospitality, media, and financial services. Participants were owners/founders or marketing leads (including in-house and hybrid arrangements with agencies/freelancers). Interviews were conducted in April–May 2025, either face-to-face or via online/telephone, modes considered as valid as in-person for qualitative interviewing (Sturges & Hanrahan, 2004). Most interviews were conducted in Greek, with two in English. Average duration was ~30 minutes. All participants received an information sheet, provided written informed consent, and opted for anonymity. We used pseudonyms (R1–R14) and removed identifying details to protect confidentiality (Orb et al., 2001). Recruitment ceased at thematic saturation (Fusch, 2015). Furthermore, data were gathered through semi-structured, in-depth individual interviews; an established and effective method in qualitative research (Apostolopoulos et al., 2019; Flick, 2018). Semi-structured interviews balance a consistent core protocol with flexibility to probe emergent issues, enabling authenticity and nuance in participants' accounts (Kvale & Brinkmann, 2009). Confidentiality and anonymity principles were rigorously applied throughout (Orb et al., 2001).

We used qualitative analysis to interpret participant experiences, perceptions, and practices. An abductive stance combined inductive and deductive procedures. Inductively, open coding allowed concepts to emerge from the data without imposing a priori frames, revealing new topics and meanings grounded in participants' language (Bennett et al., 2019; Sousa, 2014; Morse, 1994). Deductively, we also applied a sensitizing framework derived from the literature review and research questions to organize data around theoretically relevant constructs and to enhance validity (Bell & Waters, 2018). We also iterated between our emergent themes and the literature to position findings and identify gaps (Okoli, 2023).

Pattern identification thus proceeded both bottom-up, themes arising directly from data, independent of prior theory (Frith & Gleeson, 2004) and top-down, guided by pre-selected concepts and prior studies (Hayes, 1997). Such abductive blending is widely used to strengthen primary qualitative research (Azungah, 2018). Four overarching themes structured the analysis and later results: content marketing use, digital advertising use, comparative and integrated approaches, constraints and future strategies.

Table 1: Characteristics of participants in the semi-structured interviews

R	Role	Business: Vertical & Type	Business Size	Location	Number of Employees and Years of Operation	Marketing Management
R1	Head of Business Development	B2C, Retail, Electrical Appliances	Medium	Paphos	37 years, 22 employees	Internal marketing department in collaboration with an external consultant
R2	Social Media Manager & Content Creator	B2C, Medicine, Plastic Surgery Clinic	Small	Nicosia	5 years 10 employees	Internal Marketing Department

R	Role	Business: Vertical & Type	Business Size	Location	Number of Employees and Years of Operation	Marketing Management
R3	Marketing Manager	B2B, Regulatory technology	Medium	Larnaca	2 years 32 employees	Internal marketing department in collaboration with an external consultant
R4	Owner	B2C, Hospitality, Cafe, Bar	Small	Larnaca	8 years 4 employees	Internal marketing management
R5	Owner	B2C, Medicine, Wellness. Hyperbaric Treatment with Oxygen (HBOT)	Small	Paphos	1 year 1 employee	Internal marketing department in collaboration with an external freelancer
R6	Chief Operating Officer	B2B, Marketing Agency	Small	Larnaca	4 years 10 employees	Internal marketing department
R7	Owner	B2C, Real Estate, Hospitality	Small	Paphos	3 years 3 employees	Internal marketing department in collaboration with an external freelancer
R8	Head of Communications and Media	B2C, News	Medium	Nicosia	20 years 55 employees	Internal marketing department in collaboration with an external freelancer
R9	Owner	B2C Retail, Clothing	Small	Nicosia	2 years 2 employees	Internal marketing management
R10	Digital Marketing & Communications Manager	B2C, B2B, Legal, Firm	Medium	Limassol	25 years 25 employees	Internal marketing department in collaboration with an agency
R11	Copywriter	B2B, Financial Services	Medium	Limassol	6 years 60 employees	Internal Marketing Management
R12	Account Executive	B2B, Marketing Agency	Medium	Nicosia	35 years 35 employees	Internal Marketing Management
R13	Owner	B2B, IT services	Small	Limassol	10 years 2 employees	Internal Marketing Management
R14	Social Media Manager & Content Creator	B2B, Marketing Agency	Small	Paralimni, Famagusta	2 years 8 employees	Internal marketing department in collaboration with freelancers

Table 2: Thematic Analysis

Coding Frame	Thematic	Summary of Patterns
Content Marketing Use	• Key content usage objectives • Types of content produced • Use of platforms • Content strategy • Frequency of posts • Effectiveness evaluation • Key challenges	• Increase recognition, trust and potential customers (leads), strengthen relationships with the public. • Social media posts in carousels and static images and informative captions, videos, newsletters, articles. • Instagram, Facebook, LinkedIn (mainly B2B). • Strategy for increasing recognition and branding, educational content. • Strategy with plans and content themes, combined with spontaneous approaches and trend-based material. • Meta & Social Media Insights, LinkedIn analytics, Google Analytics. • Lack of time and expertise.
Digital Advertising Use	• Digital advertising platforms they use	• Facebook, Instagram, Google. • Search ads, Social Media (Meta) Ads, Video Ads

Coding Frame	Thematic	Summary of Patterns
	• Ad formats they consider most effective • Ad management • How the budget is determined • Methods for evaluating effectiveness • Changes in strategy in recent years	• Internal management, in collaboration with an external partner. • Fixed for some campaigns. Varies depending on seasonality, offers, and goals. • Impressions, Reach, CPC, CTR, Conversions, ROAS. • Video Content, Personalized advertising, targeted campaigns, investment in Google Ads.
Comparative/Integrated Approaches	• Understanding the importance of organic vs. paid marketing • Ideal budget allocation percentage • Practices considered most effective for combining strategies • Differences in organic and paid performance • Specific results in terms of recognition, traffic, sales • Examples of successful campaigns	• They work together, paid is more effective, and organic builds trust. • Organic marketing builds trust and relationships, while advertising brings speed and traffic. Paid advertising brings immediate visibility. • 90% organic, 10% paid. 60% organic, 40% paid. • Consistency, authenticity, and good knowledge of the audience. Content strategy, content pillars, KPIs. • Corporate organic content that shows people, on a more personal or influencer level, has better engagement quality. Paid content has immediate impact and can bring results with potential customers, but not always quality ones. • Significant improvement in recognition, traffic, and sales • Campaigns, videos, reels, and targeted ads.
Constraints and Future Strategies	• Key constraints in the implementation of digital marketing • Identification of support needs • Assessment of adequate information for SMEs on best practices • Practices to be followed by SMEs in Cyprus • Trends expected to dominate in the coming years • Ways to adapt to changing requirements	• Limited budget for advertising and advanced tools, difficulty competing with larger marketing teams. • Training in video creation, Google Ads, SEO, AI. • Insufficient information. • Understanding the audience, investing in quality content and training in digital marketing, being open to hiring marketers or consultants. • User-generated or employee-generated content, human-centric personalized content, video, micro-influencers, AI. • More personalized, interactive, and automated, dependent on artificial intelligence. Videos will be at the top.

4. Findings

4.1 Current Usage of Content Marketing in SMEs

Cypriot SMEs actively combine content marketing with paid ads, using formats such as carousels, images, short-form video (Reels, TikTok), Stories, newsletters, blogs, and occasional webinars. Content mixes educational tips, seasonal offers, testimonials and behind the scenes material. Instagram and Facebook are most used in B2C, LinkedIn in B2B, YouTube for long-form content and TikTok for younger audiences. The posting strategies of different organizations show distinct patterns because some companies use planned schedules which include weekly and monthly content themes while others share content based on random opportunities.

"We follow a monthly content calendar, with weekly blog articles and 3–5 social media updates per week" (R10).

"We also use Reels and TikTok videos and send newsletters to previous guests with offers" (R7).

"We publish social media posts featuring the projects our agency has run and other behind-the-scenes content, as well as fun office challenges to drive engagement and help people get to know us. We also write articles on our own platform and publish them on other well-known platforms. (R12)"

4.2 Paid Advertising Practices

Google Search Ads are preferred for high-intent conversions, while Meta (Facebook/Instagram) supports reach and retargeting. LinkedIn is used selectively for B2B but seen as costly in Cyprus. Ad management is mainly in-house, with occasional consultant input; monthly budgets range from €200 to €3,000.

"Our goal is best served by Google Ads because there is search intent. They bring the best ROI" (R3).

"We use Facebook and Instagram Ads because they give us easier access to the local audience" (R4).

4.3 Challenges Faced

The main constraints are limited budgets, time, and expertise, compounded by algorithm changes and larger competitors. Many SMEs struggle to balance marketing with other responsibilities.

"The main challenge is lack of time, since the person handling marketing has other responsibilities" (R4).

"Limited budget for advertising and advanced tools and difficulty competing with larger teams" (R10).

4.4 Measurement and Outcomes

SMEs track their business performance through GA4 and platform analytics systems and their CRM software which they use from time to time. Core KPIs include CTR, CPC, conversions, and ROI/ROAS. The conversion rates for Search Ads perform well while video content helps brands reach more people and get better engagement. The production of organic content establishes trust between businesses and their audience yet it fails to reach large audiences when companies do not pay for promotion.

"We monitor CPC, CTR, conversion rate and ROI to assess performance" (R10).

"Google Analytics, Instagram Insights, and CRM help us track leads and campaign performance" (R8).

4.4.1 Effectiveness of Organic vs. Paid

Participants view organic and paid as complementary. They believe that organic builds trust and long-term engagement, while paid ensures visibility and immediate results.

"Ads bring immediate results, whereas organic helps with branding and audience retention" (R4).

"Both are essential, organic content has very little reach without paid advertising" (R1).

4.5 Case Patterns and Strategy Shifts

B2B businesses use LinkedIn and SEO for their marketing efforts which they schedule using organized calendars. Local B2C businesses use short-form videos and geo-targeted Meta ads (Facebook and Instagram adverts). Many SMEs have shifted from boosting posts to structured, full-funnel campaigns, with budgets split differently by sector (e.g., 60-70% organic vs. 30-40% paid or heavily paid-focused for performance targets).

"Instead of simply boosting posts, I moved to creating more structured campaigns with specific goals and better targeting" (R5).

"We have adjusted our strategies to place emphasis on video-first content and to follow changes in social media algorithms" (R14).

4.6 Emerging Trends

Human-centred content, short-form video, UGC, micro-influencers and AI-assisted creation are seen as future priorities by the professionals.

> *"Human-centred content showcasing customers or employees will prevail" (R1).*
>
> *"AI-based personalisation, influencer marketing and UGC will dominate in my opinion" (R11).*
>
> *"More personalized videos with people speaking and micro-influencers will have a bigger impact locally" (R6).*

5. Discussion

Our results align closely with established work showing that SMEs benefit most when they treat content and paid media as complements rather than substitutes. International guidance (Tiago & Veríssimo, 2014) frames content as the long-term engine of trust and search visibility, while paid channels supply controllable reach and short-term demand capture, precisely what our participants described. The growing video-first emphasis and the use of short-form formats mirror global best practices, as do the reported gains from Search Ads for high-intent traffic and Meta for broad reach and retargeting. Best-practice playbooks also stress measurement discipline and iterative optimisation (clear KPIs, A/B testing, funnel tracking). Here, Cypriot SMEs show progress, using GA4, platform analytics, and in a few cases CRM, yet they still trail the more mature "data-driven" benchmarks seen internationally. Finally, our findings that organic visibility now often depends on paid amplification indicates the need for broader industry observations and practitioner surveys.

In Cyprus's small and relationship-driven market, limited budgets and lean teams shape SME marketing choices. In this light, Meta and Google Resource constraints drive reliance for their cost control and targeting and LinkedIn's higher CPMs restrict its use to selective B2B goals. The execution of campaigns faces obstacles because business owners must handle daily operations while marketing activities continue and their lack of skills in analytics and video production and PPC advertising hinders their work. The natural decline of organic reach becomes more severe for accounts which have fewer following because businesses need to pay for advertising to keep their online presence in the current environment. SMEs experience multiple advantages from their customer accessibility, well-established community relationships and genuine business approach which makes human-centered storytelling, UGC and micro-influencer collaborations most effective. Organizations which want to grow through data-based methods need to establish CRM systems and GA4 platforms for their operations.

6. Conclusion

Digital marketing is shown to be integral to SME growth. Cypriot SMEs in our sample recognise marketing as a core function and are investing in digital tools, though adoption remains limited by budgets, skills gaps and organisational resistance (Peter & Vecchia, 2020; Sharabati et al., 2024).

Moreover, the main discovery shows that content and paid advertising function as complementary elements which work together. Content serves to build audience trust while it establishes enduring value which paid media delivers instantaneously through its reach and performance metrics. Specifically, organizations selected Google to reach customers who showed strong purchase intent but they used Meta for broad audience exposure and follow-up advertising and LinkedIn served specific business-to-business marketing needs. Short-form video was shown to be the most effective format, supported by other media. Authentic, human-centred storytelling drove engagement (Lopes et al., 2022), with trends such as AI-assisted creation, UGC and micro-influencers expected to develop as trends.

Measurement practices are improving, with GA4 and platform analytics common, though analytical depth is constrained by resources. SMEs combining up to date content with targeted paid campaigns and KPI tracking reported growth in awareness, traffic and thereafter, sales.

Taking everything into account, SMEs in Cyprus are leaning toward hybrid approaches. Paid media offer speed and broad reach, while organic content builds trust. However, more precise planning, meaningful upskilling and established processes (such as content calendars) are required for further development. This study contributes to digital marketing literature by emphasising how small-market enterprises may align consistent,

audience-relevant content with tactical sponsored ads, prioritising authenticity and improving through experimentation and learning cycles.

Abstract: Circular business incentives encourage the use of biobased materials and technologies to replace fossil-based materials and look for material alternatives that support reaching overall sustainability targets. Biocomposites continue to gain acceptance as potential substitutes for conventional fossil-based plastics and composites, supported by developments in biobased fillers, fibre-matrix interfaces, and scalable processing techniques. Industrial adoption is influenced not only by material properties but also by process-level requirements, manufacturing compatibility, and technoeconomic conditions across the value chain. Given the limited availability of comprehensive techno-economic studies of emerging biocomposites, this paper adds a qualitative perspective on the conditions that influence their adoption in industrial contexts. These insights inform a preliminary framework outlining the conditions under which biocomposites may progress toward competitive industrial performance. This study combines literature-based insights with preliminary insights from interviews across multiple stages of the biocomposite value chain to examine how organisations transition toward the use of biocomposite materials. Across the interviews, the emphasis is placed on meeting fundamental technical requirements, such as achieving process stability, consistent material quality, and alignment with established product specifications, as essential conditions for adoption. Interviewees also highlight that decisions increasingly draw on environmental performance data and highly economically driven scenario-based assessments. The reference material system is restricted to polyolefin matrices combined with cellulosic reinforcement or filler fractions, representing a baseline compound for which preliminary laboratory-level extrusion trials exist. Additives to improve weathering or fire performance are added at the early stages of the material base. Profile extrusion is selected as the industrially relevant processing method for continuous profiles across various construction applications. The technical system is represented as a conceptual process flow comprising feedstock preparation, compounding and pelletizing, pellet drying (as required), profile extrusion, and downstream calibration, cooling, haul-off, and cutting. These process blocks are described generically, and throughput values are estimated from various sources to reflect realistic economic drivers.

Keywords: Biocomposites, Economic Feasibility, Process Requirements, Industrial Adoption, Technology Assessment

1. Introduction

The increasing use of biocomposites offers the potential to replace fossil-based materials with more sustainable alternatives. These materials typically incorporate industrial fibre side streams, such as sawdust, agricultural residues, and pulp fibres, combined with polymers including polyethylene (PE), polypropylene (PP), and polyvinyl chloride (PVC) through various manufacturing processes (Quarshie and Carruthers, 2014). Several application sectors, such as automotive components and decking wood plastic composites (WPC), have already successfully integrated biocomposites into large-scale production (Campilho, 2017). WPCs have gained extensive industrial acceptance by combining recycled plastics with wood-derived side streams, such as sawdust, and processing these materials into products like decking via extrusion. In 2019, Europe reported over 30 biocomposite producers, with an annual production volume exceeding 130,000 tons (Mason, 2026).

The market size is also very attractive to many players and new entrants, with a 2024 estimate of 33 billion dollars and rapid growth towards 111 billion by 2033, indicating strong promise for the adoption of biocomposites despite associated challenges (Sharma, 2025). These market developments are expected to attract manufacturers and material users seeking sustainable alternatives. In particular, biocomposites offer potential for applications requiring lightweight materials and reduced environmental impact.

Nevertheless, numerous challenges persist, including product specifications, compatibility issues, quality assurance, moisture-related problems affecting biocomposite properties, fabrication costs, supply chain availability, and inconsistent material sources, all of which necessitate advanced engineering systems (Andrew and Dhakal, 2022). Consequently, integrating biocomposites into existing manufacturing processes requires a thorough understanding of the materials before making investment decisions to optimise the benefits derived from these innovative material sources.

Although biocomposites have been already studied from material, processing, and sustainability perspectives, less attention has been given to how industrial actors evaluate the combined technical, process-related, and economic conditions required for adoption. Existing studies often examine individual barriers such as material performance, cost, or environmental impact separately, providing limited understanding of their interaction in industrial decision-making. This study addresses this gap by examining how industrial value-chain actors assess biocomposite adoption readiness and which techno-economic factors most strongly influence adoption decisions.

> RQ1 What technical, process-level and techno-economic conditions shape the industrial adoption readiness of biocomposites in profile-extrusion-based applications?
>
> RQ2 How do industrial value-chain actors evaluate the technical, process and economic conditions required for adopting emerging biocomposites in industrial applications?

By focusing on these questions, we aim to provide more information on novel material development, their potential, and the early lab-to-market possibilities, as well as the factors that affect the adoption of new technologies, using techno-economic decision criteria required for industrial adoption.

2. Methodology

This study combines evidence from a literature review, project documentation, market analyses, project meetings, and semi-structured interviews with industrial stakeholders. The objective is to develop a preliminary understanding of the technical, process-related, and techno-economic conditions influencing industrial biocomposite adoption. Given the exploratory nature of the study, the findings should be interpreted as indicative rather than statistically generalisable.

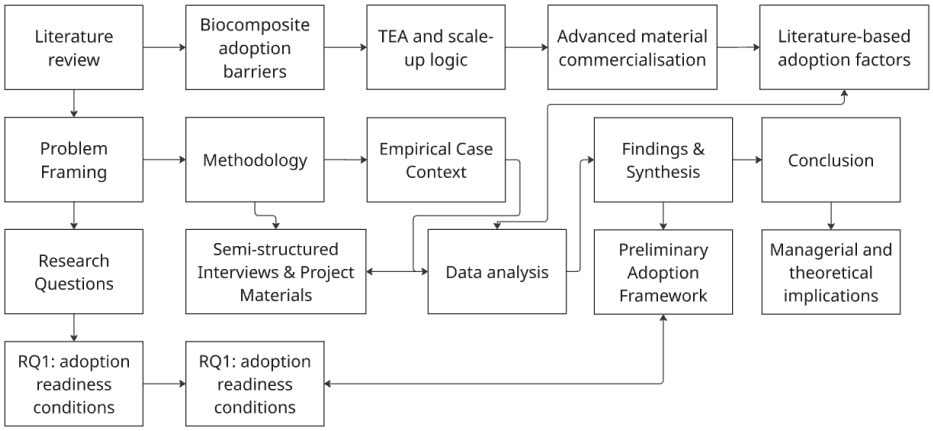

Figure 1: Overview of the preliminary research design and framework-building logic for assessing biocomposite adoption readiness

2.1 Literature Review Process for Papers

To ensure the rigour of the study's relevance (Arksey and O'Malley, 2005), various scoping search strategies were implemented to narrow down the most suitable research papers on biocomposites that were close to the project case study materials. Technical limitations are presented in case description chapter. Various programs were used to search for relevant literature, such as Litmaps, Google Scholar, Scopus, and Zotero for source control. The following topics and combinations were used to screen relevant papers: biocomposites, techno-economic analysis, life-cycle assessment, material-selection methods, circularity, and industrial scale-up. The purpose was to help synthesise supporting findings to understand material feasibility and scaling up from laboratory to industrial scale. The selected studies were used to identify transferable adoption factors. Each article was reviewed and summarized into different main categories; some papers were highly focused on certain aspects while some provided broader picture in this domain. From this preliminary study it is possible to continue towards further systematic review process. The process also involved project-related work to exchange information between other work packages to gain a better understanding of the domain-specific critical matters.

2.2 Interviews and Project Meetings

The primary empirical data for this study were collected through semi-structured interviews and project-related materials. Additional insights were obtained from project workshops involving material development experts, which helped define the problem setting and identify key areas for investigation. Respondents were selected through purposive sampling to represent different stages of the biocomposite value chain, including feedstock suppliers, material producers, manufacturers, and end users. In total, eight interviews were conducted, each lasting approximately one hour, with roughly half of the discussion dedicated to techno-economic assessment (TEA) topics. Semi-structured interviews were selected because they provide a consistent thematic structure while allowing respondents to elaborate on application-specific requirements, practical constraints, and adoption conditions (Kallio et al., 2016).

Interview transcripts were analysed using a Gioia-inspired thematic approach (Gioia, Corley and Hamilton, 2013). First-order concepts were identified directly from respondent statements and subsequently grouped into second-order themes related to technical requirements, process compatibility, economic feasibility, supply-chain readiness, and adoption conditions. The emerging themes were compared with findings from the literature review to identify converging and diverging factors affecting industrial biocomposite adoption. This approach provided a systematic structure for interpreting stakeholder perspectives and developing the preliminary adoption framework.

Table 1: Respondents background and connection to biocomposites domain

#	Value-Chain Role	Application Context
R1	Material / recycling actor	Polymer and composite materials
R2	Fibre or feedstock actor	Cellulosic raw materials
R3	Building product manufacturer	Profiles / construction components
R4	Biocomposite producer	Industrial compounds
R5	Industrial OEM / device manufacturer	Long-life components
R6	Marine / regulated end-user	Harsh environment applications
R7	Plastic product manufacturer	Moulded or processed components
R8	Circular material producer	Recycled and biobased products

The objective of the sample was not statistical representation but to capture diverse perspectives from key stakeholder groups involved in the development, production, adoption, and use of biocomposites. For the techno-economic part of the interview, the questions focused on the conditions under which biocomposites could become viable substitutes for existing materials in industrial applications. The design therefore addressed minimum technical performance requirements, acceptable cost levels, operational and investment-related barriers, manufacturing and quality assurance implications, supply-chain risks, and the techno-economic indicators most relevant for company decision-making. Benchmarking, scenario modelling and sensitivity analysis were also included to clarify what type of comparative evidence companies would need when assessing biocomposites against conventional material solutions.

3. Literature Review

3.1 Techno-Economic Analysis

In this study, techno-economic analysis (TEA) was originally planned for a preliminary level and mainly to identify core factors affecting the adoption of biocomposites in various parts of the value chain from production to end products and towards the end of life (EOL). Based on the literature review and general project feedback, TEA is an important step in adopting new concepts within business processes and should be treated as a core step in the planning stages. In recent years, the rise of digital simulation tools has increased, and predictions can become very detailed, including main economic and technical factors. (Chai *et al.*, 2022). In literature, biocomposites are complex items to estimate due to more factors compared to fossil-based plastics and much more variable material bases and related environmental push, which has many subsidised programs increasing estimation variables. It is typical also to include intricate carbon credit schemes (biochar stabilisation and burning side products), and there are trade-offs in properties between economic, technical and environmental

aspects. (Mousavi-Avval *et al.*, 2023) For this study, the adoption perspective and TEA are closely related, as often lab-scale testing fails to prove technology at industrial levels, and for that, TEA modelling is crucial to convince relevant actors of its feasibility (Zeng, 2025). Few studies about biocomposites in close fields (different material feeds) and TEA utilise life cycle costs (LCC), net present value (NPV) methods, sensitivity analysis to identify impactful economic factors, like investment into production facility, material costs, logistics, taxation, salaries, equipment and many others, depending on the situation. (Roy *et al.*, 2024)

3.2 New Technology Adoption in Material Domains

Biocomposites development can be viewed as a traditional adoption process with stage-gate decision-making and typical product design perspectives, aiming to view a holistic approach from the start when first material choices are made. In such a chain, process problems would be solved as they arise during implementation. The core focus is on customer needs and market pressure, combined with competitive advantages such as environmental pressures on fossil-based products. (Albiñana and Vila, 2012) This shows clearly that the first wave of biocomposites has been in relatively simple products like decking, with access to stable side streams. Another major step would be to diversify production towards more novel applications of biocomposites, which would require a deeper understanding of the material to produce higher-value products, an approach partially recognised in the study of advanced materials (Maine and Garnsey, 2006).

3.3 Biocomposites Adoption Barriers

Based on the literature, various issues and benefits have been presented over the last few decades of research. Still to this date, problems like moisture sensitivity, fibre matrix compatibility, thermal limits, flammability, supply variability, and processing challenges remain as challenges for advanced biomaterials adoption. (Andrew and Dhakal, 2022) As for the existing commercial product, WPC have already been recognised as an industrially mature and viable solution, though thermal issues like degradation are still present in 200 °C areas for wood-based side streams utilisation potential. A common way to improve weak properties is to use fillers to improve hydro stability or flame resistance and weather durability (UV), which is crucial in decking applications from an end product perspective. (Mitaľová, Mitaľ and Berladir, 2024) The following table is a preliminary summary of various factors; the list is not exhaustive and is indicative for the study purpose.

Table 2: Summary of various identified adoption barriers according to various sources around biocomposites.

Adoption Factor	Relevant Contents	Source
Material variability	Natural fibres and wood-based fillers vary by source, particle size, moisture content, processing history and fibre treatment. This affects reproducibility and makes consistent product quality difficult.	(Faruk *et al.*, 2012)
Fiber–matrix compatibility	Cellulosic fillers are hydrophilic, while PP, PE and similar polyolefins are hydrophobic. This creates adhesion problems unless coupling agents or compatibilizers are used.	(dos Santos, Flores-Sahagun and Satyanarayana, 2015; Andrew and Dhakal, 2022)
Moisture resistance and durability	Moisture absorption, swelling, dimensional instability and weathering reduce adoption potential, especially in outdoor or construction-related products.	(Elsheikh *et al.*, 2022; Terzopoulou, Achilias and Vouvoudi, 2025)
Processing temperature limits	Cellulosic fillers have limited thermal stability, which restricts processing temperatures and narrows the process window for thermoplastics.	(Mitaľová, Mitaľ and Berladir, 2024)
Filler loading trade-off	Increasing sawdust or fibre content improves renewable content and circularity, but can reduce tensile strength, increase water uptake, worsen melt flow and complicate extrusion.	(Hillig *et al.*, 2008; dos Santos, Flores-Sahagun and Satyanarayana, 2015; Friedrich, 2024)
Additives and compatibilizers	Coupling agents, lubricants, UV stabilisers, biocides, pigments and flame retardants are often needed to meet application requirements.	(Mitaľová, Mitaľ and Berladir, 2024; Terzopoulou, Achilias and Vouvoudi, 2025)
Process compatibility	Biocomposites must fit existing extrusion, moulding or forming systems with limited disruption. Tooling, die design, feeding, cooling and calibration strongly affect feasibility.	(Hillig *et al.*, 2008; Friedrich, 2023)

Adoption Factor	Relevant Contents	Source
Product specification fit	Industrial users evaluate materials against application-specific requirements such as strength, dimensional stability, aesthetics, moisture resistance, fire behaviour and compliance.	(Andrew and Dhakal, 2022; Friedrich, 2023)
Supply-chain reliability	Feedstock collection, storage, preprocessing, drying, particle-size control and contamination management affect product quality and cost.	(Akbarian-Saravi *et al.*, 2025; Akbarian-Saravi, Sowlati and Milani, 2025)
Economic feasibility	Adoption depends on whether higher material or processing costs can be justified through performance, sustainability value, customer demand or regulatory advantage. Differences exists also in processing methods like extrusion vs. injection moulding.	(Immonen *et al.*, 2020; Friedrich, 2024)09/09/2026 15:31:00
Circular and regulatory value	Circular-economy incentives, recycling targets and environmental performance create adoption pressure, but they do not remove technical and economic requirements.	(Bledzki *et al.*, 2012; Fernández Fortunato, Jiménez-Sáez and Hontoria, 2023)

Although biocomposites have been widely studied, with more than 12,000 publications indexed in Scopus, direct techno-economic studies remain limited, particularly for sawdust-filled PE and PP matrix composites. Most prior research focuses on material performance, processing behaviour, environmental impacts, or individual adoption barriers in isolation. Comparatively less attention has been given to how industrial actors simultaneously evaluate technical, process, supply-chain, scalability, and economic considerations when making adoption decisions. Consequently, the interaction between these dimensions remains insufficiently understood from an integrated techno-economic perspective. This study addresses this gap by examining how industrial value-chain actors assess adoption readiness and how technical, process-related, and economic factors jointly shape industrial adoption decisions.

4. Case Description

The empirical context of this study is a research project focused on advanced biocomposites and circular design. The project develops and assesses biobased and recycled thermoplastic biocomposite solutions intended to replace fossil-based plastics and conventional composites in more demanding industrial applications. The project combines material and process development, circular design, end-of-life considerations, demonstration products, techno-economic assessment, regulatory analysis, and business model exploration. The case provides a relevant setting for examining how process requirements, industrial feasibility, sustainability expectations, and market-related factors shape the potential adoption of biocomposites in industrial value chains.

4.1 Technical Case Context: Material Formulation and Extrusion Processability

In the experimental part of this project, multiple different reference biocomposite materials were produced. The commercially available plastic matrices used were recycled polypropene and biobased low-density polyethylene. In addition, various additives and aids were used to improve processability, feeding behaviour and dispersion of the compounded materials. No additives were used to make chemical modifications. Sawdust and bleached softwood kraft pulp were used as fillers.

Plastic matrices and fillers were first dried overnight, then compounded and granulated for extrusion. All biocomposite materials were tested using a lab-scale single screw extruder. A typical extrusion trial set-up is depicted in Figure 2 below. As was expected, most of the biocomposite samples showed moderate or even poor surface quality during the first extrusion trials.

Figure 2: Left: Variation of the surface quality of biocomposite samples (Image: Reijo Heikkinen). Right: A lab-scale extruder producing a biocomposite profile. (Image: Kusti Ruokamo)

Process parameters were adjusted to improve feeding behaviour, melt flow and surface quality of the extruded biocomposite profiles. At higher filler contents, increased melt viscosity created clear processing challenges and limited stable material feeding. As the results are based on lab-scale trials, they should be interpreted as preliminary, but promising. Further process optimisation may improve manufacturability and support future scale-up potential in construction profiles and other suitable application areas for extrusion technology.

5. Findings

5.1 Interviews

The interview findings indicate that industrial adoption of biocomposites is not determined solely by material sustainability. Across respondents, adoption was mainly linked to biocomposites' ability to meet application-specific technical requirements, remain economically competitive, fit existing production systems, and provide a reliable supply at an industrial scale. The results, therefore, suggest that techno-economic feasibility depends on the combined assessment of material performance, processing compatibility, cost structure, investment needs, supply-chain readiness and evidence-based comparison with existing materials. As the empirical analysis is still preliminary, the interview material is summarised using a condensed Gioia-informed structure rather than a full coding model.

Table 3: Preliminary Gioia-style summary of interview-derived adoption conditions for biocomposites

First-Order Interview Signals, Condensed	Second-Order Theme	Aggregate Dimension
Must match plastics, aluminium, steel or current composites in the target use case.	Technical equivalence	Application-specific performance threshold
Outdoor, marine and long-life uses require durability, weather resistance, fire behaviour, fixing and aesthetics.	Application-specific technical fit	Application-specific performance threshold
Material must be stable, consistent, processable and compatible with dies, moulds and temperature windows.	Process stability and manufacturability	Process compatibility
Material change may require tooling, mould modifications, QA changes, new lines or capital investment.	Operational adaptation requirements	Process compatibility
€/kg and €/part must be close to incumbent materials unless a clear value premium is justified.	Cost parity or value justification	Economic feasibility
Decisions depend on production volume, payback time, process route and raw-material price sensitivity.	Investment and payback logic	Economic feasibility
Industrial users require stable supply, predictable quality, traceability and documentation.	Supply-chain reliability	Scale and supply readiness
Confirmed customer demand, partner capability and sufficient application volume are needed before scale-up.	Market pull and ecosystem readiness	Scale and supply readiness
CO_2 footprint, LCA, circularity, recycling and regulation increasingly support material evaluation.	Environmental and regulatory value	External adoption drivers
Benchmarking and scenario modelling are needed against current material references and regulatory shifts.	Comparative evidence and scenario TEA	Decision-support logic

The preliminary interview results indicate that biocomposite adoption is mainly shaped by interrelated conditions: technical equivalence, application-specific fit, process compatibility, economic feasibility, supply-chain reliability, and evidence-based comparison with existing materials. Based on the interview findings, the aggregate dimensions can be interpreted as preliminary adoption-readiness propositions requiring validation in future studies.

5.2 Data Analysis and Comparison with Literature-Derived Adoption Factors

First, respondents emphasised that biocomposites must meet the minimum technical requirements of the target application before sustainability benefits become commercially relevant. These requirements vary strongly by use case, with stricter expectations in outdoor, long-life, marine, construction, and regulated environments. While previous studies have identified performance requirements as adoption barriers, the interviews suggest that industrial actors evaluate these requirements primarily through application-specific risk. This indicates that adoption decisions are not driven solely by material properties, but by the consequences of failure within the intended application context.

Second, process compatibility was repeatedly identified as a practical adoption condition. Biocomposites need to fit existing production systems, tooling, quality assurance routines, and subcontractor processes with limited disruption. Where major process changes or new investments are required, adoption risk increases. The findings suggest that process compatibility may represent a stronger adoption constraint than material performance itself. Even technically promising materials may face resistance if implementation requires substantial modifications to existing production systems, tooling, or quality-control procedures.

Third, cost competitiveness remains central. Respondents indicated that biocomposites should remain close to the cost level of incumbent materials, unless they provide a clearly demonstrable value premium through lower carbon footprint, circularity, weight reduction, regulatory advantage, or stronger sustainability positioning. The interviews indicate that cost competitiveness is evaluated relative to perceived value rather than solely on material price. This suggests that successful adoption may depend on demonstrating measurable operational, regulatory, or sustainability benefits that justify a cost premium.

Fourth, stable supply and material consistency were seen as decisive for industrial use. Respondents highlighted that predictable quality, sufficient volumes, documentation, traceability, and supplier reliability are necessary before biocomposites can move from trial use to wider adoption. This finding indicates that supply-chain readiness may become a decisive adoption factor once the minimum technical requirements are met. Respondents also highlighted that feedstock variability, evolving recycling streams, and inconsistent material compositions may challenge stable product quality at an industrial scale. These concerns extend beyond material properties to include logistics, traceability, recycling infrastructure, and evolving producer responsibility requirements. Furthermore, degradation effects and material-property fluctuations may limit the reuse of recycled biocomposite streams, creating additional challenges for maintaining consistent performance and supply reliability.

Finally, the interviews suggest that companies need comparative evidence before committing to new materials. Benchmarking against existing materials, scenario-based techno-economic assessment, and sensitivity analysis were considered useful tools for evaluating costs, performance, lifecycle value, investment risk, and demand uncertainty. This was partially related to literature reviews, which mostly tested different stocks and possibilities. The challenge is to demonstrate industrial adoption scale convincingly; respondents would require more than small-scale lab tests to adopt biocomposites at scale. Overall, the interview results suggest that biocomposite adoption requires moving from general sustainability promises toward application-specific techno-economic evidence. Rather than evaluating technical, economic, or sustainability factors independently, respondents viewed adoption as a combination of interconnected conditions. Material performance, processing feasibility, cost structure, supply readiness, and comparative value, therefore, need to be assessed together at the system level before industrial-scale-up decisions can be justified.

5.3 Answers to Research Questions

RQ1 Technical readiness depends on meeting application-specific requirements such as durability, moisture resistance, dimensional stability, fire retardancy, mechanical performance, aesthetics and compliance. In profile extrusion, process readiness is also critical, as feeding behaviour, melt flow, surface quality, die compatibility, and calibration affect manufacturability. Techno-economic readiness extends beyond material price and should include €/kg, €/part, production volume, throughput, tooling and QA needs, investment costs, payback time, supply risks and raw material price sensitivity. Overall, adoption depends on whether biocomposites can move from laboratory promise to stable, repeatable and economically justified production.

RQ2 Interviewed actors evaluated biocomposites mainly by comparing them with incumbent materials such as plastics, aluminium, steel and existing composites. Their evaluation logic was practical and risk-oriented, focusing on performance, production disruption, cost level, supplier reliability, documentation, regulatory relevance and customer acceptance. Sustainability value was seen as beneficial, but only after basic technical and economic requirements are met. Therefore, companies require benchmarking, scenario modelling and sensitivity analysis before committing to larger trials or investment.

6. Conclusion

Biocomposites adoption does not rely on a single strong factor but on a combination of various requirements, as described in the literature and interviews, evident in lab-scale tests and in benchmarking against existing companies (Trex, 2025) with seemingly similar products and collection lines to produce biocomposites. This paper connects industrial value-chain perspectives with material and processing barriers through a qualitative perspective. While the existing literature typically examines material performance, environmental impacts, or economic feasibility separately, the findings suggest that industrial adoption decisions are based on the interaction among technical equivalence, process compatibility, economic feasibility, supply readiness, and comparative evidence. These insights can guide future TEA modelling of sustainable biocomposite development and adoption.

The study contributes a preliminary adoption-readiness framework that extends prior adoption-barrier studies by integrating technical, process, supply-chain, and economic factors into a single adoption-readiness perspective. In practice, the framework can support early-stage screening of novel, untested biocomposite opportunities by helping developers identify critical requirements before major scale-up decisions. The key adoption conditions identified in this study are:

- Technical equivalence
- Application-specific fit
- Process compatibility
- Economic feasibility
- Scale and supply readiness
- Comparative evidence

On a lab scale, various trials should be conducted to verify quality and adjust parameters. From an economic perspective, companies can compare core factors such as €/kg and total process adoption costs for adoption review. For suppliers, biocomposites need to be well-defined, and traceability is crucial to maintain a consistent supply or accommodate changes in process parameters. There are already indications of upcoming regulations for material characterisation supporting directions, and many companies are strongly committed to environmental product declarations (EPDs) combined with LCA. (Olanrewaju, Enegbuma and Donn, 2025)

6.1 Limitations and Future Research Directions

The purpose of the study was not to provide a complete TEA model, but to identify the adoption conditions that should guide future techno-economic modelling for biocomposites in more demanding application areas.

Due to the exploratory nature of the study and the limited number of interviews, the findings should be considered indicative and validated through larger cross-sector studies.

Ethics Declaration

This study is based on semi-structured interviews with professionals representing different stages of the biocomposite value chain. Participation was voluntary, and the study's purpose was explained to the respondents. The interview data were anonymised, and no personal or sensitive data were reported in the paper.

AI Declaration

Artificial intelligence tools were used only for language refinement, including sentence condensation, grammar correction, and readability improvement. AI was not used to interpret interview data, conduct the analysis, or generate the conclusions. All analytical decisions and final interpretations remain the responsibility of the authors.

Dynamic Signal Formation: A Longitudinal Case Study of Steve Jobs's Voice

Satoshi Miyajima
Graduate School of Management, Kyoto University, Kyoto, Japan

miyajima.satoshi.3s@kyoto-u.ac.jp

Abstract: Existing signaling research has predominantly focused on the effects of signals on evaluative outcomes, while the processes through which signals are formed and transformed over time remain under-theorized. In particular, prior work has tended to treat signals as stable attributes, overlooking their temporal emergence and adaptation across shifting contexts. This study addresses this gap by reconceptualizing nonverbal signals, particularly vocal signals, as dynamic processes rather than static attributes. Building on signaling theory, the study investigates how such signals emerge, adapt, and evolve across time and context, thereby foregrounding the processual nature of signaling. To capture these dynamics, a longitudinal single-case research design is employed, analyzing keynote presentation audio data from Steve Jobs. Specifically, the analysis focuses on a series of keynote speeches delivered over a 28-year period, spanning from age 28 (1983) to age 56 (2011). This approach enables the examination of temporal variation and the identification of generative mechanisms underlying signal formation. Two exploratory quantitative analyses are conducted on acoustic features, including speech tempo, pauses, and pitch variation, allowing for a fine-grained assessment of within-individual changes over time. The findings reveal that while speech tempo remains relatively stable over time, pauses and pitch variation are systematically reorganized in response to shifts in role and organizational context. These results suggest that vocal signals are not fixed traits but evolve through continuous interaction with situational demands and accumulated career experiences. Furthermore, the accumulation of short-term adaptive adjustments appears to produce longer-term structural transformations in signaling patterns, indicating a recursive relationship between micro-level adaptation and macro-level change. By shifting the analytical focus from signal effects to signal formation, this study extends signaling theory into a temporally embedded framework that incorporates time, identity, and experience. The study contributes to the literature by providing empirical evidence for the dynamic nature of signaling and by proposing a conceptual foundation for understanding how strategic communication capabilities develop over the course of a professional career.

Keywords: Signaling Theory, Dynamic Signaling, Vocal Signals, Nonverbal Communication, Longitudinal Analysis

1. Introduction

Even highly successful executives such as Steve Jobs are not necessarily exceptional public speakers from the outset of their careers. Steve Jobs was an American entrepreneur and executive who co-founded Apple, NeXT, and Pixar, and is widely known for redefining consumer values through products such as the Mac, iPod, and iPhone (Isaacson, 2012). However, even a leader of his stature did not possess outstanding public speaking abilities when he first began his business career (Anderson, 2016).

A substantial body of research has examined how executives' strategic communication influences evaluative outcomes, yet insufficient attention has been paid to the processes through which such communication styles are formed. Prior studies have highlighted the role of gestures in impression management (Leary & Kowalski, 1990), the dominance of visual information in evaluative contexts (Tsay, 2021), and the association between stable speech tempo, pitch variation, and success rates (Miyajima, 2025). However, this line of research primarily identifies effective signals rather than adequately explaining the processes by which they are formed and evolve over time.

The purpose of this study is to build on signaling theory and dynamically examine the formation and transformation processes of nonverbal signals. To investigate phenomena that have not been sufficiently addressed in prior research and to uncover the generative mechanisms underlying such processes, a single-case study is an appropriate methodological approach (Yin, 2018). Accordingly, this study analyzes Steve Jobs's keynote presentations as a single case to explore how his vocal and other nonverbal signals were formed and transformed throughout his career, ultimately aiming to propose a theoretical framework of dynamic signaling in which signals are continuously generated over time.

The theoretical contribution of this study lies in reconceptualizing signaling theory along the long-term temporal axis of an individual life and in demonstrating the relationship between vocal signals and significant life events. While Jobs's speech tempo remained stable, his use of pauses and pitch was reorganized in response to shifts in role and organizational context, suggesting that vocal signals evolved through interaction with career turning points. The accumulation of short-term strategic adjustments led to structural updates in signal patterns. By

moving beyond an effect-centered view of signals and focusing instead on their formation process, this study advances a dynamic perspective on signaling.

2. Theoretical Background

2.1 Signaling Theory

This study is grounded in signaling theory. Signaling theory explains how, under conditions of information asymmetry, a signaler communicates unobservable attributes such as abilities or intentions to a receiver through observable signals (Spence, 1973). The receiver then infers underlying qualities from these signals, but this inferential process involves uncertainty and the possibility of strategic distortion (Crawford & Sobel, 1982; Connelly et al., 2011).

In environments characterized by uncertainty and risk, a signaler's attempt to actively shape others' perceptions can be understood as impression management. Impression management refers to the regulation of observable behaviors to influence how one is perceived by others (Goffman, 1959; Leary & Kowalski, 1990). Leaders form impressions of competence and credibility through nonverbal elements such as speaking style, vocal tone, and gestures (Bolino et al., 2016), and these behaviors can causally affect evaluative outcomes (Antonakis et al., 2011). However, prior research has focused primarily on the effects of signals, while the processes through which they are formed and transformed remain insufficiently theorized (Miyajima et al., 2025).

2.2 Dynamic Signals and Signal Formation

Nonverbal signals emitted by a signaler can be adjusted in response to situational cues and audience reactions, even within brief interactions. Miyajima et al. (2025) showed that vocal signals changed within a few minutes by comparing entrepreneurs' main pitch presentations with their question-and-answer responses. Nonverbal behavior is not necessarily consistent but depends on relational and situational context (Hall et al., 2005). Shifts in perceived power and emotional states are reflected in posture and speaking style, leading to changes in signaling (Keltner et al., 2003).

Signal transformation also unfolds over the long term through accumulated experiences and changing roles. When individuals encounter new roles, they engage in trial and error (Ibarra, 1999). Behaviors that are initially deliberate may gradually become internalized as expressions integrated into one's identity (Ashforth & Humphrey, 1993; Miyajima, 2025).

From a long-term perspective, signal formation can be understood as a process through which self-understanding and future orientation are expressed through behavior. Valsiner (2014) conceptualizes the self as comprising "I AM," identity shaped by the past, and "I WILL," future oriented intentionality, and emphasizes its continuous reconstruction over time. Extending this framework, "I HAVE" represents the current environment and links role and context to observable patterns of expression (Miyajima, 2025).

2.3 Prior Research on Steve Jobs's Presentations

Steve Jobs represents a theoretically valuable case for examining long-term signal formation. He has been positioned as a representative entrepreneur in the United States (Wong et al., 2026) and analyzed as a symbolic example of charismatic leadership and rhetorical competence (Heracleous & Klaering, 2014, 2017).

Prior research on Jobs has addressed both vocal characteristics and rhetorical–narrative dimensions. Vocal studies have identified features such as his high average pitch and wide pitch range (Niebuhr et al., 2016) and have shown that clear articulation is also associated with perceived charisma (Niebuhr & Gonzalez, 2019). In addition, rhetorical and narrative research has demonstrated that Jobs adjusted his storytelling to situational demands while maintaining consistent core themes, and that he presented future visions in ways that made them experientially real in the present (Heracleous & Klaering, 2014, 2017; Sarpong et al., 2019).

2.4 Research Gaps

Three research gaps remain in signaling theory. First, prior research has primarily examined signals in relation to evaluative outcomes and has not sufficiently conceptualized them as dynamic phenomena that evolve over time. Second, although the importance of nonverbal and behavioral signals has been recognized, the generative mechanisms through which these signals are formed and stabilized remain under-theorized. Third, signaling

theory has largely been developed within market-based contexts, and insufficient attention has been paid to signal formation across the life of executives.

2.5 Research Questions

To address these gaps, this study draws on Steve Jobs's longitudinal keynote data as a shared empirical foundation and formulates three research questions at distinct analytical levels:

> RQ1 (Theoretical Level). Within the framework of signaling theory, how should nonverbal signals be understood not as fixed attributes, but as dynamic processes that unfold over time and across contexts?
>
> RQ2 (Process Level). In the case of Steve Jobs, how were vocal and other nonverbal signals acquired, refined, and stabilized through short-term interaction and long-term experiential accumulation?
>
> RQ3 (Mechanism Level). How are changes in Jobs's self-understanding (I AM) and future orientation (I WILL) connected to the formation and transformation of his nonverbal signals?

3. Methodology

3.1 Research Design

This study conducts two quantitative analyses of Steve Jobs's keynote presentations based on signaling theory. It examines whether his vocal signals changed over time and across contexts. The research consists of two studies with distinct analytical scopes.

Study 1 compares the keynotes between early- and late-career stages, which are temporally distant from each other. By analyzing differences in duration, speech tempo, and voice pitch, it assesses whether changes in speaking style occurred.

Study 2 focuses on major turning points in Jobs's career and compares vocal characteristics across focal years. It examines the relationship between changes in role (Signaler) and organizational context (Environment) and the vocal features observed in the corresponding keynote (Signal Message) for each year. Using the same acoustic indicators, the study systematically describes differences in speaking style at these transition points.

3.2 Analytical Approach: Non–Hypothesis Testing Quantitative Design

Rather than testing predefined causal hypotheses, this study adopts an exploratory descriptive quantitative approach to document longitudinal variation in acoustic indicators. Consistent with methodological fit for process-oriented theory development (Edmondson & McManus, 2007), the analysis relates observed temporal patterns to shifts in role and context to inform theorization.

3.3 Sample

The focal case of this study is Steve Jobs. Extensive longitudinal keynote data are publicly available for Jobs, and major turning points in his career are clearly documented in biographical and historical sources. These characteristics make him a theoretically suitable case for analyzing long-term processes of signal formation.

This study focuses on publicly available keynote presentations. Other speech formats are excluded to ensure comparability, as keynote settings maintain stable purposes, audiences, and stage conditions across years, allowing temporal variation to be examined under consistent conditions.

The analysis proceeds by quantitatively extracting acoustic indicators from keynote recordings, including duration, speech tempo, and voice pitch. These measures are compared across years and examined in relation to major career turning points. Events such as business successes and failures, organizational departure and return, and changes in health status are organized chronologically to interpret shifts in vocal patterns within their experiential context.

3.4 Data Collection

In this study, the audio data and chronological information required for the analysis were systematically collected. Publicly available recordings of Steve Jobs's keynote presentations were obtained from an online archive (Moisescot, n.d.). When links in the archive were inaccessible, the relevant files were supplemented

through additional searches. Chronological information was collected from biographical sources (Isaacson, 2012).

3.5 Measures

Public speaking ability was operationalized using quantitative acoustic indicators directly derived from audio data. Each keynote recording was segmented at sentence and breathing boundaries and converted into WAV format. The following acoustic features were extracted using the Python library Librosa.

- Duration (seconds). Represents the length of spoken and silent segments, measured as the duration of spoken sentences and silent intervals in seconds.
- Speech tempo (BPM). Indicates speaking rate within a given interval, calculated as beats per minute, with higher values reflecting faster tempo.
- Voice pitch (F0, Hz). Fundamental frequency, measured in hertz (Hz), representing vocal pitch. Males generally exhibit lower F0 values than females.

These indicators are physically derived acoustic measures rather than latent psychological constructs; therefore, internal consistency reliability (Cronbach's α) is not applicable (Bollen, 1989). These measures directly capture temporal and spectral properties of speech (Boersma, 1993; Juslin & Laukka, 2003).

3.6 Analysis

In this study, a longitudinal analytical approach was employed to examine the development and evolution of Steve Jobs's public speaking abilities. The unit of analysis was defined as the year in which each keynote was delivered, and the analysis focused on three vocal indicators calculated for each year: duration, speech tempo, and voice pitch. First, descriptive statistics were used to summarize the year-by-year trends of each vocal indicator to capture long-term patterns of change.

Based on signaling theory, Jobs's role, organizational context, and keynote performance were classified for each year as Signaler (I AM), Environment (I HAVE), and Signal Message (I DID). Drawing on Miyajima's (2025) extension of Valsiner (2014), the classification relied solely on factual information documented in existing literature. Major career turning points were then positioned along a chronological timeline, and acoustic indicators before and after these events were compared to exploratorily examine their temporal correspondence.

4. Study 1

Study 1 compares Steve Jobs's public speaking at age 28 (1983) and age 56 (2011) to examine vocal differences between early- and late-career stages. To characterize duration patterns of speech ("On") and silence ("Off"), the relationship between the mean and median was analyzed, allowing a descriptive assessment of whether the distribution was homogeneous or included disproportionately long intervals.

4.1 Results of Study 1

- Duration (seconds). "On" segments were descriptively longer in 2011 than in 1983, while "Off" segments showed only minor differences (Table 1). No statistically significant differences were detected, although variability was higher in 2011.
- Speech tempo (BPM). Mean BPM did not differ significantly between 1983 and 2011, suggesting structural stability in speech rate across the two keynotes.
- Voice pitch (F0). F0 was significantly higher in 2011, with a large effect size. Although absolute variability increased, relative variability was slightly higher in 1983, indicating a more consistently elevated pitch in 2011.

Table 1: Descriptive Statistics and Nonparametric Results (1983 vs. 2011)

Measure	Year	Mean	Median	SD	IQR	CV	Min	Max	p	Δ
Duration "On" (sec.)	1983	1.68	1.50	0.71	0.94	0.42	0.73	4.20	.164	−0.19
	2011	2.23	1.77	1.34	1.80	0.60	0.27	5.74		

Measure	Year	Mean	Median	SD	IQR	CV	Min	Max	p	Δ
Duration "Off" (sec.)	1983	0.73	0.59	0.43	0.60	0.59	0.20	1.94	.391	−0.12
	2011	0.78	0.73	0.47	0.77	0.60	0.27	2.57		
BPM	1983	144.06	143.55	43.85	66.75	0.30	78.30	234.91	.507	0.09
	2011	136.48	136.00	32.05	34.55	0.23	73.83	198.77		
F0 (Hz)	1983	339.51	333.23	56.35	72.83	0.17	241.07	487.74	< .001	−0.85
	2011	479.85	486.57	73.84	119.71	0.15	306.26	590.80		

Note: "On" indicates segments in which the speaker is actively speaking, whereas "Off" indicates silent intervals between speaking segments. Nonparametric tests (Mann–Whitney U) were used. Negative Δ indicates higher values in 2011.

4.2 Discussion of Study 1

Study 1 suggests that speech tempo remained largely stable over time, whereas duration structure and pitch exhibited selective change. The absence of tempo differences indicates that vocal evolution did not occur through speed modulation, but rather through structural adjustments in pause configuration and pitch level. The significant upward shift in F0 in 2011 implies a transformation in vocal stance rather than random fluctuation.

5. Study 2

Study 2 examines whether the vocal differences identified in Study 1 reflect incidental variation or a process of nonverbal signal formation. Because a two-point comparison is insufficient, this study reconceptualizes nonverbal signals as dynamic processes that evolve over time and across contexts (RQ1).

It situates dynamic signal formation within Jobs's career trajectory and investigates how vocal indicators were acquired, refined, and stabilized through short-term adaptation and the accumulation of long-term experience (RQ2). It further examines how changes in role identity and future orientation are linked to the reconfiguration of nonverbal signals (RQ3). In doing so, the study theorizes vocal expression not merely as a technique, but as part of identity formation unfolding over time.

5.1 Results of Study 2

5.1.1 Dynamic Signal Formation Across Career Stages

Table 2 maps Jobs's role (I AM), environment (I HAVE), and keynote performance (I DID) across major career turning points. These mapped stages provide the analytical framework for examining longitudinal changes in vocal indicators.

Table 2: Steve Jobs's Signal Formation across Career Transitions

	Signaler	Environment	Signal Message
Year	I AM (Role and Position)	I HAVE (Context, Constraints, and Resources)	I DID (Observable Actions)
1983	Apple: Co-founder & CEO	Before being fired from Apple	Apple Lisa / Macintosh — graphical user interface as a signal of human-centered computing
1988	NeXT: Founder & CEO / Pixar: Chairman	Founded NeXT after leaving Apple	NeXT Computer — signaling technological purity and future-oriented OS design
1992	NeXT: Founder & CEO / Pixar: Chairman	Developing next-generation OS at NeXT while scaling Pixar as a serious animation studio	NeXTSTEP demonstrations — signaling long-term vision over short-term market success

Year	Signaler I AM (Role and Position)	Environment I HAVE (Context, Constraints, and Resources)	Signal Message I DID (Observable Actions)
1997	NeXT: Founder & CEO / Pixar: Chairman Apple: Advisor to Apple (interim return)	Apple acquired NeXT; Jobs returned without a formal CEO title but with substantial influence	Macworld Boston 1997 — signaling reconciliation, focus, and strategic simplification
2001	Apple: CEO Pixar: Chairman	After iMac success, formally appointed CEO; Apple entered the recovery phase; iPod launched	iPod introduction keynote — signaling Apple as a digital lifestyle platform
2007	Apple: CEO Pixar: Major Shareholder (acquired by Disney in 2006)	Apple transformed into a consumer electronics company	iPhone keynote — signaling category creation and Apple's role as an industry architect
2011	Apple: CEO (until August) Apple: Chairman of the Board (after August) Pixar & Disney: Largest Shareholder of Disney	Transition from operational leadership to symbolic and legacy-based authority	iPad 2 / final public appearances — signaling continuity, succession, and enduring design philosophy

Note: Signaler refers to Steve Jobs's formal role and positional status at each point in time. Environment captures the organizational and historical context surrounding the signaler, including constraints and available resources. Signal Message denotes observable actions in the form of keynote presentations and demonstrations. The table is intended to organize analytical units and does not imply causal relationships.

5.1.2 Temporal Variation in Vocal Measures

This section summarizes year-by-year variation in acoustic indicators across seven keynotes (1983–2011), treating each year as the unit of analysis. Duration, speech tempo (BPM), and voice pitch (F0) were calculated annually and presented as descriptive statistics (Table 3).

- Duration (seconds). Across all years, "On" duration exceeded "Off" duration (all $p < .001$). "On" means ranged from 1.68 to 2.87 seconds, whereas "Off" means remained below 1 second. The "On"/"Off" ratio varied (1.78–5.74), indicating changes in speech–pause structure over time.
- Speech tempo (BPM). BPM remained stable (135–158), with no significant year differences in central tendency or dispersion (Kruskal–Wallis: $p = .53$; Levene: $p = .22$).
- Voice pitch (F0). F0 showed substantial year-to-year variation, ranging from 234 Hz (2001) to 486 Hz (2011). Year effects were significant for both central tendency and variance ($p < .001$), indicating structural shifts in pitch level and variability.

Overall, duration showed moderate fluctuation, speech tempo remained stable, and voice pitch exhibited marked long-term transformation.

Table 3: Vocal Indicators by Year (Summary)

Year	"On" Mean	"Off" Mean	BPM Mean	F0 Mean (Hz)	F0 CV
1983	1.68	0.73	144	339	0.17
1988	2.87	0.50	135	379	0.32
1992	2.39	0.55	155	358	0.33
1997	1.69	0.95	143	459	0.25
2001	2.43	0.79	158	234	0.56
2007	1.78	0.52	145	398	0.29
2011	2.30	0.73	136	486	0.15

5.2 Discussion of Study 2

Study 2 suggests that vocal signals were reconfigured not only in relation to changes in role-based self-understanding (I AM), but also in response to shifts in contextual constraints and available resources (I HAVE). Across different career stages, Jobs's speaking style appears to have been adjusted in accordance with his organizational position and market environment. During the NeXT and Pixar period, future-oriented vision was emphasized; in the 1997 return phase, his speech reflected focus and reorganization; and in the iPhone and iPad era, vocal expression was shaped against the backdrop of market dominance and accumulated symbolic capital. Accordingly, vocal signals (I DID) can be interpreted as embodied expressions of the interaction between role (I AM) and context (I HAVE), while simultaneously reflecting the reconstruction of future orientation (I WILL) as a dynamic process.

6. General Discussion

This study found that specific vocal features evolved differently across Steve Jobs's career. Speech tempo remained stable, whereas duration structure and voice pitch were reorganized in response to changes in role and organizational context. Significant shifts in pitch level and variability during key transitions, such as becoming CEO or assuming a symbolic leadership role, suggest that vocal signals are shaped by role identity and symbolic function. These findings indicate a dual dynamic in which short-term vocal adjustments gradually consolidate into more stable signal structures over time.

This study offers both theoretical and practical contributions. Theoretically, it reconceptualizes signals as dynamic processes formed and updated over time and across contexts, demonstrating that vocal signals are reorganized throughout long-term career development and role transitions, thereby extending signaling theory from a static selection model to a dynamic formation perspective. Practically, it reframes speaking style not as mere technique but as a strategic capability rooted in evolving role identity and accumulated experience. Future research should evaluate the generalizability of dynamic signal formation across multiple leaders and integrate multimodal and experimental designs to further examine nonverbal signals as socially embedded capabilities.

7. Conclusion

This study reconceptualizes nonverbal vocal signals as dynamic processes embedded in time, context, and identity development. By demonstrating stability in tempo alongside selective reconfiguration of duration and pitch, it shows that signal formation is neither random nor purely tactical, but structurally linked to role transitions and internal identity change. In doing so, it advances signaling theory beyond static attribute-based models toward a dynamic formation perspective.

Abstract: Social impact measurement is critically important in many kinds of organisations, particularly hybrid organisations with a social mission. Practitioners struggle with impact measurement and management (IMM). Social IMM involves the complex task of balancing meaningful impact assessment with metrics that are practical yet sufficiently reflective of key values. The study examines social IMM as a sensemaking accomplishment. What is presented as social impact is shaped by the sense-making of what counts as social impact and what is feasible to measure. Drawing on qualitative analysis of public social impact communications from three hybrid company cases, the study investigates how social impact is made meaningful, which forms of impact become measurable, and which meanings are more implicit. The analysis proceeds in three phases: first, examining how organisations construct meanings of social impact, then how they argue these meanings. This study analyses how certain interpretations are measurable or reportable. Third, the findings are synthesized to reflect the sensemaking of social impact to advance theoretical perspectives. Social impact presentations reveal traces of meaning that go beyond what is formally documented or quantified. Quantitative indicators tend to foreground discrete outcomes, while more processual, relational, and long-term impacts can also be acknowledged rhetorically. Public impact communications play a central role in legitimizing particular interpretations of impact. By conceptualising social impact measurement as a sensemaking process, this study underscores the construction of social impact meanings. The central challenge in IMM is mediating between assignable outcomes and diffuse systemic transformations. The study highlights the need for greater reflexivity about how meaning, attention, and resources shape what counts as social impact.

Keywords: Hybrid Organisations, Hybrid Firms, Social Enterprise, Impact Measurement and Management, Social Impact, Sensemaking

1. Introduction

Social impact has become a central organising principle of hybrid organisations. From grassroots initiatives to investment funds, actors are increasingly expected to demonstrate the societal value they create. A growing infrastructure of metrics, standards, and evaluation frameworks has emerged, promising to render social impact visible, comparable, and manageable. However, social impact is not an objective phenomenon waiting to be measured; it is something actors must make sense of. Hybrid organisations construct reality using available resources. (Molecke & Pinkse, 2017) Organisational sensemaking about impact creates a shared and strategic understanding of what "impact" means at the organisational level. This understanding then serves as a reference point for action, evaluation, and experiences about impact (Drencheva et al. 2023).

Social impact is characterized by ambiguity, value plurality, and the absence of standardized evaluation criteria. Actors cannot rely on objective measures alone to guide their decisions. (Ebrahim & Rangan, 2014) They must construct interpretations of what constitutes meaningful impact. A sensemaking lens sheds new light on impact as a social, ongoing process (Ann Glynn & Watkiss, 2020), where public impact documentation is a strategic representation in this process. As impact is impossible to fully capture and codify into a simple dataset over long time horizons, simplification is necessary. Many organisations continue to invest significant time and resources into developing impact reports, often under conditions of uncertainty, resource constraints, and methodological ambiguity. The case organisations in this study can be seen as pioneering institutional actors contributing to the ongoing development of practices around social impact accountability.

This study advances the literature on the social construction of impact by operationalising meaning-making processes through the analysis of publicly available impact reports as institutional artefacts. It shows that sensemaking of social impact in hybrid organisations balances measurable outcomes and broader systemic change. We illustrate how the impact reports reveal the depth and breadth of work in both areas: how boldly they narrate the vision, and how convincingly and logically they tell the story of a value chain, and the evidence. We argue that practices of evidencing and communicating impact mediate between institutional demands for measurable outcomes and the inherently broad and indirect nature of societal transformation. Existing

boundary work literature has often focused on professional or institutional demarcation (Faulconbridge et al. 2025). This article extends the concept by examining how boundary work mediates between measurable evaluation and diffuse systemic transformation. Quantitative sensemaking of social impact codifies social impact, whereas qualitative accounts offer important experimental and contextual views on social impact. Different forms of representing social impact vary in the extent to which they constrain or enable interpretation and understanding of context.

2. Theoretical Framework

2.1 Measuring Social Impact in Hybrid Organisations

In this study, a hybrid organisation means an organisation that pursues multiple goals and values at the same time with distinct logics, such as combining market logic and social welfare logic. The economic performance is not sufficient to measure success in reaching the goals. (Doherty et al. 2014; Logue 2025). Hybrid organisations create value across social, economic, and environmental spheres, often simultaneously (Holt & Littlewood, 2015).

Impact measurement and management (IMM) can be approached in many ways. One influential way of assessing impact is the perspective provided by the theory of change that offers a structured explanation of how actions and interventions aim to create impact (Reinholz & Andrews, 2020). The theory of change allows focusing on evaluating intended outcomes through causal pathways.

Longoni et al. (2024) suggest that hybrid organizations create impact at three levels: first at the organizational and operational levels, then across the supply chain, and finally at the systemic level, for example, by influencing norms in society. Social impact within purpose-driven organisations should be understood as more than the sum of their services and direct outcomes because they create impact by expanding the capabilities of beneficiaries and communities (White 2018). In this sense, their effectiveness should be understood through the degree to which an organisation increases capabilities, and from this perspective, impact is not created by one organisation but co-created within wider interactions (White 2018). These perspectives suggest impact is not a linear outcome of innovations in hybrid organisations. It can be understood through complex social value creation, capture, and delivery processes (Logue et al. 2025).

Impacts need to be measured, evidenced, and communicated to stakeholders (Holt & Littlewood, 2015). However, measuring impact is challenging. Organisations operate in dynamic environments; their structures, missions, and impacts differ by local, legal, political, economic, and cultural conditions. Their activities, like providing jobs, training, and low-cost services/products, affect direct beneficiaries, but the real impact is broader and more complex, extending to families, communities, and ecosystems. The impacts often have complex spillover effects. (Holt & Littlewood, 2015)

Social norms, economic conditions, legal frameworks, and local markets shape both how hybrids operate and how their interventions are received (Holt & Littlewood, 2015). Organisations make decisions whether they measure social impacts or not, and these choices are influenced by social pressures, stakeholder expectations, and strategic motives. (Liston-Heyes & Liu, 2021). In their study, Golbspan Lutz et al. (2025) note that hybrid organisations may measure easily available measurable outcomes, yet some socially meaningful activities that are harder to quantify may receive less attention. This can lead to mechanistic or short-term insights, such as counting participants instead of paying attention to the long-term social mission. The social impact in its truest form is context-dependent and complex. Mechanistic measures of impact have strategic risks: they may sub-optimize focus and prevent strategic direction, trust, and innovation on social problems. (Golbspan Lutz et al. 2025) How social impact is reported guides sensemaking of social impact further, and cues in reports affect subjective experiences of impact. (Drencheva et al. 2023)

2.2 Sensemaking Lens

The essential part of social impact is inherently qualitative (Golbspan Lutz et al. 2025). IMM is a sensemaking process. Sensemaking is about organising, and it happens through labeling and bracketing. Meanings are created through categorizing, and sensemaking creates provisional boundaries. (Weick et al. 2005) Following the observations of Weick et al. (2005), sensemaking does not solve ambiguity in social impact, but it is used for creating workable and communicable, shared versions. Assessing impact requires making sense of how actions

influence outcomes, how people perceive them, and how they feed back into social processes. Sensemaking frames impact as a dynamic, relational, and context-dependent process. (Ann Glynn & Watkiss, 2020).

Context is dynamic, multi-layered, and inseparable from sensemaking. Studying action, meaning, or impact would be limited without understanding the environment, history, culture, and material conditions that influence them. Context is what gives sensemaking its content and constrains or enables organising. (Ann Glynn & Watkiss, 2020).

3. Methodology

The purpose of this study is to understand how hybrid organisations make sense of social impact in their impact reports. Qualitative research is a suitable approach, as it allows studying multidirectional, multidimensional social meanings and processes (Saldaña, 2011). The data is purposefully selected and consists of three case hybrid organisations that have published social impact reports, and they are available online. The empirical material consists of their public webpages. The analysis focuses on specific sections where they report about social impact, Tony´s Impact (Tony's Chocolonely, n.d.), Auticon´s "Making an impact" and their impact report archive (Auticon, n.d), and Ecosia´s impact communication on their website, in news and financial reports sections (Ecosia, n.d.-a; Ecosia, n.d.-b). They are institutional communication and entry points to analysis (Morgan, 2022). This study treats them as constructed narratives that offer an organisationally chosen, situated response to what counts as impact. They allow analysis of what is made visible, how meanings are structured, and what kinds of values are prioritized. These qualities make them ideal for sensemaking study, as they are storytelling worlds with meanings attached to words and labels (Näslund & Pemer, 2012). These reports construct plausible narratives of impact and reflect the organisation's hybrid identity (Helms Mills et al. 2010). As webpage content is curated and promotional, the analysis focused specifically on how social impact was communicated rather than on evaluating the actual societal impact of the firms.

The analysis logic relies on Gioia's method with hermeneutic orientation (Mees-Buss et al. 2022). The webpage content was analysed using qualitative thematic analysis. First, the webpage material about social impact was read multiple times. Second, statements related to social impact were coded and interpreted considering what they mean in practice in their social and linguistic contexts (Näslund & Pemer, 2012). The third phase of analysis involved a cross-case comparison to identify recurring patterns and differences in how the organisations framed, measured, and communicated social impact. The analysis proceeded abductively through iterative movement between the empirical material and the theoretical framework on sensemaking. This process enabled the development of broader conceptual interpretations concerning organisational logics of change and the role of impact measurement in constructing and legitimising social impact.

The hermeneutic process involves critical and constant contestation of interpretations, and the rigor comes from interpretative rigor. (Mees-Buss et al. 2022) Coding decisions and theme development were documented throughout the analysis process.

4. Findings

This section presents an interpretative analysis of how social impact is made sense of in the reports.

4.1 Auticon Makes Sense of Individual, Organisational, and Societal Impact Through Experiences and Other Measures

Auticon's impact reports reveal a hybrid approach to measuring and communicating social impact, where sensemaking plays a central role in how the organisation frames its achievements. The reports combine quantitative outcome indicators, such as employment rates, wellbeing improvements, and client satisfaction, with qualitative narratives that situate these outcomes within broader societal and organisational contexts. This dual approach reflects a deliberate process of sensemaking: Auticon interprets its impact not only in terms of causal interventions, "individuals were employed, clients experienced cultural shifts", but also in terms of systemic social transformation, highlighting barriers in traditional labour markets for neurodivergent individuals and advocating for neuro-inclusion as a wider social norm.

The social context of Auticon's reporting is central to understanding this sensemaking. Auticon operates at the intersection of a historically marginalized workforce, corporate diversity goals, and global movements for disability inclusion. By linking individual outcomes to organisational and societal effects, Auticon frames employment of autistic professionals as a solution to both labour market inefficiencies and social inequities.

Sensemaking here functions to translate complex, multi-level impact into interpretable signals for multiple audiences, including clients, funders, autistic professionals, and policymakers.

Auticon's reporting style also reveals how evaluation and communication are tools of legitimacy and advocacy. The quantitative metrics provide measurable evidence of effectiveness, addressing accountability expectations and demonstrating organisational credibility. Simultaneously, the qualitative narrative situates these metrics within a moral and social argument: success is not only measured in individual employment outcomes but also in shifting perceptions, cultural practices, and systemic inclusion. In this sense, Auticon's sensemaking does not reduce social impact to what is immediately measurable; it constructs meaning around complex societal problems, making both the results and the organisation's role in addressing them visible to diverse stakeholders. The case demonstrates that sensemaking in social impact is an interpretive practice shaped by social, cultural, and institutional expectations, reflecting both the organisation's internal goals and the pressures and norms of its external environment.

The central measurement indicators focus on the effect of employment on neurodivergent (especially autistic) consultants: employment status before joining, wellbeing, confidence, authenticity at work, and quality of life improvements. These involve both quantitative and qualitative measures. The reports also show quotes from employees, such as "..I have never felt this happy as a developer before" (Auticon 2026a) 61% of autistic employees were unemployed before joining Auticon (Auticon 2026a). A large majority report feeling able to be their authentic selves at work, and improved well-being.

Auticon reports reflect the effects on client organisations engaged with Auticon. They measure high percentages of clients report positive cultural shifts (confidence working with autistic colleagues, improved teamwork, greater empathy). They collect feedback from clients to understand how clients perceive Auticon consultants' contribution to perceived value. These are framed as evidence that neuroinclusive employment benefits organisational performance and culture. Auticon also aims for broader societal impact and evaluates efforts to shift norms and employer practices. They report on training for neuroinclusion for thousands of people globally. The reports present Auticon as both a model and a movement.

Across these dimensions, impact is presented with a combination of quantitative outcomes (surveys, percentages) and qualitative narratives (stories, broader trends), which serve multiple communicative purposes. Each level also measures the number of consultants employed, retention rates, projects delivered, and support structures. However, what is thought to have a long-term impact is supporting identity and psychological ownership of neurodivergent people in work life and a socially inclusive society where neurodivergent people are able to use their talent for the society. Being an autistic professional and contributing to society is a broader theme. These ideas of impact are experiential. They are long-term goals that are also intersubjective, not numeric. The internal sense of belonging, changes in confidence, or subtle workplace social dynamics are harder to measure.

4.2 Tony´s Chocolonely Makes Sense of Social Impact Through Better-paid Cocoa Farmers and Other Value Chain Indicators

Tony´s sensemaking anchor is "to end exploitation in cocoa". The societal context for sensemaking is the long-standing industry´s social problems and legitimacy crisis. Tony´s Chocolonely frames their social impact as a mission for correcting systemic injustice, so as a system actor but also system re-designed, aiming for social change in the cocoa industry. Social impact communication is also a response to market pressures for more ethical consumption, and the social impact is communicated to consumers to build trust. Certifications such as Fair Trade are used, but Tony´s Chocolonely raises the industry´s social standards as a role model. They highlight 100% traceability of their key raw material, cocoa.

The social impact indicators function as performative devices that construct interpretations of fairness and responsibility. The living income reference price acts as a normative benchmark, defining what a fair cocoa market should look like and anchoring claims about industry transformation. They report long-term contracts with cooperatives (e.g., 5-year partnerships), the number of partner cooperatives, and stories about them. They emphasise their sourcing principles. An essential part of social impact is to build fairer value distribution in the value chain, which means supporting fairer transactional conditions for West African producers. Paying a higher price is a key mechanism for creating impact. It is hard to measure the goal of shifting industry norms, sourcing expectations, and strengthening farmers' position in terms of autonomy and bargaining power.

The highest-level social impact goal – transforming institutional practices in the industry - is systemic and difficult to measure. Thus, Tony's primarily tracks compliance with its model, while impact ultimately depends on whether the wider system changes.

4.3 Ecosia Makes Sense of Impact Through Planting Trees

Ecosia´s business model is based on running a search engine, a browser, and redirecting their profits fully to They have a B-certification, which also influences IMM. (Ecosia n.d., a.) Ecosia emphasises transparency and publishes monthly financial reports (Ecosia n.d., b). In Ecosia, impact is measured as a financial flow, and impact is argued through accounting transparency. The metrics are the number of trees planted, revenue allocated, maps about geographic distribution, and CO_2 estimates. The impact of communication is visualized and highly quantifiable.

Impact is defined through a simple causal chain: user searches generate revenue, which funds tree planting—making it appear linear, immediate, and unambiguous. The social impact in this sense is argued to be a causal chain that sees environmental contribution as a predictable output of system use. Every search funds tree planting projects. The reports emphasise measurable outputs, such as the number of trees planted, the CO_2 offset, and the species restored. They also contextualize these achievements in broader ecological and social systems, highlighting benefits for local communities and biodiversity.

Ecosia's social impact communication can be understood as emerging at the intersection of climate urgency and increasing demand for accessible forms of ethical action and sustainable consumption. From a sensemaking perspective, this framing illustrates how complex ecological and social processes are translated into communicable and engaging forms. This highlights how social impact is necessarily selective and simplified in its representation, enabling it to become meaningful and actionable for diverse stakeholders.

Ecosia's communication emphasises participation and scalability, constructing impact as both material (through tree planting) and symbolic (through everyday user engagement). They emphasise measurable social impact in their communication. The long-term ecological processes are longer processes, and they would be harder to quantify as they are related to complex ecosystem and community processes. What "counts" as impact is narrowed to what can be measured and displayed, but planting trees is still a powerful social act, although it has uncertainties, such as survival rates and biodiversity effects. Impact is also followed and validated through visibility mechanisms: counters, financial reports, and project updates. Trust is built through transparency and traceability, suggesting that impact is something that can be seen in figures.

4.4 Cross-analysis of Findings and Abductive Conceptualisation

The cases differ in how they frame and legitimise social impact, revealing distinct forms of organisational sensemaking. Auticon focuses on individual-level interventions with societal framing, illustrating the potential for the employment of autistic professionals to generate both measurable impact and cultural change. Auticon's emphasis on employment outcomes and workplace performance indicators aligns with its positioning within a professional services market. They demonstrate both social inclusion and business value.

Tony's Chocolonely foregrounds supply chain traceability, farmer incomes, and industry-wide change, reflecting a theory of impact that extends beyond firm-level outcomes toward systemic transformation. They keep attention on structural injustice in the field while maintaining credibility in consumer markets. Ecosia uses environmental logic as they connect individual participation, using their web browser for searchers, to planting trees. They emphasise transparency and prioritize quantifiable indicators (trees planted).

Social impact measurement in the examined cases points toward an underlying tension between two logics of change: a causal intervention logic focused on attributable outcomes, and a societal transformation logic oriented toward systemic and long-term change. These logics are shown in communicating about impact. Organisations use these in varying degrees. Auticon emphasises indicators that demonstrate direct and credible outcomes. Tony's Chocolonely and Ecosia rely more on proxy indicators and narrative framing to sustain broader claims of systemic change. Systemic change is the goal of Auticon as well, but social impact indicators are more direct. Impact metrics function as tools of evaluation. They are also mechanisms of sensemaking, through which organisations simplify complexity, align stakeholders, and stabilize particular interpretations of how change occurs.

This leads to the argument that the measurement practices can be understood as boundary work, mediating between the need to evidence impact and the inherently diffuse nature of societal transformation. Social impact

reports show direct measurable outcomes and explain the intervention logics, and introduce an idea of wider societal transformation logic as well. Sensemaking is the interpretive mechanism that allows social enterprises to translate outcomes into legible social impact for diverse stakeholders, shaped by both internal goals and the social, cultural, and institutional contexts they inhabit.

5. Discussion

5.1 Overview and Contribution

For hybrid organisations, understanding social performance is just as central as economic mission (Doherty et al. 2014; Battilana et al. 2015). Assessing and measuring social impact is a complex challenge, influenced by many kinds of motives (Liston-Heyes & Liu 2021), and also strategic risks if social impact measurements are misaligned or do not build trust (Drencheva et al. 2023; Golbspan Lutz et al. 2025). Rather than being externally imposed, social impact measurement can be shaped by the sensemaking practices of hybrid organisations. Social enterprises have the power to define what social impact entails (Molecke & Pinkse, 2017).

This study operationalizes the meaning-making process in the context of publicly accessible impact reports as institutional artifacts. The social impact reports are sensemaking artifacts. A sensemaking lens frames social impact as an ongoing social process (Ann Glynn and Watkiss, 2020), with impact communications serving as strategic representations of that process. Voluntary social impact reports or communications about measuring social impact are rare, and cases selected for this study are impactful and mission-driven organisations that manage and measure their impact strategically. Sustainability reports and ESG reports are more common framings of impact, but they risk over-simplification and loss of nuance, and therefore, this study focused on impact communication by three mission-oriented organisations.

The prior literature suggests that hybrid organisations' impact assessment is a critical task that guides focus, and cues affect subjective experiences of impact, and failures or overly mechanistic measures may cause problems (Golbspan Lutz et al. 2025; Drencheva et al. 2023). Measurement serves as a form of sensemaking: it simplifies complexity into communicable indicators and aligns different internal and external audiences around particular interpretations of impact. They also influence how impact is understood, what is seen as progress, and what forms of change are rendered plausible. In this sense, a theory of change is not only operationalized through indicators but also continuously reconstructed through them, as organisations navigate between strategic positioning, stakeholder expectations, and their own evolving interpretations of what meaningful social impact entails.

By situating the case findings in the evaluation perspectives of the theory of change (Reinholz & Andrews, 2020) and socially embedded, institutional interactions in creating change (White, 2018; Longoni et al., 2024), this study observes how sensemaking of social impact reflects boundary work in showing short-term evidence and sharing visions for social, environmental, or broader change. The impact reports also reveal something about the depth and breadth of work in both areas: how boldly they narrate the vision, and how convincingly and logically they tell the story of a value chain, and the evidence. This study argues that measurement practices can be understood as boundary work, mediating between the need to evidence impact and the diffuse nature of societal transformation. Social impact management and measurement requires boundary work around legitimacy, evidence, and contextual value. These two modes of presenting impact are present to different extents, and these reflect how much shared social impact communication holds metrics and nuanced information.

5.2 Limitations and Future Study Ideas

The case firms in this study are hybrid organizations in which social impact is a central objective. They are developing market-based solutions to systemic problems; they are well-established and operate internationally. For them, business growth means also growth in impact. In this sense, they are a very purposefully selected sample in this study.

Existing studies show that social entrepreneurs rarely begin with a fixed evaluative framework; instead, they assemble available data, experiences, and narratives into provisional accounts that render their activities meaningful to themselves and to external stakeholders (Molecke & Pinkse, 2017). This shifts the focus from reported measures toward the processes through which representations of impact come to be seen as valid and useful. Future studies could explore further the enactment of social performance and temporal orientations in

understanding social impact in practice. This goes beyond just reporting social impact, which is a narrower phenomenon than enacted understandings of social impact. A cross-national and cross-sectoral comparison of enacted practices can illuminate how institutional, cultural, and welfare-state arrangements condition the interpretation and enactment of social impact. It may also help disentangle context-specific sensemaking processes that underpin and reproduce interpretations.

6. Conclusion

This study examined how hybrid organisations make sense of social impact through IMM. The sensemaking lens sees it through an ongoing interpretative process. The study focused on three case firms that are mission-driven. They are distinctive in their systematic reporting on social impact, which lies at the heart of their operations.

Impact reports tend to privilege forms of impact that can be credibly measured and communicated, although some reports incorporate more contextual and qualitative accounts of impact. By conceptualising social impact measurement as sensemaking and boundary work, balancing what can be measured and more qualitative, more complex impact, this study highlights how reporting practices differ in the extent to which they focus on measurable impact or more long-term missions with the ambiguity of social change. Quantitative indicators help stabilize particular interpretations of impact, while qualitative accounts preserve context and relational views.

Viewing impact measurement as a sensemaking process can support more strategically meaningful approaches to social impact in hybrid organisations.

Abstract: Creating value for social innovation in developing countries often faces many challenges. The Quadruple Helix model emphasizes the role of higher education institutions (HEIs) in promoting social change. This study sheds light on the role of HEIs in developing countries by examining their contribution to the development of a social innovation ecosystem. Data were collected from two focus groups and 13 interviews with various stakeholders in Vietnam. Findings show that HEIs play a translational role by aligning the different perspectives and resources of various actors within the ecosystem. Furthermore, by following a bimodal approach that simultaneously shifts their strategy toward innovation and promotes the interpersonal governance of professionals, HEIs overcome the institutional void and provide a protective space for innovation initiatives necessary for the formation of social innovation in the country.

Keywords: HEIs, Value Co-Creation, Social Innovation, Vietnam, Service-Dominant Logic, Professional Network Community

1. Introduction

Higher education institutions (HEIs) are increasingly becoming more important in addressing social challenges for national growth. The Quadruple Helix model contends that interactions among government, industry, and community are crucial to driving social change and transformation. Collaborating with these groups is challenging because they may have different, even conflicting, interests. Often, HEIs need to integrate diverse resources of these stakeholders and align their various needs to generate value in achieving system goals. Research has shown that HEIs often serve as facilitators of knowledge sharing (Chen et al, 2024) and as knowledge contributors (Marra, 2022) in addressing social issues. These practices are mainly found in developed or Western countries, leaving the phenomenon in developing countries underexplored.

Adopting the Service-Dominant Logic and the Professional Network Community theory, this research investigates the value co-creation activities of Vietnamese HEIs to support the formation and development of the country's social innovation ecosystem. The paper first presents a literature review that discusses two theoretical frameworks that provide the foundation for investigating HEIs' activities and highlights gaps in the existing body of research on social innovation ecosystems. Subsequently, the research implementation will be discussed in the methodology section, followed by the findings. The paper concludes with implications for HEIs and stakeholders to promote the effectiveness of social innovation ecosystems in developing countries.

2. Literature Review

2.1 Theoretical Framework

Two theoretical frameworks, Service-Dominant (S-D) logic and Professional Learning Community (PLC), lay the foundation for this study. From the S-D lens, service provision is implemented through interconnected systems of actors, who exchange resources and co-create value. This perspective moves away from the goods-centered view toward a service-centered logic, where service is defined as the application of specialized competencies, particularly skills or knowledge, for the benefit of another party (Vargo and Lusch, 2004, 2008). Adopting this

view, this study considers HEIs as key resource integrators that collaborate with other actors to create value for customers (Vargo and Lusch, 2016; Ystrom et al, 2025).

Complementing the S-D logic, PLC explains how educators transition from professional isolation to cross-institutional networks to share knowledge and enhance pedagogical value for learners. These networks are formed by both educators' intrinsic motivation and institutional support, which create opportunities for professional collaboration (Katz and Earl, 2010). In line with S-D logic, PLC theory focuses on enhancing educators' competence, enabling them to create greater value for students. While the collaborative activities are carried out among professionals, institutions play a vital role in supporting the formation and growth of such networks (Prenger et al, 2017).

2.2 Literature Review

Social innovation ecosystems (SIE) are generally described as dynamic, multi-actor networks that collaboratively generate and sustain socially beneficial change. Scholars define these through various lenses: structural models like the Quadruple Helis (Howald et a., 2016); behavioral mechanisms focused on resource integration (Babu et al., 2020); and political perspectives addressing power asymmetries (Avelino et al., 2019). Pel et al (2020) further conceptualize SIEs as empowering constellations built on local embedding, translocal connectivity, and discursive resonance.

Previous studies have revealed various roles of HEI in the development of an educational ecosystem. The most common function of HEIs in supporting their stakeholders is to create networks that drive systemic societal change and address social challenges (Katz and Earl, 2010; Panetti et al, 2019; Pel et al, 2020; Tallinn University, 2023). In addition, SIEs are designed to serve the educational purpose of student learning and professional skill enhancement (Prenger et al, 2017) or to facilitate the translation of scientific knowledge into commercially and socially valuable outcomes (Chen et al, 2024).

The function of HEIs requires them to build relationships and interact with a wide range of external and internal stakeholders to achieve the system's purposes, including government, not-for-profit organizations, industries, communities, academics, and students. In their relationships with these stakeholders, HEIs often engage in various activities and play different roles in supporting the ecosystem.

In their relationships with other organizations, HEIs have been found to actively collaborate with commercial enterprises to facilitate knowledge transfer from researchers to market recipients (Chen et al, 2024) or to support students in accessing high-level expertise (Panetti et al, 2019). They also work with social enterprises to address community issues (Ahmed, 2024; Leipik and Urmanavičienė, 2023). A more common activity of HEIs is conducting research to address social challenges.

While Western and developed countries have received much scholarly attention in this area, the role and inter-organizational activities of HEIs in developing countries in supporting social innovation are underexplored. Understanding how HEI can help to transform social practices in developing countries is important, as it can shed light on how to respond to social challenges in this area. This prompts the following research question for the current study.

RQ: How do Higher Education Institutions in developing countries engage with their stakeholders in the value co-creation process to foster the formation of a social innovation ecosystem in an emerging economy?

We focus on Vietnam, an emerging country that has explicitly leaned toward social innovation as part of its economic growth (STAMEQ, 2024). To address the question, the following research objectives are proposed.

1. To examine the value of co-creation activities and resource integration practices performed by HEIs in their interactions with these stakeholders.
2. To analyze the mechanisms and strategies HEIs employ to align conflicting stakeholder needs and foster ecosystem formation.
3. To evaluate the role of HEIs in providing legitimacy and capacity-building support for social innovation activities.

3. Methodology

3.1 Research Design

This study is situated within Vietnam's social innovation ecosystem in its early stages. While the social enterprise law was enacted to provide a formal legal definition, its practical implementation remains limited. This is largely due to persistent institutional voids, in which a significant lack of stakeholder awareness of social enterprises is compounded by a dearth of clear policy guidance and specialized support mechanisms.

This study adopts a qualitative research design to investigate how HEIs engage with stakeholders to foster the formation of a social innovation ecosystem in an emerging economy. Given the exploratory nature of our research question, a qualitative approach is most suitable for capturing in-depth insights and multiple perspectives on complex organizational interactions (Creswell and Poth, 2018).

3.2 Data Collection and Sampling

The study utilized purposive sampling to select participants who possess significant experience or involvement within the social innovation landscape. Data were gathered through 13 semi-structured interviews and two focus groups (Table 1). Participants include not only HEI leaders but also lecturers, policy makers, practitioners, social entrepreneurs, and NGOs, ensuring a holistic view of the ecosystem.

Table 1: List of Interviewees

No.	Type of Data Collection	Interviewee Code	Type of Stakeholders
1	FG1 (Focus Group 1)	P15a	Intermediary
2		P15b	Social enterpreneur

3.3 Data Analysis

To ensure academic rigor and transparency, the study follows the hybrid thematic analysis framework developed by Fereday and Muir-Cochrane (2006), which integrates deductive (theory-driven) and inductive (data-driven) coding. This approach allows for the interpretation of raw data through the lens of established theories while remaining open to new insights that emerge directly from participants' discourse. The analysis progressed through six systematic stages:

- *Stage 1 & 2: Developing the Code Manual and Testing Reliability.* An initial code manual was developed *a priori*, based on the research questions and our dual theoretical framework: Service-Dominant (S-D) Logic and Professional Learning Community (PLC) theory. These theories provided the foundation for identifying deductive codes related to resource integration and knowledge sharing. To establish the "postulate of logical consistency", the research team tested the manual on sample transcripts to ensure the codes were applicable and consistently understood.
- *Stage 3: Summarizing Data and Identifying Initial Themes.* The research team engaged in deep data immersion by reading and summarizing transcripts of interviews and focus groups. This process allowed for the identification of potential sub-themes, such as the "embryonic state" of the ecosystem and the prevalence of "institutional voids" in the Vietnamese context.
- *Stage 4: Applying the Template of Codes and Additional Coding.* The *priori* template was applied to the entire dataset. Simultaneously, inductive coding was employed to capture nuances not covered by the initial template. For instance, while "Relational Management" was a predefined theme, codes such as "trust-based actions" and "boundary spanning" emerged as specific, data-driven descriptors of how HEI actors navigate informal networks to overcome administrative rigidity.
- *Stage 5: Connecting the Codes and Identifying Themes.* We clustered the codes to discover overarching patterns, focusing on the three central themes of this study: Relational Management, Networked Learning, and Value Co-creation. This stage involved analyzing how HEIs act as central hubs to align the conflicting needs of different stakeholders through strategic partnerships.
- *Stage 6: Corroborating and Legitimizing Themes.* Finally, the themes were refined to ensure they accurately represented the initial data. This final interpretive phase confirmed that value co-creation in the Vietnamese ecosystem is a "tripartite" process between HEIs, practitioners, and students, resulting in a crucial "mindset transformation". By adhering to this systematic trail of evidence, the study demonstrates "interpretive rigor" and ensures that the findings are directly grounded in the participants' subjective realities.

4. Findings

The activities and strategies of HEI in collaboration with various stakeholders are centered around their relational management to align different groups and how they can support the network learning and value co-creation in the ecosystem.

4.1 Managing Stakeholders and Synergizing Resources

Based on the Service-Dominant (S-D) logic (Vargo and Lusch, 2016; Yström et al, 2025) and Professional Learning Community (PLC) (Prenger et al, 2017), we found that HEIs acted as hubs for social innovation, driven by a strategic shift in leadership vision and institutional mission. This leadership commitment facilitated boundary spanning through education, training, research, and stakeholder partnerships. However, these collaborations often remain decoupled from formal administrative structures, relying instead on informal, trust-based networks.

4.1.1 Leadership as a Foundation

Leadership is the primary catalyst for orienting stakeholder relationship management (SRM) (Anholon et al, 2026; Hazenberg et al, 2016). Recognising the significance of social responsibility, HEI leaders expressed a strong willingness to collaborate: "*We welcome all stakeholders, not only startups... Our goal is to serve the community*." (P3, HEI leader). This collaborative intent aligns with institutional long-term plans to cultivate an internal innovation ecosystem:

> *In the long term, the university aims to build an environment where students proactively engage in creative and innovative activities*. (P4, HEI leader)

When discussing the role of social innovation in institutional strategic development, leaders confirmed that these initiatives are central to their core missions. As one leader noted: *They [Social innovation and entrepreneurship] are truly part of our university's mission*. (P3, HEI leader)

Furthermore, HEI leaders shared their plan to translate these missions into formal policies and actions. Collaborating with stakeholders to integrate social innovation and entrepreneurship was viewed as a strategic pathway to enhance their educational programs:

> *In the near future, we will need to shape policies... From our university's perspective, we are beginning to develop related policies [as] a way forward in teaching*. (P5, HEI leader)

The commitment of HEI leadership toward social innovation and entrepreneurship—underpinned by a partnership-oriented approach—provides a robust foundation for staff and lecturers to actively engage with external stakeholders (Katz and Earl, 2010). Consequently, academic and administrative staff demonstrate a high level of awareness regarding social innovation and the value of collaborative partnerships:

> *The role of the university is threefold: first, to advance research in this field; second, to develop innovative human resources; and third, to provide students with volunteer and charitable opportunities to engage with the community. In this capacity, the university serves as a strategic connector, addressing the needs of various stakeholders through its diverse programs* (P8, Academic).

4.1.2 Boundary Spanning and Stakeholders' Relationship Mechanism

This strategic orientation has facilitated boundary spanning across multiple levels of the institution (Katz and Earl, 2010; Prenger et al, 2017). Internally, these efforts are evidenced by the systematic integration of social innovation into both formal curricula and extracurricular programming, often supported by international programs like the British Council:

> *Over the last three years, we have integrated social innovation and social entrepreneurship modules into our entrepreneurship courses. This progress stems from lecturer training programs organised by the British Council and Active Citizens. We also host short courses on social innovation for people outside the university*. (P7, Academic)

Externally, faculty acts as intermediaries between students and the social economy:

> *I am currently piloting a collaborative project with the social enterprise Tò He. Their president is eager to partner with academic institutions to support his ongoing initiatives. Through these connections, we can connect students with internship opportunities and support their social innovation ideas*.- (P9, Academic)

It was obvious that HEIs could be central hubs for multi-stakeholder partnerships, fostering a collaborative ecosystem where academics, practitioners, policymakers, and social organisations work together to promote social innovation (Gustafsson et al, 2026; Mason et al, 2020). The collaborations among the stakeholders were mutually transformative: while the university significantly enhanced its institutional capabilities through these external connections, practitioners and social organisations simultaneously achieved their own strategic objectives (Jackson and Temperley, 2006; Nguyen et al, 2023; Ystrom et al, 2025). This exchange of resources created a reciprocal value chain tailored to each actor's specific needs. For instance, enterprises sought access to the business school's human capital (P12, NGO) and required technical expertise in areas such as business development and impact evaluation (P13a, P15b, SE). Similarly, NGOs looked to the university for expanded training opportunities for academics, while students and short-course trainees relied on practitioners, experts, and scholarly guidance to transform their social innovation concepts into viable projects (P15a, Intermediary).

However, despite the strategic intent, these collaborative relationships relied primarily on trust-based, interpersonal networks rather than formal institutional mechanisms. Lecturers characterised these engagements as "*voluntary*," "*individualised*," or lacking a "*formal coordination framework*" (P9, P15c, 15e, P15f; Academic). External partners echoed this sentiment, emphasising the necessity of a pre-existing personal connection to initiate collaboration:

> *We don't know which department to contact... each university operates differently.* (P15c, SE)

Consequently, stakeholders often bypassed official channels to work directly with lecturers, whom they perceived as the most "*accessible and helpful in implementation*" (P11, Intermediary). Participants' insights suggested that although there was a strategic commitment to social innovation, these partnerships were

primarily driven by individual initiative and had not yet been fully integrated into the institution's formal administrative structure. This reveals a decoupling strategy in which international governance prevails to overcome the gap between formal structures and practical implementation.

4.2 Networked Learning and Value Co-Creation

The results highlight how actors within the emerging social innovation ecosystem gradually shift from fragmented collaboration to a networked learning structure that facilitates value co-creation among multiple stakeholders. The findings suggest that the sustainability of the ecosystem depends largely on ongoing knowledge exchange and collaborative learning processes. Our findings show that this process occurs through three connected mechanisms: lateral learning, knowledge integration, and mindset change, which together illustrate how networked learning practices support value co-creation within the ecosystem.

The first mechanism is lateral learning, which involves the exchange of knowledge horizontally among actors, especially among HEIs and academics. Without a centralized coordinating authority or a "main conductor" of the ecosystem, actors rely heavily on informal professional networks to share knowledge and collectively build capacities. One mechanism frequently mentioned by respondents is the Training-of-Trainers (ToT) programs organized by international NGOs, which offer opportunities for academics from different universities to collaboratively learn social innovation methods and pedagogical practices. Importantly, the knowledge acquired through these initiatives does not remain confined to training sessions but cascades across institutions. Lecturers who participate in these programs often adapt and transfer the knowledge into their teaching practices and professional networks.

> *"Many (of my students) had never heard of the concept before the course… But the program's most significant impact was personal transformation: participants shifted from indifference… to an entrepreneurial mindset." (P14a, Academic)*

These dynamics reflect the features of networked professional learning communities, where professionals work across institutional boundaries to share knowledge and enhance practices (Jackson and Temperley, 2006; Katz and Earl, 2010; Prenger et al, 2017). For example, respondents shared cases where universities collaboratively experimented with entrepreneurship and innovation curriculum models:

> *"With the knowledge learned, they will propose a solution, which could be supporting social enterprises such as strategic cash flow, or managing revenue and expenditure." (P14a, Academic)*

Such collaborative experimentation demonstrates how networked learning structures allow institutions to co-develop capabilities and collectively explore new educational practices, reinforcing the role of HEIs as knowledge hubs within the ecosystem.

While lateral learning facilitates knowledge exchange among actors, knowledge integration represents a deeper stage of networked learning, in which shared insights become embedded in institutional practices. Several respondents reported that social innovation has gradually been incorporated into formal academic programs, particularly within business and entrepreneurship education. At some universities, the topic has evolved from an optional subject to a compulsory module in the Business Administration curriculum. Teaching methods have also shifted toward experiential learning approaches, including service-learning and project-based learning, allowing students to apply theoretical knowledge to real-world social challenges.

These practices illustrate how HEIs operate as multi-actor learning platforms, integrating inputs from NGOs, practitioners, and academic communities into structured learning experiences. From the perspective of S-D Logic, such integration is a key process that combines diverse resources and competencies to generate shared value within the ecosystem (Vargo and Lusch, 2016). Through these processes, HEIs move beyond their traditional role as knowledge providers and instead function as facilitators of collaborative learning and value creation among ecosystem actors.

The most significant manifestation of value co-creation identified in the findings is a transformation in students' mindsets. Respondents emphasized that the primary objective of social innovation education is not merely to equip students with technical knowledge but to reshape their perspectives on entrepreneurship and social responsibility. The focus should move from "creating enterprises" to cultivating individuals with an *"entrepreneurial spirit and social mindset" (P1, Policy Maker)*.

This transformation is not produced by a single actor but emerges through collaborative interactions among multiple stakeholders. Practitioners contribute practical knowledge and methodologies, universities provide the

institutional learning environment, and students actively develop their own projects using local resources and addressing community needs. This process involves a tripartite collaboration between HEIs, practitioners, and students, enabling learners to move from passive knowledge recipients to active social innovators (*P15b, SE*).

Consequently, students begin to perceive themselves not only as future employees but as agents capable of addressing social challenges through entrepreneurial initiatives. This outcome demonstrates how networked learning processes ultimately translate into value co-creation, generating both individual transformation and broader societal impact.

Overall, the findings suggest that networked learning is a critical mechanism for enabling value co-creation in emerging social innovation ecosystems. Through lateral learning, knowledge integration, and mindset transformation, HEIs and their partners collectively construct new forms of knowledge and capabilities that strengthen the ecosystem's capacity for social innovation.

5. Discussion

HEIs promote social innovation by functioning as intellectual engines and innovation hubs. This research demonstrates that a strategic shift toward innovation is an essential enabler of value co-creation. The study's findings shed light on the strategies of HEIs for supporting the value co-creation process to cultivate a social innovation system in developing countries.

First, HEIs play a central role in an ecosystem that promotes social innovation when they function as intellectual engines, transforming societal mindsets (Pel et al, 2020; Prenger et al, 2018). Being an innovation hub (Pel et al, 2020; Babu et al, 2020), HEIs serve as key resource integrators and facilitate value co-creation to align the perspectives of various stakeholders (Babu et al, 2020). In line with previous studies (Katz and Earl, 2010; Jacobides et al, 2018), this research shows that a strategic shift of HEIs toward innovation provides symbolic legitimacy, empowering faculty to conduct innovation-related teaching and research under a moral institutional cover.

Furthermore, when leadership targets innovation outcomes - such as mindset change – rather than mere graduation rates, value co-creation is oriented toward the use of knowledge in real-world application. Students are becoming active social innovators rather than passive recipients of knowledge. Besides, strategic change at the top level enables HEIs to formalize resource sharing and and eventually turn informatl networks into sustainable structural coordination.

The finding of decoupling how HEIs navigate institutional voids in developing countries. This phenomenon can be viewed as a buffer for innovative action when formal and traditional academic measures have not consistently aligned with social outcomes. This gray area provides a safe place (Meyer and Rowan, 1977) for social innovation to grow without being penalized by rigid administrative requirements and regulations. It is important to note that HEIs overcome this inevitability by allowing interpersonal governance rather than relying on institutional governance. With the dual strategy from both the top - strategic shift - and the bottom – supporting lecturers to act as boundary spanners, HEIs can deal with the institutional void inherent in developing-country systems (Khanna and Palepu, 2010).

An important practical implication from this study is that HEIs should legitimize interpersonal governance by providing resources for their academics to engage in professional network activities. Providing travel budgets or time off for lecturers to network with external stakeholders is valuable in supporting academic innovation-related practices. The connections among these stakeholders can provide additional input into the development of formal structures and help avoid potential friction that might stifle social innovation.

6. Conclusion

This study provides insight into HEIs' practices for supporting the development of social innovation in developing countries. The study's findings support the Quadruple Helix model, which emphasizes the role of HEIs in a multifactor ecosystem for innovation. Furthermore, the research reveals the need for both top-down and bottom-up approaches by HEIs to address the institutional void and facilitate innovation growth in developing countries.

Designing a System that the Intrapreneur Cannot Build Alone: Institutional Design for Non-Core Business Creation and the Corporate Relay Model

So Nishina
Studio Zero, Plaid Inc., Tokyo, Japan

so.nishina@plaid.co.jp

Abstract: Individual intrapreneurs occasionally succeed at non-core venture creation; organisations almost never succeed at replicating them. This paper addresses that structural gap. Building on an empirical single-case study in which one HQ manager at a major Japanese tourism corporation launched three non-travel ventures in a single fiscal year, it shifts the unit of analysis from the individual to the institution and asks: what design allows a large organisation to reproduce that performance at scale? Existing corporate entrepreneurship research identifies the cultural and structural antecedents of intrapreneurial activity but offers limited guidance on the mechanics of HQ-to-branch venture transfer — particularly the conditions under which transfer succeeds without hollowing out the ownership capacity of the receiving unit. The Over-Competence Trap, introduced in a companion study, names this failure mode: when HQ executes all the technically demanding work of incubation, the branch that inherits the venture can operate it as a procedure but cannot adapt it as an owner. This paper designs around that trap. The Corporate Relay Model (CRM) is proposed: a three-phase institutional framework comprising demand validation at branch level, HQ-led incubation with partial delegation, and staged branch ownership transfer across three defined sub-stages. From twelve individual-level success factors identified in the companion study and the informant's explicit scalability target — growth from three ventures per year to thirty — five design propositions are derived, governing validation protocol, talent selection, phased transfer, budget architecture, and HQ role differentiation. A workload analysis demonstrates that the current single-person model operates at or near its structural ceiling, and that full CRM implementation with a three-member HQ team could raise theoretical annual capacity to approximately eighteen ventures. The CRM contributes to ambidexterity theory by identifying staged ownership transfer as a structural mechanism for resolving the Over-Competence Trap, and to implementation science by demonstrating how individual-level success factors translate into replicable institutional design. The framework applies to any large organisation with a tiered HQ-branch structure and an existing customer relationship asset.

Keywords: Corporate Relay Model; Over-Competence Trap; Intrapreneurship; Non-Core Business Creation; Institutional Design; Ambidexterity

1. Introduction

The problem is not identification; it is reproduction. A companion study to this paper (hereafter Study 1) documented an individual — the sole new-business development manager at a major Japanese tourism corporation — who created three non-travel ventures in a single fiscal year, evaluated six, and stopped three on a consistent criterion. The cognitive and behavioural logic behind that performance has been mapped. What remains is the harder question: how does an organisation build a system that does not depend on one person already possessing that logic?

The informant made the difficulty explicit. Asked whether her methods were transferable, she said: "passing the whole thing over is going to be difficult." Asked about her ambitions for scale, she named thirty ventures per year — ten times her current output — as the target for the following year. The distance between those two statements is the design problem this paper addresses.

Corporate entrepreneurship research offers a well-developed vocabulary for the antecedents of intrapreneurial activity (Burgelman, 1983; Zahra, 1991; O'Reilly and Tushman, 2016), but it is substantially thinner on the institutional mechanics of what happens after an intrapreneur succeeds: how ventures transfer to operating units without losing momentum, how branch ownership is cultivated rather than destroyed, and how the system scales without the original architect remaining perpetually involved. These are engineering questions, not cultural ones.

This paper proposes the Corporate Relay Model (CRM) as an answer. Section 2 positions the CRM within the relevant literatures. Section 3 describes the derivation method. Section 4 presents the model. Section 5 develops five design propositions. Section 6 analyses scalability. Section 7 discusses implications and limitations, and Section 8 concludes.

2. Theoretical Background

2.1 What Ambidexterity Theory Does not Solve

O'Reilly and Tushman's (2004; 2016) ambidexterity framework argues that sustained organisational performance requires simultaneous exploitation of existing capabilities and exploration of new ones. Their preferred structural solution — separating exploratory units from the core business — is well-supported empirically. What it does not address is the transfer problem: what happens when an exploratory venture must return to an exploitative unit for scaling, and how that transfer is designed so the receiving unit develops genuine ownership rather than mechanical compliance.

The Over-Competence Trap (Study 1) is a structural consequence of this gap. When HQ executes all the technically and politically demanding incubation work, the inheriting branch has witnessed the outcome but not the process. O'Reilly and Tushman identify the risk of insufficient separation between exploration and exploitation; the Over-Competence Trap identifies the complementary risk: separation so complete that the exploitative unit never learns what the exploratory unit learned.

2.2 Implementation Science and the Transfer Gap

Fixsen et al. (2005) distinguish four implementation stages — exploration, installation, initial implementation, and full implementation — and identify drivers at three levels: competency, organisational, and leadership. Their central argument is that sustainable implementation requires active capacity development at all three levels simultaneously. Applied here, transferring a venture to a branch without developing the branch's implementation competence is structurally equivalent to stopping at initial implementation without the investment enabling full implementation.

2.3 From Antecedents to Mechanics

Burgelman's (1983) distinction between induced and autonomous strategic behaviour remains useful, but the CRM operates at a level of institutional mechanics that antecedent frameworks do not reach. Zahra (1991) specifies conditions for intrapreneurial activity; Hamel (2000) argues innovation must become a firm-level competence rather than an individual trait. Neither specifies the transfer mechanisms that would make this true. The CRM is designed to fill precisely this gap: it is a transfer mechanism, not an antecedent framework.

3. Derivation Method

The CRM is derived through prescriptive theory-building from a single empirical case (Van Aken, 2004). The data source is Study 1: twelve months of AI-assisted reflective logs produced by the informant, triangulated with a 90-minute semi-structured interview conducted in March 2026. Twelve individual-level factors identified in Study 1 form the raw material for the institutional design proposed here.

The derivation follows three steps. Each factor was classified as enabling or inhibiting. Each enabling factor was translated from a description of what the informant does into a prescription for what an institution should provide. The single inhibiting factor — the Over-Competence Trap — was treated as a design constraint: the CRM must structurally prevent the conditions under which it arises. The five propositions in Section 5 are stated in testable form to enable verification in subsequent comparative research.

4. The Corporate Relay Model

4.1 The Relay Metaphor

A relay race is not a solo sprint performed by multiple people sequentially. It is a structured handoff in which each runner holds a defined zone of responsibility, the baton transfers under a specific protocol, and the receiving runner must already be in motion before the transfer occurs. Applying this logic to venture development within large organisations yields three design imperatives: define the handoff zone, specify the transfer protocol, and ensure the receiving unit is already moving before the handoff.

The name deliberately rejects two common failure modes. The 'throw it over the wall' model treats transfer as a single event: HQ declares the venture ready and branches receive it cold. The Over-Competence Trap is the opposite failure: HQ never actually transfers, because it is always more efficient for HQ to do the work than to

develop the branch's capacity. The CRM's staged transfer protocol makes neither failure the path of least resistance.

4.2 Three Phases

Phase 1: Branch Demand Validation. The branch unit completes a structured demand validation protocol before any HQ engagement. Using a standardised template, branch sales staff conduct customer-facing interviews with a minimum of five existing customers. The output specifies: the initial hypothesis, interview findings, a GO/STOP recommendation, and the relationship asset through which the proposed venture would be distributed. HQ receives only completed validation records; proposals without them are not reviewed. This operationalises two factors from Study 1 — the Relationship Asset Leverage Filter and the Demand Validation Stopping Rule — as institutional requirements rather than individual judgement calls.

Phase 2: HQ-Led Incubation. Following a GO decision, HQ assumes responsibility for the technically and politically demanding work: contract design, monetisation architecture, regulatory compliance, and internal approvals. Critically, HQ's delegation boundary is made explicit: web construction, PR, and UI decisions are delegated to the branch from the outset. This is not a concession to branch capability; it is the mechanism by which branch learning begins during Phase 2 rather than after it.

Phase 3: Staged Branch Ownership Transfer. Ownership transfers across three defined sub-stages: joint operation (HQ leads, branch co-executes); branch-led operation (branch leads, HQ advises); and branch autonomy (branch holds full decision authority, HQ monitors). Each sub-stage has an explicit GO criterion before progression: the branch can explain the venture's logic in the first; demonstrates three consecutive months of autonomous decision-making in the second; achieves single-month operational profitability in the third.

5. Five Design Propositions

5.1 P1: Demand Validation as Institutional Gate

Requiring branch units to complete a standardised demand validation protocol before HQ review reduces HQ evaluation workload and raises proposal quality, because branches unable to generate validated demand are filtered out before consuming HQ capacity.

Study 1's Demand Validation Stopping Rule was a personal judgement call that stopped all three discontinued ventures. The institutional equivalent is a formal pre-qualification gate enforced by process design rather than by the continued presence of one individual.

The informant stated: "For ideas from branches where the sales staff hadn't done any customer interviews during their normal sales activities, I forced a stop." P1 converts this personal rule into an organisational requirement.

5.2 P2: Branch Execution Capacity Predicted by Existing Performance

Selecting branch participants for Phases 2 and 3 from among the branch's top-ranked existing sales performers increases the probability of successful venture execution, because the capabilities required for new venture development correlate positively with those producing top performance in existing roles.

Study 1's Branch Performance as Execution Proxy factor was tentative but directionally consistent: the most capable branch partner drove the most active venture; the lowest-performing representative ignored new venture meetings entirely. The informant noted: "I want to try reaching out to people who are high in the internal sales and profit rankings." P2 converts this observation into a selection protocol.

5.3 P3: Staged Transfer as Over-Competence Trap Prevention

Transferring venture ownership across three defined sub-stages with explicit GO criteria at each transition — rather than as a single event — prevents the Over-Competence Trap by ensuring branch capability develops in parallel with, rather than after, HQ execution.

The Over-Competence Trap in Study 1 was not a management failure; it was a structural outcome. HQ executed everything efficiently because it was the most capable unit available. The informant's own assessment: "Right now the branch has become a 'task machine' following my instructions. I've learned that when someone

competent at HQ takes over too much of a new venture, this is what happens." The staged transfer protocol makes branch learning a Phase 2 activity, not a Phase 3 discovery.

5.4 P4: Low-Threshold Budget Architecture

Establishing a dedicated Phase 1 validation budget — capped at a level where zero-customer outcomes represent an acceptable loss — reduces the perceived cost of branch experimentation to near zero and accelerates GO decisions by replacing qualitative risk judgement with threshold comparison.

Study 1's Risk Quantification First Tactic described the informant's consistent practice of presenting worst-case cost simulations before seeking approval. The matrimonial services venture was approved immediately when the branch manager understood that zero uptake would cost approximately 200,000-300,000 yen. P4 institutionalises this reframing through budget architecture rather than presentation skill.

5.5 P5: HQ Role Differentiation and Dialogue Infrastructure

Differentiating the HQ new-venture function into distinct roles — monetisation ownership, branch relationship, and external knowledge interface — and formalising an external dialogue partner for the monetisation owner reduces single-point-of-failure dependency and addresses the psychological sustainability risk documented in Study 1.

Study 1's Isolation-Enabled Speed factor documented a full year of organisational loneliness: "There is genuinely no one inside the company to consult about this kind of thing." P5 addresses both structural and psychological dimensions: role differentiation distributes cognitive load and creates internal consultation relationships where none currently exist; an external dialogue partner ensures access to knowledge the organisation itself does not hold.

6. Scalability Analysis

6.1 The Structural Ceiling of the Current Model

The informant's target of thirty non-core ventures per year cannot be achieved within the current model. Table 1 presents a workload analysis across the four main activity categories.

Table 1: Workload analysis of the current model and projected reductions under full CRM implementation

Activity	Per Venture (Months)	3 Ventures Total	Reduction via CRM
Phase 1: Validation support	0.5	1.5	→ 0.1 (branch-led template)
Phase 2: HQ-led incubation	3–4	9–12	Partial reduction via role split (P5)
Phase 3: Transfer management	1–2	3–6	→ 0.5 via staged protocol (P3)
Internal approvals / coordination	1	3	Reduction via P1 gate and P4 budget
Total (one person)	**5.5–7.5**	**16.5–22.5**	**Structural ceiling: ~2–3 ventures/year**

The arithmetic is straightforward: a single person working twelve months cannot manage more than two to three ventures simultaneously under the current approach. The informant is at the structural ceiling of the one-person model.

6.2 What Full CRM Implementation Enables

Under full CRM implementation, two structural changes alter the arithmetic. Phase 1 workload transfers almost entirely to branch units, reducing per-venture HQ time from 0.5 months to approximately 0.1 months. Phase 3 shortens from 1–2 months to approximately 0.5 months per venture, because the branch is already operating with partial autonomy before the formal transfer begins.

Phase 2 cannot be reduced below approximately 2–3 months without compromising incubation quality. This constraint is addressed by expanding the HQ team to three differentiated roles (P5). With three roles operating in parallel and an average Phase 2 duration of 2.5 months, theoretical annual capacity is approximately 3 x 12 ÷ 2.5 = 14–18 ventures per year. The path to thirty requires either a larger HQ team or a reduction in Phase 2 duration through accumulated process learning — a three-to-five year trajectory rather than a single structural change.

7. Discussion and Limitations

7.1 Theoretical Contributions

The Over-Competence Trap is the CRM's central design problem, and the staged transfer protocol in Phase 3 is its central design response. The contribution to ambidexterity theory is narrow but specific: O'Reilly and Tushman (2016) focus on the design of the exploratory unit; the CRM focuses on the design of transfer from exploratory to exploitative unit. Structural separation protects nascent ventures from exploitation pressure; staged transfer develops the exploitative unit's capacity to take the venture on without destroying it.

Within Fixsen et al.'s (2005) implementation driver taxonomy, the CRM's five propositions map directly onto the three driver levels: P1 and P2 are competency drivers (selection and protocol); P3, P4, and P5 are organisational and leadership drivers (structure, resources, and role architecture).

7.2 Practical Implications

The informant intended to use this research to argue for organisational investment to senior management. Three propositions translate directly into that argument. The workload analysis in Section 6 provides quantitative basis for a headcount request: the current model is at its structural ceiling, and a three-person HQ team with CRM implementation is the minimum investment required to approach double-digit annual venture creation. P4's budget architecture provides basis for a budget request: a Phase 1 validation fund of approximately 300,000 yen per proposal represents low-risk pipeline investment. P3's staged transfer protocol provides basis for a governance request: formal transition criteria that protect organisational investment against the single most predictable failure mode.

7.3 Limitations

Three limitations constrain the claims made here. First, the CRM is derived from a single empirical case. The design propositions are analytically coherent but have not been tested across organisations attempting similar designs. Comparative case research is planned as a direct successor to this study. Second, the workload estimates derive from the informant's reported experience rather than from systematically collected time-use data. The structural ceiling finding is robust to reasonable variation in inputs, but specific figures should be treated as approximations. Third, the CRM assumes a tiered HQ-branch structure in which HQ holds implementation competence that branches do not yet possess. Organisations where this assumption does not hold may require a different institutional architecture.

8. Conclusion

One person doing what a department cannot is an asset and a vulnerability simultaneously. This paper has proposed the Corporate Relay Model as a structural solution to the vulnerability: a three-phase institutional framework that retains the intrapreneur's individual capabilities while building the organisational infrastructure that makes those capabilities replicable at scale.

The model's most distinctive feature is not its phases but the design logic connecting them: the Over-Competence Trap is not avoided by limiting what HQ does, but by structuring when HQ does it and in what sequence capability transfers. Phase 3's staged ownership transfer protocol is the operational expression of that logic.

For corporate entrepreneurship research, the CRM contributes a transfer mechanism to a literature dominated by antecedent frameworks. For implementation science, it demonstrates the translation step between individual-level factor identification and institutional design. For organisations seeking to scale from one successful intrapreneur to a functioning system, it offers both a quantitative argument for the required investment and a concrete protocol for making that investment produce returns.

Acknowledgements

The author wishes to thank the informant, whose candour about the experience of working alone made this research possible, and whose intention to use its findings in a real management argument is the best test an implementation scientist could ask for.

Ethics Declaration

This research involved a semi-structured interview with a single informant. Full informed consent was obtained prior to data collection, including consent to record and to use data in anonymised form for academic research purposes. No ethical clearance from an institutional review board was required, as the research does not involve vulnerable populations, sensitive personal data, or any form of deception. The informant reviewed and approved the use of anonymised quotations included in this paper.

AI Declaration

A large language model (Claude, Anthropic) was used as a writing assistance tool during the drafting phase of this paper to support the development of argument structure, section transitions, and prose style. All analytical claims, theoretical interpretations, design propositions, and conclusions are the author's own.

Abstract: Social Economy Organisations (SEOs) working in employability operate under growing pressure to document results, monitor beneficiary trajectories and demonstrate accountability to funders and partners. Yet many still rely on fragmented spreadsheets, paper files and informal recording practices, which weakens longitudinal follow-up and evidence-informed decision-making. This paper presents BI4Impact, a Business Intelligence (BI) prototype designed to support information management, indicator monitoring and reporting in SEOs delivering employability interventions. The study adopts an exploratory mixed-method design. First, an online survey mapped current information practices and perceived needs across 26 professionals from Portuguese SEOs. Second, five semi-structured interviews were conducted to identify operational bottlenecks, functional requirements and ethical concerns. Third, a preliminary validation of the prototype involved 20 potential users who assessed usability, perceived usefulness, priority functionalities and expected barriers to adoption after a guided demonstration. Findings reveal substantial data fragmentation: 61% of respondents rely on dispersed spreadsheets and 48% still combine digital records with paper-based files. At the same time, 91% expressed interest in a simple data-visualisation tool. Prototype validation showed high usability scores for navigation, visual clarity and information comprehensibility, as well as very high perceived usefulness. Participants prioritised dashboards with key indicators, automated reports for funders, structured registration of job placements and longitudinal follow-up features, while identifying the main adoption barriers as lack of implementation time, current data disorganisation and training needs. The paper contributes by documenting information-management constraints in employability-oriented SEOs, proposing a low-cost and ethics-aware BI architecture tailored to the social economy, and arguing that digital transformation in mission-driven organisations should be understood less as technological sophistication and more as organisational capacity-building for evidence use, accountability and learning. The study does not claim causal effects on employability outcomes; rather, it offers preliminary evidence on the relevance and feasibility of BI adoption in a socially oriented organisational setting.

Keywords: Business Intelligence; Social Economy Organisations; Employability; Accountability; Data Use; Social Impact.

1. Introduction

Social Economy Organisations (SEOs) play a central role in contemporary welfare, community-development and labour-market ecosystems. In many European contexts, these organisations deliver services to groups facing multiple barriers to employment, including long-term unemployment, low qualifications, disability, migration-related vulnerability, poverty, social exclusion and unstable labour-market attachment. Their work often combines social support, training, counselling, job mediation, employer engagement and post-placement follow-up. As a result, employability-oriented SEOs generate substantial operational information about beneficiaries, interventions, outputs and trajectories.

However, the capacity to transform this information into usable organisational knowledge remains uneven. Many SEOs still rely on spreadsheets, paper-based files, email exchanges and informal records to document activities and outcomes. Such practices may be adequate for short-term administrative purposes, but they are poorly suited to longitudinal monitoring, evidence-informed decision-making and systematic reporting. In employability interventions, this limitation is particularly consequential because the relevant effects unfold over time. A beneficiary trajectory may include registration, diagnosis, referral, training, job-search support, placement, dropout, job retention, re-entry into unemployment or progression into more stable employment. When these data are fragmented, the organisation's ability to understand intervention pathways is weakened.

At the same time, SEOs face growing external pressure to demonstrate accountability to funders, public authorities, partners and communities. Reporting requirements increasingly demand indicators, evidence of outputs, documentation of results and, in some cases, demonstration of social impact. Yet the infrastructure needed to produce such evidence is often underdeveloped. This creates a paradox: organisations are required to become more evidence-oriented, while frequently lacking the data architectures, staff time and analytical tools necessary to do so sustainably.

This paper addresses that problem by presenting BI4Impact, a Business Intelligence prototype designed to support information management, indicator monitoring and reporting in SEOs delivering employability interventions. The prototype was developed as a low-cost and ethics-aware artefact intended to help

organisations consolidate fragmented data, visualise key indicators, generate reports and support longitudinal follow-up of beneficiaries. Rather than presenting Business Intelligence as a technologically sophisticated corporate practice to be transferred directly into the social economy, the paper frames BI as a socio-technical capacity for evidence use.

The study adopts an exploratory mixed-method design. First, an online survey was administered to 26 professionals from Portuguese SEOs to map current information practices and perceived needs. Second, five semi-structured interviews were conducted to identify operational bottlenecks, functional requirements and ethical concerns. Third, a preliminary validation of the prototype involved 20 potential users who assessed usability, perceived usefulness, priority functionalities and barriers to adoption after a guided demonstration.

The paper makes three contributions. Empirically, it documents information-management constraints in employability-oriented SEOs. Technologically, it proposes a BI architecture tailored to the operational realities of social economy organisations. Theoretically, it argues that digital transformation in mission-driven organisations should be understood less as technological sophistication and more as organisational capacity-building for evidence use, accountability and learning.

2. Theoretical Background

2.1 Data Use and Information Fragmentation in Social Economy Organisations

SEOs occupy a distinctive position within contemporary welfare and labour-market governance. Their legitimacy derives not only from the services they deliver, but also from their capacity to demonstrate that resources are converted into social value. This expectation has intensified as public funders, philanthropic organisations and institutional partners increasingly require evidence of outputs, outcomes and impact.

However, data use in the nonprofit and social economy sectors remains constrained by organisational capacity. Recent research on nonprofit data use shows that organisations collect heterogeneous forms of data, including programme, financial, beneficiary, volunteer and community data. These data are used for reporting, internal management, communication, advocacy and service improvement. Yet organisations frequently struggle with data quality, data integration, indicator selection, staff capacity and the alignment between funder requirements and internal learning needs (Mayer and Fischer, 2023).

This problem is particularly relevant for employability-oriented SEOs. Employability interventions are rarely linear. They involve sequences of actions and interactions that may include intake assessment, skills diagnosis, training, counselling, job-search support, employer mediation, placement and post-placement follow-up. The value of the intervention depends not only on the number of beneficiaries reached, but also on whether beneficiaries progress toward more stable labour-market participation. Therefore, longitudinal information is essential.

When information is dispersed across spreadsheets, paper files or individual staff records, three risks emerge. First, operational continuity is weakened because knowledge about beneficiary trajectories remains dependent on individual workers. Second, reporting becomes inefficient because data need to be manually reconstructed for funders and partners. Third, organisational learning is limited because managers and practitioners lack timely information about intervention patterns, bottlenecks and outcomes.

2.2 Business Intelligence as Socio-Technical Capacity

Business Intelligence refers to the processes, tools and practices through which organisations collect, structure, analyse and visualise data to support decision-making. In corporate contexts, BI is often associated with integrated databases, dashboards, key performance indicators, analytical reporting and advanced decision-support systems. In the social economy, however, the value of BI must be interpreted differently.

For SEOs, BI should not primarily be understood as a mechanism for optimisation in a narrow managerial sense. Instead, it can be seen as a socio-technical capability that enables organisations to transform operational records into actionable knowledge. This distinction is important because social economy organisations operate under mission-driven logics, resource constraints and ethical responsibilities that differ from those of commercial firms.

The adoption of BI depends on more than technical availability. Research on information systems adoption has repeatedly shown that implementation is shaped by technological, organisational and environmental factors.

Technological factors include usability, compatibility, perceived usefulness, information quality and system quality. Organisational factors include leadership support, staff skills, routines, available time, data governance and readiness for change. Environmental factors include funder expectations, regulatory requirements, stakeholder pressures and inter-organisational collaboration (DeLone and McLean, 2003; Tornatzky and Fleischer, 1990; Venkatesh et al, 2003).

In SEOs, these dimensions are tightly connected. A dashboard may be visually clear, but still fail if staff lack time to update records. A reporting tool may be technically accurate, but create ethical concerns if access rules and data minimisation principles are unclear. A prototype may be useful for managers, but burdensome for frontline professionals if it increases administrative workload. Therefore, BI adoption in SEOs must be evaluated as a socio-technical process.

2.3 Accountability, Evaluation and Organisational Learning

Accountability is a central concept in the governance of social economy organisations. SEOs are accountable to multiple stakeholders: beneficiaries, staff, volunteers, funders, public authorities, community partners and society at large. These accountabilities may not always align. Funders may prioritise quantitative outputs and compliance indicators, while practitioners may value qualitative progress, trust-building and long-term empowerment. Beneficiaries may experience success in ways that are not fully captured by standard employability indicators.

This plurality makes information systems politically and ethically significant. Data systems do not merely record reality; they help define what becomes visible, measurable and reportable. If a system only captures short-term placements, it may underrepresent the complex work involved in preparing disadvantaged beneficiaries for labour-market participation. Conversely, if a system captures too much personal information, it may create risks related to privacy, surveillance and administrative burden.

Recent literature on nonprofit accountability emphasises the relationship between evaluation, data utilisation and learning. Evaluation data become meaningful when they are not merely produced for external reporting, but incorporated into organisational reflection and decision-making. In this sense, accountability can be understood as both external and internal: external accountability concerns the responsible use of resources and communication of results, while internal accountability concerns the capacity to learn from evidence and improve practices (Cavicchi and Vagnoni, 2023; Handley, 2025; Robichau et al, 2025).

BI tools can support both dimensions when appropriately designed. Dashboards can make key indicators visible to managers and teams. Automated reports can reduce the administrative burden of funder reporting. Longitudinal tracking can help organisations understand whether beneficiaries remain employed after placement. However, these benefits depend on data quality, ethical governance and organisational use.

2.4 Social Impact Measurement and Ethical Digital Transformation

The social economy has been increasingly influenced by debates on social impact measurement and management. Public and philanthropic funders often expect organisations to measure their contribution to social inclusion, employability, well-being or community development. However, social impact is difficult to define and measure, particularly when interventions address complex and long-term social problems (OECD, 2023; OECD, 2024).

Employability interventions illustrate this difficulty. A job placement may be an important output, but it does not automatically indicate sustainable inclusion. Retention, job quality, income stability, confidence, skills development and reduced dependence on social support may also matter. Some of these dimensions are quantifiable; others require qualitative interpretation. Therefore, digital tools for impact-oriented organisations should avoid reducing social value to simplistic metrics.

Ethical digital transformation in SEOs requires attention to proportionality, data minimisation, informed consent, access control, transparency and responsible interpretation. Beneficiary data can be sensitive, especially when it concerns unemployment, disability, social vulnerability, migration status or household conditions. A BI prototype for this context must therefore be designed with safeguards. These include collecting only necessary data, restricting access according to roles, anonymising or aggregating data where possible, and ensuring that indicators are used for support and learning rather than punitive judgement (Qian-Khoo et al, 2025).

3. Methodology

3.1 Research Design

The study adopted an exploratory mixed-method design structured in three sequential stages: an online survey, semi-structured interviews and preliminary prototype validation. This design was selected because the research problem concerns both organisational practices and technology adoption. Understanding the feasibility of BI in employability-oriented SEOs requires mapping existing information practices, interpreting operational bottlenecks and assessing user perceptions of the proposed prototype.

The research was exploratory rather than confirmatory. It did not aim to test causal hypotheses about the effect of BI adoption on employability outcomes. Instead, it sought to identify current constraints, translate them into functional requirements and evaluate the perceived relevance and usability of BI4Impact among potential users.

3.2 Data Collection

The first stage consisted of an online survey administered to 26 professionals from Portuguese SEOs working in or around employability interventions. The survey focused on current data-recording practices, monitoring and reporting routines, perceived difficulties and interest in digital visualisation tools. Respondents were asked about tools used to register beneficiary information, the extent of data centralisation or fragmentation, use of paper-based files, existence of indicators and perceived usefulness of dashboards and automated reports.

The second stage involved five semi-structured interviews with professionals familiar with employability interventions and organisational reporting requirements. The interviews explored the practical meaning of information fragmentation, difficulties in beneficiary follow-up, reporting burden, perceived risks of digital tools and functional requirements. Interview topics included registration practices, data quality, duplication of work, longitudinal tracking, indicator monitoring, funder reporting, access to information, staff training and ethical concerns.

The third stage consisted of a preliminary validation of BI4Impact with 20 potential users. Participants attended a guided demonstration of the prototype and subsequently assessed several dimensions: navigation, visual clarity, information comprehensibility, perceived usefulness, priority functionalities and expected barriers to adoption. The validation focused on early-stage acceptance and feasibility rather than full implementation.

3.3 Analytical Approach

The survey data were analysed descriptively, with particular attention to frequencies and percentages regarding data fragmentation, use of spreadsheets, reliance on paper records and interest in visualisation tools. Interview data were used to interpret these patterns and identify functional and ethical requirements. Prototype validation results were analysed in terms of perceived usability, usefulness, priority features and adoption barriers.

The three stages were integrated through a requirements-oriented logic. Survey results identified broad patterns; interviews explained operational causes and consequences; prototype validation assessed whether BI4Impact responded to the identified needs.

4. Results

4.1 Current Information Practices

The survey revealed substantial fragmentation in the information practices of employability-oriented SEOs. A majority of respondents reported reliance on dispersed spreadsheets, while a significant proportion indicated that digital records were still combined with paper-based files. Specifically, 61% of respondents relied on dispersed spreadsheets and 48% combined digital records with paper files.

These findings suggest that many organisations operate with hybrid and weakly integrated information environments. Data may exist, but it is not necessarily structured in a way that supports longitudinal follow-up, indicator monitoring or efficient reporting. In practical terms, beneficiary information may be distributed across multiple files, staff members, folders and formats.

Interviewees confirmed this pattern. They described situations in which different teams maintained separate spreadsheets, information had to be manually copied between systems and historical data were difficult to retrieve. Some participants noted that reporting to funders required substantial manual effort because the necessary information was not available in a consolidated format. Table 1 summarises the main empirical findings from the three stages of the study.

Table 1: Summary of Empirical Findings

Research Stage	Main Focus	Key Findings
Survey with 26 professionals	Current information practices and perceived needs	61% rely on dispersed spreadsheets; 48% combine digital records with paper files; 91% expressed interest in a simple data-visualisation tool
Five semi-structured interviews	Operational bottlenecks and requirements	Fragmented records, duplication of work, difficulty in longitudinal follow-up, manual reporting burden, concerns about data protection and staff workload
Prototype validation with 20 potential users	Usability, usefulness and adoption barriers	High perceived usability for navigation, visual clarity and information comprehensibility; very high perceived usefulness; main barriers: lack of implementation time, data disorganisation and training needs

4.2 Perceived Need for Data Visualisation

Despite the fragmented information environment, the survey revealed strong interest in digital support for data visualisation. Ninety-one per cent of respondents expressed interest in a simple data-visualisation tool. This result is important because it suggests that professionals recognise the value of better information systems, provided that they are simple and operationally useful.

Participants did not describe a need for highly complex analytics. Instead, the most valued functionalities were practical: dashboards with key indicators, automated reports for funders, structured registration of job placements and longitudinal follow-up features. This indicates that the immediate digital transformation need in these organisations is infrastructural. Before advanced analytics can be meaningful, SEOs need reliable mechanisms for structuring, accessing and interpreting basic operational data.

4.3 Operational Bottlenecks

The interviews identified four major bottlenecks. First, data fragmentation created inefficiency and uncertainty. Participants reported that information about beneficiaries, interventions and outcomes was often distributed across different files and people. This made it difficult to obtain a complete view of each beneficiary's trajectory.

Second, longitudinal follow-up was weak. Organisations could often document initial participation or placement, but had greater difficulty monitoring what happened after the intervention. In employability work, this is a major limitation because the sustainability of outcomes depends on what occurs after placement. Third, reporting was burdensome. Participants described the preparation of reports for funders and partners as time-consuming because data needed to be manually compiled and verified. Fourth, ethical and organisational concerns influenced attitudes toward digitalisation, particularly data protection, controlled access, staff training and data-cleaning needs.

4.4 Prototype Validation

The preliminary validation of BI4Impact produced positive results. Participants assessed the prototype favourably in terms of navigation, visual clarity and information comprehensibility. They also reported very high perceived usefulness, especially in relation to dashboards, automated reporting and beneficiary follow-up.

The most prioritised functionalities were dashboards with key employability indicators, automated reports for funders and partners, structured registration of job placements, longitudinal follow-up of beneficiary trajectories and filtering by intervention, period, beneficiary profile and outcome status. The main expected barriers to adoption were lack of implementation time, current data disorganisation and training needs. This

finding reinforces the socio-technical interpretation of BI adoption. Even a useful and understandable prototype requires organisational conditions for implementation.

5. BI4Impact Prototype and Proposed Architecture

5.1 Prototype Rationale and Functional Components

BI4Impact was designed as a Business Intelligence prototype tailored to employability-oriented SEOs. Its purpose is to support information management, indicator monitoring and reporting by transforming fragmented organisational records into structured and visual information. The prototype is grounded in four design principles: simplicity, operational relevance, longitudinal visibility and ethical data use.

The prototype includes four main functional components. The first is a structured data-registration layer that organises information about beneficiaries, intervention history, training activities, job placements, follow-up contacts and outcome status. The second is an indicator dashboard that visualises key indicators related to employability interventions, such as number of beneficiaries, intervention phases, completed activities, placements, active follow-ups and pending records.

The third component is an automated reporting module intended to reduce the administrative burden associated with funder and partner reporting. The fourth is a longitudinal follow-up module that supports monitoring after placement or intervention completion, allowing organisations to document whether beneficiaries remain employed, require additional support or re-enter intervention pathways.

5.2 Socio-Technical Architecture

The architecture of BI4Impact is presented in Figure 1. The model connects fragmented organisational records to structured data, BI dashboards, operational use, accountability use and learning use. The final purpose is organisational capacity-building for evidence-informed work.

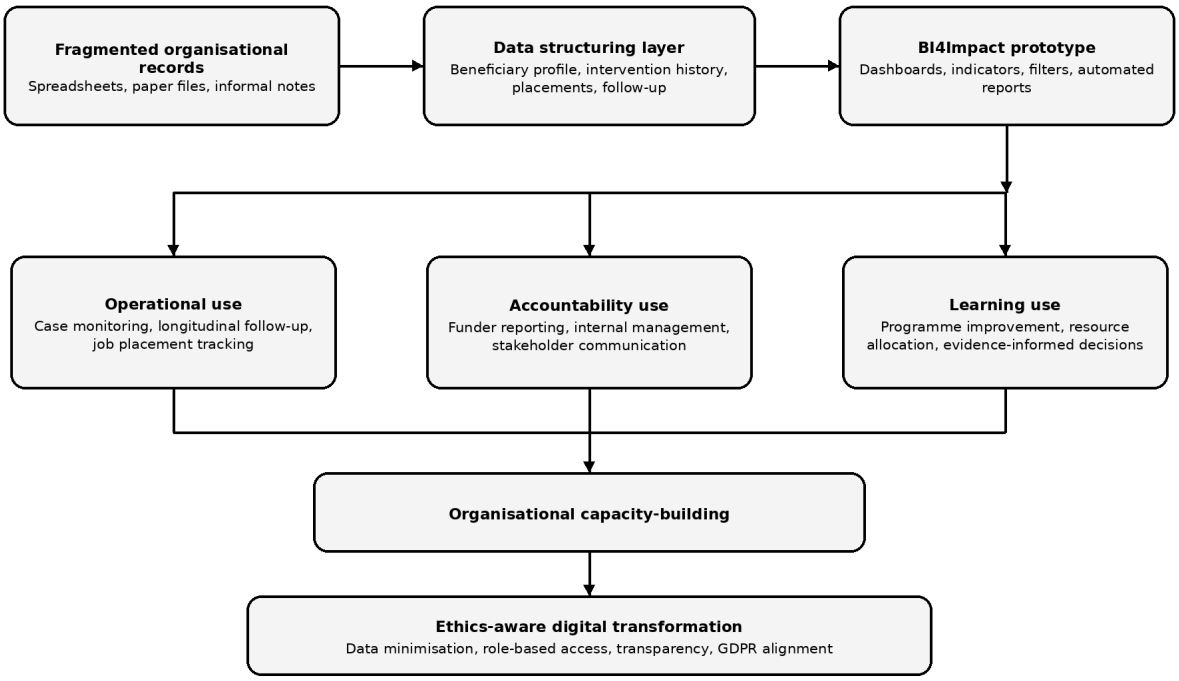

Figure 1: BI4Impact socio-technical architecture for evidence use in employability-oriented SEOs.

The figure positions BI4Impact as an intermediary between fragmented records and organisational use. It also emphasises that the value of the prototype is not limited to reporting. The same structured information can support operational monitoring, external accountability and organisational learning.

Because employability-oriented SEOs work with potentially vulnerable beneficiaries, ethical design is central. BI4Impact should not promote excessive data collection or intrusive monitoring. Instead, it should help

organisations use necessary information responsibly. Data should be limited to what is necessary for intervention, follow-up and reporting; access should be role-based; reporting should privilege aggregated indicators whenever possible; and interpretation should remain contextual and professional.

6. Discussion

The findings confirm that employability-oriented Social Economy Organisations (SEOs) face a structural information-management problem. This problem is not primarily the absence of data, but the fragmentation of data across spreadsheets, paper files and informal recording routines. This finding is consistent with Mayer and Fischer's (2023) analysis of nonprofit data use, which shows that nonprofit organisations often collect multiple types of data but struggle to transform them into integrated and actionable organisational knowledge. In the present study, the reliance on dispersed spreadsheets and hybrid paper-digital records illustrates this gap between data collection and data use.

This fragmentation has direct implications for accountability, evaluation and organisational learning. As Cavicchi and Vagnoni (2023) argue, digital information systems can support accountability in welfare-oriented organisations when they help structure information and make reporting processes more transparent. However, the present findings also show that accountability cannot be reduced to the production of indicators for external stakeholders. In line with Robichau et al (2025), evaluation information becomes organisationally valuable when it supports learning and data utilisation practices, rather than serving only compliance-oriented reporting. BI4Impact therefore responds to a dual need: improving external accountability to funders and partners, while also strengthening internal learning about beneficiary trajectories, intervention bottlenecks and follow-up needs.

The high level of interest in a simple data-visualisation tool suggests that Business Intelligence adoption in this context should not be framed as a demand for advanced analytics. Participants valued basic but operationally consequential functionalities: dashboards with key indicators, automated funder reports, structured registration of job placements and longitudinal follow-up. This aligns with the DeLone and McLean (2003) information systems success model, which emphasises the importance of system quality, information quality and perceived usefulness. In the case of SEOs, these dimensions are strongly associated with simplicity, clarity and operational relevance. A technically sophisticated tool would have limited value if it increased administrative burden or failed to fit existing organisational routines.

The validation of BI4Impact also supports a socio-technical interpretation of digital adoption. The positive assessment of navigation, visual clarity and information comprehensibility is consistent with technology acceptance research, particularly the emphasis placed by Venkatesh et al (2003) on perceived usefulness and ease of use as determinants of user acceptance. However, the main barriers identified by participants - lack of implementation time, data disorganisation and training needs - show that adoption depends on more than individual perceptions of usefulness. These barriers correspond to the organisational and environmental dimensions highlighted in the technology-organisation-environment framework proposed by Tornatzky and Fleischer (1990). In this sense, BI implementation in SEOs requires not only a usable artefact, but also leadership support, staff training, data-cleaning routines and alignment with funder requirements.

The findings also contribute to current debates on digital transformation in the social economy. The European Commission (2021) stresses the role of the social economy in building more inclusive and resilient economic systems, but this role increasingly depends on the capacity of organisations to demonstrate results, coordinate partnerships and communicate social value. At the same time, the OECD (2023, 2024) emphasises that social impact measurement should support organisations in measuring, managing and maximising their impact. The present study suggests that such ambitions require basic data infrastructures before more complex impact measurement frameworks can be realistically implemented. In many employability-oriented SEOs, the priority is not advanced impact modelling, but the consolidation of reliable operational data that can support follow-up, reporting and decision-making.

This point is particularly important in relation to employability interventions. Immediate outputs, such as the number of beneficiaries registered or job placements achieved, provide only a partial view of organisational contribution. As the OECD (2023, 2024) notes, social impact measurement requires attention to outcomes and to the processes through which social value is created. In employability work, this means that job placement should be complemented by information on retention, progression, re-entry into support pathways and other forms of social and labour-market inclusion. BI4Impact addresses this need by emphasising longitudinal visibility rather than isolated output reporting.

The study also reinforces the importance of ethical digital transformation. Beneficiary data in employability-oriented SEOs may concern unemployment, disability, poverty, migration status, social vulnerability or other sensitive dimensions. For this reason, BI tools should not intensify surveillance or encourage excessive data collection. The ethical design principles incorporated into BI4Impact - data minimisation, role-based access, aggregation and responsible interpretation - are consistent with the caution expressed in recent literature on digital impact measurement. Qian-Khoo et al (2025), for example, argue that digital impact measurement tools should be developed with attention to situated organisational learning, rather than imposed as neutral technical solutions. Similarly, Handley (2025) shows that accountability in small nonprofit organisations is shaped by stakeholder ambiguity, networks and trust, which means that data systems must be sensitive to relational and organisational contexts.

From this perspective, BI4Impact should be understood as a capacity-building artefact rather than as a purely technical solution. This interpretation is also supported by Al-Daraba et al (2025), whose review of BI adoption factors highlights that implementation is shaped by the interaction between technological, organisational and human factors. In the present study, the prototype was valued because it made information clearer and more usable, but participants also recognised that implementation would require time, training and prior data organisation. This confirms that digital transformation in SEOs is not simply a matter of introducing software; it is a process of changing routines, improving data quality and creating conditions for evidence-informed decision-making.

The findings have practical implications for SEOs, funders and technology developers. First, SEOs should treat data organisation as a strategic capability rather than a secondary administrative task. Without coherent data structures, organisations remain dependent on individual memory, fragmented files and manual reconstruction of information. Second, funders should avoid increasing reporting demands without supporting the informational capacity needed to meet them. If accountability requirements are not accompanied by investment in data systems, training and implementation time, they risk increasing administrative burden without improving learning. Third, technology developers should design BI tools for the social economy around usability, minimal data burden, role-based access and alignment with existing workflows.

The study also highlights an important tension in contemporary social impact measurement. On the one hand, SEOs need stronger data infrastructures to demonstrate accountability and improve their interventions. On the other hand, excessive measurement can distort organisational priorities or reduce complex social processes to narrow metrics. This tension has been widely recognised in debates on accountability and social impact evaluation (Handley, 2025; OECD, 2023; Robichau et al, 2025). BI4Impact attempts to address it by focusing on practical evidence use rather than metric proliferation. The prototype is designed to make existing information more coherent and actionable, not to impose a technocratic model of social value.

In employability interventions, this distinction is crucial. Employment outcomes are influenced by multiple factors beyond the control of SEOs, including labour-market conditions, employer behaviour, public policy, health, family responsibilities and local opportunity structures. Therefore, a BI tool should not be used to attribute causal responsibility simplistically. Instead, it should help organisations understand patterns, identify follow-up needs, detect gaps in service provision and communicate results transparently. This modest but realistic understanding of BI is aligned with the broader argument that digital transformation in mission-driven organisations should strengthen evidence use, accountability and learning, while preserving professional judgement and ethical responsibility.

7. Conclusion

This paper presented BI4Impact, a Business Intelligence prototype designed to support information management, indicator monitoring and reporting in employability-oriented Social Economy Organisations. Based on an exploratory mixed-method design involving a survey, semi-structured interviews and preliminary prototype validation, the study identified substantial data fragmentation and strong interest in simple, usable and visually clear data-visualisation tools.

The contribution of the paper is threefold. Empirically, it documents information-management constraints in Portuguese SEOs working in employability. Technologically, it proposes a low-cost BI architecture oriented towards dashboards, automated reports, job-placement registration and longitudinal follow-up. Theoretically, it frames BI adoption as a socio-technical capacity-building process that connects accountability, organisational learning and ethical data use.

The study does not claim causal effects on employability outcomes. Its contribution is more modest and, arguably, more realistic: it shows that evidence-informed work in SEOs depends on the capacity to transform fragmented operational records into usable organisational knowledge. For mission-driven organisations, digital transformation should therefore be understood less as the adoption of sophisticated technologies and more as the development of practical, ethical and sustainable capacities for evidence use.

Several limitations should be acknowledged. The survey sample was modest, the interviews were exploratory and the prototype validation assessed perceived usefulness rather than long-term use in real organisational settings. Future research should examine the implementation of BI4Impact in SEOs over time, assess how staff incorporate dashboards into decision-making routines, and investigate whether improved data integration affects reporting quality, follow-up practices and organisational learning. Comparative studies across different types of SEOs would also be valuable, particularly to understand how organisational size, funding model and digital maturity influence BI adoption.

Despite these limitations, the study provides preliminary evidence that BI adoption is relevant and feasible in employability-oriented SEOs when designed around simplicity, ethical safeguards and organisational capacity-building. BI4Impact offers a practical contribution to the digital transformation of the social economy by supporting a form of evidence use that is operationally grounded, socially oriented and attentive to the realities of mission-driven organisations.

Ethics Declaration

This study involved professionals and potential users of a Business Intelligence prototype rather than vulnerable beneficiaries. Participation was voluntary and based on informed consent. No personally identifiable beneficiary data were collected, processed or reported. Survey, interview and validation data were analysed in aggregated form. The prototype was designed according to principles of data minimisation, role-based access and responsible information use.

AI Declaration

AI-assisted tools were used to support language refinement, structural revision, formatting adaptation and consistency checking of the manuscript. The authors remain fully responsible for the research design, data interpretation, scholarly argument, references and final content of the paper.

mervi.rajahonka@xamk.fi

Abstract: Digital business transformation is increasingly shaping the operating conditions of small and medium-sized enterprises (SMEs) across all industries. In Finland, where digital services are widely used and broadband connections are reliable, customers primarily search for and use services through various digital channels, creating new demands for digital business capabilities among SMEs. However, access to technology alone does not guarantee successful digital transformation. SMEs operating in traditional sectors, in particular, often struggle to translate digital skills into concrete business development and a competitive advantage. This highlights the need for effective support models that go beyond mere access to digital tools. This paper examines the impacts of a digital business training and coaching model on business development orientation, growth and competitiveness among SMEs. Using the Digital Steps programme implemented in South Savo, Finland, as a case study, the study draws on survey data and qualitative interviews with participating companies. The target group consisted of micro-enterprises and small businesses, including sole traders operating in the service, tourism, retail and other traditional industries. The analysis explores perceived competency development, the adoption of digital tools and initial business-related outcomes, with particular attention paid to differences related to the intensity of participation. The findings indicate that combining structured training with company-specific coaching helps SMEs translate digital skills into improved marketing, customer engagement and operational efficiency. These developments are associated with perceived improvements in competitiveness and growth potential, highlighting the role of tailored digital business training in supporting SME development in a digital business environment. While the immediate effects on revenue and employment were limited, participants reported visible impacts. Moreover, more intensive participants reported business outcomes such as access to new networks and markets and improved competitiveness, rather than merely knowledge gains or tool adoption. Overall, the findings highlight the importance of supporting SMEs' digital development through regional business support systems that seek scalable and impactful digitalisation initiatives.

Keywords: Digital Business, Business Training, Digital Skills, SME, Competitiveness

1. Introduction

Digital business transformation is reshaping the business environment of small and medium-sized enterprises (SMEs) across all industries, while digital technologies are reducing the distance between businesses and people. At the same time, this transformation is creating a divide between SMEs that can capitalise on digitalisation and those that cannot. In Finland, where digital services are widespread and broadband connections are reliable, customers increasingly search for and use services primarily through digital channels. However, access to technology alone does not guarantee successful digitalisation.

Recent crises have increased uncertainty and volatility across companies of all sizes. In this increasingly unpredictable environment, digital transformation has become a critical means of strengthening resilience and adapting to rapid change. During the COVID-19 pandemic, many companies were compelled to digitalise their operations; however, the sudden and unplanned nature of this shift limited its effectiveness compared with a more strategic and deliberate approach (Kuosmanen et al., 2024). When integrated into business strategies and everyday operations, digital transformation can substantially enhance a company's adaptive capacity and resilience (Al Omoush et al., 2025). Moreover, the adoption and diffusion of digital technologies in SMEs have been shown to improve value creation and innovation performance (Hassan et al., 2023). Nevertheless, these benefits only materialise when digital tools are adopted in ways that are appropriate to the company's context and capabilities. Many SMEs lack the internal resources required to achieve this independently or to access external expertise.

The *Digital Steps – Towards More Customer-Centric Digital Business* project was a regional development initiative carried out between 2023 and 2025. The project aimed to strengthen the digital business capabilities of micro-enterprises and small business in South Savo, Finland, with a particular focus on sole traders and rural companies operating in traditional industries. It combined digital business education with company-specific coaching and sparring, supporting SMEs in translating digital skills into concrete business practices. This study

examines the impact these actions had on the participating SMEs through the following two research questions:

RQ1. How do digital business training and coaching impact SMEs' business development orientation, growth and competitiveness?

RQ2. How does the intensity of participation affect the perceived gains?

To address these questions, the study examines the survey conducted in 2025 and eight interviews carried out in the summer of 2024. Data was collected from entrepreneurs and their employees that had participated in one or more of the following project activities: practical digital skills training, company-specific coaching, competence assessments, self-learning materials, and targeted development pathways for e-commerce businesses.

The rest of the paper is structured as follows. The next section provides a theoretical framework and background information on SMEs' needs and challenges in terms of digital competences. Section 3 provides more detailed information about the Digital Steps training model and services. Section 4 includes the survey results and insights gained from the interviews. Finally, in the 'Discussion and Conclusions' section, we discuss the main findings, their implications and the main limitations of the study.

2. SMEs' Digital Competence Needs and Challenges

In SMEs, obstacles to digitalisation are more often related to human and organisational issues than to the technology itself. These challenges include established cultural practices, employees' resistance to change, gaps in relevant knowledge and skills, constrained resources, and limited willingness to take risks. (Schvertner, 2017.) Karadağ et al. (2024) demonstrate that information technology (IT) plays a significant role in high-performing SMEs, but that, on its own, it is not sufficient to achieve superior performance. Effective digitalisation also requires digital maturity, a clear digital strategy and adequate employee skills (Karadağ et al., 2024).

Kahveci (2025) conceptualises digital transformation as a continuous process compromising four stages: Digital Awareness, Digital Strategy and Roadmap, Digital Adoption and Implementation, and Digital Continuous Improvement. The process begins with recognising and understanding the digital tools and technologies relevant to the company, followed by the development of the skills needed for their effective use. Through this structured and continuous approach, SMEs can enhance growth, improve efficiency, create greater value and foster innovation (Kahveci, 2025).

Artificial intelligence (AI) has also brought about changes in terms of the business landscape. It is reshaping the nature of work, automating routine tasks and creating new business models. However, the adoption of AI in SMEs is not self-evident. According to Alaranta et al. (2025), the key bottlenecks in SMEs include skill gaps, cost and resource constraints, issues regarding data availability and quality, resistance to change, concerns related to cybersecurity, ethical use and regulation, uncertainty regarding return on investment (ROI), as well as integration challenges. In SMEs, the timely and well-managed use of artificial intelligence, supported by continuous learning and collaboration, can become an important factor in strengthening competitiveness.

Digitalisation opens new avenues for more efficient customer orientation. Its core aim is to recognise and understand the interactions between a company and its customers. Companies are encouraged to view their activities as embedded in customers' everyday lives, including their routines, processes and interactions. This perspective enables companies to support customer value more effectively than by focusing solely on the provision of individual services. The digitalisation of services has facilitated increasingly seamless customer interactions through online channels, while the shift towards electronic distribution channels has significantly accelerated the development of new digital services. (Koivisto et al., 2021.)

Digitalisation has been found to improve companies' turnover, with particularly strong potential in small companies, where the overall level of digitalisation tends to be lower (Kuosmanen et al., 2024). In a quickly changing environment, digitalisation offers SMEs a way to survive and build resilience. Every entrepreneur must reconsider their business strategy as the operating environment changes, with online shopping having drawn customers away from local shops. After the pandemic, rising energy prices stemming from the situation in Ukraine, inflation and changes in consumer purchasing behaviour have had a radical impact on the business landscape and the way business is conducted. (Spolander et al., 2025.)

The impacts of company training can be categorised into participants' reactions, the development of their competences, changes in their behaviour, and targeted results, such as business outcomes (Kirkpatrick &

Kirkpatrick, 1994). To better understand how digitalisation contributes to SMEs' competitiveness and resilience, the underlying mechanisms can be conceptualised. According to Meier et al. (2025), digital transformation is a multidimensional process in which technological, organisational, knowledge-based and strategic elements interact to shape SME competitiveness through resources, capabilities and market positioning. In this view, digital transformation forms the foundation for enhancing competitiveness and achieving a competitive advantage. Extending this perspective, resilience can be understood as a higher-order capability that enables SMEs to maintain their adaptability, performance and competitiveness under conditions of uncertainty (Nongnuch et al., 2026). Thus, digital transformation supports both competitiveness and long-term resilience in SMEs.

The need for guidance in digitalisation is particularly pronounced in Eastern Finland and South Savo. During the period 2024–2025, the economic outlook weakened, growth expectations became more moderate and investment activity remained restrained. At the same time, companies in the region appear to be adapting to this prolonged period of uncertainty. (Ohlsbom et al., 2024a; Ohlsbom et al., 2025.) SMEs in South Savo perceived notable development needs in sales and marketing (58%), while 28% reported development needs related to personnel and training (Ohlsbom et al., 2024b).

3. Digital Steps Training Model

The project supported micro-enterprises and small and medium-sized enterprises (SMEs) in South Savo, particularly sole traders and rural businesses, in developing their digital skills and strengthening customer-oriented digital business practices. The project reached a total of 180 SMEs through a digital skills assessment and delivered 96 digital skills training sessions. In total, 134 SMEs participated in these training sessions, coaching activities and targeted development programmes designed to address the specific needs of SMEs (Ollanketo & Pylvänäinen, 2025). The participant profile was characterised by a predominance of women (77%) and most were aged between 30 and 54 (62%), followed by those aged over 54 (31%). The vast majority of participants (approximately 90%) were small businesses, primarily sole traders and micro-enterprises employing between one and nine people.

The project was initiated to strengthen SMEs' digital business capabilities, particularly in the development of digital marketing, sales and customer orientation, as well as in improving productivity through digital tools and operating environments. Companies needed to enhance their skills in a rapidly evolving digital landscape and to strengthen their ability to leverage customer insights for business development. A key focus of the project was data- and knowledge-driven decision-making, with a strong emphasis on target groups, as well as improving accessibility as a driver of growth.

The project provided a practical and agile training and coaching model that effectively addressed these needs; companies were offered a comprehensive package of practical digital training, company-specific coaching, skills assessments, self-study materials and tailored coaching pathways for e-commerce businesses.

When joining the project, the entrepreneur completed a digital skills assessment using a digital tool and had a sparring discussion with a business advisor, during which they were coached and provided with tailored training recommendations. The digital skills assessment allowed the project to identify the SME's training needs, and the training programme was planned based on the results. As the project progressed, additional training needs emerged through training sessions and participant feedback. Continuous dialogue therefore proved essential.

The skills needs identified placed particular emphasis on digital marketing, as well as the use of artificial intelligence and the opportunities it offers. The training sessions (Table 1) focused on practical, immediately applicable skills. For example, in the training on Meta advertising, participants prepared and launched ads during the session; they then analysed performance in a follow-up session and refined their campaigns, including the use of A/B testing, while the final sessions focused on gaining a deeper understanding of the tools and consolidating key learnings. Table 1 summarises the main training topics, the number of sessions delivered for each topic, the total number of participants in each specific training module, and the average number of participants per session.

Table 1: Training topics and participation.

Training	Session	Participants	Participants per Session
Canva clinic	8	41	5.1
Introduction to Facebook and Instagram advertising	6	58	9.7
Mobile video shooting and editing	6	42	7.0
Mobile photography workshop	5	35	7.0
Optimise your website	4	18	4.5
Writing for the web	4	28	7.0
Google Ads Basics	3	28	9.3
Using ChatGPT in everyday tasks	3	34	11.3
Leveraging AI in content creation	3	34	11.3
Customer acquisition on Instagram	3	30	10.0
Turn IG Reels into revenue	3	26	8.7
Optimise your Meta pixel and audiences	2	9	4.5

Create persuasive social media advertising – Advanced training	1	5	5.0
Advanced search engine optimisation training	1	6	6.0
Accommodation entrepreneurs: Take control of Booking	1	14	14.0

The training portfolio was closely tailored to skills needs identified among the participating SMEs, particularly in the areas of digital marketing and the practical application of AI, highlighting a strong demand for immediately applicable digital competences. Social media marketing trainings proved especially popular. More advanced topics attracted smaller but engaged participant groups, suggesting that SMEs prioritised foundational digital marketing skills before adopting more specialised optimisation practices.

Awareness of digital business trends and emerging platforms was promoted through open digital information sessions, for which there was clear demand among SMEs. In total, the project organised 16 free, open webinars and 10 face-to-face events, attracting 669 individual participants. They covered a broad range of topics, from customer-centric digital business models, AI adoption and digital marketing in different platforms to automation and improving productivity.

The e-commerce training programme was delivered twice: first for beginners and then for growth-oriented e-commerce businesses, with a particular focus on international markets. The programme covered key e-commerce topics including internationalisation, digital marketing and customer acquisition, live and social commerce, influencer and UGC marketing, distribution channels and the development of the participants' own e-commerce concepts.

In addition, 46 SMEs participated in company-specific digital coaching sessions, delivered by digital business advisors and outsourced eBusiness experts. The digital coaching provided highly practical support to the SMEs. The coaching sessions often focused on activities such as developing websites or online stores, planning and

implementing digital marketing actions and monitoring results. Rather than providing ready-made solutions, the work was carried out collaboratively, starting from the entrepreneur's own goals and needs.

4. Impact on Competences, Practices and Business Outcomes

4.1 Survey

A participant impact evaluation survey was conducted in June–July 2025 using the Webropol survey tool. The survey was distributed to all 189 programme participants, with 38 responses received (a response rate of 20%). No background questions were included, so respondents are assumed to represent typical participants: sole traders, micro-enterprises and small businesses in the service, tourism, retail and other traditional sectors. The questionnaire covered areas such as new knowledge and skills acquired, the adoption of digital tools, improved customer understanding and relationships, and the development of new products or services. Respondents self-assessed the outcomes on a scale from 1 (strongly disagree) to 5 (strongly agree), and open-ended responses were also collected.

Responses were distributed fairly evenly among participants who engaged occasionally (13), moderately (11) and very intensively (12), with only two respondents participating solely in the digital skills assessment. Participation levels were self-defined (occasional: up to three sessions; moderate: a few sessions; intensive: several sessions plus mentoring or coaching).

On average, the most frequently reported benefits were increased knowledge and expertise, the development of operating methods, the adoption of digital tools, and a greater appreciation of the value of business data (e.g., website or social media analytics). Improvements in customer understanding and relationships were also common. However, the programme had a notably smaller impact on measurable business outcomes, such as staff recruitment, the launch of new businesses, increased exports, the generation of new ideas, the development of scalable solutions, or increased revenue. Overall, Figure 1 indicates strong impacts on competence gains (C) and behavioural changes (B), but limited effects on business outcomes (A).

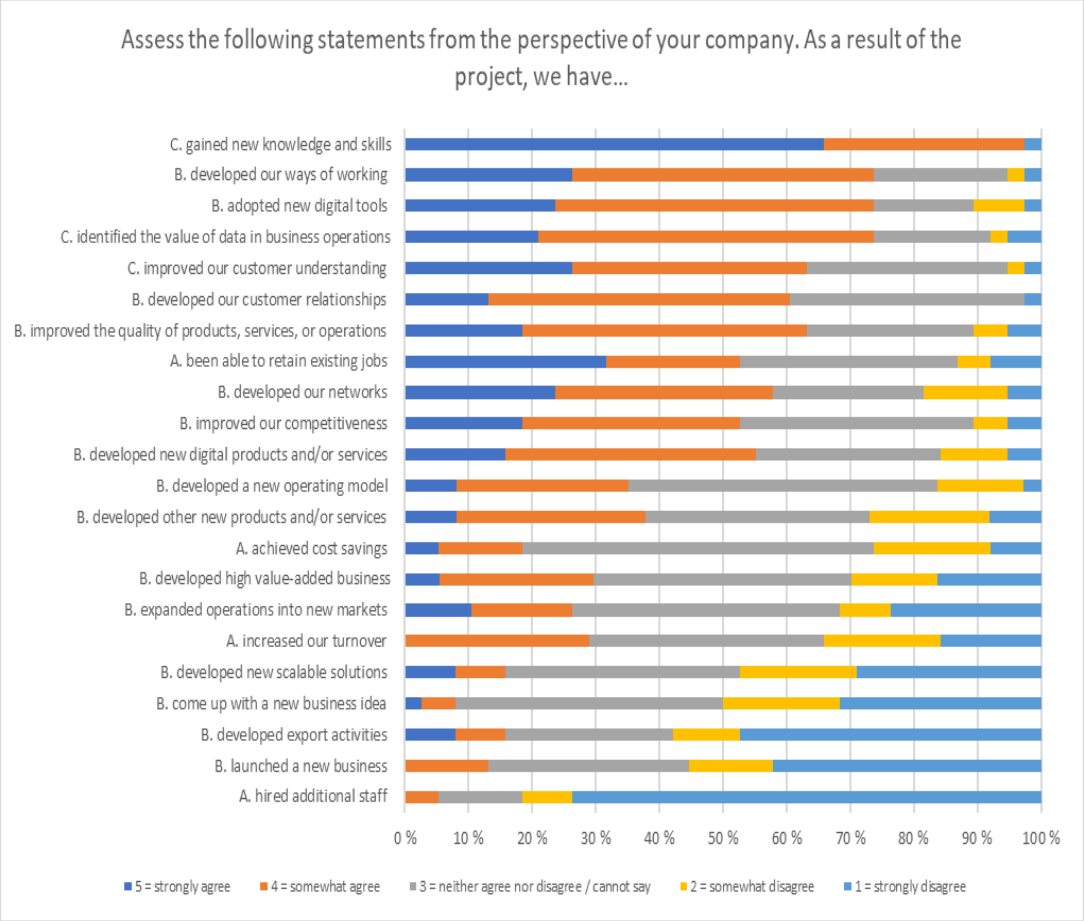

Figure 1: Responses to the statements in the questionnaire from the company's perspective.

A comparison between respondents who participated very intensively and those who participated only occasionally showed clear differences in terms of perceived impacts, especially in business outcomes. The highly engaged participants reported significantly greater benefits in export development, network building and high value-added business development. They also more often noted improvements in entering new markets, customer understanding and competitiveness.

The open-ended responses further highlighted key benefits, including access to information beyond one's professional *bubble* and up-to-date insights in a rapidly evolving digital environment. Many participants reported that they had gained directly applicable knowledge, particularly in the areas of business renewal and development, as well as in recognising the essential role of social media marketing.

Respondents appreciated the opportunity to reflect on their company's current situation and received practical support for concrete issues. Gaining new perspectives and inspiration for marketing development was considered important, along with learning about customer segmentation and AI use. Some participants noted increased confidence and a willingness to experiment with new solutions, such as using AI tools and creating social media advertisements independently. This led to more active customer communication and improved use of digital data. Overall, digital competence increased in multiple ways, enthusiasm for development grew, practical problems were resolved, and valuable contacts were established for future support.

A range of training formats—workshops, sparring sessions and information sessions—supported both long-term development and rapid responses to specific needs. Several respondents highlighted the importance of adapting to the digital business environment; as one of them noted: 'We have moved from the era of automatic data processing into the Digital Age, led by data and intelligence'. In particular, participants in the e-commerce pathway reported improved customer orientation in their online stores, the adoption of relevant digital tools and better use of data in decision-making.

4.2 Interviews

During the interim evaluation, eight long-term participants were interviewed in the spring and summer of 2024 to gain an in-depth understanding of their digital development needs. The thematic interviews covered the company's background, participation experiences, lessons learned, benefits and future plans, and were analysed using content analysis (Patton, 2002). The companies interviewed were mainly sole traders or micro-enterprises from diverse sectors (e.g., agriculture, clothing retail, physiotherapy, crafts). Participants were primarily drawn from those who had also taken part in earlier projects, with a few additional participants included. The entrepreneurs had varied backgrounds, with a clear distinction between digital beginners and more advanced, development-oriented participants.

Some entrepreneurs were actively pursuing growth, with the aim of expanding into domestic and international markets, as they saw increasing opportunities abroad. Their plans included launching international online stores or further scaling existing e-commerce operations. These participants emphasised the need for continuous monitoring of global trends and customer interests, as well as ongoing business development. In contrast, some entrepreneurs nearing retirement planned to close their businesses and had limited interest in growth, focusing instead on maintaining a sufficient income. Several respondents also highlighted global uncertainty, noting that the rapidly changing and unpredictable environment makes even short-term planning difficult.

Digital beginners needed simple, easy-to-use solutions and practical guidance. They often saw digital business as separate from their core activities, with digital tools playing only a minor role in their day-to-day work. Since they were typically not digital natives, they found skill acquisition challenging and often repeated training sessions, reviewing recordings and taking detailed notes. Producing content was difficult for some, leading to cautious use of channels such as social media. AI tools were usually tested carefully and were seen as potentially useful. Despite significant enthusiasm for digital development, putting the tools into practice proved demanding and progress was often slow.

For digitally advanced entrepreneurs, digital business is an integral part of daily operations, sometimes alongside brick-and-mortar activities. These people are strongly motivated to develop this area, investing in social media or e-commerce depending on their focus. They continuously analyse performance, monitor their environment and competitors, and actively seek new learning opportunities. AI is used routinely and broadly, for example, in text and image editing and for translations.

Despite differing needs, both groups benefited from the project. There are clear business impacts from participation in the project. Through digital business development, companies gained new customers, increased sales, reduced costs and developed new products.

Adopting new channels and tools can significantly increase the visibility of small businesses. Improved website functionality enhances the user experience, increases visitor numbers and boosts sales. When development is implemented coherently, business processes become faster and more efficient. Greater marketing knowledge and digital skills directly improve performance; for example, understanding how social media works helps businesses reach potential customers more effectively.

Many entrepreneurs highlighted increased confidence as regards experimenting and trying out new approaches as a key outcome. Their ability to monitor developments and maintain a positive attitude toward continuous improvement was also strengthened, providing them with a solid foundation for ongoing independent development, even in cases where external support may be needed.

5. Discussion and Conclusions

Digital business transformation is increasingly shaping the operating environment of small and medium-sized enterprises (SMEs), but access to technology alone is insufficient to ensure success in this area. SMEs operating in traditional sectors, in particular, often face challenges in translating digital skills into concrete business development, which underscores the need for effective support models that focus on enabling practical application, learning and long-term capacity building.

This paper examined how the Digital Steps programme influenced SME development, growth and competitiveness. The target group included entrepreneurs operating in the services, tourism, retail and other traditional sectors. The study examined how digital business training and coaching impacted SMEs and how the level of participation affected the perceived gains. The results were based on survey data and qualitative interviews with participating companies.

Digital business training and coaching influenced companies primarily through the development of skills and the adoption of digital tools. A better understanding of customers, the use of data and the renewal of internal processes are the most notable outcomes. The effects on business growth, exports and recruitment are clearly more limited and require a longer time horizon to materialise. Furthermore, the immediate effects on revenue and employment were limited.

Many entrepreneurs noted that the information, training and mentoring helped them keep pace with the rapidly evolving digital operating environment. Several companies reported concrete outcomes: new online stores were established, the quality of websites improved and social media marketing was strengthened. The project was also seen as encouraging experimentation with new solutions, such as artificial intelligence. Mentoring was repeatedly highlighted as one of the most valuable forms of support, providing companies with guidance, direction and confidence for their development. Motivational effects were also significant: participation inspired renewal, introduced new perspectives and helped clarify companies' digital strategies.

Although customer orientation was a central to all training, it was not easily adopted by all participants. In the competence assessments, entrepreneurs often described their customer understanding as already being 'in good shape', but discussions revealed that they did not collect customer feedback systematically or use data to support decision-making. This observation reinforced the need to strengthen competence in the *practical methods* of customer orientation, not merely as an attitude, but as concrete actions that support business development. In many cases, what was learned during the project could be transferred directly into the companies' own operations, which increased the perceived impact of the training.

Our results indicate that the combination of structured training and company-specific coaching, as well as a wide range of training formats—including workshops, sparring sessions and information sessions—supported both longer-term development work and rapid responses to specific needs. It also proved highly useful for entrepreneurs from diverse backgrounds, ranging from digital beginners to more development-oriented and digitally advanced entrepreneurs. (Rajahonka, 2025.)

In answering our second research question, it is worth emphasising that the companies that participated more intensively reported business-related outcomes, such as gaining access to new networks or markets, or improving competitiveness, and not just impacts related to acquiring new knowledge or adopting new digital

tools. They also mentioned expansion into new markets, improved customer understanding and increased competitiveness more frequently.

In the interim interviews and the survey conducted at the end of the programme, participants were also asked to provide feedback on their future development needs and the type of training they would like to receive in the future. They expressed a strong desire for similar courses to continue in the future, as the need for this type of support remains ongoing. Key areas identified for further development include digital marketing, customer management and communication, and internationalisation—topics that represent persistent challenges and are rapidly evolving. Internationalisation, particularly in the context of online retail and sales, was seen as requiring external expertise, new perspectives and peer support.

Just as the companies interviewed differed in their starting points and objectives, their outlook for the future was also twofold. Some entrepreneurs were actively developing their businesses and seeking growth, while others were approaching retirement age and planning to wind down their operations. Consequently, their expectations regarding future training also varied.

Evaluating the impact of digital skills development and SME growth is challenging due to the short duration of the project. The Digital Steps project received funding on three occasions, which made it possible to measure the impact among the companies that participated in the activities during several project periods. In this article, we present the results from the interim evaluation interviews conducted with participating entrepreneurs (2024), as well as the findings from the evaluation survey conducted at the end of the most recent project (Digital Steps – More Customer-Oriented Digital Business, 2023–2025).

The projects had a concrete impact on the entrepreneurs' businesses. A clear and recurring theme in their feedback is that the project has led to increased sales, new customers and stronger online visibility. The digital skills acquired have strengthened the entrepreneurs' self-confidence and their willingness to use digital solutions as part of their everyday operations. The findings highlight the importance of supporting SMEs' digital development through regional business support systems.

This study is subject to several limitations, including a short observation period, reliance on self-reported outcomes, and the case-specific nature of the programme, which may limit the generalisability of the findings. Future research could complement self-reported data with more objective information. Additionally, replicating the study across different contexts and incorporating comparative designs would improve the generalisability of the findings.

Abstract: University–industry collaboration is frequently promoted as a means of strengthening innovation in small and medium-sized enterprises (SMEs), particularly in regional ecosystems where firms and higher education institutions (HEIs) interact closely. This paper investigates whether small companies that collaborate with HEIs exhibit higher innovation activity than firms without such partnerships and assesses whether this relationship varies across firm characteristics. The study draws on survey data collected in 2025 from 291 small companies (fewer than 50 employees and less than €10M revenue) in South Karelia, Finland; the analytic sample includes 242 firms with complete information. In the survey, firms report recent innovation activity, cooperation partners, and other information, such as perceived barriers and enablers to development. Using logistic regression, we estimate the relationship between HEI collaboration and a binary indicator of whether the firm developed a new product, service, or process within the past two years. The results show a positive and statistically significant relationship between HEI collaboration and innovation activity. In substantive terms, the results indicate that the likelihood of innovating is 41.7 per cent among non-collaborating firms and 55.7 per cent among collaborating firms, holding covariates constant. We further report marginal effects to facilitate interpretation and to assess whether the relationship differs by firm size, revenue class, industry, and municipality. The estimated collaboration effect is broadly stable across these categories, suggesting that HEI collaboration is positively associated with innovation activity, and that there is little meaningful variation in the effect measured separately by firm size, revenue class, industry, or municipality. The analysis is exploratory and based on cross-sectional survey data; accordingly, the findings should be interpreted as associational rather than causal. By focusing on small firms in a non-metropolitan setting, the study complements prior evidence that is often dominated by high-tech or R&D-intensive contexts. Overall, the results highlight HEI collaboration as a promising—and broadly relevant—lever for supporting innovation activity in small firms and for informing place-based innovation policy and institutional outreach.

Keywords: Higher Education Institutions, University-Industry Collaboration, Innovation Activity, Regional Innovation Ecosystems, Smes, Finland

1. Introduction

Small firms are central to regional economies, yet their innovation activities are often constrained by limited internal resources and restricted access to specialised knowledge. Collaboration with higher education institutions (HEIs) is frequently promoted as a mechanism through which small enterprises can access external expertise, talent and problem-solving capacity. Still, evidence on whether such partnerships are associated with everyday innovation outcomes across different types of small firms remains mixed.

The study is guided by two research expectations. First, small firms that collaborate with HEIs are expected to be more likely to report recent innovation activity than firms without such collaboration. Second, this association is expected to be observable across different types of small firms, rather than being limited to particular firm-size groups, revenue classes, industries or municipalities. These expectations reflect the idea that HEI collaboration may provide an accessible channel for external knowledge exchange in regional SME contexts, especially where firms have limited internal R&D capacity.

This paper examines the relationship between HEI collaboration and innovation activity among small firms in South Karelia, Finland. It draws on survey data collected in 2025, which provides a regional snapshot of firms' innovation activities and cooperation partners. Using data from 242 firms and logistic regression, we assess whether firms that collaborated with an HEI during the previous two years were more likely to introduce a new product, service, or process. We also examine whether this relationship differs by firm size, revenue class, industry, or municipality.

While existing literature frequently assumes that the benefits of external collaborations are contingent on a firm's internal absorptive capacity, size, and technical intensity (Audretsch and Guenther, 2023; Brunswicker and Vanhaverbeke, 2015; Lee and Miozzo, 2019) this study advances theoretical debates by exploring alternative pathways for knowledge transfer. Specifically, we contribute to the open innovation literature by highlighting how practice-oriented, informal HEI collaborations, such as student projects and internships, operate through a

Doing, Using, and Interacting (DUI) learning mode (Lee and Miozzo, 2019). By bypassing the need for complex administrative infrastructure, these informal partnerships facilitate an "innovation without research" model that is uniquely suited for smaller enterprises (Apa et al., 2021).

This paper, therefore, moves beyond merely confirming prior associations in a new non-metropolitan setting. Our exploratory results indicate a positive association between HEI collaboration and innovation: holding covariates constant, the predicted probability of innovating is 41.7 per cent for non-collaborating firms and 55.7 per cent for collaborating firms. Marginal-effect estimates are stable across firm size, revenue class, industry, and municipality. In other words, firms that reported collaborating with an HEI were more likely to report innovation activity, and this difference appears relatively similar across different types of firms in the sample. By showing that the collaboration–innovation association does not systematically vary by these categories, our findings suggest that regional HEI collaboration may provide a broadly accessible knowledge channel for diverse small firms, including those with limited internal resources.

2. Theoretical Foundation

Small and medium-sized enterprises (SMEs) often face resource constraints that limit their capacity to sustain formal in-house research and development (R&D), making external knowledge sourcing an important route to innovation (Brunswicker and Vanhaverbeke, 2015). To overcome these limitations, SMEs increasingly collaborate with universities and other higher education institutions (HEIs) to access complementary knowledge, resources and capabilities that support innovation and scaling efforts (Cao et al., 2026).

HEIs can play an important role in SME open innovation by providing access to scientific knowledge, specialist expertise, research infrastructure and skilled talent that resource-constrained firms may struggle to develop internally (Brunswicker and Vanhaverbeke, 2015; Cao et al., 2026; Rantala et al., 2026). However, the benefits of external knowledge depend partly on SMEs' absorptive capacity, defined as the ability to recognise, assimilate, and commercially exploit external knowledge (Cohen and Levinthal, 1990; Grandinetti, 2016). This is particularly important because many SMEs innovate through informal, practice-based and externally supported activities rather than through formal in-house R&D. As a result, their university engagements often differ from the more structured R&D collaborations typical of large corporations (Apa et al., 2021; Brunswicker and Vanhaverbeke, 2015; Cao et al., 2026).

Recent literature highlights the importance of practice-oriented and informal university-SME collaborations, including student projects, internships, mentoring, networking and day-to-day interactions, as channels through which tacit and context-specific knowledge can be exchanged (Apa et al., 2021; Brown and Frame, 2016; Darabi et al., 2020). For SMEs, these less formal mechanisms can be particularly valuable because they rely on relational learning, trust and problem-solving rather than on the more resource-intensive structures associated with formal R&D contracts or technology-transfer agreements (Apa et al., 2021; Darabi et al., 2020). Reflecting this broader understanding, theoretical perspectives on SME-university collaboration have moved beyond linear technology-transfer models towards knowledge co-development and value co-creation logics, in which HEIs are embedded in local innovation ecosystems and work with firms to co-develop practical solutions rather than merely supplying codified research outputs (Cao et al., 2026; Osorno-Hinojosa et al., 2022).

This aligns closely with the "Doing, Using and Interacting" mode of learning, which emphasises innovation through experience-based problem-solving, applied use and interaction with external partners (Lee and Miozzo, 2019; Parrilli and Radicic, 2021). Unlike the more formal Science, Technology and Innovation mode (Jensen et al., 2007), which is often associated with codified research, laboratory-based knowledge and structured R&D activity, the DUI perspective highlights the importance of tacit knowledge, workplace learning and context-specific collaboration. This is particularly relevant for SMEs, whose innovation processes are often embedded in everyday operational challenges rather than formal R&D systems.

Existing literature often suggests that formal R&D partnerships are more accessible to larger SMEs or firms in science-based and high-technology sectors (Audretsch and Guenther, 2023; Lee and Miozzo, 2019). However, practice-oriented and informal forms of HEI collaboration, such as student projects, internships, mentoring and networking, may operate through a DUI learning mode, where knowledge is exchanged through doing, using and interacting rather than through formal R&D structures alone (Apa et al., 2021; Parrilli and Radicic, 2021). This suggests that HEI collaboration may provide a relatively accessible channel for external knowledge exchange among diverse SMEs, including firms with limited internal R&D capacity (Apa et al., 2021; Cao et al., 2026).

From this perspective, informal HEI-SME collaboration should not be seen as a weaker form of formal R&D partnership, but rather as a different route through which SMEs can access knowledge, test ideas and develop solutions that fit their own business context. It also broadens how university–industry collaboration is understood, moving beyond formal technology transfer towards more practical, trust-based and co-created forms of engagement.

Based on this reasoning, we expect HEI collaboration to be positively associated with innovation activity among small firms, and for this association to be observable across firm sizes, sectors, revenue classes and municipalities.

3. Data and Methods

This study uses survey data collected in 2025 as part of the EK-Inno project in South Karelia, Finland. The data consists of phone interview responses from 242 small firms (1–49 employees and annual turnover below €10 million). Table 1 presents descriptive statistics. The dependent variable is innovation activity, measured as a binary indicator of whether the firm reported developing a new product, service, or process during the past two years. The outcome captures whether a firm reported such activity during this period. It therefore measures innovation activity rather than the commercial or performance impact of innovation. Approximately 47 per cent of firms report having innovated (Table 1).

The independent variable is HEI collaboration, coded as 1 if the firm reported collaborating with LAB University of Applied Sciences, LUT University, or another HEI in response to the item "Which organisations have you collaborated with during the past two years?", and 0 otherwise. In the survey, approximately 36 per cent of companies have collaborated with a HEI.

The survey measured firms' main industry using the Finnish TOL 2008 classification. TOL 2008 is the Finnish implementation of the European NACE Rev. 2 industrial classification and is used by Statistics Finland as a framework for statistics on economic activity, including production, employment and national accounts (Statistics Finland, 2008). For the analysis, the original TOL main sections were recoded into five broader sector groups because several individual industries contained only a small number of observations, making detailed industry-level comparisons unreliable. The five categories are: agriculture, forestry and fishing (A); industry, including mining, manufacturing, energy, water supply and waste management (B–E); construction (F); market services, including trade, transport, accommodation and food services, and information and communication (G–J); and finance, business, public and other services (K–S).

In the analysis, we include variables for firm size (number of employees), revenue class, and industry to account for observable differences in firms' resources and baseline innovation propensity, and municipality fixed effects to capture unobserved local conditions (e.g., proximity to HEIs and regional support structures) that may jointly shape collaboration opportunities and innovation.

As the dependent variable is binary, we estimate a logistic regression model. Specifically, we model the probability that firm *i* reports innovation activity (i.e., having developed a new product, service, or process during the past two years) as a function of collaboration with a higher education institution (HEI) and a set of firm characteristics. The model takes the form

$$\log\left(\frac{P(innovated_i = 1)}{1 - P(innovated_i = 1)}\right) = \alpha + \beta_1 HEI_{collab_i} + \gamma X_i + \delta_m + \varepsilon_i,$$

where HEI_collab_i is an indicator of whether the firm i collaborated with an HEI during the past two years. X_i includes categorical variables for the number of employees, revenue class, and industry group, while δ_m denotes municipality fixed effects to account for unobserved local context and spatial differences in access to HEIs and regional support structures. Parameters are estimated by maximum likelihood, and we report heteroskedasticity-robust standard errors. Because log-odds coefficients are not directly interpretable in probability terms, the results are additionally presented using predictive margins and marginal effects (average changes in predicted probabilities associated with HEI collaboration) in Figures 1-5, which are reported overall and within firm-size, revenue, industry categories, and municipalities, to assess potential heterogeneity in the collaboration–innovation association.

Given the cross-sectional survey design, the estimated relationships should be interpreted as exploratory and associational, rather than causal. In particular, HEI collaboration may be endogenous to innovation propensity

(e.g., more innovative firms may be more likely to seek partnerships), and unobserved factors may jointly influence both collaboration and innovation.

Table 1: Sample characteristics and key variables

Dependent Variable (Binary)	Mean	SD	N	n
Innovated (0/1) (company developed a new product/service/process in the last 2 years)	0.467	0.499	242	
Independent Variable (Binary)				
Collaborated with: Higher education institution(s) (0/1)	0.364	0.482	242	
Firm Characteristics (Categorical)				
Firm size: 1 employee				59
Firm size: 2-4 employees				126
Firm size: 5-9 employees				32
Firm size: 10-19 employees				15
Firm size: 20-49 employees				10
Revenue class: €0–0.2 million				98
Revenue class: €0.2–0.4 million				47
Revenue class: €0.4–1 million				56
Revenue class: €1–2 million				21
Revenue class: €2–10 million				20
Industry category: Agriculture, forestry and fishing				24
Industry category: Industry				22
Industry category: Construction				45
Industry category: Market services				92
Industry category: Finance, business, public, and other services				59

Note: The original survey included 291 firms; observations with missing values were excluded, leaving a final analytic sample of 242 firms.

4. Analysis

Table 2 reports the logistic regression estimates. Our interpretation focuses on Model 3, which includes the full set of variables. Model 2 excludes municipality fixed effects; the estimated coefficients are substantively unchanged. Model 1 is included as a baseline specification. In Model 3, HEI collaboration is positively and statistically significantly associated with innovation activity ($\beta=0.624$, $p<0.05$). To aid interpretation, we translate the log-odds estimates into predicted probabilities and marginal effects in Figures 1–5.

Figure 1 presents predictive margins from Model 3, showing the predicted probability of innovating for firms with and without HEI collaboration, holding other included variables constant (95% confidence intervals). Figure 1 indicates that, overall, there is a substantial association between collaboration (pooled across firms) and innovation outcomes. Specifically, the predicted probability of introducing a new product, service, or process is 41.7 per cent for firms that did not collaborate with an HEI, compared with 55.7 per cent for firms that did collaborate.

Figures 2, 3, 4, and 5 instead report the marginal effect of HEI collaboration on the probability of innovating, evaluated separately across four firm characteristics (number of employees, revenue, industry, and municipality). Figure 2 shows that the estimated effect is highly stable across employee-size groups, ranging from approximately 13.6 to 13.8 percentage points. Figure 3 presents the corresponding estimates by revenue class and likewise suggests only limited variation: the marginal effect ranges from 12.3 percentage points in the 0.2-0.4 million euro category to 14.3 percentage points in the 0-0.2 million euro category.

Figure 4 further indicates that industry classification is not associated with meaningful heterogeneity in the collaboration effect; the estimated marginal effects are similar across sectors, ranging from 11.1 to 14.1 percentage points. Figure 5 reports the average marginal effect of HEI collaboration on the probability of innovation by municipality. The point estimates are broadly similar across locations (ranging from 12.3 to 14.0), with the exception of Rautjärvi (7.7 percentage points). The confidence intervals are quite wide, indicating limited precision. Taken together, the figure provides no strong evidence that the collaboration–innovation association differs systematically across municipalities in this sample.

In the regression estimates, some revenue and industry categories are statistically significant predictors of baseline innovation propensity; however, the implied differences are substantively small. For instance, in Model 3, the coefficients for industry categories 2, 4, and 5 are only marginally significant ($p<0.1$) relative to category 1, and when expressed in predicted-probability terms, they correspond to differences of at most 3 percentage points. Overall, Figures 2–5 provide no evidence of meaningful heterogeneity in the association between HEI collaboration and innovation across firm characteristics.

5. Discussion and Conclusion

Our findings provide exploratory empirical evidence that small enterprises engaged in HEI collaboration report higher levels of innovation activity, and that this positive association may extend across the broader SME landscape. Building on previous open innovation studies (Apa et al., 2021; Brunswicker and Vanhaverbeke, 2015; Cao et al., 2026), the analysis shows that the collaboration–innovation association remains positive after accounting for firm size, revenue class, industry, and municipality, and that it appears broadly stable across these categories. This suggests that, in small-firm regional contexts, HEI collaboration may provide a valuable

knowledge channel for a broad range of firms rather than being confined to a narrow group of larger, higher-revenue, or more technology-intensive firms. This finding qualifies absorptive capacity arguments by indicating that some forms of HEI engagement may reduce the capability threshold required for small firms to access and use external knowledge (Apa et al., 2021; Cohen and Levinthal, 1990; Grandinetti, 2016). Although the survey does not distinguish between different types, intensities, or durations of HEI engagement, the survey context suggests that this binary indicator likely captures a heterogeneous mix of collaborations perceived by small firms as meaningful interaction with an HEI. These may include relatively low-threshold and practice-oriented forms of engagement (e.g., student projects and internships) alongside more formal cooperation. This interpretation is consistent with research showing that informal, practice-oriented university–SME collaboration can support innovation by providing firms with access to external knowledge and problem-solving capacity (Apa et al, 2021).

In this sense, the findings can be interpreted alongside the DUI mode of learning, in which innovation emerges through doing, using, and interacting rather than through formal R&D alone (Lee and Miozzo, 2019). The observed association between HEI collaboration and innovation across diverse small firms is theoretically consistent with the DUI learning perspective, but the interpretation of informal and practice-oriented mechanisms should be treated as theoretically plausible rather than directly observed in the model. Nevertheless, this interpretation is consistent with recent evidence from Finnish SMEs, which shows that firms may use academic research not only for direct commercialisation but also to develop knowledge capital and support broader company development (Rantala et al, 2026). Because the study is based on cross-sectional survey data, the findings should be interpreted as associational rather than causal.

Geographical proximity can make informal HEI–SME collaboration easier to develop. Tacit knowledge is often shared through repeated contact, trust and a shared understanding of local conditions, all of which are more likely to emerge within local or regional innovation ecosystems (Boschma, 2005). For many smaller firms, particularly those outside major cities or knowledge-intensive clusters, as was the case in our study, nearby universities may become important partners because alternative sources of expertise, such as corporate R&D centres or specialist consultants, are less accessible. Johnston and Prokop (2025) describe this as a “location push effect”. However, our findings suggest that geographical proximity alone does not necessarily explain firms’ engagement with HEIs. Although the region studied included a university in one of the Finnish towns, the companies in our data based in this town did not appear to differ markedly from those located farther from the university. This indicates that the presence of a nearby university may create opportunities for collaboration, but it does not automatically lead to stronger or more distinctive HEI–SME engagement. In this context, regional HEIs can still act as important local innovation intermediaries. Still, their role depends not only on physical proximity, but also on the accessibility, relevance and practical organisation of collaboration opportunities.

Several limitations should be noted. First, the cross-sectional design means that the analysis identifies associations rather than causal effects. More innovative firms may be more likely to seek HEI collaboration, and unobserved managerial capabilities or growth orientation may influence both collaboration and innovation. Second, both collaboration and innovation are self-reported, which may introduce response bias. Third, the HEI collaboration variable does not distinguish between different types, intensities or durations of engagement. Fourth, some subgroup estimates are based on small numbers of firms, meaning that the heterogeneity analysis should be interpreted as exploratory. The logistic regression models estimate the main association between HEI collaboration and innovation activity, but they do not test more complex interaction effects, such as whether the association is stronger for particular industries, size groups or revenue classes; instead, heterogeneity is examined descriptively through subgroup-specific marginal effects. Finally, the sample is drawn from a single Finnish region, meaning that the findings may not be easily generalisable to other contexts. Instead, the study is likely to be particularly relevant to settings characterised by small-firm dominance, limited internal R&D capacity, and relatively close institutional proximity between firms and HEIs, while also offering broader analytical insight into how HEI collaboration may support innovation in resource-constrained SME environments.

The findings of this study offer implications for educational institutions and regional policymakers. Because the results suggest that HEI collaboration is positively associated with innovation activity across a broad range of small firms, with little evidence of systematic differences by size, industry, or municipality, policies should reflect this inclusivity. It appears unjustified for practitioners to restrict innovation funding or support programmes exclusively to stronger-performing, science-based, or high-tech enterprises (Johnston and Prokop, 2025). Instead, policymakers should focus on reducing administrative barriers and fostering practice-oriented, informal engagement models that better reflect the diversity of SMEs. By doing so, HEI partnerships may provide a broadly accessible route for supporting innovation activity across diverse small firms in regional ecosystems.

Ethics Declaration

This study used aggregated survey data from small firms in South Karelia, Finland, collected through the EK-Inno project. No individuals or firms are identifiable. As the study involved no sensitive personal data or interventions, formal ethical approval was not required under the institution's guidelines. Participation was voluntary, and the data were used solely for research purposes.

AI Declaration

AI tools, including Scopus AI, ChatGPT and Grammarly, were used to support the research and writing process. These tools assisted with literature exploration, language editing, improving clarity, conciseness and academic tone, and refining wording and structure during the drafting process. The authors made all empirical analyses, interpretations and final decisions about the content. The authors reviewed and approved the final manuscript and take full responsibility for its accuracy, integrity and originality.

Examining the Challenges of Indian Deep-Tech Startups: Pathway for Sustainable Entrepreneurial Practices

Shalini Katare, Vimala Raja Priya Mudapaka, Jayshree Patnaik
Indian Institute of Technology Hyderabad, Kandi, India

jpatnaik@em.iith.ac.in

Abstract: Deep-tech startups are rooted in scientific and engineering innovations and hold transformative potential for addressing critical societal challenges in healthcare, clean energy, water treatment, and sustainable infrastructure. Unlike traditional digital startups, which scale swiftly via continuous innovation, deep-tech startups confront distinctive hurdles due to lengthy R&D periods, intensive capital investments, stringent regulatory compliance, and unpredictable market penetration. These conditions expose them to the Valley of Death (VoD), a critical phase in which promising innovations fail to reach commercial viability before funding is exhausted. This vulnerability stems from a fundamental misalignment between experimental outcomes and commercial viability, further compounded by systemic gaps in institutional support, including inadequate legal frameworks and limited market awareness in emerging market contexts. Despite growing scholarly interest in both the Valley of Death and the Technology–Organization–Environment (TOE) framework, there is limited research to explain how technological, organizational, and environmental conditions collectively produce specific commercialization barriers for deep-tech startups. This study addresses this gap through qualitative research with five deep-tech startups in India operating across agritech, healthcare technology, neurotechnology, nanotechnology, and cybersecurity. Thematic analysis of semi-structured interviews resulted in interrelated themes, each representing a different aspect of the TOE framework. The results reveal that technological, organizational, and environmental barriers are not isolated phenomena but dynamically reinforce one another, giving rise to three interrelated Valley of Death barriers: funding gaps, market translation failure, and legitimacy deficits. The proposed TOE–VoD framework therefore suggests that overcoming commercialization challenges in deep-tech startups requires an integrated perspective that simultaneously addresses technological, organizational, and environmental dimensions. The framework further provides founders with a diagnostic tool, policymakers with a rationale for multi-dimensional interventions, and researchers with a foundation for comparative and longitudinal inquiry into deep-tech commercialization across emerging market contexts.

Keywords: Deep-Tech Startup, Valley of Death, TOE Framework, Commercialization, Emerging Markets

1. Introduction

Deep technology, commonly referred to as deep tech refers to startups whose business models are founded on breakthrough scientific discoveries or advanced engineering innovations, rather than the incremental application of existing technologies (Mierzejewska, 2019). First coined in 2015, the term captures a category of startups operating across biotechnology, nanotechnology, artificial intelligence, quantum computing, advanced materials, healthcare technology, robotics, and autonomous systems (Thu et al., 2024). Unlike conventional technology startups that leverage existing platforms to build products and services, deep-tech startup develops the foundational scientific and engineering capabilities themselves, a distinction that fundamentally shapes their funding requirements, development timelines, and path to commercialization (Giones and Brem, 2017). Global investment in deep tech has grown substantially, with the sector attracting fifty billion dollars in venture capital investment in 2024 (Basilio et al., 2023). In India, deep-tech entrepreneurship has emerged as a strategic priority, with startups addressing critical societal challenges in agritech, healthcare, water treatment, neurotechnology, and cybersecurity attracting increasing attention from investors, incubators, and policymakers.

Despite this growth, deep-tech startups face a structural challenge that distinguishes them sharply from mainstream startups, the Valley of Death. The Valley of Death describes the critical phase between research-driven technological innovation and commercial viability. At this point, deep-tech startups have either developed a technology or written a business plan with a prototype ready to implement, but have not yet obtained enough financing to move their products to production (Markham et al., 2010). Deep-tech startups often struggle to transition beyond the Valley of Death because of inadequate capital, operational challenges, and a lack of credibility with prospective customers (Nedayvoda et al., 2020). Research shows that the majority of all start-ups experience the Valley of Death on several occasions during the commercialization process, and that the vast majority of corporate spin-outs and government-supported startups also experience these challenges (Gbadegeshin et al., 2022). Murray et al. (2023) identify the Valley of Death as a product of systemic entrepreneurial conditions rather than individual startup failings, arguing that overcoming it requires

simultaneously addressing networking and ecosystem conditions, value proposition and customer creation, strategic focus, and financing. However, what remains absent in literature is a structured account of the specific conditions that determine how deep a startup Valley of Death is and which mechanisms produce each distinct failure mode. Existing frameworks identify that a gap exists, but do not explain what causes it to be wider or narrower for different startups operating in different contexts.

The Technology–Organization–Environment framework, developed by Tornatzky and Fleischer (1990), provides a systematic way to analyze the factors impacting a firm's ability to implement and commercialize new technologies across three dimensions. The technological component of the TOE framework represents the nature of the foundational technology and its level of maturity and protection. The organization component reflects the organizational capacity, resources and processes the firm has to leverage new technologies or innovations. The Environment component consists of the external conditions in which the organization operates (e.g. institutions, markets and ecosystems), which may either facilitate or impede the firm's ability to commercialize innovative technologies. While the TOE framework has been widely applied to technology adoption decisions in established firms (Oliveira and Martins, 2011), it has not been studied in depth with respect to commercialization challenges faced by deep-tech startups. Furthermore, the TOE framework has not been integrated with the Valley of Death concept. Consequently, existing studies identify the contextual conditions surrounding a startup but fall short of explaining how these conditions translate into specific commercialization barriers. This integration represents the theoretical gap by addressing the following research questions:

RQ1: What mechanisms hinder deep-tech startups from overcoming the Valley of Death in the process of translating breakthrough innovations into scalable and commercially viable solutions?

RQ2: How do technological complexity, organizational capabilities, and environmental conditions influence a deep-tech startup's ability to navigate the Valley of Death?

Collectively, these research questions seek to examine both the barriers faced by deep-tech startups and the contextual conditions that give rise to the Valley of Death (VoD). Drawing on qualitative evidence from deep-tech startups in India, this study develops an integrated TOE–VoD conceptual framework that explains the underlying mechanisms of commercialization failure while offering practical guidance for enhancing commercialization success.

2. Methodology

A qualitative research design is appropriate because the study addresses how and why questions that require contextual depth rather than statistical breadth, specifically examining how founders commercialize breakthrough innovations and why certain conditions create commercialization barriers while others do not. (Denzin and Lincoln, 2011). The interpretive stance adopted in this study prioritizes founders' lived experiences over statistical generalization, consistent with its theory-building rather than theory-testing orientation.

Purposive sampling was employed to select participants who could provide real-time insights into the deep-tech commercialization process. Inclusion criteria required that each startup be engaged in research-intensive innovation in domains such as biotechnology, nanotechnology, artificial intelligence, healthcare technology, or advanced materials; that the startup had achieved at least a working prototype; and that the founder or senior executive had direct experience navigating funding and commercialization challenges. Five deep-tech startups based in India were selected as shown in Table 1. Semi-structured interviews were conducted with founders and co-founders between July 2025 and early 2026, lasting 60-80 minutes each. Interviews were conducted online, audio-recorded with consent, and transcribed verbatim. Data analysis followed Braun and Clarke's (2006) six-phase thematic analysis framework: familiarization, coding, generating themes, reviewing themes, naming themes, and writing up. The analysis began with repeated reading of transcripts to develop familiarity with the data, followed by manual open coding to generate first-order codes in the language of informants. Axial coding was then applied to identify connections across first-order codes, producing second-order codes that captured the underlying conceptual constructs. Second-order codes were iteratively reviewed and consolidated into aggregate themes aligned with the three TOE dimensions. Themes were discussed among researchers to validate interpretations and ensure that the conceptual categories accurately reflected their experiences.

Table 1: Case Overview

Company Name	Founding Year	Sector	Product / Service offered	Estimated TRL
Sputnik Brain	2023	Neural Interface	Neural interfaces for stress reduction and mental health	TRL 6–7 (clinical pilots, pre-launch)
Quekey	2024	Cybersecurity	AI-driven software and design solutions	TRL 5–6 (validated prototype)
Neer Shakti Systems	2022	Nanotechnology	Nanotechnology-based machines,	TRL 9 (commercially deployed)
Sense Health Technologies Pvt. Ltd.	2017	Deep Learning	AI-based sensing technologies	TRL 5–6 (validated prototype)
GreenPod Labs	2019	Agri-tech	Patented active packaging sachets	TRL 9 (commercially deployed)

Note: Technology Readiness Level (TRL) are estimated based on publicly available evidence and founder interviews, mapped against the NASA/ISO TRL scale (Mankins, 1995; NASA, 2023), as startups do not routinely self-report. There are 9 TRL levels: Basic principle observed, concept formulated, Experimental proof of concept, validation in laboratory, validation in relevant environment, prototype demonstration in relevant environment, demonstration in operational environment, complete and qualified system and actual system in use.

3. Findings and Discussion

The findings highlight technological, organizational, and environmental dimensions contributing to the Valley of Death barriers faced by deep-tech startups. The analysis moves from aggregate themes through second-order codes and first-order inductive coding, demonstrating the analytical trail from raw data to theoretical interpretation. Each dimension is interpreted in relation to its corresponding VoD barrier as the themes are presented with the systemically integrated TOE–VoD framework as shown in Table 2.

Table 2: Coding Tree

Aggregate Theme	Second Order Codes	First-order Codes (Verbatim Informant Language)
Technology (T)	**T1** Innovation readiness	"Upgrading and bringing change with time is the law — continuous year-on-year improvement is not a phase but an operating principle." "Writing research papers is five percent of the job — 95% is the struggle that you have to go through. If the technology is not taken to the market and from there you are not earning money, then it's not a sustainable model."
	T2 Technical uncertainty	"The chance of success is less than 0.10% — that means your chance of failure is 99.9% in this sector. Any company you start from scratch is bound to fail. That's how the odds are." "High risk and low probability of success in deep tech startups—failure is normalized in deep tech."
	T3 Knowledge protection	"The patent process in India is quite slow — in the US or Europe it takes a maximum of six months, but the waiting period in India is quite long." "We prioritized technology, patents, and teams over early revenue—building IP protection first before approaching investors."

Aggregate Theme	Second Order Codes	First-order Codes (Verbatim Informant Language)
Organization (O)	**O1** Resource mobilization	"The biggest challenge any company has is funding, no matter if it is deep tech or any other company." "Mismanagement of funds and capital leads to loss of investor confidence and financial waste." "Many international suppliers from China, Taiwan, and South Korea were unwilling to ship to India, even after receiving full payment. Orders were sometimes cancelled after delays of 60 to 70 days."
	O2 Organizational learning	"Initially, we deployed product exterior packaging, which was harder to open in the field—we got the feedback that this had to be simplified. We did change this." "When you came up with this product, the product is already market fit. The only thing is how you enter the market. That is the challenge." "Most of the startups have a solution, but many do not know how to enter the market—that is the problem."
	O3 Commercial strategy	"Per month, the cost of pricking is about 4000 rupees—what we are offering is that per month you don't need to even pay 400 rupees." "Affordability as a key design and market driver—pay-less model—cost efficiency in India." "Partnerships provide visibility but not guaranteed revenue."
Environment (E)	**E1** Policy & regulation	"We have validated it. Now the next step is the clinical trial—if we get the regulatory approval, then of course India will accept." "Many startups in this sector face the challenge of compliance. But we built this with compliance from the very first day." "Regulatory approval delays — certification challenges — heavy regulation as a structural feature of the market environment."
	E2 Ecosystem support	"I reached out to approximately 170 to 180 professors worldwide—only a small fraction responded, and just three agreed to meet." "These platforms are good for any startup, but they will not fill your stomach. You have to go and own that business yourself."
	E3 Market conditions	"Every technology has a phase—incubation, adaptability, then the market adopts it. It's just like how EVs were in the early 2000s—there was not much adoption. But now every third person has an EV." "Deep tech success depends on public acceptance and understanding of the technology behind the product."

3.1 Technological Dimension

Three second-order themes were identified within the technology dimension: innovation readiness (T1), technical uncertainty (T2), and knowledge protection (T3). Collectively, these themes reveal why deep-tech startups experience a structural funding gap that differs qualitatively from the financing constraints typically faced by conventional startups.

3.1.1 Innovation Readiness (T1)

Innovation readiness indicates how developed a startup main technology has progressed from basic research towards commercial viability. Across all five startups, founding decisions were driven by unmet societal problems. GreenPod Labs stated its mission directly: *"The company vision is to minimize the food waste and food losses in the developing countries,"* while Sense Health's motivation was rooted in the understanding of the magnitude of diabetes in India. Shane and Venkataraman (2000) argue that identifying solutions to customer problems forms the foundation of entrepreneurial opportunity creation. However, in deep-tech startups,

entrepreneurs often face a tension between prioritizing long-term societal or technological problems and responding to immediate market demand when setting development priorities.

Innovation processes were described as continuous rather than milestone-driven. Neer Shakti Systems articulated the operating principle: *"Upgrading and bringing change with time is the law—continuous year-on-year improvement is not a phase but an operating principle."* QueKey described the *"research to market gap—lab to market—commercialization challenges are the real barrier after research is done."* This extends Chesbrough's (2010) regarding the "lab to market" gap; but in the case of the Indian deep-tech context, it is not one significant transition but rather a continual source of challenges through many lengths of time that far exceed most investor horizons.

3.1.2 Technical Uncertainty (T2)

Technical uncertainty refers to the unpredictability associated with R&D in deep technology. Neer Shakti Systems stated, "The *chance of success is less than 0.10%—that means your chance of failure is 99.9% in this sector. Any company you start from scratch is bound to fail. That's how the odds are.* QueKey also elaborated on the development experience: *"There were many hiccups, long sleepless nights—we kept trying and trying, and then finally it worked."* While T1 refers to where on this developmental trajectory a startup is currently located, T2 is a broader measure of the unpredictability of that trajectory, irrespective of the company's current stage. Ghosh and Nanda (2010) demonstrate that this uncertainty generates investor risk perceptions categorically different from software ventures, where technical risks are lower and feedback loops substantially faster. Investor reluctance is therefore rational rather than uninformed, and overcoming the funding gap requires better mechanisms for communicating risk rather than simply better technology.

3.1.3 Knowledge Protection (T3)

Knowledge protection captures the challenge of securing a competitive advantage through intellectual property (IP) mechanisms in weak, slow, or costly formal systems. QueKey described the structural problem: *"*In *our universities it is not that much talked about how a patent could be filed—only researchers who do PhDs get to know about all these things."* Teece (1986) identifies the appropriability regime as a key determinant of whether innovators can capture returns from their innovations. In weak IP environments, founders face a disclosure dilemma that further widens the funding gap. Revealing sufficient technical detail to attract investors increases the risk of knowledge appropriation in settings with weak IP enforcement (Khanna & Palepu, 1997), while the absence of supportive policy signals limits the institutional assurances that investors rely on when direct assessment of technological potential is difficult (North, 1990).

Altogether, T1, T2, and T3 intensify the funding gap by making the startup proposition illegible, unpredictable, and indefensible to investors simultaneously. Innovation immaturity means investors cannot assess commercial viability. Technical uncertainty means the risk profile cannot be quantified using standard frameworks. Weak IP protection means a competitive advantage cannot be guaranteed even if the technology succeeds.

3.2 Organisational Dimension

The organizational dimension encompasses the internal capabilities, resources, and strategic processes that shape a startup's ability to transform technological innovation into commercial traction. Three sub-themes emerged: resource mobilization (O1), organizational learning (O2), and commercial strategy (O3).

3.2.1 Resource Mobilization (O1)

Resource mobilization captures the startup capacity to secure, manage, and deploy financial and operational resources. Neer Shakti Systems stated, "The *biggest challenge any company has is funding—no matter whether it is deep tech or any other company,"* adding that *"mismanagement of funds and capital leads to loss of investor confidence and financial waste."* Sense Health talked about how sustained grant-based bootstrapping could be used to help fund an organization until they could produce something from their pre-clinical stage. Brush, et al., (2001) indicated that when making investment decisions, potential investors consider resource mobilization capability in conjunction with technology development maturity. O2 is an organizational dimension of resource mobilization since it is an internal capability of a company, but O2 also exists in the funding gap, which refutes the notion that the funding gap is a technology-based issue in VoD literature (Auerswald and Branscomb, 2003). Thus, organizational inefficiency in resource management adds an additional barrier to technology-driven barriers.

3.2.2 Organizational Learning (O2)

Organizational learning captures how startups develop an understanding of target customers and the behavioral factors shaping adoption. GreenPod Labs described the approach: *"Before any product development, we spend more than 15 days with the customer to understand their pain points."* The consequence of insufficient market learning was illustrated concretely: *"Initially, we deployed product exterior packaging that was harder to open in the field—we got the feedback that this had to be simplified. We did change this."* Sense Health described the mismatch between research assumptions and commercial reality: *"When you came up with this product, the product was already market fit. The only thing is how you enter the market. That is the challenge."* According to Eisenmann et al. (2012), the primary reason for startup failures is the effect of premature scaling, which occurs when a startup invests in its product before achieving product-market fit; this risk is augmented in deep tech by the long lead times between Development and the opportunity to make a correction.

3.2.3 Commercial Strategy (O3)

Commercial strategy captures the startup approach to market positioning and revenue design. Affordability is a dominant factor in commercial strategy in the Indian context. Sense Health framed the affordability logic: *"Per month, the cost of pricking is about 4000 rupees—what we are offering is that per month you don't even need to pay 400 rupees."* Neer Shakti Systems reinforced this: *"Affordability as a key design and market driver—pay-less model—cost efficiency in India."* Strategic positioning and legitimacy signaling emerged as a second mechanism within this theme. GreenPod Labs described a deliberate 60-40 focus between long-term and short-term goals as a commercial discipline, Prahalad (2004) argues that emerging market commercialization requires fundamental business model redesign rather than price adaptation. Chesbrough and Rosenbloom (2002) identify the value creation versus value capture distinction: the activities that build credibility and those that generate revenue require different organizational logics, and technically-oriented founding teams consistently conflate them.

Collectively, O1, O2, and O3 produce the market translation barrier by limiting the startup capacity to convert technical capability into commercial traction. Insufficient organizational learning results in product development decisions that are guided by assumptions rather than evidence of actual customer needs. An inadequate commercial strategy means there is no viable pathway from innovation to sustainable revenue in an emerging market context. These failures are mutually reinforcing; with weak resource mobilization it is less likely to invest in learning, and a startup without market learning is unlikely to develop a viable commercial strategy.

3.3 Environmental Dimension

The environmental dimension encompasses the external policy, ecosystem, market, and institutional conditions that shape a startup's operating context but remain largely beyond its direct control. This theme includes policy and regulation (E1), ecosystem support (E2), and market conditions (E3). These themes collectively produce the legitimacy deficit, the most structurally intractable VoD barrier because it cannot be resolved through startup internal action alone.

3.3.1 Policy and Regulation (E1)

Policy and regulation capture the institutional and regulatory environment. QueKey said, *"Many startups in this sector face the challenge of compliance. But we built this with compliance from the very first day,"* Sputnik Brain said that data privacy restrictions in neurotechnology are typically a barrier to R&D, as they can delay go-to-market activities regardless of the readiness of the technology. Neer Shakti Systems said that the number of regulations involved is an impediment to getting to market quickly, even after completing testing and evaluations. North (1990) states that the institutional model defines the rules of the game, while Aldrich and Fiol (1994) demonstrate that emerging technologies need to develop their legitimacy through a combination of cognitive beliefs and social-political factors to gain acceptance; therefore, delays in approval will delay that process. Regulatory approval serves as an institutional signal of credibility, and its absence creates a trust deficit regardless of the underlying technical quality of the innovation.

3.3.2 Ecosystem Support (E2)

Ecosystem support captures the role of the broader innovation infrastructure. Sense Health described institutional affiliation as a primary legitimacy signal: Sputnik Brain described the challenge of accessing ecosystem actors from outside established networks: *"I reached out to approximately 170 to 180 professors*

worldwide — only a small fraction responded, and just three agreed to meet." Neer Shakti Systems offered a grounding counter-perspective: *"These platforms are good for any startup, but they will not fill your stomach. You have to go and own that business yourself."* Etzkowitz and Leydesdorff (2000) argue that the university-industry-government triple helix is the structural foundation of innovation legitimacy, while Stinchcombe's (1965) liability of newness captures the compounding difficulty for startups outside strong ecosystems; every relationship must be built independently without the warm introductions that institutional affiliation provides.

3.3.3 Market Conditions (E3)

Market conditions capture the external demand for deep-tech innovations. Neer Shakti Systems framed adoption in lifecycle terms: *"Every technology has a phase—incubation, adaptability, and then the market adopts it. It's just like how EVs were in the early 2000s—there was not much adoption. But now every third person has an EV."* As Sputnik Brain notes*, "Deep tech success depends on public acceptance and understanding of the technology behind the product."* QueKey stated that the lack of elite institutional history for their founding team led to investors viewing as a non-viable start-up, and, therefore, legitimacy deficits can exist via social proxies (external factors) rather than just via technical merit. Rogers (2003) identified that the main factor that determines the diffusion rate for a given product is the compatibility of the new product with existing business processes, while Sarasvathy (2001), in explaining effectuation theory, stated that entrepreneurs create product opportunities where there were previously none, using effectual reasoning methods. In emerging markets, demand for new technologies often needs to be built rather than assumed, resulting in substantially longer commercialization and sales cycles.

Taken together, E1, E2, and E3 contribute to the emergence of a legitimacy deficit through distinct but complementary mechanisms. The absence of regulatory approval weakens institutional validation, limited ecosystem maturity restricts borrowed credibility, low market awareness slows technology adoption, and social proxies increasingly shape investor and customer judgments in place of direct technical evaluation. Critically, the legitimacy deficit is the most persistent of the three Valley of Death barriers because it is the least susceptible to actions undertaken solely within the startup.

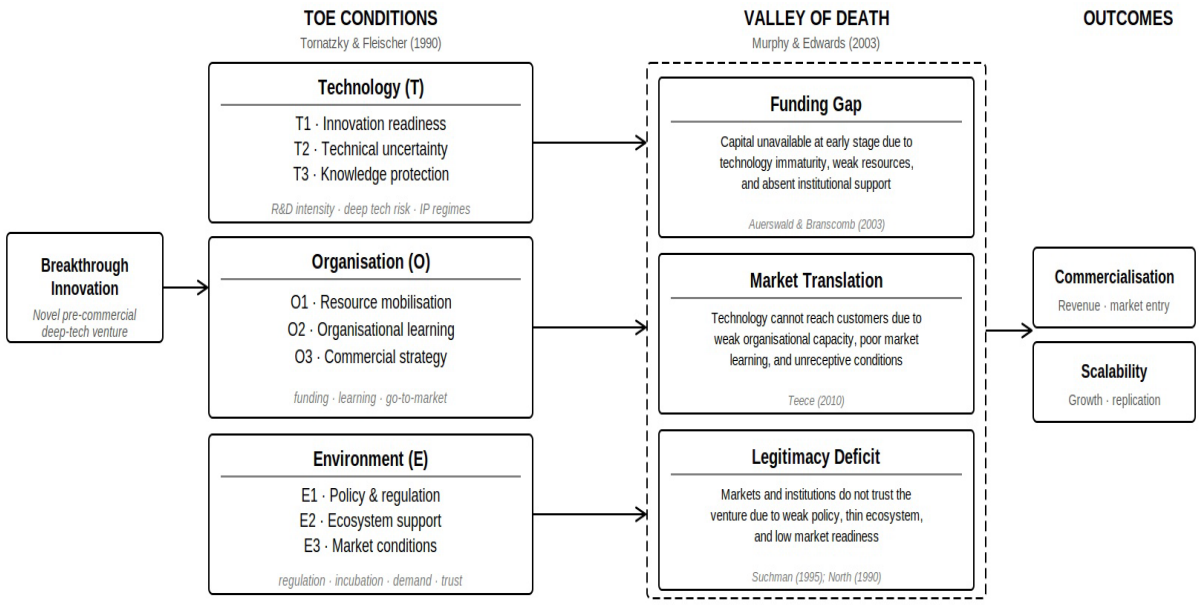

Figure 1: TOE and VoD framework

The critical theoretical insight this study offers, represented in Figure 1 by the convergence of all three TOE dimensions into the Valley of Death zone, is that the three barriers are simultaneous and, are mutually reinforcing rather than sequential. The funding gap is produced by the interaction of unproven technology, dysfunctional resource management, and a lack of institutional risk reduction in the environment. The market translation barrier is exacerbated when the technology is immature, and the marketplace is not receptive. Additionally, when a technology is socially unfamiliar, the legitimacy deficit is deepened by the failure to communicate a trustworthy position commercially.

This holistic view of the intersection of the three TOE dimensions builds upon the original conception of

Tornatzky & Fleischer (1990) that the TOE framework constitutes three independent categories of analysis for deep-technology commercialization; a weakness in one TOE dimension creates barriers for other dimensions. As illustrated through QueKey, Sputnik Brain, and Neer Shakti Systems, poor management of organizational resources exacerbates the funding gap when coupled with immaturity of technology. Poor commercial positioning exacerbates the legitimacy deficit when coupled with institutional weaknesses as illustrated through Sense Health and GreenPod Labs. Therefore, it is not adequate to only address one dimension, but all three must be addressed at the same time. Therefore, the integrated TOE-VoD framework is different from previous independent applications of either the TOE Framework (Oliveira & Martins, 2011) or the VoD concept.

4. Conclusion

This study develops an integrated TOE–VoD framework to explain why deep-tech startups in India struggle to cross the Valley of Death. The findings demonstrate that technological conditions, organizational capabilities, and environmental factors do not operate independently; instead, they collectively intensify three interconnected barriers: the funding gap, market translation failure, and legitimacy deficit. Addressing any single barrier in isolation is insufficient; all three must be navigated concurrently. The framework offers founders a diagnostic tool, policymakers a case for multidimensional intervention, and researchers a foundation for longitudinal and comparative inquiry into deep-tech commercialization across emerging market contexts.

Max Weber on Entrepreneurship: Exploring His Examples

Tor Helge Pedersen
Inland University of Applied Sciences, Lillehammer, Norway

tor.helge.pedersen@inn.no

Abstract: Although Max Weber (1864–1920) is often associated with topics other than entrepreneurship, in several accounts of entrepreneurship research, Weber is included among classic contributors (Aldrich, 2005; Botelho et al., 2024; Landström, 2005). The literature especially referred to his study "Protestant Ethic and the Spirit of Capitalism" (1904–1905), in which Weber explored the connection between this religious doctrine (religious values) and the rising entrepreneurial spirit. However, some literature also indicates that Weber discussed entrepreneurship in several publications and approached it in different ways (e.g., Swedberg, 2000; Landström, 2005). These entrepreneurship discussions were spread across publications, not a specific work. Few scholars have explicitly explored these issues relative to entrepreneurship. This paper follows up this gap and explores examples of Weber's discussions of entrepreneurship and its relevance to contemporary research by asking the following: How did Weber understand and discuss entrepreneurship—and what was his relevance to contemporary entrepreneurship research? This theoretical exploration is based on approximately eight publications drawn from a larger corpus of publications that Weber wrote between 1889 and 1920. In addition, it draws on the contemporary literature on Weber. This paper identifies five examples in which Weber discusses entrepreneurship foremost using the term "entrepreneur." These examples are discussed and grouped into three conceptualizations of entrepreneurship. Finally, the paper illustrates the relevance of these concepts. This discussion will interest those intrigued by classic contributions to the topic.

Keywords: Max Weber, Sociology of Entrepreneurship, Entrepreneur, New Businesses.

1. Introduction

In his large scholarly production, Max Weber (1864–1920) discussed different forms of socioeconomic organizations, their origins and historical emergence, their forms and further developments. Weber has been discussed in relation not only to public sector innovation (Kattel, 2015) but also entrepreneurship. Swedberg (2005b) argued early that while "much attention has been directed at Weber's concept of bureaucracy, and some of his analysis of industrial workers, very little effort has been made to understand his view of entrepreneurship" (pp. 130–131). In several accounts of entrepreneurship research, Weber is somewhat connected to entrepreneurship, for example, understood as starting new enterprises (Schoonhoven & Romanelli, 2001; Aldrich, 2005; Casson, 2003; Thornton, 1999; Botelho et al., 2024; Ruef & Lounsbury, 2007). Although Weber's ideas on entrepreneurship are often connected to his study "Protestant Ethic and the Spirit of Capitalism" (1905/1930), it is also posited that Weber's ideas are spread over publications (Landström, 2005; Tulumello, 2005), such as the posthumous "Economy and Society" (1922/1968) and "General Economic History" (1923/1927). More recently, publications from the late 1800s in economics (Swedberg, 2000) and legal history (Ruef & Lounsbury, 2007) are perceived as conveying his ideas on entrepreneurship. Against this backdrop, it is still relevant to explore Weber's publications regarding entrepreneurship. Correspondingly, this paper asks the following: How did Weber understand and discuss entrepreneurship—and how does that relate to contemporary entrepreneurship research?

Methodologically, this theoretical exploration is based on approximately eight to 10 publications of Weber drawn from a larger sample of 12 to 15 relevant works written between 1889 and 1920 and published between 1889 and 2019 in German and English. The search process included obtaining an overview and identifying relevant publications, such as Weber's compilations, versions, and translations. For example, some of these compilations and translations build on the original German texts and are translated and assembled by at least seven translators and/or editors (e.g., Talcott Parsons, Max Rheinstein, Edward Shills, Hans Gerth, C.W. Mills, Don Martindale, Gertrud Neuwirth, and Keith Tribe). In this search, a second area of literature (on Weber and entrepreneurship) helped identify key texts from Weber's production and how they are interpreted relative to entrepreneurship. Examples here comprise the authors cited herein (e.g., Swedberg, Landström, and Ruef). The selection process resulted in eight publications used in the paper (Weber, 1889b; 1889/2003; 1898/1990; 1905/1930; 1927; 1947; 1948; 1968/1978). Publications that had overlapping content (e.g., Weber, 1954, 2019) or the same content in German were excluded or less used (e.g., Weber, 1922; 1923). For example, even though the first German edition of "*Wirtschaft und Gesellschaft*" (Weber, 1922) uses the word "*unternehmer*" (literally "undertaker") at least 39 times, it is covered in the English translation (Weber, 1968) or other compilations. The same is true of the first German "*Wirtschaftgeschicte*" (Weber, 1923), which was covered at least 38 times in the English translation (Weber, 1927). Finally, chapter 2 of Weber (2019), though it is a new translation, is also

less used, because earlier translations (1968/1978) were sufficient to discuss one of Weber's works on the topic of entrepreneurship. Another limitation concerns inclusion of other literature. Entrepreneurship is a broad field, and this paper has, to some extent, concentrated on publications within the sociology of entrepreneurship often associated with sociocultural interpretations of entrepreneurial phenomena (Aldrich, 2005) or how contexts can influence the propensity to undertake entrepreneurial activities and the role of entrepreneurship in society (Landström, 2005). "Entrepreneurship" can be defined and conceptualized in different ways: the coupling of spheres, opportunity recognition, and the establishment of organizations. This paper has concentrated mostly on the establishment of organizations. These two limitations are the result of the discussion question and the purpose of the paper. The purpose of the paper is to discuss Weber example on entrepreneurship in relation to current theory and research. It is a theoretical paper that challenges some of the current theory and research through the work of Weber, because the Weber examples discussed are not restricted only to societal level of analysis. As will be discussed, Weber's understanding of entrepreneurship, arguably, also included organizational and individual levels of analysis. The rest of the paper is organized as follows: After briefly presenting Weber's examples of entrepreneurship (Part Two), these examples are grouped into concepts and discussed in Part Three.

2. Weber on Entrepreneurship: Five Examples

Weber came from a German intellectual context, where several other scholars used the term "entrepreneur." In Weber's scholarly production, there are several examples of when he studied or touched upon topics, such as the emergence of new organizational forms. He briefly discussed the development of the joint stock company as an example of a credit instrument or the means for the rational assembly of capital (Weber, 1927), the historical emergence of the legal–rational bureaucracy (Weber, 1922/1968, 1948), and the factors that promoted the development of the modern state (Weber, 1948). As previously mentioned, he also discussed several examples of entrepreneurship. "While Weber is usually not credited with having a theory of entrepreneurship, he clearly does" (Swedberg, 2005a, p. 87). Swedberg (2000) and Landström (2005) discussed the first four examples of entrepreneurship below.

2.1 Example 1: Relationship Between "Protestant Ethic" and Entrepreneurial Attitudes and Activities

As briefly noted, Weber's (1905/1930) book is considered central to his thoughts on the entrepreneur (Swedberg, 2000). As he noted, "For it was this idea [a calling] which gave way of life of the new entrepreneurs its ethical foundation and justification" (1905/1930, p. 75). "[T]he entrepreneur emerged with an utterly clear conscience" (Weber, 2002, p. 312; quoted in Lehmann, 2005, p. 19). Swedberg (2000) emphasized that Weber examined the change in the attitude toward entrepreneurship and how religion helped develop a positive attitude toward moneymaking and work. This "facilitated the more general change in attitude toward the entrepreneur" (p. 26) and "provided the cultural legitimation needed to shape the economic behavior of individuals in ways that, in the aggregate, led to the rise of capitalism" (Thornton, 1999, p. 21). The ethic applied equally to businesspeople, professionals, and workers (Weber, 1905/1930 p. 177). Hence, although this theory was not explicitly directed toward entrepreneurship, many Puritans took it up (Brouwer, 2002, p. 88). It was not only the commercial aristocracy who were entrepreneurs and "bearers of the attitude we have called the spirit of capitalism. It was much more the rising strata of the lower industrial middle classes" (Weber, 1905/1930, p. 65).

2.2 Example 2: The Charismatic Leader as the Catalyst of Change

A second example is Weber's discussion of charisma (e.g., 1922/1978; 1947). Swedberg notes, "Weber's view of entrepreneurship is often identified with his theory of charisma" (2000, p. 25). Weber discussed charisma mainly in the context of religion and the military, not the business world, and he argued that the charismatic leader has only functioned as an important motor of change during the early stages of humankind (Swedberg, 2000; Landström, 2005). He said, "The immediate effect of charisma in economic as in other connections is usually strongly revolutionary; indeed, often destructive, because it means new modes of orientation" (1947, p. 373; see also 1922/1978, p. 255).

2.3 Example 3: The Entrepreneur as the First Official of an Enterprise

A third example is found in Weber's writings in the late 1890s (1898/1990) and in his sociopolitical writings of the 1910s (1922/1978; 1948; 1994). Weber wrote, "Entrepreneurship means the taking over an organization of some part of an economy, in which people's needs are satisfied through exchange for the sake of making a profit and at one's own economic risk" (1898/1990, p. 57; translated in Swedberg, 2000, p. 26). Furthermore, in the 1910s, Weber emphasized entrepreneurship much more as the skillful direction of enterprises that respond to opportunities in a market economy (p. 26), rather than the economic operation of a single individual or the personality of the individual entrepreneur (Swedberg, 2000; Landström, 2005). Weber said that it is a distinctive feature of "the modern entrepreneur that he conducts himself as the first official of his enterprise" (1922/1978; 1948). He contrasted the entrepreneur with the bureaucrat (Swedberg, 2000; Landström, 2005). The entrepreneur was more than a manager in public and private bureaucracies (Weber, 1948). In his discussion of bureaucracy (1922/1978, Ch. 3), Weber noted that the capitalist entrepreneur "is the only type who has been able to maintain at least relative immunity from subjection to the control of rational bureaucratic knowledge" (1922/1978, p. 225). The entrepreneur is the only person who can keep the bureaucracy at bay (Swedberg, 2000; Landström, 2005).

2.4 Example 4: The Political Entrepreneur

A fourth example is touched upon by Weber while discussing government, parliament, politics (*Politik als Beruf*), and the political order, here using the term "political entrepreneur" (1918/1994; 1919/1994). In addition, Weber closely identified entrepreneurial and political action: "The struggle for power and the acceptance of full responsibility for one's cause which is the consequence of such power—this is the very element in which the politician and the entrepreneur live and breathe" (Weber, 1918/1994, p. 161).

2.5 Example 5: Entrepreneurs in Business Partnerships and Trading Ventures

The fifth example is found in his first book (Weber, 1889b), which was partially built on one of his dissertations (Weber, 1889a). It dealt with legal institutions of medieval capitalism, various forms of limited and unlimited partnerships that emerged with the revival of maritime and inland trade, and urban craft production (Roth, 1968/1978). This book received a translation in 2003 by Lutz Kaelber (Weber, 1889/2003) and explicitly discussed the entrepreneur in different partnerships, often reserving the term "entrepreneur" for the party authorized to make decisions. This work is, for example, not included by Swedberg (2000), Landström (2005), and Tulumello (2005). However, the 1889b publication was described by Roth (1968/1978).

The five examples above can be grouped into three conceptualizations of entrepreneurship, as shown in Table 1.

Table 1: Entrepreneurship: Weber's conceptualizations and uses of the term "entrepreneur"

Conceptualization of Entrepreneurship	Focus, Keywords
Protestant businesspeople with ethical motivations	The drivers of entrepreneurial forces in society (social, religious, and societal values, ethics, and doctrines), affecting the entrepreneurial spirit/orientation Societal and individual level
Charisma: charismatic leader that makes other people follow	Extraordinary type of personality, vision, and revolutionary change Also interpreted regarding the routinization of charisma (resulting in organizational form)
Entrepreneur as the first official of a business or political enterprise, medieval business partnerships included	Organizations, organizational level, entrepreneurs as leaders

Examples 3 to 5 concern establishing and/or steering organizations or groups. The focus was arguably the organizational level, hence its inclusion in Concept 2 in the table. Among these, the political entrepreneur (Weber, 1918/1994; 1919/1994) can be viewed as a variant of Example 3. Even though it is touched upon by several authors (Swedberg, 2000; Parsons, 2020), these publications are often discussed regarding politicians and concepts of politics and will not be followed up in the discussion. Example 1 is also partly or indirectly about establishing a business enterprise—at least its ethical motivations. However, this example also regards societal and religious values, ethics, and doctrines.

3. Discussion

This section starts by discussing and illustrating the contemporary relevance of Weber's conceptualizations of entrepreneurship. Subsequently, the section highlights the importance of Weber's early work on entrepreneurs.

3.1 Contemporary Relevance of Examples

Different scholars have extrapolated a so-called "Weber thesis" about the connections between the Protestant ethic, entrepreneurial activity (entrepreneurship), and economic development (e.g., Dana, 2009; Grytten, 2013). Within psychology, McClelland (1961) interpreted Weber as follows: "the connection seen by Max Weber between Protestant Reformation and the rise of the entrepreneurial spirit, which provided the jumping off point for this study" (p. 391). McClelland (1961, p. 11) also stated that Weber laid the groundwork for understanding the social and psychological origins of economic forces, such as entrepreneurship. This publication of Weber's (1905/1930) has been connected to much research on entrepreneurship, for example, the relationship between religion–entrepreneurship–economic activity–economic progress (e.g., Nunziata & Rocco, 2024; Grytten, 2013), the relationship between Protestant ethics and entrepreneurship (Dana, 2009; Brouwer, 2002), or the relationship between Calvinism and entrepreneurial attitudes. Weber argued that the Protestant ethic created a positive attitude toward working and earning money, "which facilitated the development of capitalism and entrepreneurship" (Landström, 2005, p. 45). Collins (1986, p. 134n) has argued that the personality type of the Schumpeterian entrepreneur bears a strong resemblance to Weber's Puritan businessman driven by the Protestant ethic. Even though its contemporary relevance is questioned, Weber's "observation that religious beliefs might account for disparities in economic development across countries" (Botelho et al., 2024, p. 343) is about cultural influence since religion is one important dimension of culture (Barro & McCleary, 2003). Weber explored the cultures of entrepreneurial societies (Schoonhoven & Romanelli, 2001), and some "institutional research has concentrated on the interplay between societal norms, values, and entrepreneurship" (Botelho et al., 2024, p. 343).

Even though the second conceptualization (charisma) is seen as less important in a capitalist society (Swedberg, 2000, p. 25) and is not identical to entrepreneurship (Landström, 2005, p. 45), it has influenced later works. For example, Schumpeter's entrepreneur has been seen as a subtype of Weber's charismatic leader (Carlin, 1956). A second example is Biggart's (1989) study of direct selling organizations (e.g., through home parties), which originated in the 1950s, a study theoretically inspired by Weber's work on charisma. Third, Weber discussed the routinization of charisma; for example, a founder's vision is entrenched in an organizational form. Inspired by this, Eisenstadt formulated the notion of institutional entrepreneurship in connection with innovating elites (1964; 1980). This idea was further developed and/or adopted by Paul DiMaggio (1988) in institutional analysis as a solution to the critique of not having a theory of action and agency (within this type of theory). DiMaggio (1988) defined "entrepreneurs" as actors "with sufficient resources who see in them an opportunity to realize an interest that they value highly" and, consequently, might create "new legitimate organizational forms" (DiMaggio, 1988, p. 14). His work later generated a great deal of research, relatively speaking (e.g., Caronna, 2007).

Several scholars later discussed the third conceptualization and use of the term "entrepreneur" in Weber's works (Jagd, 2002; Swedberg, 2003; Swedberg, 2005a; Love, 2015; Parsons, 2020), for example, Swedberg notes: "According to Weber, the entrepreneur plays a crucial role in the capitalist economy by being the one who makes the central decisions in the firm and who directs its bureaucracy" (2005a, p. 87). Swedberg (2000) said that Weber's "early definition of entrepreneurship" sets Schumpeter's individualistic entrepreneurs into perspective" (2000, p. 27).

For entrepreneurship to exist, according to Weber, you first and foremost need a modern enterprise(s) or organization that is capable of successfully and methodologically exploiting profit opportunities; a creative personality with lots of good ideas is not enough. (Swedberg, 2000, pp. 27–28)

Regarding types of profit making in business enterprises in the market economy, Weber said: "To a large degree, even though the consumer has to be in position to buy, his wants are 'awakened' and 'directed' by the entrepreneur" (1922/1978, p. 92). Discussing entrepreneurs and uncertainty as well as entrepreneurial action, Parsons (2020) saw Chapter Two of "Economy and Society," where Weber (1922/1978) investigated consumer and entrepreneurial action as a key publication.

3.2 Weber's Partnership Study: A Variant of the Third Conceptualization

Even though Weber's early book was translated into English in 2003 (Weber, 1889/2003), it has received little attention, though it is considered the earliest sociological treatment of entrepreneurship (Ruef, 2009). Weber (1989b, 1889/2003) investigated the legal origins, emergence, and differences of the general partnership, (especially) unilateral and bilateral *commenda*. As a methodological tool, Weber identified three characteristics of modern legal forms of partnership and asked how these features developed. He distinguished partnerships with these characteristics: "the development of the institutions covered in this study up to the point where all significant characteristics of the general partnership are present: firm, solidary liability, and separate fund" (1889/2003, p. 169). For example, even though the general partnership and (bilateral) limited partnership have several similarities, for example, separate funds, "both institutions arrived at it historically from a completely different point of departure" (1889/2003, p. 181). Weber traced the general partnership to family households (p. 88) or the family craft enterprises of medieval inland cities, such as Florence, households with family and other members, often surviving several generations (Roth, 1968/1978). This partnership has solidary liability (joint liability) that distinguishes it from the bilateral *commenda* (limited partnership). The partners are the entrepreneurs in the general partnership.

The bilateral and unilateral *commenda* originated from institutions of overseas trade: the *societas maris* (bilateral *commenda*) from Pisa (1889/2003, p. 68) and the older unilateral *commenda* from Genoa and Pisa (Roth, 1978). Weber (1889/2003) writes that the (bilateral) *societas maris* "resulted in more extensive innovations [that] reflected the transition from the unilateral *commenda* to a partnership with bilateral contribution of capital" (p. 68). The holder of the *commenda* was the entrepreneur (p. 73). The unilateral *commenda*, conversely, lacked a separate fund, and the investor was often the entrepreneur (Weber, 1889/2003, p. 67). Unlike the general partnership, both were ad hoc associations for trading ventures. Weber argued that these three partnerships were medieval roots in modern forms, such as the limited partnership, silent partnership, and the firm (liable companies) (1889/2003), and he saw "the limited partnership with partnership assets is the more advanced form" (1889/2003, p. 135). These partnerships were the medieval roots of contemporary organizational forms (Weber, 1889/2003).

Weber also briefly discussed partnerships and entrepreneurship in later publications (1927 1947; 1948). Weber (1927) argued that the *commenda*, a temporary organization, evolved over time into a permanent enterprise but differently in Southern and Northern Europe. In the South, the traveling merchant was the entrepreneur; in the North, the entrepreneur was at home. Weber (1927) also mentions the practice of owning parts of ships and shareholders of several vessels, thus clearly aware of different partnerships, such as the boat partnership or *carati* partnership. Furthermore, Weber discussed the entrepreneur and *commenda* in relation to profit-making activities (1947) and the Genoese *maonae* enterprise (1948).

The relevance is historical examples, not practical entrepreneurship, for example, of "the conditions under which modern risk-taking entrepreneurial institutions developed" (Scaff, 2004, p. 646). However, this publication from 1889 is overlooked in many accounts on entrepreneurship (including Landström & Swedberg) but later received positive attention by others as pioneering or path-breaking work on entrepreneurship (Ruef, 2005; 2009; 2010; Ruef and Lounsbury, 2007). It is seen as a study of commercial law's "influence in the creation of partnerships among medieval entrepreneurs" (Ruef, 2009, p. 58), thus, more exemplary of the legal creation of organizations rather than the Schumpeterian creation of organizations through innovation (Ruef, 2005, p. 69). Hence, these two examples represent different classical theories about how new businesses are created.

4. Conclusion

This paper has presented Weber's examples of the term "entrepreneur" and exemplified their possible contemporary relevance. However, this relevance is not practical; it is only historical and theoretical. The first conception is a theoretical argument that values in societies may still influence entrepreneurial orientation or the social-psychological origin of entrepreneurship (e.g., McClelland, 1961). Even though the second conception is less relevant today, we know that the notion of institutional entrepreneurship was inspired by the same Weber publication and later resulted in studies of institutional entrepreneurship. In relation to the third concept, Weber's first book has received the most attention in this paper. Such historical examples are theoretically useful. Williamson (1982, p. 111) and later Greif (1999, p. 334) have argued that historical examples or business history can be the data source for studying organizational innovation, for example, using contemporary theories such as transaction cost economics or other theories. The same argument is relevant to the study of entrepreneurship.

As noted, the partnerships were medieval roots in contemporary organizational forms; the general partnership (*compagnia*) is the root of the firm (liable companies) and general partnership (Weber, 1889/2003). Similar to general partnerships today, the medieval variant had a joint name and was an association of partners (p. 181). In addition, the temporary associations developed into organizational forms and permanent industrial enterprise, when these spread over time (Weber, 1927). Weber considered the bilateral *commenda* (i.e., *societas maris*) to be the medieval root of the modern limited partnership (p. 136) and the unilateral type to be the medieval precursor of both a modern commission agency and a silent partnership (p. 135). For example, the former has its examples in contemporary Silicon Valley venture capital firms and the Norwegian KS Limited Partnership (*kommandittselskape*t), which was very popular in the 1980s and the main method of raising (risk) capital in shipping and other larger projects.

However, Weber studied only three forms of partnership from Southern Europe. There existed several forms with other geographic origins in Scandinavia, with names such as the *felag*, *helmingarfelag*, *hjafelag*, and *partrederi* (e.g., Bugge, 1899). Such variations could be followed up on in future studies of historical examples of entrepreneurship. It could also be followed up by contemporary studies of business partnerships of different kind. For example, the jointly owned shipping company (partrederi) is an organizational form still used today in entrepreneurial ventures in coast of Norway and elsewhere in Europe. Furthermore, the early Weber started out in a German intellectual context, where others had the same research interest but came under the shadow of Weber. Future studies could explore the ideas of such scholars (e.g., Gustav Lastig). Finally, as noted by Swedberg and others, the late Weber, though within the third conception (see table 1), connected entrepreneurship to modern capitalist economy with organizations (and entrepreneurs) capable of calculate, direct and awake customer wants (Weber, 1898/1990; 1922/1978). This example has been less discussed in this paper and could be further discussed in future studies.

Abstract: Digital technologies open up new possibilities and opportunities for family businesses to innovate and grow. They change the way companies think and implement innovation. Digital innovation supports new products, processes, and business models, and changes innovation processes. Family businesses in the Czech Republic are managed by the founding generation or the first generation of successors and are active in traditional industries. Research on Czech family businesses in the field of innovation is minimal. The innovation activities of companies operating in the Czech Republic are monitored by the statistical office according to the Oslo Manual methodology, without a focus on family businesses, including findings related to digital technologies and innovation. The aim of this paper is to determine how digital technologies are changing innovative behaviour and generational decision-making in the field of innovation in family businesses. To this end, a questionnaire survey was conducted on a research sample of 200 of the largest Czech family businesses. This ranking of family businesses is determined by Forbes based on selected financial indicators and specific characteristics related to family ownership. The results of the questionnaire survey made it possible to answer the following research questions: What digital tools are used in the innovation process? How does the introduction of digital technologies influence the implementation of certain types of innovation? How do the attitudes of the founding generation and the successor generation towards digital transformation differ? What are the main barriers to the introduction of digital technologies in family businesses operating in traditional industries? The questionnaire is evaluated using descriptive statistics. At the same time, cluster analysis, Ward's technique with Euclidean distance, is applied, which allows the research sample of the largest family businesses to be divided into groups based on criteria related to innovation behaviour and generational decision-making. Family businesses must transform to survive and grow, because the skills and approaches needed to implement innovation and thus grow the business today are very different from those needed by previous generations.

Keywords: Digital Transformation, Digital Innovation, Family Business, Innovative Behaviour, Generational Decision-making, Cluster Analysis

1. Introduction

Modern technologies open up new possibilities and opportunities for family businesses to innovate and grow. However, innovation is not just about implementing new technologies, but also about changing the ways in which a company thinks about and implements innovation (Hinings et al., 2018). In the digital age, innovation refers to new products, processes, or business models enabled by digital technologies or embedded in data and software (OECD, 2019). According to Bornhausen and Wulf (2024), digital innovations are riskier than conventional innovations due to their complexity, rapid pace, and generational perception.

Digital capabilities and investments in innovation, research, and development are among the key priorities for family businesses in Central and Eastern Europe (PwC CEE, 2024). At the same time, Filep et al. (2023) point out the existing differences between the characteristics of family businesses in Western Europe and those in Central and Eastern Europe due to differing economic and historical developments, while also noting that research on family businesses in Central and Eastern Europe is minimal.

There is no official database of family-owned businesses in the Czech Republic. Innovation activities carried out by companies in the Czech Republic are tracked by the Czech Statistical Office using the methodology of the Oslo Manual (2018), without a specific focus on family-owned businesses. The latest report by the Czech Statistical Office on innovation activities in the Czech Republic for 2020–2022 also lacks findings related to technology use and digitalisation.

According to the concept of socio-emotional wealth (SEW), decision-making regarding innovation is based not only on financial indicators but also on the desire to maintain control, family identity, and continuity across

generations (Berrone et al., 2012). In this context, digitalisation can be perceived as a threat, as it requires openness to external knowledge and disrupts the established hierarchy in decision-making (López-Muñoz et al., 2025).

This paper aims to address gaps in research on family businesses, particularly in the areas of innovation behaviour and digitalisation, using a sample of the 200 largest Czech family businesses according to the Forbes ranking. It seeks to analyse innovation behaviour and the impact of digital tools on innovation behaviour in large family businesses, including an examination of the attitudes of founders and their successors. To this end, a questionnaire survey was conducted, and the results were evaluated using descriptive statistics. At the same time, cluster analysis was applied to define a typology of companies based on their approach to innovation, digitalisation, and financing.

2. Literature Review

Filep et al. (2023) highlighted the existing differences between the characteristics of family businesses in Western Europe and those in Central and Eastern Europe. A defining characteristic of these businesses is their age, which is around 30 years. For the most part, they are managed by the founding generation or the first generation of successors. They focus primarily on long-term goals and sustainability. They predominantly represent the small and medium-sized enterprise sector. A significant portion of family businesses are active in traditional industries. However, the level of innovation is lower than in Western Europe.

According to a PwC CEE study (2024), 64% of family businesses in Central and Eastern Europe—including the Czech Republic—are owned by the first generation, while 36% have been passed on to the second or subsequent generations. This is also confirmed by a survey by AMSP ČR (2024), which found that the largest share of family businesses is owned by their founders, though this applies primarily to the smallest firms. A survey by MSP ČR (2024) indicates that the largest proportion of family businesses are established as limited liability companies (68%), with a quarter operating as self-employed individuals. Kljucnikov et al. (2021) report that limited liability companies perform better in terms of local innovation than other firms structured under different legal forms. In two-thirds of firms with multiple owners, direct ownership by family members predominates, while just under one-fifth are structured as family funds.

Large family businesses are less innovative than non-family businesses because they seek to keep ownership and control in the hands of family members, which leads to a reluctance to take risks and invest in the uncertain outcomes of science and research. A company's innovativeness is examined from various perspectives. According to Steinerowska-Streb and Wziatek-Stasko (2020), the innovative capacity of family firms is determined by the continuous development of knowledge among owner-managers. Family firms whose owner-managers continuously expand their knowledge introduce significantly more product and marketing innovations. According to Urbaníková et al. (2020), there is a statistically significant relationship between company size, the generation managing the company, and the number of types of innovations introduced. They point out that second-generation family businesses can therefore be considered more innovative than first-generation family businesses. Uhlaner et al. (2026) highlight the link between social capital and product innovation as applied to small and medium-sized enterprises. Skrbková and Rydvalová (2026) examine how size, age/generation, and family ownership—both individually and in combination—influence the innovativeness of family businesses. It was found that medium and large family businesses are perceived by potential successors as more innovative than small businesses. Folvarcná et al. (2020) concluded that there is a relationship between succession in family firms and the selection of various sources of invention and financing for innovation activities. The greatest effects in implementing innovations are achieved through intergenerational collaboration.

According to a PwC CEE study (2024), family businesses in Central and Eastern Europe intend to focus over the next two years on innovation and digital transformation, new sources of revenue, and adapting to changing customer preferences. An OECD study (2019) defines digital innovation as new products, processes, or business models enabled by digital technologies or embedded in data and software. At the same time, innovation processes are changing thanks to the use of AI-based analytics and other digital technologies. Tutar et al. (2024) highlight the importance of digital innovations in managing uncertainty in family businesses through new organisational structures and business models based on digital innovations.

According to a PwC CEE study (2024), NextGen sees its role primarily in modernizing management structures and driving digital transformation. They aim to shift companies from intuitive management to more professional processes. While founders often focus on survival and continuity, NextGen views the transformation of the company through technology as essential for remaining competitive in the digital era. Similarly, the authors

Worek et al. (2025) examined the challenges family businesses face in adopting and implementing technology. They point out that family businesses often adopt technology slowly due to concentrated ownership, risk aversion, and a focus on non-financial goals.

Mikušová and Stanovska (2025) found that the approach to digitalisation among historically young family businesses does not differ significantly from the attitudes of owners in countries with a long history of family businesses. They also identified several groups of barriers to digitalisation: resources, change, data security, and employees.

3. Methodology

The methodological framework describes the research process and the methods used to analyse the data.

3.1 Methodology for Selecting the Research Sample and Conducting the Survey

The research sample was set by a purposive selection from the list of the 200 largest Czech family-owned companies featured in Forbes magazine (2025). The ranking has been published since 2021 and is compiled based on average values over the last three years for key indicators, namely revenue, EBITDA, and the number of employees. The original database of 200 companies was verified through an analysis of the public registry, focusing on the consistency of the surnames of statutory representatives and owners. After excluding 19 entities (failure to meet the definition, mergers), the initial sample consisted of 181 companies.

Data collection was conducted electronically using Google Forms via a structured questionnaire divided into

an identification section, innovation behaviour and decision-making across generations, and the status of digitalisation and digital transformation. The questionnaire contained 26 questions (dichotomous and polytomous questions with single or multiple-choice options). A total of 181 companies were contacted, and 90 completed questionnaires were received, resulting in a response rate of approximately 50%. Structure of the research sample (n = 90) highlighting the most significant weights only:

- Organisational structure: single business entity (72.2%), holding company (27.8%).
- Management: joint founder and successor (43.3%), exclusively second generation (32.2%), formal transfer of authority from the first to the second generation while maintaining the founder's influence (11.11%), founder-led management (7.78%), third-generation management (3.33%), transition from second to third generation (2.22%).
- Size by No. of employees: 250–499 employees (30.0%), 100–199 employees (21.1%), companies with 200 to 249 employees (13.33%) and those of 500 to 999 employees (13.33%).
- Revenue: over CZK 1 billion (56.7%), CZK 0,5–1 billion (28.9%), and CZK 0,1–0,5 billion (14.44%).
- Economic activity (CZ-NACE): manufacturing (48.9%), wholesale and retail trade, including repair of motor vehicles (16.7%), construction (14.4%), professional, scientific, and technical activities (4.44%), and others.
- Legal form: joint-stock company (48.89%), limited liability company (47.78%), other (3.33%).

Research questions: Q1: What digital tools are used in the innovation process? Q2: How does the adoption of digital technologies affect the implementation of certain types of innovations? Q3: How do the attitudes of the founding generation and the succeeding generation toward digital transformation differ? Q4: What are the main barriers to the adoption of digital technologies in family-owned businesses operating in traditional industries?

3.2 Cluster Analysis Method

Cluster analysis was performed using the Jamovi software program v2.7, which is designed for statistical data analysis. The cluster analysis was conducted in the following steps:

- **Data preparation and standardisation:** The Likert scale items were transformed into 8 composite variables (arithmetic means in seven cases and a sum in one case) covering innovation barriers (average barriers: overall intensity of perceived innovation barriers, abbreviated as **BARR** in the tables), financing dimensions (1. internal: own resources and family contributions, **INT**; 2. market: banking/loan products, external investors, and customer financing, **MKT**; 3. subsidies, **SUB**), digital technologies (operational and production technologies: automation, ERP/CRM, IoT, **TECH**; digital business and data infrastructure: artificial intelligence, cloud solutions, e-commerce, **DBI**; security

and sustainability: cybersecurity and energy-efficient technologies, **SUST**) and the digitalisation index (the sum of areas in which the company implements digital innovations, **DIX**). Due to differing scales, the data was standardized to z-scores, using the formula $z = \frac{x-\mu}{\sigma}$, where x = raw score, μ = mean and σ = standard deviation.

- **Hierarchical cluster analysis:** Ward's method (Ward, 1963; Henning et al., 2015) was used to determine the optimal number of clusters, including interpretation of the dendrogram and analysis of the increase in the linkage distance.
- **Non-hierarchical cluster analysis:** Application of the K-means method using the Hartigan–Wong algorithm. To eliminate sensitivity to initial conditions and find the global optimum, 50 random iterations were performed.
- **Validation:** The quality of the clustering was verified using an analysis of variance (the ratio of between-cluster to within-cluster sums of squares, ANOVA), testing the significance of differences between clusters.
- **Characteristics of typological groups:** Calculation of centroids for individual clusters and subsequent description of typological groups based on attitudes toward innovation, digitalisation, and financing.

4. Results

The results of the questionnaire survey are presented using descriptive statistics, and the results of the cluster analysis performed using Jamovi software are supported by calculations and accompanied by commentary.

4.1 Innovation and Digitalisation in Family Businesses – Interpretation of Questionnaire Survey Results

The survey revealed that innovation is an integral part of the philosophy and values of family businesses. As many as 63.33% of respondents agreed with this statement. The primary strategic benefit of implemented innovations is most often seen in expansion and the development of new opportunities (26.67%). The primary responsibility for initiating and implementing innovations most often lies with the successor generation (30.00%), followed by family management (25.56%) and the founder or owner (17.78%). The level of agreement between the founding and successor generations regarding the need to innovate is high, at 58.89%.

In terms of the type of innovation activities, innovations in internal business processes are implemented most frequently (46.67%), followed by product innovations (43.33%). Marketing and organisational innovations are implemented the least. The nature of the innovations implemented is predominantly incremental, accounting for 76.67% of family businesses, while radical innovations are implemented by only 23.33% of family businesses. The share of turnover invested in innovation most often ranges from 4% to 10% of turnover (46.67%).

A significant barrier (rating scale 3) to implementing innovative activities is considered to be the shortage of qualified personnel (42.2%) and the administrative complexity and lack of clarity surrounding grant programs (30.00%). Financial constraints (37.78%) and a conservative approach and the desire to maintain best practices (38.89%), prioritizing long-term survival and family values over risky innovations (37.78%), and a lack of knowledge of the market or technologies (40.00%) are considered moderately strong barriers (rating scale 2). The weakest barriers (value scale 1) are the fear of losing family influence due to the entry of external partners or investors (41.11%) and differing views among family members regarding risk and the direction of innovation (48.89%). The data are presented in Figure 1 as follows.

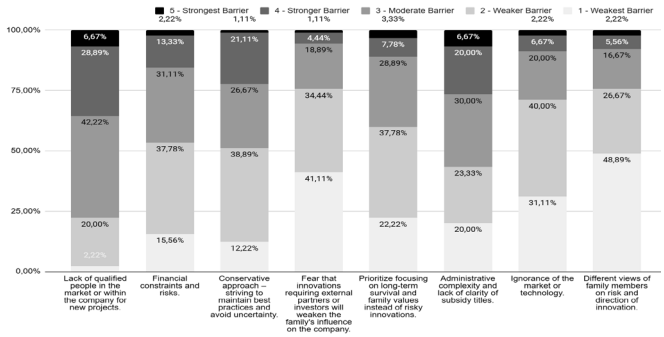

Figure 1: Distribution of Barrier Weights

Innovations are primarily financed from internal sources. The most common responses are on the rating scale of 4 (33.33%) and 3 (30.00%). Financing innovations through banking products is rated at levels 3 and 4 on the scale, each accounting for 30.00%. The use of grants as a source of innovation financing is relatively limited. The highest share was recorded at level 2 (36.67%). Deposits or loans from family members play a minor role in financing innovation, and assistance from external investors or external non-family creditors is also used minimally. Deposits or payments from customers also represent a marginal source of innovation financing.

The primary significance of digitalisation for family businesses is most often seen in operational efficiency and the automation of existing activities (58.89%). This is followed by strategic development and changes to the business model (16.67%) and changes to the company's innovative DNA as a means of ensuring the long-term survival of the family legacy (11.11%). The current level of digitalisation among companies is relatively high. The most common response is a situation where most key processes are digitally managed and data is shared (51.11%). Another 20.00% report the use of advanced technologies to manage the entire company, and 16.67% report the presence of standard digital tools without full system integration. The sample is thus characterized by a relatively high, yet varying, degree of digital maturity.

For the next three years, the most strongly emphasized digital priorities (rating scale 5) include ERP/CRM enterprise information systems (52.22%) and cybersecurity (45.56%), automation and robotics (34.44%), cloud solutions (34.44%), e-commerce and digital sales channels (27.78%), artificial intelligence and machine learning (38.89%), and sustainable and energy-efficient technologies (35.56%). The Internet of Things is most frequently rated with a medium score of 3 (33.33%).

In the area of digital innovation, companies most frequently digitize internal processes (83.3%), making this area the clear dominant domain of digital transformation. Digital communication and collaboration were cited by 55.6% of respondents, digital manufacturing and operations by 50.0%, digital security also by 50.0%, and digital commerce and marketing by 43.3%. The highly specialized area of business forecasting or failure prediction appeared only once (1.1%).

The founding generation's attitude toward the adoption of new digital technologies is predominantly positive, with the most common responses falling on a rating of 4, accounting for 37.78%. The successor generation's attitude is significantly more open. The most common responses fall on a rating of 5, accounting for 60.00%. The primary source of digital know-how is most often the successor generation (54.44%), followed by younger non-family employees (13.33%) and founders who are actively educating themselves in the digital field (13.33%).

The most common impact of digitalisation on a company's ability to innovate is an increase in efficiency and capacity for implementing innovations (37.78%), followed by improved data-driven decision-making (25.56%). A smaller group of respondents (15.56%) views digitalisation primarily as a tool for maintaining operations, without any significant direct impact on the company's ability to innovate.

4.2 Hierarchical Cluster Analysis

A hierarchical cluster analysis was conducted to identify typological groups of family businesses. The analysis was based on eight aggregated variables (z-scores) representing key areas of digitalisation, financing, and perceived barriers to innovation. A total of 90 family businesses were analysed. The Euclidean metric was used to calculate distances, and Ward's method (Ward.D2) was selected as the clustering method. Based on the dendrogram analysis (Figure 2) and the analysis of the increase in linkage distance (breakpoint at level 10), a solution with four clusters was selected.

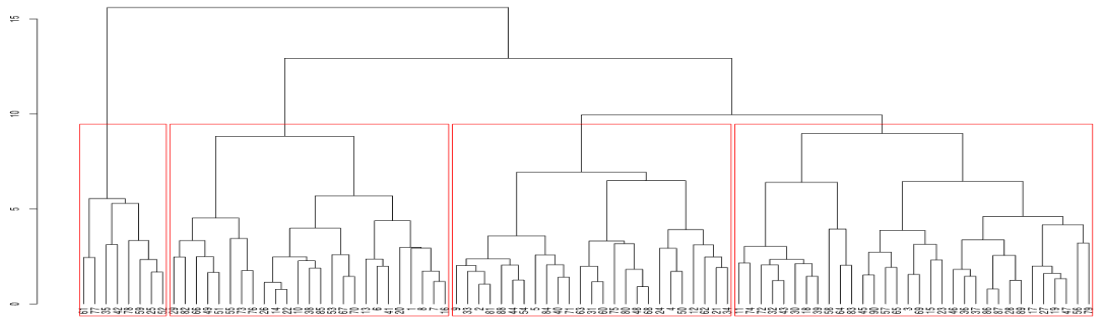

Figure 2: Dendrogram

This classification exhibits optimal internal homogeneity and a balanced structure (n = 25, 25, 32, and 8), which better reflects the heterogeneity of the sample than a model with higher aggregation. This result confirms that family businesses in the sample under study do not form a homogeneous group but can be classified into several systematically distinct types. Alternative models incorporating additional variables (attitudes, management, and innovative behaviour) exhibited lower stability and poorer interpretability (dominance of a single cluster). The original specification was therefore retained for the final segmentation, while the additional variables are used for subsequent cluster profiling.

4.3 Non-hierarchical Cluster Analysis (K-means)

The results of the hierarchical procedure were followed by a non-hierarchical K-means analysis (the Hartigan–Wong algorithm) with the aim of refining the classification of 90 companies. Eight standardized variables (z-scores) covering the dimensions of digitalisation, financing, and barriers were included in the model. Based on prior testing, the solution was fixed for k = 4. To eliminate the influence of the initial configuration of the centroids, 50 random initialisations were used, from which the solution with the lowest intra-cluster variability was selected. The resulting model explains 41% of the total variability (292.4 out of a total of 712.1 in between-cluster variability); see Table 1.

Table 1: Sum of squares

Clusters	Cluster 1	Cluster 2	Cluster 3	Cluster 4	Between Clusters	Total
Value	124.4	53.7	112.4	129.2	292.4	712.1

The companies were divided into four relatively balanced groups (n=23, 29, 27, 31). Three clusters are of comparable size, while one cluster is significantly smaller.

Cluster 2 (n = 9) identifies a minority segment with unique characteristics. The interpretation and profiling of individual types of family businesses were conducted based on centroid analysis (Table 2) and a profile graph (Figure 3), which confirm qualitative differences in the companies' approaches to innovation and digitalisation.

Table 2: Centroids of clusters

Cluster #	DIX	SUST	DBI	TECH	SUB	MKT	INT	BARR
1	0.128	-0.089	0.882	-0.103	-0.405	-0.144	0.733	-0.773
2	-0.552	1.401	1.383	1.551	0.547	2.130	0.860	0.613
3	-0.580	-0.344	-0.601	-0.853	-0.781	-0.437	-0.209	0.590
4	0.572	-0.048	-0.525	0.370	0.823	-0.131	-0.613	-0.118

The Cluster Profiles plot provides a visual representation of centroid values across individual variables. The graph shows that individual clusters have specific combinations of high and low values across the various dimensions. The identified clusters are not only quantitatively distinct but also differ qualitatively in their approach to innovation, digitalisation, and financing.

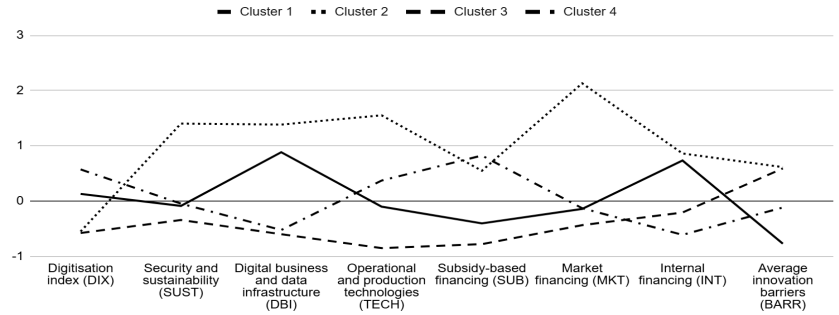

Figure 3: Cluster Profiles plot

Based on a centroid analysis, four distinct types of family businesses were identified, differing in their combination of digitalisation levels, methods of financing innovation, and perceived barriers.

Cluster 1 (n=23): The group of family-owned companies exhibits a high level of digital infrastructure (0.88) and a strong reliance on internal financing (0.73). Minimal perceived barriers (−0.77), combined with slightly above-average overall digitalisation, indicate the ability to implement innovation processes smoothly and autonomously without the need for external resources.

Cluster 2 (n=9): This smallest segment comprises the most technologically advanced companies, with the highest scores in both infrastructure (1.38) and operational technologies (1.55). A key feature is the intensive combination of market-based (2.13), grant-based, and internal financing. Higher perceived barriers (0.61) likely reflect the high complexity and risks of cutting-edge technology projects.

Cluster 3 (n=27): A typical characteristic is overall below-average digital and technological performance across all dimensions (index −0.58), accompanied by low utilisation of all forms of financing. Above-average perceived barriers (0.59), combined with investment passivity, indicate a defensive strategy and the existence of significant structural constraints.

Cluster 4 (n=31): Companies with the highest overall level of digitalisation (0.57), which is, however, closely linked to the use of grant programs (0.82) amid a shortage of internal resources (−0.61). The digitalisation strategy is selective—focused more on operational technologies (0.37) than on comprehensive data infrastructure (−0.52).

4.4 Testing the Statistical Significance of Differences Between Identified Clusters

The statistical significance of the differences between clusters was verified using one-way analysis of variance. The results (see Table 3) confirmed highly significant differences ($p < 0.001$) for all eight variables. The key differentiating factors are, in particular, digital infrastructure ($F = 43.02$), market financing ($F = 32.22$), and operational technology ($F = 30.44$).

Table 3: One-Way ANOVA (Fisher's)

	DIX	SUST	DBI	TECH	SUB	MKT	INT	BARR
F	9.58	8.88	43.02	30.44	28.08	32.22	15.88	12.49
df1	3	3	3	3	3	3	3	3
df2	86	86	86	86	86	86	86	86
p	< .001	< .001	< .001	< .001	< .001	< .001	< .001	< .001

Despite local violations of homogeneity of variances in some dimensions—such as digital business and data infrastructure, internal financing, and protection and sustainability (Levene's test, $p < 0.05$)—the ANOVA results can be considered robust given the balance of the sample and the high level of significance; see Table 4.

Table 4: Homogeneity of variances test (Levene's)

	DIX	SUST	DBI	TECH	SUB	MKT	INT	BARR
F	0.784	2.994	3.486	1.148	0.752	1.673	3.509	2.713
df1	3	3	3	3	3	3	3	3
df2	86	86	86	86	86	86	86	86
p	0.506	0.035	0.019	0.334	0.524	0.179	0.019	0.050

Descriptive statistics (see Table 5) confirm the cluster profiles: Cluster 4 exhibits the highest level of digitalisation (M = 0.57), while Clusters 2 and 3 are well below average (M = -0.55; -0.58). The relatively low standard deviation within the groups demonstrates their internal homogeneity and confirms the practical usefulness of the identified typology for distinguishing between companies' technological and financial strategies.

Table 5: Group descriptives

	Cluster	N	Mean	SD	SE
Digitalisation index (DIX)	1	23	0.1278	0.893	0.1862
	2	9	-0.5522	0.598	0.1995
	3	27	-0.5796	0.846	0.1629
	4	31	0.5719	0.963	0.1729

	Cluster	N	Mean	SD	SE
	4	31	-0.1313	0.623	0.1119
Internal financing (INT)	1	23	0.7326	0.909	0.1896
	2	9	0.8600	1.302	0.4339
	3	27	-0.2085	0.704	0.1354
	4	31	-0.6126	0.654	0.1174
Average innovation barriers (BARR)	1	23	-0.7735	0.833	0.1737
	2	9	0.6133	0.400	0.1332
	3	27	0.5900	1.038	0.1998
	4	31	-0.1181	0.761	0.1366

5. Conclusion

The results of the questionnaire survey showed that internal management and operational tools, particularly ERP and CRM systems, play a significant role in the innovation processes of the companies studied (research question Q1). The implementation of technologies primarily supports process-based and incremental innovation (research question Q2). At the same time, it was found that the founding and successor generations view digital transformation positively, but with varying degrees of enthusiasm (research question Q3). The main barriers to the adoption of digital technologies include a shortage of qualified personnel, a lack of best practices, long-term survival concerns, and financial constraints (research question Q4).

The results of the cluster analysis revealed the existence of four distinct groups of family businesses, which differ primarily in terms of their level of digitalisation, technological maturity, and access to innovation financing. These differences were further statistically confirmed using analysis of variance (ANOVA).

Ethical approval was not required for this study since the study relied solely on anonymised data.

AI Declaration

In preparing this manuscript, the authors used artificial intelligence (AI) tools to support selected research and writing tasks. Relay.app was used during data collection for automated web scraping (to construct the sample of Czech family firms based on Forbes rankings) and for generating survey invitations via Google Forms. ChatGPT (5.X Plus) supported language editing, proofreading, and methodological descriptions. AI was used only for operational and editorial support and did not generate data or perform analysis or interpretation. All AI outputs were reviewed and verified by the authors, who retain full responsibility for the study design, data collection, analysis, interpretation, and final content of the manuscript.

Abstract: Comparative measurement has become a central feature of research and policy analysis in innovation and higher education, where indicators are widely used to assess performance, support benchmarking, and inform decision-making. Yet measuring complex and institutionally embedded phenomena such as academic entrepreneurship remains challenging. These difficulties extend beyond data availability to the conceptual and interpretive conditions that govern how heterogeneous and evolving practices are translated into cross-country indicators. Drawing on the sociology of quantification and the literature on innovation indicators, this paper examines how academic entrepreneurship is rendered measurable in comparative settings. It argues that measurement cannot be reduced to a purely technical exercise but rather involves a series of structured choices related to conceptual definition, proxy selection, institutional context, and data representation. Academic entrepreneurship spans a wide range of activities, from formal commercialisation, such as patents and spin-offs, to broader forms of engagement that are often only partially visible in conventional data sources. As a result, empirical representations are necessarily selective, capturing some dimensions of activity while others remain only partially captured or inferred. To address these challenges, the paper develops an interpretive framework that specifies the key analytical conditions that shape comparative measurement. These include boundary ambiguity, proxy-based observation, institutional variation, functional comparability, temporal alignment, causal interpretation, and communicative simplification. These conditions explain why formally comparable indicators do not always support equivalent interpretations across contexts, and how measurement choices shape the representation of academic entrepreneurship. This paper contributes a diagnostic framework that renders these conditions analytically explicit and provides a basis for a more transparent and reflexive use of indicators in cross-country analysis. Rather than proposing a new measurement instrument, it clarifies what comparative indicators can and cannot capture. The paper also outlines implications for research and policy, emphasising the importance of explicit definitions, theoretically grounded proxy selection, and context-sensitive interpretation. Reframing measurements as an interpretive analytical practice contributes to a more differentiated understanding of comparative evidence in innovation and higher education research.

Keywords: Academic Entrepreneurship; Comparative Measurement; Cross-Country Analysis; Innovation Indicators; Higher Education; Interpretive Framework.

1. Introduction

Comparative measurement has become an increasingly prominent feature of research and policy analysis in innovation and higher education. Indicators are widely used to describe complex phenomena, compare institutional or national performance, and inform public decision-making. However, a substantial body of literature has shown that such indicators are not neutral representations of reality, but reflect the assumptions and choices embedded in their construction (Espeland and Stevens, 2008; Merry, 2016; Power, 1999; Saltelli, 2007; Porter, 1995). Measurement is, therefore, not reducible to a purely technical exercise, but involves conceptual choices that shape how phenomena become observable in practice. Recent work has increasingly foregrounded measurement itself as an object of critical inquiry, particularly in contexts where constructs are diffuse, evolving, and institutionally embedded (Beer, 2016; Mennicken and Espeland, 2019; Saltelli et al., 2020).

These issues are particularly relevant in the context of academic entrepreneurship. Universities, as key actors in research and innovation systems, are expected to contribute to economic and societal development beyond their traditional roles in research and teaching. This expectation is reflected in recurrent debates on entrepreneurial universities, knowledge transfer, university engagement, and innovation policy (Etzkowitz and Leydesdorff, 2000; Audretsch, 2014; Siegel and Wright, 2015; Perkmann et al., 2013). Recent literature also highlights the increasing conceptual breadth and heterogeneity of academic entrepreneurship across disciplines and institutional contexts (Cunningham et al., 2024). This expanding agenda has generated demand for forms of evidence that can be used across institutional and national contexts, often in the form of comparative indicators and benchmarking exercises (OECD, 2015; OECD and JRC, 2008; Saltelli et al., 2020).

The growing use of international benchmarking frameworks and comparative policy instruments reinforces these developments — these increasingly position universities within global innovation systems. In many cases, such metrics are embedded in funding mechanisms, evaluation regimes, and institutional strategies. As a result, measurement not only informs analysis but may also influence organisational behaviour, policy priorities, and the strategic positioning of higher education institutions. The increasing reliance on indicators, therefore, amplifies the importance of understanding how measurement design shapes both what becomes observable and how it is subsequently interpreted (Espeland and Sauder, 2007; Espeland and Stevens, 2008; Saltelli et al., 2020).

Translating academic entrepreneurship into comparable indicators remains methodologically demanding. The phenomenon encompasses formal commercialisation activities, such as patents, licences and spin-offs, as well as broader forms of knowledge mobilisation, including collaborative research, consultancy and informal exchange (Perkmann et al., 2013; Abreu and Grinevich, 2013), as well as recent work highlighting the diversity of actors, mechanisms and institutional configurations through which academic entrepreneurship is enacted across disciplines (Cunningham et al., 2024). Some of these activities are visible in administrative or statistical data infrastructures, while others are relational or context-specific. Consequently, empirical representations tend to rely on forms of selective visibility, whereby some dimensions are stabilised in the data while others remain only partially observable (Espeland and Stevens, 2008; Merry, 2016).

Existing empirical approaches provide useful but partial perspectives. Technology transfer statistics make some forms of knowledge commercialisation visible but tend to privilege activities that are formally recorded and institutionally codified (Grimaldi et al., 2011; Arundel and Es-Sadki, 2021). Broader innovation and entrepreneurship indicators may incorporate variables related to higher education or venture creation, but they do not necessarily isolate academic entrepreneurship as a distinct object of analysis (Godin, 2006; OECD and JRC, 2008; OECD, 2015; Acs et al., 2019). In particular, composite indices such as the Global Entrepreneurship Index aggregate heterogeneous dimensions of entrepreneurial activity, making it difficult to isolate the specific contribution of universities and academic actors. These approaches suggest that measurement design plays an active role in shaping how phenomena are made comparable across settings, rather than simply reflecting underlying similarities (Saltelli, 2007; Saltelli et al., 2020).

A central difficulty is that academic entrepreneurship is not a clearly bounded empirical object. It overlaps with adjacent concepts such as knowledge transfer, university–industry interaction, public engagement, and innovation performance (Perkmann et al., 2013; Bozeman et al., 2015; Cunningham et al., 2024). While related, these concepts are not interchangeable, as each implies different theoretical assumptions, levels of observation, and forms of evidence. Comparative measurement is therefore exposed to the risk of conceptual ambiguity, in which indicators may aggregate analytically distinct yet empirically overlapping phenomena (Fiss, 2011; Ragin, 2008).

This paper examines academic entrepreneurship as a problem of comparative measurement. It analyses the conceptual and methodological conditions under which academic entrepreneurship is translated into cross-country evidence. The central question is how specific measurement choices shape what counts as academic entrepreneurship in comparative indicators. By foregrounding these issues, the paper treats measurement as a structured analytical practice with an intrinsically interpretive dimension rather than a purely technical procedure.

The paper makes two main contributions. First, it develops a conceptual account of the factors shaping the quantification of academic entrepreneurship, highlighting issues of conceptual definition, selective visibility, and the role of data infrastructures. Second, it introduces and systematises an interpretive framework that integrates the main analytical dimensions under which comparative indicators can be meaningfully constructed and interpreted. Rather than simply aggregating existing measurement challenges, the framework specifies how these dimensions interact and jointly shape the scope and interpretability of comparative evidence. In doing so, the paper advances a more transparent and reflexive use of indicators in cross-country research on academic entrepreneurship and innovation policy. By articulating the interdependencies between conceptualisation, proxy selection, and contextual interpretation, the paper positions the interpretive logic of measurement as a central analytical concern, rather than a secondary methodological issue.

2. Academic Entrepreneurship and the Conditions of Quantification

Academic entrepreneurship is commonly associated with the mobilisation of academic knowledge beyond the boundaries of universities, encompassing diverse ways in which knowledge is translated into economic and

societal value (Etzkowitz and Leydesdorff, 2000; Audretsch, 2014). Some strands of the literature emphasise formal commercialisation activities such as patenting, licensing, and spin-off creation (Rothaermel et al., 2007; Siegel and Wright, 2015), whereas others adopt a broader view encompassing collaborative research, consultancy, contract research, researcher mobility, and entrepreneurship education (Perkmann et al., 2013; Abreu and Grinevich, 2013). This plurality reflects both variation in how knowledge circulates and differences in how entrepreneurial activity is variously conceptualised in the literature (Abreu and Grinevich, 2013; Perkmann et al., 2013). Recent reviews further highlight the increasing heterogeneity and conceptual fragmentation of academic entrepreneurship across disciplines and institutional domains (Cunningham et al., 2024), reinforcing the interpretive challenges associated with its measurement.

This conceptual scope creates difficulties in quantifying academic entrepreneurship (Espeland and Stevens, 2008; Mennicken and Espeland, 2019). When defined narrowly, indicators can be more precise but risk excluding important forms of knowledge mobilisation. Broader definitions, by contrast, allow for more inclusive representations, but often at the expense of conceptual precision. These trade-offs are not specific to this field but reflect a more general feature of innovation measurement, where conceptual developments often evolve faster than the statistical infrastructures available to capture them. The measurement process is therefore shaped not only by data availability, but also by the evolving relationship between conceptual frameworks and statistical systems, as well as by the institutional purposes for which indicators are constructed and used (Godin, 2006; Smith, 2005; OECD, 2015; Freeman, 1987). These challenges are further compounded by the heterogeneity of innovation processes and the diversity of indicators used to capture them, which may only be partially aligned with the underlying phenomena (Stundziene et al., 2024).

Visibility is inherently selective (Espeland and Stevens, 2008; Merry, 2016). Some activities produce observable records, while others are embedded in relationships, practices, or informal exchanges. Patents and spin-offs can be counted more easily than problem-solving interactions, network participation, or knowledge diffusion through human capital. As a result, empirical representations tend to privilege activities that are codified, legally recognised, or institutionally reported, while other forms remain only partially observable or are captured indirectly (Bozeman et al., 2015; Arundel and Es-Sadki, 2021), reflecting broader challenges in aligning indicators with heterogeneous forms of innovation activity (Stundziene et al., 2024).

This selective visibility has important analytical consequences. Activities that are consistently recorded tend to be over-represented in empirical analyses, while less visible forms of engagement may be under-analysed or entirely excluded. In effect, this introduces a bias in how academic entrepreneurship is conceptualised and analysed, as empirical research becomes aligned with what is measurable rather than with the broader range of underlying practices (Merry, 2016; Espeland and Sauder, 2007). Over time, this dynamic may reinforce particular interpretations of academic entrepreneurship, especially those centred on formal commercialisation, while marginalising other forms of knowledge mobilisation that are less readily captured by quantification (Espeland and Sauder, 2007; Saltelli et al., 2020).

Against this background, measurement does not merely reflect reality but may reinforce specific representations of phenomena, particularly when indicators are used repeatedly in comparative and evaluative contexts. Activities that are consistently measured tend to acquire analytical and policy relevance, while less visible activities may remain peripheral, even when they are substantively significant (Espeland and Sauder, 2007; Espeland and Stevens, 2008; Saltelli et al., 2020).

The sociology of quantification helps explain why these conditions matter. Quantification transforms heterogeneous qualities into comparable numbers, thereby establishing equivalences across observations while setting aside aspects that resist standardisation (Espeland and Stevens, 2008; Mennicken and Espeland, 2019). In the case of academic entrepreneurship, this process can reinforce narrower interpretations centred on formal commercialisation, even when the literature recognises broader forms of academic engagement and knowledge mobilisation (Perkmann et al., 2013; Abreu and Grinevich, 2013).

Historical work on science and innovation indicators has long emphasised these dynamics (e.g., Godin, 2006; Freeman, 1987; OECD, 2015). Indicators are influenced not only by theoretical considerations but also by institutional priorities, policy agendas, and available data infrastructures. In academic entrepreneurship, commonly used indicators therefore reflect the administrative visibility of specific activities rather than the full range of practices through which academic knowledge contributes to economic or societal change. Data infrastructures thus play an important role in shaping both what can be measured and how phenomena are represented in comparative analysis (Espeland and Stevens, 2008; Mennicken and Espeland, 2019).

The issue is not that indicators are inherently limited, since all measurement involves selective simplification, but whether the assumptions behind those reductions remain visible when indicators are interpreted, compared, and communicated (Espeland and Stevens, 2008; Mennicken and Espeland, 2019). This becomes particularly relevant in cross-country settings, where questions of conceptual definition, proxy interpretation, and institutional arrangements intersect with data infrastructures, making the interpretation of comparative evidence fundamentally context-dependent (Godin, 2006; Janger et al., 2017; Stundziene et al., 2024).

These conditions affect not only the availability of data but also shape the scope within which academic entrepreneurship can be studied. What becomes measurable, in turn, tends to structure both empirical research and policy attention, creating feedback effects between measurement practices and conceptual development (Espeland and Sauder, 2007; Saltelli et al., 2020). As a result, the challenges of quantification extend beyond technical limitations to questions of how phenomena are defined and made comparable across contexts. These dynamics are particularly evident in cross-country research, where differences in institutional settings and data infrastructures further complicate the interpretation of indicators and constrain the portability of measurement practices across national systems.

3. An Interpretive Framework for Comparative Measurement

The discussion above identifies a set of challenges in measuring academic entrepreneurship. These challenges can be organised into an interpretive framework that clarifies the conditions under which comparative indicators can be meaningfully constructed and used. Its purpose is primarily diagnostic: to make explicit the assumptions underpinning comparative indicators and to support more careful interpretation in cross-country research (Espeland and Stevens, 2008; Mennicken and Espeland, 2019).

Table 1 summarises these analytical conditions, their associated interpretive risks, and the implications for using comparative indicators. It highlights that comparative measurement is shaped by multiple interacting factors rather than by isolated technical choices. The framework should therefore be understood as an interpretive tool that clarifies key analytical distinctions (OECD and JRC, 2008), helping to identify where interpretive risks may arise, how they relate to one another, and the conditions under which comparative indicators can support meaningful conclusions. In this sense, it encourages a shift from viewing indicators as self-evident measures to treating them as context-dependent representations requiring critical examination (Espeland and Stevens, 2008; Saltelli et al., 2020).

Table 1: Analytical conditions shaping comparative measurement in academic entrepreneurship

Dimension	Core Question	Measurement Condition	Interpretive Risk	Analytical Implication	Anchoring Literature
Conceptualisation	What counts as academic entrepreneurship?	Boundary ambiguity	Narrow indicators interpreted as comprehensive representations	Explicitly define construct boundaries and distinguish academic entrepreneurship from adjacent concepts	Perkmann et al. (2013); Siegel and Wright (2015); Abreu and Grinevich (2013); Bozeman et al. (2015)
Operationalisation	What does the observable trace represent?	Proxy-based observation	Proxies interpreted as reflecting institutional, disciplinary, or administrative factors rather than entrepreneurial activity	Specify proxy–construct relationships and limit inference to what indicators can meaningfully capture	Griliches (1990); OECD (2015); Arundel and Es-Sadki (2021); Godin (2006)
Contextualisation	Do indicators have the same meaning across settings?	Institutional variation	Similar indicators reflecting different underlying practices across contexts	Interpret indicators in relation to institutional configurations, data infrastructures, and policy contexts	Edler and Fagerberg (2017); Godin (2006); OECD (2015); Janger et al. (2017)
Comparability	Are indicators substantively equivalent?	Functional non-equivalence	Formal harmonisation masking substantive differences between cases	Distinguish statistical comparability from substantive equivalence and interpret variation in	Ragin (2008); OECD and JRC (2008); Saltelli

Dimension	Core Question	Measurement Condition	Interpretive Risk	Analytical Implication	Anchoring Literature
				relation to contextual differences	(2007); Saltelli et al. (2020)
Temporality	Does the indicator match the process?	Temporal misalignment	Short-term variation interpreted as structural change	Align indicators with process dynamics, time lags, and cumulative effects	Edquist (2011); Dosi (1982); Hall et al. (2010)
Causality	What explains observed variation?	Endogeneity	Indicators interpreted as causal evidence rather than descriptive patterns	Avoid causal claims without an appropriate analytical design and account for feedback effects	Edler and Fagerberg (2017); Fiss (2011); Ragin (2008); Hall et al. (2010)
Communication	How is evidence presented?	Representational simplification	Aggregation and visualisation can obscure uncertainty and heterogeneity	Communicate scope conditions, uncertainty, and limits of aggregation explicitly	Espeland and Stevens (2008); Espeland and Sauder (2007); Saltelli et al. (2020); Beer (2016)

While the dimensions presented in Table 1 are analytically distinct, they should not be read as separate or sequential steps in a measurement process. In practice, they tend to overlap and influence one another. For example, how academic entrepreneurship is conceptualised will shape what can plausibly be observed, and therefore which proxies are used. Those proxies, in turn, affect how far indicators can be compared across institutional contexts. A similar overlap exists between institutional variation and functional equivalence, since differences in organisational practices and data infrastructures affect both which indicators are captured and how they can be interpreted. Questions of timing also matter when measurement takes place can influence how observed variation is related to underlying processes.

For this reason, the framework is better seen as a set of interrelated analytical conditions than as a sequence of steps to be followed. Its aim is not to provide a standard procedure, but to draw attention to the tensions that arise across these dimensions and to the way they shape the interpretation of comparative indicators.

Seen from this perspective, measurement in academic entrepreneurship cannot be reduced to a technical task. It involves a series of analytical choices—conceptual, methodological, and contextual—that carry interpretive implications (Mennicken and Espeland, 2019). Indicators provide structured representations of complex phenomena, but their usefulness depends on how the assumptions underlying them are made explicit and accounted for. What matters is not only how indicators are constructed, but how different elements of the measurement process interact.

The framework does not assume that all dimensions are equally important in every case. Rather, it is intended to guide a selective and context-sensitive application, depending on the research question, the available data, and the level of analysis. In some studies, the key issue may be whether proxies adequately reflect the underlying construct. In others, institutional differences or temporal alignment may be more critical. By making these conditions explicit, the framework helps clarify the scope and limits of empirical claims. It can be used as a lens to support interpretation, especially in cross-country research, where apparently comparable indicators may in fact reflect different practices and institutional arrangements.

From this angle, comparative indicators are not simply descriptive tools. They also shape how differences are made visible and interpreted, through the definitions, proxy choices, and conventions embedded in their design (Espeland and Stevens, 2008; Saltelli et al., 2020). Indicators that look similar on paper may correspond to quite different underlying practices, even where statistical categories have been harmonised. This is why it is important to distinguish between statistical comparability and substantive equivalence in cross-country analysis (OECD and JRC, 2008; Ragin, 2008).

These issues become particularly evident in cross-country comparisons. Differences in institutional arrangements, reporting practices, and data infrastructures affect both how indicators are produced and what they mean. The challenge, therefore, goes beyond data quality to questions of interpretation and functional equivalence.

Temporal and causal aspects add a further layer of complexity. Academic entrepreneurship unfolds over uneven and often extended time horizons, while many indicators are reported annually. As a result, short-term variation may reflect cyclical effects, policy changes, or shifts in reporting practices rather than deeper structural change. At the same time, indicators may capture both current conditions and the cumulative effects of earlier developments, including path-dependent processes in which present outcomes reflect past trajectories. This complicates causal interpretation and limits the extent to which descriptive comparisons can support causal claims (Edquist, 2011; Dosi, 1982; Hall et al., 2010).

Communication should also be seen as part of the measurement process. The way indicators are presented—through rankings, scorecards, or composite indices—shapes how they are understood. These formats can suggest a level of precision or comparability that the underlying data do not fully support and may influence organisational behaviour and evaluation practices (Espeland and Stevens, 2008; Espeland and Sauder, 2007; Saltelli et al., 2020). Measurement, therefore, involves not only producing indicators but also how they are communicated and used.

By making these analytical conditions explicit, the framework supports a more transparent and reflexive use of comparative indicators in the study of academic entrepreneurship. It also suggests that the strength of comparative analysis depends less on identifying a single best measure than on ensuring consistency between conceptual definitions, empirical proxies, and the claims that follow from them.

4. Conclusion

This paper examines academic entrepreneurship as a problem of comparative measurement, showing that the challenges involved extend beyond data availability to the conceptual and interpretive conditions under which indicators are constructed and used. Academic entrepreneurship encompasses multiple forms of knowledge mobilisation, not all of which are equally visible in conventional data. Empirical representation thus involves selective visibility, whereby some activities become observable evidence while others remain only partially captured.

The paper contributes by developing an interpretive framework that clarifies the analytical conditions under which comparative indicators can be meaningfully constructed and interpreted. These conditions — relating to conceptualisation, proxy-based observation, institutional context, comparability, temporality, causality, and communication — highlight that formally comparable indicators do not necessarily support substantively equivalent interpretations. Rather than neutral descriptors, indicators shape how academic entrepreneurship is represented and interpreted through the assumptions embedded in their design and use.

More generally, this perspective contributes to ongoing debates on the role of indicators in innovation and higher education research. It highlights that the analytical value of comparative measurement lies less in producing definitive representations than in enabling structured, transparent engagement with complex and context-dependent phenomena. Indicators are therefore most useful when understood as tools that support interpretation rather than as self-contained measures of performance.

This does not suggest that comparative measurement should be rejected. Indicators nevertheless remain essential for research, policy analysis, and institutional learning. Their analytical value, however, depends on the transparency of conceptual definitions, the explicit articulation of proxy–construct relationships, and sensitivity to institutional and contextual variation. Comparative evidence is most informative when treated as partial and interpretable, rather than as a complete or definitive representation of academic entrepreneurship.

Measurement is thus better understood not simply as a technical exercise, but as a structured analytical practice with an inherently interpretive dimension. This paper contributes by making explicit the conditions under which comparative indicators can support meaningful analysis and by showing how these conditions shape both the production and interpretation of evidence in cross-country contexts. These insights have implications for both research and policy. For researchers, the framework highlights the importance of clearly defining the object of analysis, specifying proxy–construct relationships, and interpreting comparative evidence in relation to institutional context rather than relying on formal comparability alone. It also underscores the value of combining quantitative indicators with qualitative evidence on data production, institutional meaning, and user interpretation. For policy and practice, the findings underline the need for caution in using rankings and composite indicators, emphasising the importance of communicating scope conditions, data limitations, and the interpretive nature of comparative evidence.

The framework also opens an agenda for future research. Further work is needed to examine how specific indicators behave across institutional settings, how data infrastructures shape the visibility of academic entrepreneurship activities, and how measurement practices influence organisational behaviour and policy choices. Comparative research would benefit from approaches that combine quantitative indicators with qualitative insights, as well as from greater attention to the processes through which indicators are constructed, interpreted, and used in practice.

These considerations suggest that the value of comparative indicators lies less in their ability to provide definitive assessments than in their capacity to support informed and context-sensitive analysis. When used reflexively, indicators can contribute to a more nuanced understanding of academic entrepreneurship, even amid conceptual ambiguity and partial observability. On the other hand, when treated as self-evident measures, they risk narrowing the analytical space and reinforcing simplified representations of complex phenomena. The paper does not seek to resolve the measurement problem, but to clarify its analytical boundaries. By making explicit the conditions under which comparative evidence is produced and interpreted, it supports a more transparent and analytically grounded use of indicators in research and policy.

bernardo.leso@ufrgs.br

Abstract: Generative artificial intelligence (GenAI) is rapidly transforming work processes in the creative industries, particularly in design-related activities where experimentation, speed, and originality are central to value creation. While existing studies have explored the technical capabilities and economic potential of GenAI, less attention has been given to how design professionals incorporate these tools into everyday practice and how their perceptions shape patterns of adoption. Inspired by technology adoption theories, particularly the Technology Acceptance Model (TAM) and the Unified Theory of Acceptance and Use of Technology (UTAUT), this paper investigates how professional designers interpret and integrate GenAI into their work. The study adopts an exploratory qualitative approach, based on 10 semi-structured interviews with designers working in agency and freelance contexts in Brazil. Data were analyzed through content analysis combining inductive coding with conceptually informed interpretation. The findings reveal three central themes. First, GenAI is frequently perceived as a co-agent in the creative process, often described as an "assistant" or "intern" operating under human supervision. This perception reflects the role of perceived usefulness and performance expectancy, core constructs in TAM and UTAUT, in supporting the integration of AI tools into creative workflows. Second, designers identify important tensions and limitations, including aesthetic homogenization, loss of creative singularity, and uncertainty regarding authorship and copyright. These concerns illustrate how perceived risks and ethical considerations may shape adoption dynamics beyond purely instrumental factors. Third, GenAI is widely understood as a productivity lever that accelerates operational stages, expands experimentation, and redistributes effort toward more strategic and conceptual tasks. The findings suggest that GenAI adoption in design can be partially explained by traditional acceptance constructs such as usefulness and effort expectancy. Also, its adoption unfolds within a broader transformation of creative labor, in which designers increasingly shift from execution to curation of AI-generated outputs while navigating tensions over originality, autonomy, and institutional pressure to use technology. This study contributes to current discussions on digital transformation, technology adoption, and innovation in the creative industries.

Keywords: Generative Artificial Intelligence; Creative Industries; Technology Adoption; Technology Acceptance Model; Unified Theory of Acceptance and Use of Technology

1. Introduction

In recent decades, digital technologies have driven transformations across productive, cultural, and creative sectors. More recently, generative artificial intelligence (GenAI) has intensified this movement by enabling the creation of texts, images, videos, and code from large volumes of data and user prompts, thereby enhancing efficiency, innovation, and creative capabilities (Dwivedi et al., 2023; Daugherty et al., 2023). Its economic impact is estimated to reach trillions of dollars globally (Chui et al., 2023).

Creative industries (such as advertising, marketing, design, and digital production) are particularly sensitive to these transformations, as they combine artistic and commercial logics in content production (Anantrasirichai and Bull, 2022). In this context, GenAI tends to reconfigure creative work by automating tasks, expanding expressive possibilities, and demanding new professional competencies (Božić, 2024; World Economic Forum, 2025). At the same time, its adoption raises challenges related to authorship, ethics, originality, and professional adaptation (Appel, Neelbauer, and Schweidel, 2023; Öztaş and Arda, 2025).

Despite the growing popularisation of generative AI tools such as ChatGPT, Midjourney, and DALL·E, their incorporation into the everyday practices of creative professionals remains at an early stage and is still in the process of stabilisation (Öztaş and Arda, 2025). In this context, although recent literature has advanced in explaining adoption through models such as TAM and UTAUT, gaps remain in understanding how these technologies are effectively integrated into creative processes and how they reconfigure designers' work in practice.

Addressing this gap, this study aims to understand how design professionals have adopted generative artificial intelligence and how they perceive its impacts on creative work. Based on semi-structured interviews with designers operating in different contexts of the Brazilian market, the article contributes by: (i) identifying patterns of GenAI incorporation into creative processes; (ii) analysing emerging tensions related to co-agency, authorship, and aesthetics; and (iii) discussing the reconfiguration of the designer's role, particularly the shift from execution to curation and creative direction. In doing so, the study advances the understanding of technology adoption beyond predictive models, highlighting how GenAI integration unfolds as a sociotechnical process within creative practices. Additionally, it offers practical implications for professionals and organisations by clarifying the limits and possibilities of using generative AI in creative contexts.

2. Theoretical Background

2.1 GenAI Adoption

In recent years, advances in deep neural networks have enabled the emergence of generative artificial intelligence (GenAI), a subfield characterised by the ability to produce original content, such as text, images, videos, and code, based on patterns learned from large volumes of data, often with quality comparable to human production (Lim et al., 2023). These systems are based on deep learning models, such as large language models (LLMs) and generative adversarial networks (GANs), which, in addition to processing information, generate new data instances from user inputs (Gupta et al., 2024). In the case of LLMs, such as OpenAI's GPT, this capability manifests as the production of coherent, contextually relevant text from prompts, significantly expanding the possibilities for interaction and creation (Chui et al., 2023).

It can be inferred that the popularisation of GenAI was driven by the launch of ChatGPT in 2022, which made these capabilities widely accessible, followed by the rapid expansion of specialised tools such as Midjourney, DALL·E, and Stable Diffusion for generating multimodal content. More recently, the emergence of generative AI agents has been observed, which go beyond content production by incorporating capabilities for planning and executing complex tasks autonomously. These systems interact with different tools and digital environments, approximating the role of assistants or collaborators within workflows (Chui and Roberts, 2024; Mollick, 2023).

Given this integration of GenAI into workflows, there is an increasing demand to understand both its technical capabilities and the conditions that sustain its adoption in practice. In this sense, classical technology acceptance models, such as the Technology Acceptance Model (TAM) and the Unified Theory of Acceptance and Use of Technology (UTAUT/UTAUT2), have been used to explain the intention to use digital systems, including generative AI tools (Liu et al., 2025; Huy et al., 2024; Ghimire and Edwards, 2024). In summary, TAM proposes that technology adoption is mainly influenced by perceived usefulness and perceived ease of use (Davis, 1989). In contrast, UTAUT extends this perspective by incorporating performance expectancy, effort expectancy, social influence, and facilitating conditions (Venkatesh et al., 2003). Recent studies in the context of GenAI confirm the relevance of these factors, showing that perceived performance gains, ease of use, and institutional pressures positively influence usage intention, while ethical and privacy concerns may act as inhibitors (Liu et al., 2025; Ghimire and Edwards, 2024).

In the literature on creative industries, the use of these theoretical frameworks has advanced the understanding of why professionals adopt digital tools. In the field of design, for example, studies based on TAM find that external factors such as facilitating conditions (e.g., infrastructure/support) and the quality of outcomes influence the intention to use generative tools for creation in art and design (Zhu, Ren, and Shen, 2025). Liu et al. (2025) proposed and tested an extended UTAUT model to explain the intention to use AI-based creativity support tools, with 435 participants from creative industries. This approach included four UTAUT constructs (performance expectancy, effort expectancy, social influence, and facilitating conditions), three risk factors (ethical concerns, privacy, and dependency), one contextual factor (regulatory environment), and two user demands (interactivity and personalisation). The results indicated a positive effect of performance expectancy, effort expectancy, social influence, and regulatory environment on intention to use; a negative effect of ethical and privacy concerns; and interactivity and personalisation as antecedents of effort expectancy. Facilitating conditions and concerns about dependency did not directly predict intention (Liu et al., 2025).

These results confirm that TAM and UTAUT theories are important tools for understanding technology adoption by users, providing an appropriate theoretical foundation for the objective of this research. Therefore, this study draws on the core constructs of both models, such as perceived usefulness, performance expectancy, perceived effort, and social influence, to understand professionals 'perceptions of this emerging technology.

2.2 Generative AI in the Context of the Creative Industry

The introduction of generative artificial intelligence (GenAI) into creative contexts has brought significant changes to work routines and the very nature of content production. Studies indicate that its applications span the creation, analysis, enhancement, and manipulation of information, with particular emphasis in the field of design, where content creation and enhancement applications, such as image and text generation, have been highlighted for their transformative potential (Anantrasirichai and Bull, 2022). In this context, the relationship between designers and their tools is undergoing a reconfiguration. Rather than functioning merely as passive instruments, generative AI systems are increasingly understood as creative collaborators, with partial agency in processes of visual and narrative conception (Anantrasirichai and Bull, 2022). This dynamic has been described as co-agency, in which creativity emerges from the interaction between human and non-human agents, requiring new forms of coordination and trust (McCormack et al., 2020).

However, the emergence of such co-agency does not occur without tensions. At the aesthetic level, studies suggest that AI-generated content tends to reproduce recurring patterns learned from large datasets, resulting in an "artificial aesthetic" marked by homogeneity and predictability, with perceptible traces of its machine origin (Manovich and Arielli, 2024). As AI models are trained on cultural datasets, they learn recurring patterns, often producing images that are stereotyped or idealised. This tendency manifests in a recognisable "default style" in the outputs of tools such as Midjourney, reinforcing a sense of visual homogeneity. In contrast to the human capacity to introduce singularities and fine-grained nuances, AI-generated images remain generic, producing the culturally widespread impression of an aesthetic that the authors term "artificial aesthetic" (Manovich and Arielli, 2024). On the other hand, at the ethical and legal level, concerns emerge regarding authorship, originality, and the potential unauthorised use of pre-existing works, given the opacity of the training processes underlying these systems (Škiljić, 2021; George, 2023).

These limitations generate effects that extend to the organisation of creative work, requiring a reassessment of tasks, timing, and roles. To further contextualise this within creative industries, Öztaş and Arda (2025) show that the introduction of AI is experienced simultaneously as an opportunity to expand expressive capabilities and as a competitive requirement in a market that values efficiency and time reduction. The authors point to the acceleration of workflows and productivity gains, but also to frictions such as the feeling of shortcutting and alienation when creative stages are abbreviated, as well as aesthetic homogenisation and uncertainties regarding authorship. One of the main transformations observed by the authors is the emergence of curation in creative work, in which the designer's role shifts from execution to conception and organisation of AI-generated artefacts. In this new model, professionals emphasise that human intentionality remains an irreplaceable differentiating factor (Öztaş and Arda, 2025).

3. Methodological Procedures

3.1 Description of the Research Context

The study was conducted within the context of Brazilian creative industries, with a focus on the design and advertising segments, which combine artistic and commercial activities in content production and account for a significant share of employment and added value in the sector (Firjan, 2022). Heterogeneous organisational structures, including large agencies, independent studios, and freelance professionals, characterise these segments.

The research focused on professionals engaged in the production of visual and audiovisual content, packaging design, and product development, areas in which the adoption of GenAI technologies has been expanding as support for creative processes. The sample consisted of ten designers operating across different contexts of the Brazilian market (Table 1), including agencies and independent practices, all with experience using generative AI tools in their workflows. Participants were selected based on criteria for effective use, albeit sometimes experimental, of generative AI tools in their creative processes.

This is an exploratory qualitative study based on semi-structured interviews (Table 2), appropriate for investigating emerging phenomena and understanding perceptions and practices in specific contexts. The interviews were conducted individually, in a remote format, recorded with consent, and subsequently transcribed.

Table 1: Profile of interviewees

Interviewee	Age	Experience	Role	City	Interview Format
E1	39	18 years	Design Project Manager	Porto Alegre	Online – 38 min
E2	24	3 years	Designer and AI Creator	Porto Alegre	Online – 23 min
E3	35	9 years	Brand Strategist	São Paulo	Online – 36 min
E4	29	10 years	Motion Designer	Porto Alegre	Online – 32 min
E5	38	20 years	Strategic Designer	Porto Alegre	Online – 50 min
E6	32	8 years	Graphic Designer	Porto Alegre	Online – 41 min
E7	31	10 years	Designer	Porto Alegre	Online – 40 min
E8	52	33 years	Designer	Porto Alegre	Online – 37 min
E9	38	22 years	Designer	Porto Alegre	Online – 1h 09 min
E10	62	40 years	Artist and University Professor	Porto Alegre	Online – 1h 15 min

Data analysis was conducted using content analysis, inspired by Bardin (2016) and Gioia (2012), to identify recurring patterns in participants ’perceptions and practices. The data were organised iteratively into analytical categories based on the relationship between interview excerpts and the research objectives, enabling the development of interpretations of the incorporation of GenAI into creative work. This approach enables the examination of technology adoption as a situated practice, going beyond usage intentions and highlighting how GenAI is integrated into creative processes.

Table 2: Guiding Questions Aligned with the Research Objectives

Theme	Guiding Questions	Objective of the Analysis
Profile	What is your name and age? What is your current role? How many years of experience do you have in the field?	To understand the profile and level of professional experience.
Adoption and Use of Generative AI	Do you use generative artificial intelligence in your work? Which generative AI tools do you currently use and how frequently? At which stages of the creative process has generative AI been most applied? How does AI integrate with other design tools you were already using? Do you use generative AI collaboratively (sharing knowledge about the tool with other professionals) or individually? What differences have you perceived in your work before and after using these generative AI tools?	To understand how the technology is being incorporated into work practices.
Benefits and Challenges of Generative AI Use	What are the main benefits you identify in the use of generative AI? What challenges or difficulties have arisen during implementation? How do you assess the impact of generative AI on the final quality of projects?	To understand the benefits and challenges of using the technology.
Perceptions of Generative AI Use	What are your concerns or apprehensions regarding the use of this technology? Do you consider that generative AI complements or replaces human creative work? How do you see the role of generative AI in the future of design?	To understand professionals’ perceptions of the technology.

4. Results and Discussion

The analysis of the interviews revealed a heterogeneous use of generative AI tools among design professionals, with different technologies performing specific roles throughout the creative workflow, in line with previous findings (Öztaş and Arda, 2025). Table 3 summarises this landscape, outlining the functions, benefits, and challenges associated with the main tools. In addition to the tools presented in Table 3, applications with occasional or experimental use were also mentioned, highlighting the field's still exploratory nature (e.g., Figma AI, After Effects, Magnific AI, KlingAI, Higgsfield, DeepSeek, Gemini, and Google Veo 3). Overall, a combination of technologies that complement one another in designers' practices can be observed, with variations depending on the type of activity and work context.

Table 3: Perceptions of the use of each generative AI tool

Generative AI Tool	Usage among Interviewees (%)	Functions Used in Creative Process Stages	Perceived Benefits	Perceived Challenges	Creative Role of the Tool
ChatGPT	90%	Support in presentations; Generation of images and concepts; Research and references; Brainstorming and ideation; Text refinement and structuring; Image editing.	Increased productivity; Support in idea visualisation.	Need for verification; Risk of incorrect or unreliable outputs.	Ideation and structuring assistant
AI Tools Integrated in Adobe Software	60%	Removing or adding elements; Colour or material adjustments; Image quality enhancement.	Image generation integrated into the Adobe ecosystem.	Difficulty in controlling fine adjustments.	Integrated refinement tool within the Adobe suite
Midjourney	30%	Generation of conceptual and expressive images; Rapid compositions and prototyping; Creation of backgrounds and visual variations to explore art direction.	Rapid generation of visual alternatives for image creation.	Hallucinations; Credit limitations.	Catalyst for art direction
ComfyUI	30%	Customisable node-based pipelines; Local execution; Model switching and integration of pre-/post-processing.	Greater privacy and customisation.	Learning curve; Requirement for specialised hardware.	Builder of specific local processing workflows

Based on this empirical foundation, the analysis enabled the identification of three interpretative axes that structure the incorporation of GenAI into creative work: (i) AI as a co-agent in creative processes; (ii) the limits and challenges associated with its adoption; and (iii) AI as a productivity tool.

4.1 Generative AI as Co-Agency

Throughout the interviews, professionals described GenAI as an auxiliary support in their projects, in roles analogous to those of assistants or interns. This idea became explicit in several statements, such as that of E4: "It's as if you were an art director, and AI were your intern," and of E7: "I see it very much as, in a way, my intern, who gathers options that I can use with my know-how." In both cases, although respondents indicated that the tool was part of their work, generative AI remained a technology under supervision and without autonomy.

These statements align with what the literature refers to as co-agency, shared creativity between human and non-human agents, with human direction (McCormack et al., 2020). Thus, the technology supports the professional's creative practice in a meaningful way by adapting to the style of that specific human partner (McCormack et al., 2020; Mollick, 2023). In this context, artificial intelligence shifts from being merely a tool or instrument that passively supports human creativity to a new type of active creative assistant, a movement that helps explain its incorporation and persistence within the workflow.

This view of AI as an "intern" reflects elements of perceived usefulness and ease of use, as proposed in TAM, which identifies these factors as central to the adoption of new technologies. Among the designers interviewed, AI is adopted and maintained in the workflow precisely because it is perceived as useful for exploring creative options, reducing operational tasks, and enhancing the quality of outputs (Davis, 1989).

As a practical consequence, professionals noted that work has been reoriented towards curation: AI generates materials under human command, while the designer focuses on ideation, direction, and selecting generated images. This transformation was described as a shift from the production of artefacts to the selection and integration of AI-generated texts and images, with the final product composed. The shift in focus towards conception under human direction implies that the professional assumes roles of creative direction or leadership, while the system executes stages under their command (Öztaş and Arda, 2025).

It is important to note that not all interviewees feel satisfied with this shift in the scope of work. Although ease of use has been widely recognised, a perception of loss of autonomy and authorship in the process emerges. As summarised in E4's statement: "Sometimes I take a long time making something, but everything I put there I decided […] It's a strange relationship between generating solutions with AI and actually making something hands-on."

Thus, overall, the results indicate that designers position themselves in an intermediate space between the instrumental use of AI and effective collaboration. While they preserve their role as decision-makers and creative leaders, they also recognise, albeit with some apprehension, that AI already performs functions previously attributed solely to humans.

4.2 Limits and Challenges of Technology Adoption: Artificial Aesthetic and Authorial Uncertainty

Design professionals recognise generative artificial intelligence as a tool capable of expanding creative repertoires; however, they also point to significant limitations related to aesthetic quality and issues of authorship. Concerns related to the visual outcomes of generated images are evident, as illustrated by E2's statement: "As everything is very new, there are still many aberrations. I say 'aberrations' because the face looks strange, the hand looks strange—I generate a lot of images like this… It is difficult." Regarding aesthetic aspects, interviewees reported recurring anatomical flaws and visual inconsistencies, associated with what they refer to as system "hallucinations."

Beyond these technical inconsistencies, a perception of a generic and standardised aesthetic also emerged, recognised as having artificial characteristics, as noted by respondent E6: "Nowadays, everything looks the same to me, doesn't it? It is not just me having a designer's eye; I think the more we work with this, the more obvious it becomes that, in my view, when AI makes an image, it is lazy. For example, going on iFood. I do not know if this has happened to you. You go to order a pizza, (you see) an AI-generated pizza image, and then you think, hmm(?)." These statements directly resonate with Manovich and Arielli (2024), who describe AI's tendency to produce an "artificial aesthetic," characterised by recurring and stereotyped patterns, resulting in homogeneous and culturally impoverished images.

Another recurring point in the interviews concerns the cultural risk of homogenisation, as articulated by respondent E8: "On Shutterstock, there are many vanilla flowers generated by AI. Imagine in 50 years, maybe no one will know what the real flower looks like anymore. That changes cultural perception itself." These accounts reinforce the critique that AI, by operating on large datasets, tends to reduce cultural diversity, replacing singularities with repetitive models. In line with Manovich (2017), these findings support the idea that the automation of aesthetic choices and the application of algorithmically learned visual patterns may lead to the standardisation of cultural imagination, reducing variability and promoting a dominant aesthetic.

At the legal and ethical level, concerns emerged regarding copyright and authenticity. Some interviewees pointed to the exploitation of creative work without compensation to original authors. As discussed by respondent E6: "[…] AI takes ideas from everything that exists, puts it together, and the (original) author does not earn money from it, receives neither recognition nor remuneration." These perceptions converge with the literature identifying intellectual property issues in generative AI tools due to the lack of clarity regarding authorship and the use of training datasets (Appel, Neelbauer and Schweidel, 2023), highlighting risks of plagiarism and, consequently, copyright infringement (Škiljić, 2021; Božić, 2024), and advocating for the creation of regulatory mechanisms to ensure authenticity and attribution in synthetic content (George, 2023). The absence of clear mechanisms for transparency and traceability exacerbates this uncertainty, as summarised by E8: "You cannot really know how safe it is to use an AI-generated image."

Based on the adapted UTAUT framework proposed by Liu (2025), the findings of this section can be interpreted as risk perceptions that modulate intention to use. Criticism of the "artificial aesthetic" and the risk of cultural homogenisation reflect ethical concerns, while uncertainties regarding authorship, transparency, and traceability relate to privacy and intellectual property risks. Finally, the demand for clear rules underscores the regulatory environment's role in facilitating adoption.

Thus, the results indicate that, although generative AI is perceived as a valuable resource for design, it comes with aesthetic and legal limitations that hinder its everyday adoption. The convergence between professionals' accounts and the literature suggests that acceptance of the technology depends not only on technical advances but also on the development of mechanisms of legitimacy, whether aesthetic, capable of overcoming visual standardisation, or regulatory, capable of ensuring copyright and authenticity.

4.3 Generative AI as a Productivity Tool and Expansion of Creativity

One of the most frequent themes in the semi-structured interviews was the perception that generative AI optimises time in the creative process, positively impacting productivity. In addition, the tool has the potential to redistribute effort, as illustrated by designer E3's statement: "It makes me spend energy on thinking, rather

than executing things where my value does not lie." This statement reveals a shift in the development of work processes, with less time devoted to operational activities and more space for creative reflection (Dwivedi et al., 2023; Liu et al., 2025). This supports the findings of Božić (2024), who highlights AI's ability to automate repetitive tasks, such as data analysis, graphic design, and image editing, allowing professionals to focus on more strategic and creative aspects of their work.

In addition to reducing effort, interviewees emphasised gains in quality and speed, improving the performance of their projects. Participant E9 observed that the tools can generate better results more quickly, stating: "[…] sometimes even with hours it would not be as good." Similarly, E1 pointed to expanded access to resources: "We can deliver things that we could not before, because they required a high-end studio." These statements highlight how AI can democratise creative expression, enabling smaller agencies to perform tasks previously restricted to contexts with greater investment (Božić, 2024).

However, this perceived quality gain is not unanimous. The adoption of these tools has also been reinforced by institutional pressures, particularly in corporate environments seeking to standardise their use as a competitiveness strategy. As reported by respondent E4: "the company even evaluates us based on how much we are using artificial intelligence […] we have been using it to meet increasingly demanding and faster-paced requirements, but not necessarily because of quality." This statement shows that, in certain contexts, the adoption of generative AI shifts from an individual choice to an organisational requirement, where usage is monitored and valued as a productivity indicator, even when output quality is not the primary driver. This scenario reveals tensions between professional autonomy and efficiency demands imposed by organisational structures.

These accounts align with UTAUT theory (Venkatesh et al., 2003), which posits that effort expectancy and performance expectancy are determinants of adoption, as technologies that reduce the effort required to perform a task tend to be more widely used (Jain, Garg, and Khera, 2022). Furthermore, perceived benefits related to performance expectancy act as a component that fosters initial willingness to use the technology and supports a positive evaluation of AI tools (Gursoy et al., 2019).

In the context of design, therefore, the ability of generative AI to optimise time and expand experimentation emerges as a decisive factor for its incorporation into professional routines, balancing the aesthetic and authorial challenges discussed previously. This emphasis on efficiency and performance gains aligns with the constructs of perceived usefulness (TAM) and performance expectancy (UTAUT), identified as key factors in technology acceptance.

5. Conclusion

This study analysed how design professionals have adopted GenAI and how they perceive its impacts on creative work. The findings indicate that it is incorporated as a co-agent in creative processes, in roles analogous to assistants under human supervision, while simultaneously introducing tensions related to aesthetics, authorship, and the standardisation of production.

Despite these challenges, the technology is perceived as a strategic ally, capable of optimising processes, expanding experimentation, and democratising access to creative resources. These results reinforce the centrality of factors such as perceived usefulness and performance expectancy in adoption, while also highlighting the influence of organisational pressures that, in certain contexts, make its use less voluntary.

The incorporation of GenAI also implies a reconfiguration of the designer’s role, shifting from execution to conception, curation, and creative direction, in which human intentionality remains central. These findings suggest that technology adoption is not limited to an individual decision but rather constitutes a situated sociotechnical process that reshapes practices and work relations.

As limitations, the study highlights the sample's size and profile, as well as its geographical concentration, and the emergent nature of the phenomenon analysed. Future research may further explore factors such as social influence and voluntariness of use in different organisational contexts.

Ethics Declaration

Ethical approval was not required for this study. The questionnaire used included an introductory section informing participants about the purpose of the research, assuring anonymity, and requesting their informed consent prior to participation.

AI Declaration

OpenAI's ChatGPT was used to support language refinement and word count adjustments; all content was reviewed and validated by the authors.

Bridging Institutional Fragmentation: Designing a Coordinated Support Infrastructure for Deep-Tech Scale-Up in Europe

Olga Rantanen
LAB University of Applied Sciences, Lappeenranta, Finland

olga.bogdanova@lab.fi

Abstract: Deep technology ventures are widely recognized as critical drivers of industrial transformation and sustainability transitions. Yet their progression from laboratory validation (TRL 4-5) to pilot and demonstration scale (TRL 6-7) remains structurally constrained within fragmented European innovation systems. While substantial public funding instruments and research infrastructures exist, deep-tech startups continue to face persistent coordination failures in accessing capital, pilot facilities, and industrial validation environments. Drawing on exploratory qualitative insight from an in-depth interview with an experienced startup mentor within an EIT HEI project, this study identifies recurring systemic bottlenecks in the TRL 4-7 transition. These include limited visibility and accessibility of mid-scale pilot infrastructures, fragmented and poorly sequenced funding architectures, and misalignment between blended finance instruments and long development cycles. Anchored in entrepreneurial ecosystem theory, regional innovation systems literature, and the "valley of death" framework, the paper combines this empirical diagnosis with a structured desk analysis of European support mechanisms, including the European Innovation Council (EIC), EIT Knowledge and Innovation Communities (KICs), Horizon Europe, Eurostars, InvestEU, and Research and Technology Organisation (RTO) networks. The analysis demonstrates that Europe's deep-tech scale-up gap reflects not an absence of support, but insufficient institutional integration and orchestration across funding and infrastructure domains. In response, the study advances a design-oriented framework for coordinated support infrastructure within EIT HEI ecosystems. The proposed model conceptualizes EIT HEI as a systemic intermediary performing three functions: (1) venture-stage diagnostic alignment, (2) infrastructure and blended finance brokerage, and (3) cross-institutional ecosystem orchestration. By integrating dispersed opportunity structures into a coherent navigation architecture, the framework aims to reduce transaction costs and improve pathway continuity for research-intensive ventures. The paper contributes to ongoing debates on Europe's deep-tech scale-up challenge by reframing fragmentation as a coordination problem and proposing institutional design principles for enhancing systemic alignment within innovation ecosystems.

Keywords: Deep-tech Scale-up, Valley of Death, Entrepreneurial Ecosystems, Institutional Fragmentation, Ecosystem Orchestration

1. Introduction

Deep technology ventures have become increasingly important in Europe's efforts to renew industry, strengthen strategic competitiveness, and support sustainability transitions. Unlike many conventional startups, these ventures are built around scientific and engineering advances that must be translated into practical applications in fields such as advanced materials, energy, biotechnology, and digital systems. Their development is therefore not only a matter of entrepreneurial capability or investor interest, but also depends on the institutional environments through which scientific knowledge, technical validation, industrial partnerships, and commercialization pathways are connected (Autio et al., 2018; Grande et al., 2025).

A particularly difficult point in this journey appears between laboratory validation and pilot or demonstration scale, typically associated with Technology Readiness Levels 4-7. At this stage, ventures must move beyond proof of concept and demonstrate that their technologies can function in more realistic operating conditions. When access to validation settings, industrial engagement, and suitable finance remains disconnected, promising firms risk losing momentum before reaching commercial viability.

This problem is especially visible in Europe. On paper, the region has a substantial innovation support architecture, including public funding instruments, research infrastructures, university-based initiatives, industrial networks, and intermediary organizations. Yet despite this dense landscape of programmes and institutions, European deep-tech ventures continue to face difficulties in moving from laboratory validation to demonstration and scale-up (Grande et al., 2025). This creates a paradox: significant support mechanisms exist, but they do not consistently produce smooth scale-up pathways. The central problem may therefore lie not in the absence of support as such, but in how the available pieces fit together.

Although previous research has examined deep-tech finance, infrastructure access, entrepreneurial ecosystems, regional innovation systems, and intermediary organizations, less attention has been given to how these support domains can be coordinated into coherent pathways for ventures moving through TRL 4-7. This paper responds to that gap by examining the TRL 4-7 transition as a coordination challenge within European deep-tech

ecosystems. Drawing on an expert interview conducted within an EIT HEI-funded venture support project, together with a structured desk analysis of European support mechanisms, the study identifies recurring bottlenecks in funding sequencing, pilot infrastructure access, and support-system navigation. Based on this analysis, the paper develops a design-oriented framework that positions EIT HEI actors as systemic intermediaries performing three interconnected roles: venture-stage diagnostic alignment, infrastructure and blended-finance brokerage, and cross-institutional ecosystem orchestration. In doing so, the paper contributes to debates on deep-tech scale-up by reframing Europe's scale-up gap as an institutional coordination problem rather than a simple shortage of support instruments.

2. Literature Review

2.1 Deep-tech Scale-up and the Valley of Death

Deep-tech entrepreneurship differs from conventional startup development because it is closely tied to scientific discovery, engineering complexity, and long commercialization pathways (Grande et al., 2025). Deep-tech ventures often require specialized facilities, technical validation, regulatory knowledge, industrial partners, and substantial capital before they can demonstrate commercial viability (Grande et al., 2025; Muscio, Simonelli and Vu, 2023). Their development therefore depends not only on entrepreneurial capability, but also on the institutional conditions through which scientific knowledge is translated into industrial application (Autio et al., 2018; Asheim, Isaksen and Trippl, 2019).

The transition from laboratory validation to pilot and demonstration scale is commonly described through the "valley of death" framework (Auerswald and Branscomb, 2003; Markham, 2002). This concept refers to the gap between technical feasibility and commercial viability, where technologies have moved beyond proof of concept but are not yet mature enough to attract sustained private investment or large-scale market commitment (Auerswald and Branscomb, 2003; Markham, 2002). In deep-tech contexts, however, the valley of death should not be understood only as a funding gap, because financial constraints interact with infrastructure access, industrial validation, customer engagement, and development timing (Muscio, Simonelli and Vu, 2023; Grande et al., 2025). Ventures at TRL 4-7 often need several forms of support at the same time: access to pilot facilities, opportunities for testing and validation, industrial partners, regulatory guidance, customer feedback, and patient capital (European Commission, 2026b; Grande et al., 2025). When these elements are not connected, the transition from validation to demonstration becomes slower, more uncertain, and more costly (Auerswald and Branscomb, 2003; Muscio, Simonelli and Vu, 2023). Recent work on European deep-tech and sustainability-oriented innovation similarly shows that scale-up barriers are multidimensional and involve the interaction of finance, infrastructure, validation, and industrial engagement (Muscio, Simonelli and Vu, 2023; Grande et al., 2025).

2.2 Ecosystem Fragmentation and Coordination Failure

Entrepreneurial ecosystem theory provides a useful lens for understanding why the existence of many support instruments does not necessarily produce effective scale-up outcomes (Isenberg, 2010; Autio et al., 2018). The ecosystem perspective argues that entrepreneurship depends not only on individual firms, founders, or resources, but also on the quality of interaction among entrepreneurs, investors, universities, support organizations, public agencies, infrastructures, and markets (Isenberg, 2010; Autio et al., 2018). From this perspective, the availability of resources is only one condition for venture development, while the visibility, accessibility, and sequencing of those resources are equally important for firms moving through development stages (Autio et al., 2018; Reischauer, Güttel and Schüssler, 2021).

Regional innovation systems literature makes a similar argument from a territorial and institutional perspective (Cooke, 2016; Asheim, Isaksen and Trippl, 2019). It emphasizes that innovation performance depends on how knowledge institutions, firms, infrastructures, policy actors, and intermediary organizations are connected across regions and governance levels (Cooke, 2016; Asheim, Isaksen and Trippl, 2019). This is especially relevant for Europe, where deep-tech ventures often operate within multi-level support environments involving universities, RTOs, regional development agencies, European funding programmes, and sectoral innovation networks (EIT, 2024; Grande et al., 2025; European Commission, 2026a). Such environments may contain considerable resources, but they can still remain difficult to navigate when instruments operate through different eligibility rules, timelines, access points, and institutional priorities (European Commission, 2026a; European Commission, 2026b; Eureka Network, 2026a). Europe's deep-tech scale-up challenge can therefore be

interpreted less as a problem of absolute scarcity and more as a problem of weak systemic alignment (Autio et al., 2018; Cooke, 2016; Grande et al., 2025).

2.3 Innovation Intermediaries and Ecosystem Orchestration

The role of innovation intermediaries is important in fragmented ecosystems because intermediaries can reduce search costs, connect firms to relevant resources, translate between institutional logics, and support collaboration across organizational boundaries (Reischauer, Güttel and Schüssler, 2021; Bäumle, 2025). In ecosystem settings, intermediation goes beyond providing isolated advisory services and may involve orchestrating relationships among actors, aligning resources with venture needs, and creating continuity between different stages of development (Reischauer, Güttel and Schüssler, 2021; Leceta and Könnölä, 2021). This orchestration role is especially relevant where innovation ecosystems contain multiple specialized actors but lack a single navigable route through funding, infrastructure, validation, and market-access domains (Leceta and Könnölä, 2021; Vujovic and Baloutsos, 2025). It is also relevant for EIT HEI ecosystems, where universities, startups, incubators, RTOs, public agencies, investors, and European-level programmes may all be present but not necessarily integrated into a clear pathway for ventures (EIT, 2024; Leceta and Könnölä, 2021; Vujovic and Baloutsos, 2025).

3. Methodology and Data

3.1 Research Design

This study utilizes an exploratory qualitative design and draws on two sources of evidence: an expert interview with a startup mentor engaged in an EIT HEI-funded project, and a structured desk study of European support mechanisms. The interview provides practice-level insight into the challenges and support needs. The desk study maps how support is formally organized across funding, infrastructure, and intermediation domains. Where the two sources converge, interpretive confidence is stronger; where they diverge, the divergence is treated as analytically informative.

3.2 Interview Data

An in-depth semi-structured interview with an experienced startup mentor in an EIT HEI project was conducted in January 2026. The interviewee was selected based on their direct and sustained engagement with deep-tech ventures at TRL 4-7, and a number of supported startups (15) over a five-to-six-month period. This cross-case exposure partially compensates for the inferential constraints of a single-interview design, as observations reflect patterns across multiple ventures rather than a single firm's experience (Neergaard and Leitch, 2015; Ahmad and Wilkins, 2025). The supported ventures were registered companies at TRL 4-5, operating in materials and industrial innovation with B2B orientations and developing research-based technologies for industrial application.

3.3 Desk Study

The desk study examined European support mechanisms relevant to TRL 4-7, focusing on the EIC, EIT KICs, Horizon Europe, Eurostars, InvestEU, and RTO networks. The documents included programme descriptions, work programmes, implementation guidelines, and strategic documents. Analysis was guided by four questions: what type of support is offered; which development stage it targets; whether it addresses single or combined support functions; and how explicitly it connects to adjacent instruments or stages (Hall and Steiner, 2020; Kayesa and Shung-King, 2021).

3.4 Data Analysis

The interview transcript was coded around venture characteristics, support needs, access conditions, and coordination gaps. Desk-study documents were coded by instrument type, target stage, support function, and degree of institutional linkage. Both datasets were then compared to identify alignments and mismatches between formal support structures and practitioner-observed experience.

4. Results

4.1 Deep-tech Venture Needs and Bottlenecks

According to the interview, support requirements demonstrate consistency in terms of the mutual relationship between the needs. While the most frequently mentioned problem was a lack of adequate funding, it rarely occurred in isolation. Deep-tech ventures needed help not only with determining the right funding instruments but also with sequencing funding sources to align with technical milestones. Another critical issue, closely tied to financing, was accessing pilot customers. The term 'pilot customer' referred to early-stage industrial clients who could simultaneously serve as testers and facilitators of market-related learning. This was further supported by validation, including guidance on proving that laboratory solutions work well in conditions closer to reality. In addition, scale-up preparation emerged as an interrelated need, as ventures had to understand which partnerships or facilities were required before building their production capacities. However, the interview showed that each of these concerns required a specific engagement on the part of a support provider. As the interviewee noted, "repeated interaction gives time to dig deeper and actually find the real problems," which cannot be done in one-time meetings.

According to the interviewee, four bottlenecks were recurrent in the cases when support had been provided. The first problem was poor visibility and access to pilot and demonstration infrastructure, which were critically important for ventures at the point of transition to scaling. Second, there was fragmentation and poor sequencing of funding pathways, which required not only a choice of instruments appropriate to a given stage of venture development but also an understanding of the process by which they gradually combine. Third, there were few options for continuity of support across all domains, which meant that issues such as funding, validation, industrial contacts, and infrastructure needs should have been addressed simultaneously, but not as independent matters, which current support frameworks were designed for. Finally, there was a lack of visibility and unclear entry points for seeking support, which meant that discovering available resources was accidental, and many firms were unaware of their existence. In the interviewee's words, "there is no real pipeline inside the European Union funding that would make it really clear for anyone that these things are happening and available."

4.2 European Support Architecture for Deep-Tech Ventures at TRL 4-7

The desk study analyzes Europe's formal support framework covering the mid-TRL commercialization trajectory. According to Horizon Europe's General Annexes, the TRL 4-7 stage encompasses "technology validated in a lab", "environmentally tested and validated", "technical validation/demonstration" through "system prototype demonstration in an operational environment" - the stage where instruments start mentioning validation, piloting, deployment and scaling, and when coordination needs for ventures are at their peak (European Commission, 2026b).

Across all considered sources, the framework proves quite wide-ranging but is still distributed across four functional domains. The domain of funding is covered by Horizon Europe Research and Innovation Actions and Innovation Actions aimed at collaborative R&D, testing, and demonstration with specified TRL targets (European Commission, 2026b; European Commission, 2026c). EIC Transition funds technology maturation based on previous EU-funded achievements, supporting maturation from TRL 3-4 to TRL 5-6 stage, supplemented with business-readiness elements, yet only for those TRL 3-4 results achieved under specified upstream EU-funded project types (European Innovation Council, n.d.-a). EIC Accelerator provides funding for maturation at TRL 6-8 through grants combined with equity/quasi-equity investments and Business Acceleration Services (European Innovation Council, n.d.-b). Eurostars represents a unique case in that it funds collaborative R&D oriented toward the market, led by innovative SMEs, within a competitively ranked project portfolio with national-level joint funding. It is relevant for ventures looking to work with international partners and collaborate in piloting during the TRL 4-6 phase, even though pathway continuity would still depend on national criteria and scheduling differences among consortium members (Eureka Network, 2026a; Eureka Network, 2025a; Eureka Network, 2025b).

In the domain of advisory and intermediation services, the EIT KIC framework delivers partner network-based assistance focused on finance access, customer networks, and market development, segmented by stages of business development but not by formal TRL (EIT, 2024; EIT, n.d.). EIC Business Acceleration Services and Coaching supplement the mix with stage-specific coaching, business-to-business and corporate buyer matching and special partner access via the Ecosystem Partnership Programme (European Innovation Council, n.d.-c;

European Innovation Council, n.d.-d; European Innovation Council, n.d.-e). The financing domain is represented by InvestEU with guarantee-backed instruments and advisory support via the Advisory Hub, targeting demonstration, deployment, and scaling (European Commission, n.d.-a; European Commission, n.d.-b). Finally, in the infrastructure domain, the RTO networks link applied research competence with pilot facilities and industrial collaboration, presenting themselves as intermediaries between knowledge creation and its application (EARTO, n.d.).

Formal connections exist among the various instruments in the described framework. Thus, EIC Transition is explicitly tied to previous EU funding. EIC Accelerator features Fast Track and Plug-In routes for projects previously funded under Horizon or nationally, as well as Seal of Excellence schemes for proposals that remain unfunded despite being strong candidates (European Innovation Council, n.d.-b). There is also a particular Fast Track route from Eurostars-3 to the EIC Accelerator program, indicating that Eurostars is conceived as one of the steps in a broader sequencing strategy leading to the scaling stage (Eureka Network, 2025c). Moreover, according to the EIC Work Programme 2026, STEP Seal proposals can be referred to InvestEU implementing partners as candidates for venture debt funding (European Commission, 2026a).

Thus, the framework is quite extensive and formally interconnected in several ways. However, this does not necessarily mean it is navigable in practice - its impact on venture pathway continuity will be discussed below.

4.3 Coordination Gaps Between Venture Needs and Support Structures

By integrating the interview findings and the desk study, it becomes evident that a misalignment issue lies at the core of the problem with support provision in deep tech. Specifically, there is an important gap between the integrated nature of venture needs and the segmented structure of support tools. Three misalignments stand out in this regard.

First, integrating venture needs and segmenting support instruments. As demonstrated in the interview, deep tech companies need funding to validate ideas, run pilots, and build networks that enable pilots. This is an interconnected, iterative process based on guidance, network building, and the evaluation of outcomes. On the other side of the spectrum, desk research revealed that the functions mentioned are distributed among separate instruments covering each element of the development process. It means that startups have to integrate support on their own rather than follow some coordinated pathway.

Second, the availability of necessary infrastructure and practical accessibility. Desk research confirmed the existence of various infrastructure-related support tools in the ecosystem under discussion. Nevertheless, these opportunities can be accessed via completely different pathways (consortia membership, award of company status, partner network, or bilateral arrangement), thus making ventures face the problem of fragmented opportunities despite the objective existence of relevant capacities. Mentoring and advisory services follow the same pattern - although they are technically available, they are not always coordinated throughout the entire venture development process.

Finally, formal linkages between support tools versus the practical navigability of the support ecosystem. The desk research showed that there are several ways for handoffs from one program to another. Thus, it proves that the ecosystem of support in deep tech is not completely isolated, at least at the programme level. However, experience from interviews shows that these links do not work properly for companies, as access is mostly accidental, and many support tools remain unknown to the ventures that need them. Thus, there is a clear gap between the institutionally constructed interconnectedness of programmes and their navigation in practice.

The conclusions about the nature of the problem revealed in this case study can be summarized in Table 1.

Table 1: TRL-specific venture needs, support options, and support limitations in the European deep-tech support architecture

TRL	Main Needs	Support Options	Main Limitations
4	Lab validation, early business case development, next-step planning, seed funding	Horizon Europe grants; EIC Transition (where eligible from prior EU-funded results); EIT KIC pre-seed support; RTO infrastructure and technical collaboration	Fragmented entry points; restricted eligibility in several schemes including EIC Transition; low venture awareness of available support; weak pathway continuity

TRL	Main Needs	Support Options	Main Limitations
5	Validation in relevant environment, pilot facility access, first industry contacts, sustained diagnostic mentoring	Horizon Europe RIAs/IAs; EIC Transition (where eligible from prior EU-funded results); Eurostars (subject to national co-funding alignment); EIC BAS (for EIC-funded companies); EIT KIC networks; RTO infrastructure and technical collaboration	Pilot access is uneven and instrument-dependent; support functions spread across separate programmes; Eurostars pathway continuity subject to national eligibility and funding timetable variation across consortium partners
6	Technology demonstration, scale-up planning, blended finance, investor and customer readiness	EIC Accelerator; Eurostars (subject to national co-funding alignment); Horizon Europe IAs; EIC BAS; EIT KIC acceleration support; InvestEU; RTO infrastructure and technical collaboration	Coordination demands peak: demonstration, validation, mentoring, and finance require combining multiple instruments simultaneously; Eurostars does not include built-in scale-up finance; no single instrument covers the full TRL 6 support need
7	Operational prototype demonstration, deployment planning, scaling finance, procurement and customer access	EIC Accelerator; EIC Accelerator STEP Seal / InvestEU referral; InvestEU; EIC BAS; EIT KIC scale-up support; RTO infrastructure and technical collaboration	Dedicated scale-up finance more accessible than at earlier stages; navigation remains complex and multi-instrument; no single coordinated entry point into the combined finance and deployment support landscape

4.4 Toward a Coordinated Support Model in EIT HEI Ecosystems

The implications of the results point towards a distinct model design: improving support for deep-tech scaling at TRL 4-7 does not require more instruments but rather better mechanisms for alignment, accessibility, and continuity amongst those that already exist. In this section, an integrative model will be proposed in which EIT HEI actors function as systemic intermediaries, performing three intertwined roles. The model is not meant as an alternative to existing instruments in Europe, but rather as a reframing of the role of EIT HEI nodes to build a coherent navigation architecture for research-intensive ventures.

4.4.1 Venture-stage Diagnostic Alignment

During the TRL 4-7 stage, companies' challenges are iterative and overlapping. Technical validation, industrial testing, customer validation, regulatory validation, and financial needs occur together and evolve dynamically as venture development progresses. Successful support required iterative engagement to understand the actual constraints underlying perceived needs. The first step of the support programme for deep tech companies, therefore, is the systematic diagnosis of venture readiness at each development stage and the identification of the particular bottlenecks, in terms of a combination of factors. The objective would be to develop a progression pathway for each venture based on a realistic assessment of its technological and market potential. This would provide a much more tailored form of support for research-intensive ventures than general startup support and would create a basis for the subsequent two intermediary roles: structured and purposeful brokerage and orchestration.

4.4.2 Infrastructure and Blended Finance Brokerage

The desk study demonstrated that instruments for venture support were available in Europe but scattered across multiple institutions with different access mechanisms, eligibility criteria, and goals. In terms of intermediary functions, brokerage would mean actively matching needs diagnosed by the intermediary institution with infrastructure, collaborations, and funding opportunities provided by other institutions. According to the model proposed, EIT HEI actors would provide venture connections to RTOs, KIC partners, industrial clients, and other instruments, including the Eurostars and InvestEU programmes. In addition to brokerage, the model requires intermediary involvement in planning grant funding, blended finance, and follow-up investments during venture development.

4.4.3 Cross-institutional Ecosystem Orchestration

The above discussion of diagnostic alignment and brokerage highlights the deep tech companies' needs and how they can be matched to available infrastructure and financing instruments. However, what makes these intermediary roles necessary at all is the condition of low ecosystem-level integration, under which ventures cannot easily access support instruments. EIT HEI ecosystems are proposed to function as meso-level

orchestration intermediaries, connecting universities, incubators, RTOs, public institutions, investors, funding bodies, and infrastructure providers.

In conclusion, the three roles of intermediary institutions discussed together represent a coherent support model, the main strength of which is creating structural access to the resources of existing support programs rather than providing support itself. Only diagnostic alignment would ensure that brokerage is not random; only brokerage that intermediaries provide would make orchestration produce tangible benefits for ventures. The model's major institutional innovation is thus the positioning of EIT HEI not as a support program node but as a systemic intermediary.

5. Discussion and Conclusion

In relation to the paper's aim of examining the TRL 4-7 transition as a coordination challenge, this study suggests that the European scale-up problem for deep-tech companies is better understood as a coordination problem than as a simple under-supply of assistance. This finding supports entrepreneurial ecosystem and regional innovation systems research, which argues that innovation outcomes depend not only on the availability of actors and resources, but also on the quality of connections among them (Autio et al., 2018; Cooke, 2016; Asheim, Isaksen and Trippl, 2019). The key weakness is not only that support is fragmented, but that ventures are often left to combine funding, pilot access, validation, mentoring, and industrial contacts by themselves. This makes the valley-of-death problem more than a financing gap; it also becomes a problem of sequencing and institutional navigation.

The contribution of this paper is therefore to treat fragmentation in European deep-tech support as an institutional design issue. The proposed framework positions HEI-connected actors as systemic intermediaries that can support diagnostic alignment, infrastructure and blended-finance brokerage, and cross-institutional ecosystem orchestration. This argument is consistent with previous research on innovation intermediaries and ecosystem orchestration (Reischauer, Güttel and Schüssler, 2021; Leceta and Könnölä, 2021; Bäumle, 2025). This would not replace existing instruments, but could make them more usable by reducing search costs and improving continuity across support domains. At the same time, the framework should not be read as a simple institutional fix. If poorly designed, an additional intermediary role could add another layer to an already crowded support landscape.

Overall, the study remains exploratory and should be interpreted with caution. Its empirical base is narrow, relying on one expert interview and one EIT-related support case, although the interviewee's experience covered several ventures. The desk study also captures formal support mechanisms more clearly than informal access practices or regional differences. Future research should therefore test the proposed framework through multiple case studies and interviews with founders, investors, RTOs, and policy actors. Despite these limitations, the paper shows that improving deep-tech scale-up in Europe may require not only more support, but better coordination of the support that already exists.

Ethics Declaration

The interview participant participated voluntarily and was informed of the study's purpose and the intended academic use of the material. No sensitive personal data was collected. The interview transcript was used in anonymized form, and identifying details not relevant to the analysis were omitted. The study did not involve vulnerable participants, medical data, or interventions requiring formal ethical approval under institutional or national research ethics procedures.

Abstract: In the context of accelerating digital transformation and the increasing demand for transversal competencies, higher education institutions are challenged to adopt innovative pedagogical approaches that foster entrepreneurial mindsets across different fields of study. Hackathons, originally rooted in software development, have evolved into interdisciplinary learning environments that promote creativity, collaboration and problem-solving. This study explores the role of a hackathon—*Digit'all MakerDay*—as a capacity-building mechanism for almost 200 students enrolled in non-STEAM (Science, Technology, Engineering, Arts and Mathematics), professional higher education courses, at Polytechnic University of Cávado and Ave (Portugal). The primary objective of the hackathon was to introduce the participants to emerging fields such as technology and robotics, while simultaneously fostering entrepreneurial skills, innovation capacity, and teamwork. The event was structured during a whole day around key phases, including initial training, challenge presentation, ideation, prototyping, and final project presentation, simulating real-world innovation processes. A quantitative research approach was adopted through the administration of a post-event questionnaire to participating students. The survey aimed to assess the perceived development of both technical and transversal competencies identified by the World Economic Forum, including creativity, communication, adaptability, and problem-solving—skills highlighted as critical for future employability. The findings suggest that participation in the hackathon significantly contributed to the development of entrepreneurial attitudes and a broader set of personal and behavioral competencies. Additionally, students reported increased confidence in engaging with technological concepts such as robotics, despite their non-STEAM background. The collaborative and challenge-based nature of the hackathon environment proved particularly effective in stimulating innovation and experiential learning. This study reinforces the value of hackathons in the preparation of future professionals for responsible innovation. It also highlights their potential to bridge the gap between non-STEAM education and emerging technological domains, contributing to more holistic and future-oriented entrepreneurial education models.

Keywords: Hackathons, Entrepreneurship, Non-STEAM Students, Innovation and Technology, World Economic Forum Skills

1. Introduction

The accelerating pace of digital transformation has fundamentally reshaped the demands placed upon higher education graduates. As automation, artificial intelligence and emerging technologies progressively reconfigure labour markets, the competencies required for professional success are shifting in both nature and urgency. According to the Future of Jobs Report (World Economic Forum, 2023), employers anticipate that 44% of workers' core skills will be disrupted within five years, with analytical thinking, creative reasoning, technological literacy, resilience and adaptability identified as the most critical capabilities for the near-future workforce. Self-efficacy skills — including curiosity and lifelong learning, and motivation and self-awareness — have also emerged as growing priorities, reflecting the increasing premium placed on workers capable of adapting to continuously disrupted workplaces (World Economic Forum, 2023). These developments place higher education institutions at a crossroads: traditional curricula, largely designed around knowledge transmission, are proving increasingly insufficient to prepare graduates for a complex and volatile professional environment (Baierl and Thamm, 2023).

This challenge is particularly acute for students enrolled in non-STEAM (Science, Technology, Engineering, Arts and Mathematics) programmes, fields such as management, social services, communication or health sciences, where engagement with technological and entrepreneurial domains has historically been limited. Yet the boundaries between technical and non-technical professional roles are becoming increasingly blurred, and entrepreneurial thinking, digital fluency and the capacity to collaborate across disciplinary boundaries are no longer the exclusive province of engineers or computer scientists (Garcez, Franco and Silva, 2023). Entrepreneurship education (EE) has emerged as a pivotal response to this challenge, evolving considerably

beyond narrowly vocational frameworks centred on business plan development and towards broader educational models that cultivate entrepreneurial mindsets, attitudes and behaviours across all fields of study (Komodromos, 2025). Research grounded in social learning theory further underscores that entrepreneurial competencies are not innate but are developed through structured practice, observation, mentorship and active participation in entrepreneurial ecosystems — findings that carry significant implications for the design of EE programmes targeting non-STEAM student populations (Rocha et al., 2024).

In this context, experiential and challenge-based learning methodologies have gained growing recognition as more effective approaches to developing the transversal competencies demanded by contemporary employers. Hackathons have emerged as one of the most prominent expressions of this pedagogical shift. Originally rooted in software development culture, they have evolved considerably in scope and format and are now widely adopted across disciplines and institutional contexts as tools for stimulating creativity, entrepreneurial thinking and teamwork (Schulten and Chounta, 2024). Hackathons vary in duration and structure — from single-day events to 48-hour marathons — but share a common emphasis on collaborative challenge-framing, rapid ideation, prototyping and public presentation, which closely mirrors the conditions under which entrepreneurial competencies are naturally activated.

The empirical literature consistently demonstrates that hackathon participation fosters a broad spectrum of competencies. Studies report improvements in teamwork, creativity, communication and real-world problem-solving, making learning more engaging and practically relevant (Oyetade, Zuva and Harmse, 2024). Surendran et al (2023) found that extracurricular hackathons significantly enhance students' awareness of personal and professional skills — including ideation, product development, leadership, resilience and teamwork — whilst also positively impacting employability and entrepreneurial competencies. Szymanska et al. (2020) demonstrated that a single hackathon event can outperform semester-long entrepreneurship courses in developing entrepreneurial self-efficacy, a key antecedent of entrepreneurial intention and behaviour. More recently, hackathons have been linked to the development of technological entrepreneurship, with Grigoreva et al`s (2024) finding that, under certain conditions, hackathon outcomes extend beyond immediate learning gains to become drivers for student entrepreneurial ventures. The challenge-based structure of hackathons also aligns naturally with the EntreComp framework (European Commission, 2016), which identifies ideas and opportunities, resources, and into action as the three core areas of entrepreneurial competence to be cultivated across educational contexts (Eimler and Straßmann, 2023).

Despite this growing body of evidence, important gaps remain. Much of the existing research on educational hackathons has focused on students with technical or STEAM backgrounds, leaving underexplored the question of how such events affect students from non-technical disciplines. Moreover, the systematic assessment of learning outcomes — particularly in relation to internationally recognised competency frameworks — continues to vary considerably across studies. There is therefore a need for empirically grounded research that examines the impact of structured hackathon experiences on non-STEAM student populations, explicitly linking outcomes to established employability frameworks and employing rigorous statistical analysis to substantiate perceived competency development. It is within this context that the present study is positioned. This paper reports on the Digit'all MakerDay, a full-day hackathon designed for and implemented with approximately 200 students enrolled in non-STEAM professional higher education programmes at IPCA, in Portugal. The event introduced participants to emerging technological fields, including robotics, whilst creating conditions for the development of entrepreneurial skills, innovation capacity and collaborative competencies. Through a quantitative approach combining pre- and post-event questionnaires, this study examines participants' perceptions of competency development aligned with the World Economic Forum (2023) skills framework, analyses whether hackathon participation produced statistically significant changes in entrepreneurial attitudes, and identifies the key predictors of overall participant satisfaction.

2. Methodology

The present study adopts a quantitative research approach, based on the administration of a structured questionnaire to higher education students. Data collection was carried out in March 2026, within the context of the Digit'all MakerDay — Applied Robotics in Industry hackathon event, held at IPCA, in Portugal.

Data collection was conducted in two stages. In the pre-event phase, 137 students enrolled in Professional Higher Technical Courses, representing different programme areas, completed the questionnaire. In the post-event phase, 85 students completed the questionnaire. To enable longitudinal tracking of individual responses between the two phases, participants were asked to enter their student identification number as an anonymous

linking code, ensuring that pre- and post-event responses from the same individual could be matched for paired analyses whilst preserving confidentiality. The difference between pre- and post-event response rates (137 vs. 85) is attributable to voluntary participation in the post-event phase and to students who were absent or chose not to complete the second questionnaire. Paired analyses — namely the Wilcoxon signed-rank test — were conducted exclusively on the subset of matched responses (n = 85), whilst descriptive analyses of pre-event data draw on the full pre-event sample (n = 137).

The data collection instrument consisted of a structured questionnaire administered in two stages: before and after the hackathon event. The pre-event section focused on participants' initial expectations regarding the hackathon experience and their anticipated development of entrepreneurial competencies. The post-event section assessed participants' perceptions of the experience across several dimensions, including digital skills, pitch presentation abilities, and the expected impact on their academic and professional trajectory. The entrepreneurial competencies assessed were based on the framework established by the World Economic Forum (2023), and motivational factors underlying participation were also explored.

Data collection was conducted via a QR code made available to participants after the event. The collected data were subsequently processed and analysed using descriptive statistical techniques, with the aim of characterising the sample and identifying patterns in students' perceptions. Where appropriate, inferential comparative analyses were conducted between the pre- and post-event questionnaire responses, including the Wilcoxon signed-rank test for paired samples, Spearman correlation analysis, and multiple linear regression, to identify the key predictors of overall participant satisfaction. Regression analyses were conducted on the post-event dataset (n = 85), as all predictor variables — facilitator support quality, contribution of guidance to the final pitch, final project presentation experience, and contact with industry partner ESI Robotics — were measured exclusively in the post-event questionnaire. Listwise deletion was applied, resulting in a final analytical sample of 85 participants for the regression models.

3. Results

3.1 Descriptive Analysis of General Dimensions

Table 1 presents the descriptive statistics relating to participants' perceptions across the key dimensions of the hackathon experience. Overall, the results reveal positive evaluations across all variables analysed, with mean scores exceeding 3.7 on a five-point Likert scale (1 = very poor; 5 = excellent).

Table 1: Descriptive statistics: general evaluation of the hackathon experience

Variable	Mean	Median	SD	Min	Max	Q1	Q2	Q3
To what extent were your initial expectations of the hackathon met?	3.80	4.00	0.870	1	5	3.00	4.00	4.00
How do you evaluate the quality of support provided by the facilitators?	3.96	4.00	0.837	2	5	3.00	4.00	5.00
How did the guidance received at the hackathon contribute positively to the final pitch?	3.80	4.00	0.856	2	5	3.00	4.00	4.00
How do you evaluate the contribution of the topics covered to your personal competency development?	3.79	4.00	0.952	1	5	3.00	4.00	5.00
How do you evaluate the contribution of the topics covered to your professional and academic development?	3.81	4.00	0.809	2	5	3.00	4.00	4.00
How do you evaluate the experience of presenting the final project at the hackathon?	3.74	4.00	0.897	1	5	3.00	4.00	4.00
How do you evaluate the contact with ESI Robotics for your professional future?	3.81	4.00	0.805	2	5	3.00	4.00	4.00

The highest mean was recorded for the quality of facilitator support (M = 3.96, SD = 0.837), suggesting a highly favourable perception of the mentoring provided during the event. The contribution to professional and academic development (M = 3.81, SD = 0.809) and the contact with industry partner ESI Robotics (M = 3.81, SD = 0.805) were also rated highly, indicating that participants recognised concrete practical value and potential career impact from the experience. The realisation of initial expectations (M = 3.80, SD = 0.870) and the contribution of guidance to the final pitch (M = 3.80, SD = 0.856) obtained equally positive scores. The variable

with the greatest response dispersion was the contribution to personal development (SD = 0.952), suggesting more differentiated perceptions of the hackathon's personal impact among participants. The experience of presenting the final project recorded the lowest mean (M = 3.74, SD = 0.897), though this remained within the positive range; this result may reflect varying levels of confidence and prior experience with public presentations. Notably, the median was 4 across all variables, with the majority of responses concentrated between values 3 and 5, reinforcing the overall pattern of positive perceptions.

3.2 Evolution of Perceived Entrepreneurial Competencies Between Pre- and Post-Hackathon

Prior to the hackathon, participants reported favourable expectations regarding the overall experience (M = 3.55, SD = 0.730) and the final project presentation/pitch (M = 3.29, SD = 0.729). Following the event, both dimensions recorded higher mean scores — the realisation of initial expectations (M = 3.76, SD = 0.951) and the final presentation experience (M = 3.75, SD = 1.036). Table 2 presents the descriptive comparison between pre- and post-event assessments.

Table 2: Pre- and post-hackathon descriptive comparison

	Pre-Hackathon: General expectation	Pre-Hackathon: Pitch expectation	Post-Hackathon: Expectations met	Post-Hackathon: Pitch experience
Mean	3.55	3.29	3.76	3.75
Median	4	3	4	4
SD	0.730	0.729	0.951	1.036
Min	2	2	1	1
Max	5	5	5	5
Q1	3	3	3	3
Q2	4	3	4	4
Q3	4	4	5	5

The Wilcoxon signed-rank test for paired samples was applied to assess pre- to post-hackathon differences. No statistically significant difference was found between initial expectations and their subsequent realisation ($Z = -1.455$; $p = 0.146$), suggesting that the hackathon broadly met participants' prior expectations. However, a statistically significant difference was identified between the initial expectation regarding the pitch presentation and the actual experience of presenting the final project ($Z = -3.192$; $p = 0.001$), indicating that the real pitch experience substantially exceeded participants' initial expectations. This interpretation is reinforced by the rank analysis, which revealed a substantially higher number of positive ranks (n = 28) compared to negative ranks (n = 8) for the pitch experience variable.

Regarding the entrepreneurial competencies identified by the World Economic Forum (2023), participants highlighted — prior to the hackathon — creative thinking (n = 37), curiosity and lifelong learning (n = 28) and analytical thinking (n = 24) as the competencies they most expected to develop. Following the event, creative thinking remained the most valued competency (n = 36), but notable increases were observed in resilience, flexibility and agility (from n = 17 to n = 25), technological literacy (from n = 14 to n = 17) and empathy and active listening (from n = 15 to n = 19). These results suggest that the practical and collaborative nature of the hackathon contributed to broadening participants' awareness of transversal competencies associated with adaptability, interpersonal interaction and technological capacity.

3.3 Relationship Between Initial Expectations and Overall Satisfaction

Spearman correlation analysis revealed a strong and statistically significant positive association between the realisation of initial expectations and overall participant satisfaction ($\rho = 0.704$; $p < 0.001$). This result indicates that participants whose expectations were more fully met tended to report higher levels of overall satisfaction with the experience. The magnitude of the correlation suggests that expectation management and fulfilment constitute a central factor in participants' positive evaluation of the hackathon.

3.4 Relationship Between Personal Development and Professional/Academic Competency Development

A strong and statistically significant positive correlation was found between the perceived contribution of the hackathon to personal competency development and its contribution to professional and academic competencies ($\rho = 0.791$; $p < 0.001$). This result suggests that participants tend to perceive personal and professional/academic development as interlinked dimensions of the formative experience provided by the hackathon: the more positively participants evaluated the personal impact, the more positively they also tended to evaluate the academic and professional impact.

3.5 Variables with the Greatest Influence on Overall Participant Satisfaction

Spearman correlation analysis revealed moderate to strong positive associations between overall satisfaction and all variables examined: facilitator support quality ($\rho = 0.608$; $p < 0.001$), contribution of guidance to the final pitch ($\rho = 0.679$; $p < 0.001$), final project presentation experience ($\rho = 0.643$; $p < 0.001$), and contact with industry partner ESI Robotics ($\rho = 0.596$; $p < 0.001$).

Given that all variables entering the regression model were drawn from the post-event questionnaire, the analysis was conducted on the post-event sample ($n = 85$). After listwise deletion of cases with missing values on any of the model variables, the effective analytical sample comprised 85 participants, consistent with the degrees of freedom reported in the regression output ($F(4,80)$ and $F(2,82)$).

A multiple linear regression analysis was subsequently conducted to identify which variables had the greatest predictive capacity for overall satisfaction. The full model was statistically significant ($F(4,80) = 23.721$; $p < 0.001$), explaining approximately 54.3% of the variance in overall satisfaction ($R^2 = 0.543$). However, only two variables contributed significantly in the final model: the perceived contribution of guidance to the final pitch ($\beta = 0.291$; $p = 0.050$) and the final project presentation experience ($\beta = 0.281$; $p = 0.027$). Facilitator quality and industry contact did not yield significant independent contributions when considered alongside the remaining variables.

A more parsimonious regression model, retaining only the two significant predictors, was also estimated. This model maintained high statistical significance ($F(2,82) = 45.857$; $p < 0.001$) and explained approximately 52.1% of the variance in overall satisfaction. Table 3 presents the results of this parsimonious model.

Table 3: Parsimonious regression model: predictors of overall satisfaction

Predictor Variable of Overall Satisfaction	Coefficient (β)	P value (variable)	p value (model)	R^2
Constant	0.896	0.004	< 0.001	0.521
Contribution of hackathon guidance to the final pitch	0.422	0.001		
Experience of presenting the final project	0.322	0.005		

These results confirm that the most determinant factors for overall participant satisfaction were the perceived utility of the guidance received during the hackathon for the preparation of the final pitch ($\beta = 0.428$; $p = 0.001$) and the final project presentation experience ($\beta = 0.343$; $p = 0.005$). The practical component associated with the development and delivery of the pitch thus appears to occupy a central role in participants' holistic evaluation of the hackathon experience.

4. Discussion

The results of this study are broadly consistent with the existing literature on the educational value of hackathons, whilst offering novel evidence specific to non-STEAM student populations. Across all dimensions evaluated, mean scores exceeded 3.7 on a five-point scale — a pattern of favourable perception that mirrors findings reported by Surendran et al (2023), whose extracurricular hackathon study similarly documented high participant appreciation of personal skill development, leadership and teamwork. The highest-rated dimension — facilitator support quality ($M = 3.96$) — reinforces the argument of Kolb and Kolb (2022) that a skilled mediator between challenge and action is a central determinant of experiential learning quality. The perceived contribution to professional and academic development ($M = 3.81$) and the industry contact with ESI Robotics ($M = 3.81$) further suggest that participants recognised concrete, future-oriented value in the experience,

corroborating evidence that industry-embedded hackathon formats strengthen the perceived connection between academic training and professional practice (Grigoreva et al, 2024).

The pre- to post-event analysis produced two complementary findings. The absence of a statistically significant difference between initial expectations and their realisation ($Z = -1.455$; $p = 0.146$) indicates that the hackathon broadly met what participants anticipated. By contrast, a statistically significant improvement was found in the pitch presentation experience relative to prior expectations ($Z = -3.192$; $p = 0.001$), with positive ranks substantially outnumbering negative ones ($n = 28$ vs. $n = 8$). This finding is particularly meaningful for non-STEAM students, who typically have limited exposure to entrepreneurial public presentation. It resonates directly with Szymanska et al. (2020), who demonstrated that immersive, time-pressured hackathon settings generate marked gains in entrepreneurial self-efficacy by pushing participants beyond their comfort zone through action rather than instruction.

The shifts observed in World Economic Forum-aligned entrepreneurial competencies between pre- and post-event further enrich this picture. Whilst creative thinking remained the most valued competency at both moments, post-event data showed notable increases in resilience, flexibility and agility (from $n = 17$ to $n = 25$), technological literacy (from $n = 14$ to $n = 17$) and empathy and active listening (from $n = 15$ to $n = 19$). These shifts suggest that the collaborative, challenge-based format expanded participants' awareness of relational and adaptive competencies — precisely those that the World Economic Forum (2023) identifies as among the fastest-growing in labour market importance. This pattern is consistent with Oyetade, Zuva and Harmse (2024), who argue that hackathon participation activates competency awareness that extends beyond technical problem-solving to encompass the interpersonal and adaptive dimensions of professional practice.

The regression analysis identified guidance for the pitch ($\beta = 0.428$; $p = 0.001$) and the final presentation experience ($\beta = 0.343$; $p = 0.005$) as the two significant predictors of overall satisfaction, together explaining 52.1% of its variance. This finding positions the pitch as the integrative capstone of the hackathon — the moment in which participants synthesise their learning and demonstrate their competencies publicly. It aligns with Grigoreva et al (2024) argument that the final presentation stage is pivotal in converting hackathon participation into durable entrepreneurial attitudes, and with the strong correlation found between personal and professional development ($\rho = 0.791$; $p < 0.001$), which suggests that students experience these as inseparable dimensions of the same formative process — a view consistent with holistic models of entrepreneurship education such as EntreComp (European Commission, 2016).

5. Conclusion

This study provides empirical evidence that a structured, single-day hackathon can serve as an effective mechanism for developing entrepreneurial and technological competencies among non-STEAM higher education students — a population underrepresented in the existing hackathon literature. Drawing on pre- and post-event data from 137 students and 85 students at IPCA respectively, the findings demonstrate that participants evaluated the experience positively across all dimensions analysed, with the pitch-related components emerging as the primary drivers of overall satisfaction, accounting for over half of its variance.

Three principal contributions stand out. First, the pitch presentation experience — both the guidance received throughout the process and the act of presenting publicly — is the most decisive factor in shaping participants' holistic evaluation of the hackathon, with direct implications for event design: structured coaching and mentoring throughout the ideation-to-presentation pipeline should be treated as a non-negotiable feature of hackathon formats targeting non-STEAM students. Second, hackathon participation broadened participants' perceived entrepreneurial competencies, with a statistically significant improvement in the pitch experience and notable post-event increases in resilience, technological literacy and empathy — competencies explicitly aligned with the World Economic Forum's (2023) future-of-work priorities. Third, the strong integration between personal and professional development ($\rho = 0.791$) reinforces the value of holistic, experiential approaches to entrepreneurship education across all disciplinary contexts.

This study is subject to certain limitations. The sample is drawn from a single institution and a specific programme type, which constrains the generalisability of the findings. Outcomes are based on self-reported perceptions rather than objective skill assessment, and the absence of a longitudinal follow-up precludes conclusions about the durability of the observed effects over time. Future research should employ longitudinal designs, comparative samples across disciplines and institutions, and objective performance measures to further validate and extend these findings. Nonetheless, the evidence presented here supports the value of hackathons

as inclusive pedagogical tools capable of bridging the gap between non-STEAM education and the entrepreneurial and technological competency demands of a digitally transformed economy.

Ethics Declaration

This research adhered to all ethical standards required for studies involving human participants. Prior to the administration of the questionnaire, ethical clearance was sought and obtained from the relevant institutional ethics committee. Participants were fully informed about the nature and purpose of the study and provided their consent to participate voluntarily. Anonymity and confidentiality were ensured throughout the data collection and analysis process.

A formal reference to the ethical approval granted for this study is included as attached to this paper.

AI Declaration

Artificial Intelligence (AI) tools were used in the development of this paper to support language refinement and structural editing. Specifically, ChatGPT by OpenAI was employed to assist with the rephrasing of academic text, grammar correction, and improving the clarity and coherence of certain sections, such as the discussion and conclusion.

All substantive academic content, including research design, data analysis, interpretation of findings, and critical arguments, was developed by the authors. The outputs generated by the AI tool were carefully reviewed, edited, and integrated into the manuscript with full academic oversight to ensure accuracy, originality, and scholarly integrity.

Designing Entrepreneurial Viability for Mid-Career Entry under Static Uncertainty

Yohei Sato
Chiba University, Chiba,Japan

yohei.sato@chiba-u.jp

Abstract: Regional innovation ecosystems increasingly depend on experienced human capital, yet mid-career professionals remain systematically underrepresented in entrepreneurial entry. Existing entrepreneurship theories—from Knightian uncertainty to effectuation and lean experimentation—implicitly assume that entrepreneurial failure is reversible and that uncertainty can be reduced through action. While these assumptions hold for early-career founders, they become problematic for individuals embedded in dense life-course commitments. This paper argues that mid-career non-entry is not primarily psychological but structural, driven by static uncertainty—action-independent risks such as income discontinuity, constrained re-employment, and identity loss. We introduce the Life-Aligned Entrepreneurship Framework (LAEF), distinguishing between dynamic uncertainty (reducible through action) and static uncertainty (irreducible without institutional intervention). Under high commitment conditions, individuals optimize not expected value but survival viability under a ruin constraint. Building on this framework, we propose Static Uncertainty Design (SUD), a set of institutional mechanisms—administrative, contractual, and epistemic—that reduce irreversibility and enable entrepreneurial action. Using a qualitative case study of a regional entrepreneurship program in Japan, we show that mid-career individuals prioritize resolving static uncertainty before engaging in opportunity exploration. The paper contributes to entrepreneurship and innovation policy by reframing ecosystems as systems of downside-risk allocation and by offering actionable design principles for reducing downside risk and mobilizing experienced human capital.

Keywords: Mid-career Entrepreneurship; Regional Ecosystems; Institutional Design; Uncertainty; Entrepreneurship Policy

1. Introduction

Entrepreneurship is widely regarded as a key driver of innovation and regional renewal. Yet a persistent paradox remains: mid-career professionals—those with the greatest expertise and networks—are systematically less likely to initiate new ventures.

Conventional explanations emphasize opportunity cost or risk aversion. However, these accounts are insufficient. Mid-career individuals are often better equipped to manage uncertainty; the issue is not capability but feasibility.

Existing entrepreneurship theories conceptualize uncertainty as reducible through action (Knight, 1921; Sarasvathy, 2001; Ries, 2011; Dixit & Pindyck, 1994). These frameworks implicitly assume reversibility: that failed entrepreneurs can recover through re-entry or iteration. While plausible for early-career actors, this assumption becomes theoretically fragile under conditions where failure entails irreversible consequences.

This limitation is not merely empirical but conceptual. By treating uncertainty as primarily action-dependent, existing theories overlook a class of risks that persist regardless of entrepreneurial behavior. As a result, they systematically under-explain non-entry among individuals facing high structural exposure.

Life-course theory (Elder, 1998) highlights how accumulated obligations—financial, familial, and professional—shape decision-making. Combined with institutional rigidities such as limited labor mobility, these conditions create risks that cannot be mitigated through entrepreneurial action.

We conceptualize these as static uncertainty: action-independent risks that introduce the possibility of irreversible loss. This fundamentally shifts entrepreneurial decision-making from expected value maximization to survival under a ruin constraint.

To address this, we introduce the Life-Aligned Entrepreneurship Framework (LAEF), distinguishing static and dynamic uncertainty, and propose Static Uncertainty Design (SUD) as an institutional solution. Integrating entrepreneurship, institutional theory, and design science, we reframe ecosystems as systems of downside-risk allocation, illustrated through a case study in Japan.

This paper makes three contributions to the literature.

First, it introduces the concept of static uncertainty, extending existing theories that treat uncertainty as primarily action-dependent by identifying a class of risks that are structurally embedded and irreducible through entrepreneurial action.

Second, it develops the Life-Aligned Entrepreneurship Framework (LAEF), which reconceptualizes entrepreneurial decision-making under high commitment conditions as a problem of survival viability under a ruin constraint rather than expected value maximization.

Third, it proposes Static Uncertainty Design (SUD) as an institutional approach to reducing irreversibility, offering a set of actionable design mechanisms that enable entrepreneurial entry without requiring changes in individual risk preferences.

Together, these contributions shift the focus of entrepreneurship research from opportunity discovery to viability design under structural constraints.

2. Conceptual Framework: Static Uncertainty and Entrepreneurial Feasibility

2.1 Entrepreneurship Under Uncertainty

Uncertainty is a foundational concept in entrepreneurship research. Knight (1921) distinguished between measurable risk and unquantifiable uncertainty, positioning entrepreneurs as actors who operate under conditions where probabilities cannot be known in advance. This perspective highlights the inherently uncertain nature of entrepreneurial activity.

Subsequent research has focused on how entrepreneurs respond to uncertainty. McMullen and Shepherd (2006) conceptualize entrepreneurial action as a process triggered when individuals perceive both the presence of uncertainty and the desirability of resolving it. This emphasizes the role of perception and judgment in entrepreneurial decision-making.

Effectuation theory (Sarasvathy, 2001) further develops this perspective by proposing that entrepreneurs begin with available means and iteratively co-create opportunities through stakeholder interaction. The principle of affordable loss suggests that entrepreneurs limit their exposure by committing only what they can afford to lose.

Similarly, the lean startup approach (Ries, 2011) emphasizes rapid experimentation and validated learning, allowing entrepreneurs to test hypotheses and adapt their strategies under uncertainty. Real options theory (Dixit & Pindyck, 1994; McGrath, 1999) complements these approaches by framing entrepreneurial decisions as staged investments that preserve flexibility.

Despite their differences, these frameworks share a common assumption: uncertainty can be managed and reduced through action. This assumption underlies the logic of experimentation, iteration, and adaptive learning.

2.2 Static vs. Dynamic Uncertainty

While existing frameworks emphasize action-dependent uncertainty, they do not fully account for uncertainties that persist regardless of entrepreneurial behavior. This paper introduces a distinction between dynamic and static uncertainty.

Dynamic uncertainty arises from the external environment of the venture, including market demand, technological feasibility, and competitive dynamics. It is inherently reducible through experimentation and learning.

Static uncertainty, in contrast, arises from the entrepreneur's embeddedness in institutional and life-course structures. It includes risks such as income discontinuity, loss of professional identity, reduced employability, and constraints imposed by family and financial commitments.

A key characteristic of static uncertainty is its irreducibility through entrepreneurial action. A founder may validate a business model or improve product-market fit, but this does not reduce the risk of career discontinuity or long-term income instability.

From an institutional perspective (North, 1990; Scott, 2014), static uncertainty reflects the structure of labor markets, social norms, and organizational practices. It is not merely an individual concern but a systemic feature of the environment.

Static uncertainty differs from general uncontrollable risk in that it is structurally embedded in institutional and life-course conditions and remains invariant to entrepreneurial action.

2.3 The Ruin Constraint

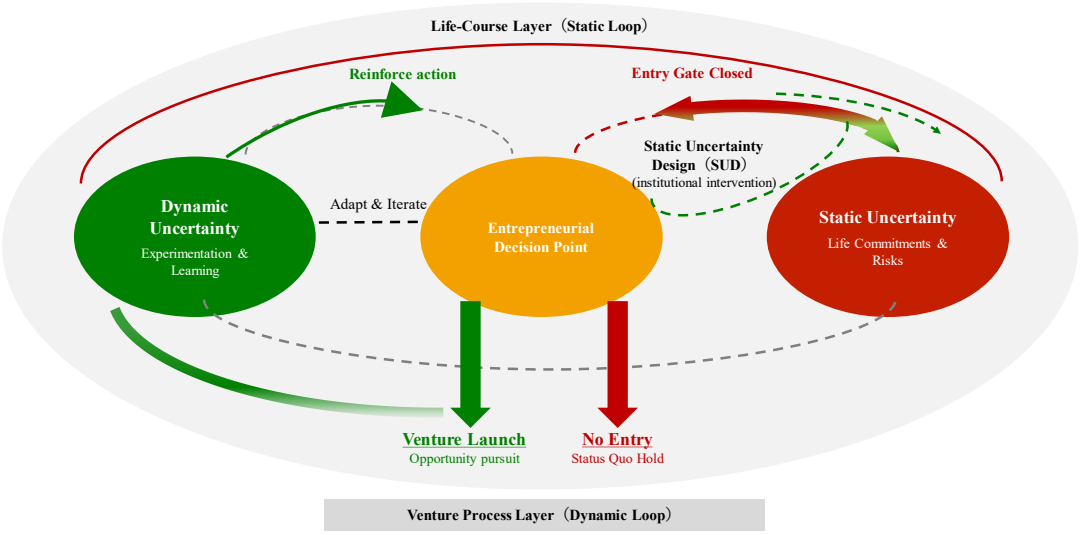
Under conditions of low commitment, individuals may evaluate entrepreneurial opportunities based on expected value. However, when potential losses threaten long-term viability, decision-making shifts toward avoiding catastrophic outcomes.

We conceptualize this as a ruin constraint: individuals will engage in entrepreneurship only if the probability of falling below a minimum acceptable level of life resources remains sufficiently low.

This concept aligns with real options reasoning (Dixit & Pindyck, 1994), where irreversible investments are approached cautiously under uncertainty. However, in the context of mid-career entrepreneurship, the irreversibility extends beyond financial capital to encompass life-course consequences.

The presence of a ruin constraint fundamentally alters decision-making behavior. Individuals prioritize stability over potential gains, and even highly attractive opportunities may be rejected if they involve unacceptable downside risk.

2.4 Dual-Loop Model of Entrepreneurial Action



The distinction between static and dynamic uncertainty leads to a dual-loop model of entrepreneurial action.

The Static Loop involves assessing and managing life-related constraints, including income stability, career continuity, and family obligations. The Dynamic Loop involves opportunity exploration, experimentation, and business model development.

For mid-career individuals, the Static Loop precedes the Dynamic Loop. Entrepreneurial action begins only after static uncertainty has been sufficiently addressed.

This sequencing explains observed behavioral patterns in mid-career entrepreneurship, where individuals delay business development activities while focusing on securing structural stability.

Figure 1. Dual-loop model illustrating how static and dynamic uncertainty shape entrepreneurial feasibility

3. Static Uncertainty Design (SUD)

3.1 From Individual Risk Management to Institutional Design

The preceding discussion established that static uncertainty represents a structural constraint that cannot be reduced through entrepreneurial action alone. Existing entrepreneurship frameworks emphasize behavioral responses such as experimentation, affordable loss, and staged commitment, but these approaches presuppose that uncertainty is reducible through action. Static uncertainty, by contrast, persists independently of entrepreneurial learning because it is rooted in employment systems, income structures, and life-course commitments.

This shifts the analytical focus from the entrepreneur to the institutional environment in which entrepreneurial decisions are embedded. Rather than asking how individuals can better tolerate risk, the relevant question becomes how institutional arrangements can reduce structural exposure.

This perspective aligns with institutional theory, which emphasizes that economic behavior is shaped by formal rules, informal norms, and organizational practices (North, 1990; Scott, 2014). It also resonates with design science, which treats social systems as objects of intentional design aimed at improving feasible action (Hevner et al., 2004; Simon, 1996).

We therefore define Static Uncertainty Design (SUD) as the deliberate construction of institutional mechanisms that reduce irreversibility in entrepreneurial entry by lowering exposure to static uncertainty. SUD does not operate by increasing expected returns or encouraging greater risk tolerance. Rather, it changes the structure of downside risk, transforming entrepreneurship from a high-stakes binary decision into a more reversible and staged process.

3.2 A Typology of Static Uncertainty Design

To operationalize SUD, we propose three complementary mechanisms: administrative, contractual, and epistemic SUD. Each addresses a distinct dimension of irreversibility.

3.2.1 Administrative SUD: Identity and Employment Continuity

Administrative SUD refers to institutional arrangements that preserve professional identity and continuity with prior employment. In many labor markets, leaving employment entails not only income loss but also identity disruption and reduced re-entry prospects.

Mechanisms such as leave-of-absence programs, guaranteed re-entry pathways, and dual-role arrangements mitigate these risks by ensuring that entrepreneurial engagement does not require a complete break from existing career trajectories.

3.2.2 Contractual SUD: Income Stabilization and Risk Sharing

Contractual SUD addresses the financial dimension of static uncertainty. For many mid-career individuals, the central concern is not the absence of upside potential but the possibility of unacceptable downside loss through income discontinuity.

Institutional mechanisms such as minimum income guarantees, hybrid employment contracts, and phased commitment models help stabilize income and distribute downside risk across organizations and support systems. These arrangements reduce the likelihood of breaching the ruin constraint during the early stages of venture development.

3.2.3 Epistemic SUD: Redeployability of Outcomes

Epistemic SUD addresses the long-term consequences of entrepreneurial failure by increasing the future value of entrepreneurial experience.

Mechanisms such as formal skill certification, recognition of entrepreneurial experience, and structured network development improve the redeployability of human capital. By making entrepreneurial activity legible and transferable beyond the venture itself, epistemic SUD lowers the perceived long-term cost of failure.

3.3 SUD as Coordinated Ecosystem Design

Although the three dimensions of SUD can be analytically distinguished, their effectiveness depends on coordinated implementation. Static uncertainty is multidimensional, and addressing only one source of downside exposure may be insufficient to enable entrepreneurial action.

For example, income stabilization without credible career reversibility may still leave individuals exposed to long-term identity loss. Likewise, employment continuity without minimum financial security may not satisfy the ruin constraint. Effective entrepreneurial feasibility therefore depends on institutional complementarity across multiple domains.

This highlights the role of entrepreneurial ecosystems not simply as providers of resources, but as coordinators of structural feasibility. Traditional ecosystem approaches emphasize funding, mentorship, and infrastructure.

From the perspective of static uncertainty, however, the more fundamental issue is whether individuals can access these resources without incurring unacceptable irreversible risk.

SUD therefore reframes entrepreneurial ecosystems as systems for configuring downside-risk allocation rather than merely opportunity support.

3.4 Design Principles for Reducing Static Uncertainty

Three design principles follow from this framework.

First, reversibility must be structurally credible.

Entrepreneurial flexibility cannot be assumed behaviorally; it must be institutionally supported through mechanisms that preserve employment continuity and future options.

Second, downside risk should be distributed rather than concentrated.

Without SUD, individuals bear the full burden of failure. Effective ecosystems reduce this concentration by sharing risk across employers, governments, and support organizations.

Third, entrepreneurial commitment should be staged rather than binary.

Traditional models often assume a sharp transition from employment to venture creation. SUD enables gradual engagement, allowing individuals to test opportunities without fully sacrificing livelihood stability.

Taken together, these principles shift entrepreneurial feasibility from an individual psychological issue to a system-level design problem. Under high static uncertainty, entrepreneurial participation depends less on willingness to take risks than on whether institutions make action survivable.

4. Case Study: Static Uncertainty and Mid-Career Entrepreneurial Entry in Japan

4.1 Research Context

To illustrate the role of static uncertainty in shaping entrepreneurial entry, this study examines a regional entrepreneurship support program in Japan designed to attract mid-career professionals into venture creation. The program targeted individuals primarily between their mid-30s and early 50s, many of whom had established careers in corporate organizations or public institutions.

Japan provides a suitable high-static-uncertainty context due to rigid employment structures, limited labor mobility, and strong organizational attachment, all of which increase the life-course costs of entrepreneurial failure.

4.2 Methodological Approach

This study adopts a qualitative case study approach to examine decision-making processes among mid-career individuals under conditions of static uncertainty. Data were collected over a four-month period from November 2025 to February 2026 through program observation and semi-structured interviews with eight participants.

The eight participants were selected from an entrepreneurship training program administered by a local government, which had received twenty applications in total. Because the author served as a mentor for the program, he conducted the study using these participants as the focal cases.

Using an abductive coding approach, the analysis focused on how participants sequenced life-constraint evaluation (static uncertainty) and opportunity exploration (dynamic uncertainty). Rather than seeking statistical generalization, the study provides process-level evidence for theory building in an underexplored domain.

4.3 Pre-Entry Phase: The Dominance of the Static Loop

A consistent pattern across participants was that life-related constraints remained salient as they considered potential business opportunities. In the early stages of the program, participants also spent time reflecting on their personal and structural circumstances, including household finances, career continuity, and family responsibilities.

Key concerns included minimum income requirements for household stability, financial obligations such as mortgages and education costs, the feasibility of re-entering the labor market after failure, and the impact of entrepreneurial activity on family members. Importantly, these considerations were largely independent of the specific opportunities under discussion. Participants often expressed interest in entrepreneurial ideas but hesitated to engage more actively until they had a clearer sense of these constraints.

This behavior reflects the operation of the Static Loop described in the conceptual framework. Rather than immediately engaging in opportunity evaluation or experimentation, participants first sought to understand whether entrepreneurial entry was compatible with their broader life conditions. As one participant noted, “The business idea is important, but I’m worried about what happens if I fail.”

4.4 Negotiation of Constraints: Toward Bounded Risk

As participants progressed through the program, a second phase emerged characterized by active negotiation of constraints. Rather than treating static uncertainty as fixed, participants sought ways to reduce downside exposure through flexible work arrangements, return options with employers, household financial adjustments, and external support.

These activities did not directly advance business development. Instead, they were aimed at transforming unbounded risk into bounded risk by reducing the probability of catastrophic outcomes to an acceptable level.

4.5 Transition to the Dynamic Loop

A notable shift in behavior occurred once participants achieved sufficient clarity regarding their downside exposure. At this point, attention moved from life-related constraints to business-related activities such as market exploration, early prototyping, partner engagement, and business model iteration.

These activities are characteristic of the Dynamic Loop and were largely absent in earlier stages. This transition suggests that engagement with dynamic uncertainty is contingent on the prior resolution of static uncertainty.

4.6 Variation in Outcomes

Not all participants moved toward venture formation during the program period. However, even among those whose plans had not yet solidified, engagement in the program followed a similar pattern. Participants who did not progress further at this stage often noted that unresolved static constraints made it difficult for them to move forward. In contrast, those who advanced toward venture creation had generally identified mechanisms that reduced their downside exposure.

This variation reinforces the paper’s central argument: entrepreneurial entry is shaped not only by opportunity quality or individual capability, but by the structure of downside risk faced by the individual.

4.7 Interpretation Through the Lens of SUD

The observed behaviors can be interpreted as informal attempts to implement elements of Static Uncertainty Design. Efforts to secure return options reflect administrative SUD, attempts to maintain partial income correspond to contractual SUD, and participation in programs that enhance skills and networks aligns with epistemic SUD.

However, these mechanisms were often incomplete or uncertain, limiting their effectiveness. Where more structured support was available, participants were more likely to transition toward entrepreneurial action.

4.8 Implications of the Case Study

The case supports the proposed framework by showing that mid-career entrepreneurial action is sequential: individuals first seek to reduce static uncertainty and only then engage dynamic uncertainty. The findings also suggest that institutional mechanisms materially shape this transition.

While based on a single exploratory case, the consistency of observed patterns indicates that static uncertainty provides a meaningful lens for understanding entrepreneurial feasibility under high-commitment conditions.

5. Implications: Reframing Entrepreneurial Ecosystems as Systems of Downside-Risk Design

5.1 From Resource Provision to Structural Feasibility

The findings suggest a fundamental shift in how entrepreneurial ecosystems should be understood. Existing approaches emphasize resources such as funding, mentorship, infrastructure, and networks to support venture creation by reducing dynamic uncertainty.

However, for mid-career professionals, these resource-based approaches are often insufficient. The main barrier is not a lack of capability or opportunity, but structural exposure created by static uncertainty. The core challenge is therefore not simply providing resources, but ensuring that individuals can access them without incurring unacceptable irreversible risk.

This requires moving from a resource-based to a feasibility-based view of ecosystems. In this view, ecosystem effectiveness depends less on the volume of support offered than on whether support can be accessed without violating survival constraints.

Entrepreneurial ecosystems fail not only when resources are absent, but when existing resources remain practically inaccessible under non-ruin conditions.

5.2 Implications for Ecosystem Design

Reframing ecosystems as systems of downside-risk design has several implications.

First, ecosystems must directly address static uncertainty by embedding elements of Static Uncertainty Design (SUD) into their core architecture rather than treating them as optional add-ons. Programs that include income support, employment flexibility, or re-entry pathways are more likely to attract and retain mid-career participants.

Second, ecosystems should be evaluated by their ability to reduce irreversibility. Traditional metrics such as startup counts or capital raised capture outcomes but not feasibility conditions. More relevant indicators may include access to partial-income pathways, availability of re-entry options, and the extent to which participation can occur without full livelihood disruption.

Third, ecosystem design must account for heterogeneity in life-course conditions. Early-career and mid-career individuals face fundamentally different constraints, and effective support systems must reflect this variation.

5.3 Policy Implications: From Incentives to Risk Redistribution

The analysis also has important implications for public policy. Many entrepreneurship policies assume that increasing incentives—such as grants, tax benefits, or subsidies—will increase entrepreneurial activity. While such measures may influence behavior at the margin, they do not resolve structural exposure created by static uncertainty.

For mid-career individuals, the key issue is not the attractiveness of potential gains, but whether potential losses are tolerable. Policies that increase upside without reducing downside are therefore unlikely to meaningfully change entry behavior.

Effective policy should instead focus on redistributing risk through mechanisms such as:

- Temporary leave arrangements for entrepreneurial activity
- Labor-market re-entry pathways
- Income stabilization during early venture stages
- Portability of benefits such as healthcare and pensions

These measures do not eliminate uncertainty but reduce the likelihood that entrepreneurial entry results in irreversible loss. In this sense, enabling entrepreneurship requires institutions to share downside risk rather than concentrate it on individuals.

5.4 Organizational Implications: The Role of Firms

Firms play an important but often overlooked role in entrepreneurial feasibility. For many mid-career professionals, leaving employment is itself a major source of static uncertainty. Organizational policies can therefore materially shape entrepreneurial entry.

Firms can contribute to SUD through:

- Sabbatical or entrepreneurial leave programs
- Hybrid internal–external work arrangements
- Recognition of entrepreneurial experience upon return

Such practices reduce the cost of entrepreneurial experimentation while preserving longer-term career viability.

From a strategic perspective, firms can view support for employee entrepreneurship not as a loss of talent, but as an investment in human capital and ecosystem development. This shifts the employment relationship from a zero-sum model toward a more dynamic and interconnected one.

5.5 Theoretical Implications for Entrepreneurship Research

The introduction of static uncertainty and SUD has several implications for entrepreneurship theory.

First, it challenges the dominant assumption that uncertainty is primarily dynamic and reducible through action. Distinguishing static from dynamic uncertainty clarifies why existing frameworks under-explain non-entry in high-commitment contexts.

Second, it extends the understanding of rationality in entrepreneurial decision-making. What is often interpreted as risk aversion may instead reflect rational behavior under a ruin constraint. Models of entrepreneurial entry should therefore better account for downside thresholds and survival considerations.

Third, this perspective connects entrepreneurship research with institutional theory and design science by framing entrepreneurial feasibility as a function of institutional arrangements rather than individual disposition alone.

5.6 Implications for Regional Development

From a regional development perspective, mobilizing mid-career professionals is critical because they possess domain expertise, managerial experience, and professional networks.

Yet without institutional support, this potential remains underutilized. Regions that successfully implement SUD are more likely to attract and activate experienced human capital.

This suggests that regional policy should prioritize institutional environments that enable entrepreneurial participation across life stages. Rather than focusing only on startups as economic units, policymakers should also focus on the conditions that make entrepreneurial entry viable for the people most capable of creating them.

6. Conclusion: Designing for Viability in Entrepreneurial Systems

This paper examined the underrepresentation of mid-career professionals in entrepreneurship and argued that it reflects structural constraints rather than individual risk preferences. Specifically, it identified static uncertainty—irreducible, life-course–embedded risks—as the primary barrier to entry.

By distinguishing static from dynamic uncertainty, the paper highlights a limitation in existing theories that assume uncertainty can be reduced through action. Under high commitment, decision-making is governed by a ruin constraint rather than expected value maximization.

The Life-Aligned Entrepreneurship Framework (LAEF) conceptualizes entrepreneurial feasibility as a dual-loop process in which the Static Loop precedes the Dynamic Loop. Building on this, Static Uncertainty Design (SUD) was introduced as an institutional approach to reducing irreversibility through employment continuity, income stabilization, and redeployability of outcomes.

The case study demonstrated that mid-career individuals resolve static uncertainty prior to engaging in entrepreneurial activity, supporting the proposed framework. These findings suggest that ecosystems should be understood as systems that manage downside risk rather than simply promote opportunity.

For policymakers and organizations, the implication is clear: increasing incentives is insufficient without reducing structural exposure. Enabling entrepreneurship requires redistributing risk across institutions rather than concentrating it on individuals.

Future research should examine how static uncertainty varies across contexts and how institutional configurations influence entrepreneurial feasibility. While this study is based on a single case, it provides a foundation for rethinking entrepreneurship as a problem of viability design.

Enabling mid-career entrepreneurship ultimately requires a shift from encouraging risk-taking to designing for viability. Ensuring that the "survival game" can be sustained is essential to unlocking experienced human capital.

Ethics Statement

This study did not require formal ethical clearance under the applicable institutional guidelines. Participants were informed about the use of anonymized data for research purposes, and no personally identifiable information is reported.

AI Declaration

A large language model (LLM) was used to support linguistic refinement and structural organization of the manuscript. The author reviewed and revised all generated content, and all conceptual and analytical contributions are the author's own.

Abstract: Current sustainability frameworks, such as the Triple-Layered Business Model Canvas (TLBMC), succeed in mapping environmental and social impacts but often fail to address the 'entrepreneur-or-investor-eye view' or the fast-changing realities and/or perceptions of the start-up space. To bridge this gap, this paper proposes the Venture-as-a-Product (VaaP) model; based on a dynamic 12-Slot-Scale able to synthesize diverse rubrics such as, for example, BMCs, it allows start-ups to define their ventures' flows and services by addressing client value and investor-readiness simultaneously. The framework expands the Osterwalder-Joyce-Paquin 9-slot-foundations by introducing a Perceptual Alignment Layer (PAL) of common denominators, including Operational Mapping, Internal Balancing, and Accountability Profiles. The dynamic scaling allows for affording a diagnostic, predictive, and iterative tool for start-ups, incorporating Suh's Axiomatic Design to ensure structural stability and methodologies like, for example, Greiner's Growth Phases to anticipate organizational crises. By transforming traditional static 'canvas elements' into modular dynamic 'Nodes', the VaaP model enables founders to communicate complex flow trajectories and risk-mitigation strategies to stakeholders. Specifically, the paper highlights how one of the added slots (Scalable Integrity) integrates 'Trust Engineering', turning intangible entrepreneurial perceptions into assessable milestones. This research offers a start-up-friendly template that balances the requirements of a sustainable future with the firm metrics of financial backing, ultimately empowering founders to navigate uncertainty while offering investors a clear view of risk, return, scalability, and credibility. It also offers venture builders or startup studios/factories a means to integrate their portfolios.

Keywords: Business Model Innovation (BMI), Business Model Canvas (BMC), Axiomatic Design, Entrepreneurship, Start-up Investment, Sustainability, Minimal Viable Product (MVP), Viable System Model (VSM), Venture-as-a-Product (VaaP), Venture-Builder Ecosystems, Start-up Factory.

1. From Impact Mapping to Venture Engineering

The integration of diverse market-relevant segments into a core business strategy has been significantly advanced by the Triple-Layered Business Model Canvas (TLBMC) (mapping economic, environmental, and social value (Osterwalder and Pigneur, 2010; Joyce and Paquin, 2016)) as well as by various propositions to extend its nine-stage-range (Matricano and Liguori, 2026). However, for entrepreneurs and investors in the burgeoning 'start-up factory' and venture-builder ecosystem, these tools remain inherently descriptive and static. They succeed at mapping impact but often fail to capture the 'investor-eye view' or the fast-changing realities and perceptions of the entrepreneur.

This paper addresses this gap by proposing the Venture-as-a-Product (VaaP) model. It applies a recently proposed generative Architecture for Canvas Ecosystems (ACE) Framework (Schmitt, forthcoming). While preserving the intuitive grasp of the visual canvas layout as well as its familiar logic, it adds further BMC layers (by applying a perceptual alignment layer) to interact with ACE's cybernetic feedback loops to benefit entrepreneurs and start-up investors. While Business Model Innovation (BMI) is typically viewed as a series of discrete strategic shifts, the ACE-approach reframes BMI as a continuous, cybernetic process based on an iterative knowledge management model (termed SICECE[1] (Schmitt, 2025)) which provides the structural 'rigging' and motivates and rationalizes canvas expansions as exemplified in this paper's entrepreneurship and start-up investment context.

Building on the synthesis of dynamic knowledge creation models (Schmitt, 2025) and the proposed Canvas architecture (Schmitt, forthcoming), this research offers three distinct contributions to the field of Business Model Innovation (BMI):

[1] The SICECE cycle (seizing/stewarding, imbedding/immersing, collating/collaborating, encompassing/edifying, curating/consolidating, effectuating/easing) reverses and extends Nonaka's renowned SECI (socialize, externalize, combine, internalize) and Ba model (Nonaka, Toyama and Konno, 2000) to personalize knowledge management and knowledge co-creation (system-in-development) serving a for community of knowledge workers characterized by diverse abilities, contexts, means, and ends (ACME) (Schmitt, 2025).

- *The Entrepreneur-versus-Investor Pillar (The 4th Layer):* A dedicated fourth layer to the TLBMC is introduced specifically designed to address the 'internal' concerns of the founder. This layer acts as a structural dashboard for technical founders to communicate venture health and 'investor-readiness' through common denominators like 'Operational Mapping' and 'Accountability Profiles' able to complement traditional BMCs by integrating start-up metrics not explicitly covered yet.
- *Kinetic Cybernetic Governance:* Moving beyond the static snapshot limitation of current canvases, traditional TLBMC elements are transformed into modular dynamic 'Nodes': Fusing the TLBMC starting slot with the ninth Slot (i) of the SICECE's cycle creates a metabolic 'Curation Body' scaffolding which enables active governance, where the business model functions as a diagnostic, predictive, and iterative navigation system.
- *The Due-Diligence Reshuffle:* Logically re-ordering this 4th-layer start-up rubrics creates the 5th-layer 'VaaP-Logic'. This contribution allows founders to repurpose their operational milestones into a predefined sequence that mirrors the 'investor-eye view'. This transforms an entrepreneur's to-do list into a professional due-diligence asset, leading with team capacity and technical affordances to build institutional trust and credibility.

By synthesizing these three novel approaches, the VaaP model transforms the BMC from a passive static report into a modular, scalable, iterative, dynamic, and high-fidelity asset - an essential progression towards developing a sustainable future of venture building (de Giorgio and Maffei, 2026). This heuristic enables the re-use of created knowledge assets instead of sisyphean efforts consuming time and attention, ultimately offering entrepreneurs to present investors with transparency concerning risk, return, and scalable integrity (SICECE Slot 12: I).

Based on a longitudinal research and publication trajectory combining conceptual analysis, systems thinking, and design science research methodologies (Schmitt, 2016, 2021), the aim is to provide a startup-friendly heuristic that caters for the straightforwardly codifiable vital drivers of viable start-ups and, in chorus, treats the venture itself as a modular product. This paper acts as an illustrative scenario[2] for the mentioned cybernetic-feedback-loop-enhanced Architecture for Canvas Ecosystems (ACE) (Schmitt, forthcoming).

2. Literature Review

As the longitudinal academic research has been complemented by the author's founding of a Mauritian start-up, the layers' criteria are rooted in the first-hand experiences gained (Schmitt, 2022, 2023; Schmitt and Jolicoeur, 2024). The 'realities' of start-ups have, for example, been laid out as a hierarchy of entrepreneurial 'altitudes' depicting seven venture-complexity levels: 1. Initial Ideation, 2. Niche Slots, 3. Advancing into Complex Territories, 4. 'Wicked' Territories and Radical Change, 5. SES: Social Entrepreneurship and Transformations, 6. SE: System Entrepreneurs and System Evolution, and 7. Entrepreneurial Stage-Growth Barriers (Schmitt, 2018; Schmitt and Jolicoeur, 2024). Start-up ideations of transforming conventional agendas into novel world-making realities are, hence, facing an 'up-hill' battle already, not to be further complicated by cumbersome, non-integrated entrepreneurial toolsets. The mini-tracks theme is, hence, being re-interpreted by focusing on the sustainable future of the entrepreneurs' finite cognitive and attention capacities in the context of rethinking Business Modeling: Infoxication (Cornella, 2000) and knowledge wastes manifest as losses of know-how, memory, time, money, and status, alongside negative impacts on well-being and relationships. A review of 51 studies identified recurring knowledge conversion failures (Ferenhof, Durst and Selig, 2015) across all BMC and SICECE stages: S: Poor tools and underutilized people; I: Communication barriers and reinvention; C: Misfit infrastructure and poor coordination; E: Lost resources and scatter; C: Separation of knowledge, responsibility, and feedback; and E: Skill barriers and disrupted workflows.

[2] As this platform is still under development, neither its testing in a real-world application space nor the publication of a case study is possible. While case studies, following Yin's definition, evaluate the performance of designed objects in complex, specific, real-world settings (Yin, 2009), illustrative scenarios extend this scope to artifacts' suitability/utility within a synthetic environment, which may include more generalizable or even ideal contexts (Peffers *et al.*, 2012).

2.1 Rethinking and Repurposing Static BMCs as Systemic Nodes and Flow Dynamics

Schuricht's study of 928 publications (Schuricht, 2026) across five identified BMC-clusters informs about a three-fold feature of their static but process-oriented modelling logic: (1) Action verbs implicitly operationalize static components, (2) an implicit generic flow logic accommodates diverse cluster manifestations, and (3) static elements can be effectively repurposed as dynamic nodes for continuous, holistic orchestration. By re-interpreting these multi-disciplinary canvasses as configurations of meaningful nodes, the focus shifts to their connecting 'flow profiles' (e.g., network patterns, flow directionalities, exchange types, magnitudes and constraints). The ACE framework explicates these patterns and further amplifies them.

2.2 Towards an Architecture for Canvas Ecosystems (ACE)

The traditional Business Model Innovation (BMI) discourse treats the 'Business Model' as a static map of value. This paper proposes to explicate Schuricht's observations (section 2.1) to expand the width and depth of the BMC architecture and to address its shortcomings in the entrepreneurial contexts. Figure 1 shows the integration of these objectives based on the classic BMC layout, flow, and TLBMC entities (a1-i0: blue, green, and yellow labels). It further integrates the Axiomatic Design Loop (AD) (Suh, 1995). The right side depicts the extension slots (jkl) of the SICECE (consolidating, effectuating/easing). All twelve slots (a1-l) have been labelled to highlight their distinct but complementing function. The axiomatic design cycle with its stages (a1:CA, c3:FR, e5:DP, g7:PV) and design matrices (b, d, f, h) are also shown.

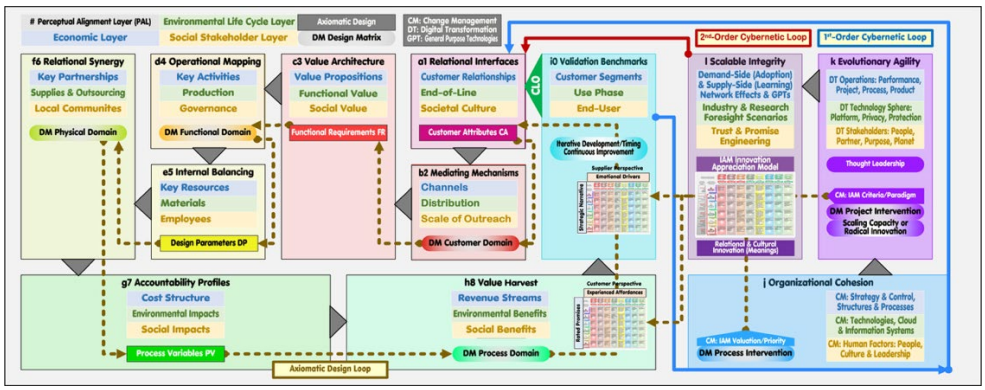

Figure 1: TLBMC Layout (left) with cybernetic ACE loop extensions (right) (Schmitt, forthcoming)

Slot i0 (fusing the 9th SICECE curating i-slot and BMC:0 starting slot) acts as the Validation Benchmark. In the context of the '3D-Map of Dynamic Knowledge Creation' (Schmitt, 2025), Slot i0 functions as the system's Metabolic Gateway, the control node in a cybernetic loop where the 'Functional Intent' (slot a1: what was expected) is compared to the 'Operative Reality' (slot h8: what has been delivered) (Table 1). This common i0-Slot profides the 'ideal sensor/vantage point': If value propositions fail, new BMC assessments are triggered.

For a Venture Builder, this slot may act as the 'Curation Body' that monitors the entire portfolio. It allows the builder to detect a 'Perceptual Mismatch' across multiple ventures at once, triggering a potential CL0:operative disruption for CL1:tactical or CL2:strategic corrections to preserve the 'Knowledge Heritage' of the start-up factory. It allows to pool the outcomes of otherwise isolated start-up projects (see Lean Canvas application in a startup studio space (Meijer, 2019; Maurya, 2022)) for time-saving recalls, re-uses, and resourcefulness. Table 2 (blocks A and B) differentiates this synthesis of the BMC, AD, SICECE, and CL:012 further.

Table 1: VaaP Structural Alignment to Venture Building Requirements

VaaP Slot	VB Industry Needs	Source Context	Designer/Provider Logic
a-c (Foundation)	Repeatable Ideation	(Meijer, 2019)	Standardizing 'Capacities' and 'Tech Affordances'.
d-g (Integrity)	De-Risking Scaleups	(Belingheri and Lechner, 2025b)	Mapping 'Path Dependencies' and 'Compliance'.
i (Sensor)	Portfolio Curation	(Schmitt, 2025)	The 'Brain' that audits mission-alignment.
j-l (Agility)	Rapid Pivotability	(de Giorgio and Maffei, 2026)	Engineering 'Trust' and 'Scalable Integrity'.

4. Early-Stage Start-up BMC Dilemmas: Proof of TLBMG Gap[2]	fails to consider intermediaries in complex supply chains	under-representation of stakeholder views & external forces	lack of strategy & mission-driven start-ups support	lack of iterative & experimental depth: build-measure-learn	absence of founder-managerial compe-tence mapping	shallow financial insights, often lack of layer-integration	qualitative-only bias lacking quantitative 'audit-ready' metrics	rigid structure without focus on iterative processes	over-simplification, no competitive & regulatory trends	tensions - layers lack vertical coherence, missing MVP-PMF	no cycling/scaling or dynamic capability, no VSM logic (Beer)	no exit alignment for investors, no IP policy of patenting
5. Co-Confidencing[3] Pre-seed venture formation supporting IP commercialisation (Dennis, 2026)[4]	Ecosystem participation. tangible industry engagement & strategic partnerships	Shifting geography- to network-dependency, project-based validation assisting strategic positioning	Prioritizing demonstrated performance for credibility-building, validated use cases, actual demand contexts/conditions	Staged progression for accumulating evi-dence/competency, competitive platforms for deploying under pressure, pilot or lighthouse projects	Reverse-engineering key judging criteria, compounding effects via facilitated knowledge spillovers, use of structured tools for resource efficiency	Institutional orchestration for investor-mentor-market access, distributed SME networks, fostered B2B collaborations	Mechanism for early-stage risk compression for building judgement, execution capability, adaptability, traction	Systematic, parallelised experimentation vs. sequential & path-dependent venture discovery model, secured grants/awards	Parallel multiple-team discovery avoiding initial framing biases for increased certainty	Scalable & replicable approaches, adaptive execution & rapid iteration to amplify credibility	Strict eliminations for substantive validation, third-party endorsements reduce uncertainty, shaping venture trajectories	Shift from venture- to ecosystem-centric thinking (kaizen) for scalable pipelines, participation in IP commercialisation
Legend: Transitions/Flows versus **Stages/States/Stocks** (depicted as an iterative cycle in analogy to the colour wheel)												

(Osterwalder and Pigneur, 2010; Joyce and Paquin, 2016) and (based on: (Schmitt, 2025), (Suh, 1995; Beer, 1979; Argyris and Schön, 1997)

While Table 2 (block A) summarizes the mentioned foundational paper (Schmitt, forthcoming), it also exemplifies how the Minimal Viable Product (MVP) Tool as well as the Stage-Growth-Model (Greiner, 1998; Levie and Lichtenstein, 2009) have been integrated as two further rubrics with their stages and transitions. Table 2 (rows B1-3/a-i) details the the triple-layer-9-Slot-TLBMC (Osterwalder and Pigneur, 2010; Joyce and Paquin, 2016). The dynamic and cybernetic feature (block A) now also apply to the TLBMC (block B): its three static sBMCs have been transformed into three iterative dynamic dBMCs rubrics.

The shortcomings we referred to are summarized (Table 2, row B4) as the dilemmas start-ups face (aligned to the slots concerned) when dealing with the conventional static sBMCs. Just adding a few more elements, however, is not sufficient: in order to take advantage of these novel affordances, the start-up also needs to hone the necessary insights and interdependencies required which forms part of its success and has been summarized (Dennis, 2026) and framed as an co-confidencing experience (Untamala, 2014) (block B, rows 5). Table 2 (block B/j-l) shows how the initially unpopulated TLBMC Slots have been utilized with additional complementing methodologies addressing change management (Leavitt, 1962; Heisig, 2009), the digital transformation canvas (Elia *et al.*, 2024), and general purpose technologies patterns (Cantner and Vannuccini, 2012). Based on these foundational layers, section 3 focuses on their expansions towards the three research contributions based on the ACE.

2.3 Venture-as-a-Product (VaaP), Venture Builders, and the 'Industrialized' Startup

The paper proposes a shift towards a Venture-as-a-Product approach (VaaP). Much like 'Software-as-a-Service' (SaaS) standardized software delivery, VaaP 'productizes' the internal architecture of the startup itself. In this view, the venture is not just a vehicle for a product; it is a modular, high-fidelity asset engineered for scalability, trust, and divestment. Venture Builders (or Startup Studios) treat venture creation as a repeatable, industrialized process (Belingheri and Lechner, 2025a). Recent research in 'Smart Manufacturing' highlights a bottleneck: the 'sisyphus' cycle where founders struggle to communicate technical maturity (de Giorgio and Maffei, 2026). VaaP addresses this through the 12-Slot 'structural rigging' based on fusing the SICECE cycle with Axiomatic Design (Suh, 1995) principles, allowing builders to 'decouple' core missions from operational changes during pivots.

3. Towards Entrepreneurial Support, Venture-as-a-Product, and ACE

3.1 An Illustrative ACE Scenario: Mapping Neglected Start-up Realities and Knowledge Friction

Table 3 (row C1) shows the Perceptual Alignment Layer[3] (PAL) which defines an overarching semantic space (by preserving the intuitive grasp of the original canvas logic) for expanding the canvas structure with appropriately termed BMC-type layers/rubrics. To identify the fit-for-purpose candidates and terms for the slots (a-l), the shortcomings and co-confidencing evidence (Table 1 rows B45) have been transformed into 'Prescriptive Logic (validators)' (Table 3, rows C234). These validators together with a generative meta-framework dyad were used to derive the terms for the 4th 'Start-up' dBMC 12-Slot-Layer/Rubric and to ensure their linguistic and conceptual consistency across all 12 slots. Like their dTLBMC counterparts (Table 1 rows B1-3), they are progressing and comply with the Perceptual Alignment Layer (PAL) which essentially acts as a 'Translation Engine' to prevent the frictions and wastes cited earlier. This sequence utilizes a stock/state (conceptual nodes: acegIk) and flow/transition (metabolic gates: bdfgil) logic, mirroring Axiomatic Design's mapping between domains to visualize the venture's developmental 'pulse'. The priority of these elements follows a 'Centrifugal Expansion' logic across three evolutionary phases:

- Phase 1 (a–c: External Intent) establishes the venture's relational interface and value architecture to bridge initial trust and ideation gaps.
- Phase 2 (d–f: Internal Integrity) focuses on engineering the internal engine through operational mapping and resource balancing.
- Phase 3 (g–i: Systemic Stability) establishes the accountability profiles and validation sensors necessary for risk compression.

Table 3: Continuation of Table 1 with Perceptual Alignment Layer (PAL)

12-Slot Scale	a	b	c	d	e	f	g	h	i	j	k	l
C.												
1. Perceptual Alignment Layer (PAL)	a Relational Interfaces	b Mediating Mechanisms	c Value Architecture	d Operational Mapping	e Internal Balancing	f Relational Synergy	g Accountability Profiles	h Value Harvest	i Validation Benchmarks	j Organizational Cohesion	k Evolutionary Agility	l Scalable Integrity
2. Prescriptive Logic (Validators)	*External Intent - Initial Trust & Ideation*			*Internal Integrity - Capacity & Financial Depth*			*Systemic Stability - Risks & Validation*			*Interventionist Authority - Agility & Scale*		
3. BMC Augmentation (Structural Agency)	Stakeholder Inclusion: Ensuring external forces (customers/partners) are actually modeled.			Strategic Depth: Moving past 'shallow financial insights' to mission-driven resource allocation			Iterative Validation: Checking for PMF and circumventing the 'rigid structure' of static canvases.			Exit/Investor Alignment: Ensuring the structure supports IP transfer and investor requirements.		
4. Co-Confidencing (Process Agency)	Supportive Sharing: Building trust with the ecosystem and university IP sources.			Meaning-making: Converting R&D results and raw data into a coherent 'Founder Narrative'.			Practicing: Actively testing the tech under pressure; risk compression via experimentation.			Scaling Integrity: Moving from 'My Startup' to 'Ecosystem Asset' (IP commercialization).		
5. 4th BMC Layer: Start-up Canvas	a Client Acquisition & Retention	b Compliance & Competition for Dominant Design	c Vision/Mission & Institution Building	d Research & Development Agenda	e Capacities & Organizational Know How	f Sponsors & Financial Backing	g Technologies (Physical/Social)	h Flows, Change, & Projections	i Risks & Path Dependencies	j MVP & other Entrepreneurial Toolsets	k Growth Barriers: Incipient, Growth, & Maturity Stages	l Innovative Steps & IP considerations
D.												
1. Prescriptive Logic (Validators)	*The Foundation (Foundational Inputs)*			*The Integrity (Structural Alignment)*			*The Stability (Systemic Governance)*			*The Agility (Evolutionary Feedback)*		
2. Investor Focus	Management Quality	R&D Velocity	Adoption Potential	Moats & Barriers	Technical Assets	Capital Efficiency	Institutional Credibility	Traction Metrics	Risk Resilience	Operational Agility	Scaling Stages	Returns & Exit
3. Pitch Deck Label	Team-Talent-Trust	Innovation & IP	Market & Access	Competitive Edge	Systems & Stack	Runway & Funding	Vision & Strategy	Growth & Results	Moats & Mitigation	MVP & Iteration	Scale-up Roadmap	Exit & ROI
4. VSM Role	S1: Capability Assessment	S4: Future Scanning	S1: Market Interface	S2: Conflict Resolution	S3: Internal Operations	S3: Resource Allocation	S5: Policy & Identity	S3*: Audit & Verification	S4: Environmental Adaptation	S3/S4: The Ops Room	S5: Evolution & Change	S1-S5: Total System Synergy
5. Contextual Description Focus	'Management Quality' by quantifying certitude of founders' expertise & ability to internalize knowledge.	'Flow of Technical Discovery' by constantly refreshing 'Means' of production to maintain competitive relevance.	'Startup Composition' to meet customer attributes to ensure 'Market-Size' potential is met with systematic adoption approach.	'Venture Approach' to navigate competition & 'Dominant Design' constraints, turning legal/industry friction into structural advantage.	Physical & social technical constructs ('Attractive Technology' stack) providing backbone for accountability & audit-ready metrics.	'Financial Consistency' by aligning 'Sponsors' with venture's burn-rate & capital needs, mitigating risk of contractual collapse.	'Venture's ultimate 'Ends' (vision & mission) transforming simple startup into credible institution that investors can trust for long-term exits.	Monitors projections & operational reality conversion (Value Harvest) to benchmark against 'Favorable Performance'.	Identifies path dependencies & challenges for 'Resilience' required to handle market volatility without systemic failure.	Utilizes toolsets like MVP to manage contingencies for 'Operations Room' view needed for immediate re-engineering (CL1).	Navigates growth barriers by applying creative 'Policy Direction' (S5) to overcome Greiner's crises.	Projecting innovative steps & IP options catalyzing venture's 'Scalable Integrity' for high-value exit or sustainable expansion.
6. 5th VaaP Layer: Investors' View	a<-e Capacities & Organizational Know How	b<-d Research & Development Agenda	c<-a Client Acquisition & Retention	d<-b Compliance & Competition for Dominant Design	e<-g Technologies (Physical/Social)	f Sponsors & Financial Backing	g<-c Vision, Mission & Insti-tution Building	h Flows, Change, & Projections	i Risks & Path Dependencies	j MVP & other Entrepreneurial Toolsets	k Growth Barriers: Incipient, Growth, & Maturity Stages	l Innovative Steps & IP Creation/Protection
7. Key Interests of Venture Capitalists [1]:	6/6 quality of management	3/3 high likelihood of customer adoption	7/3 Large market size & growth	1/1 positive influence of other investors	4/3 Attractive product & technology	2/2 low valuation 2/1 risk-limiting contractual services	5/5 attractive busi-ness strategy/model	3/1 favorable performance to date	3/4 favorable competitive position	-/1 costs to monitor investment	2/- good fit in VC investment portfolio	2/1 financial market conditions & exit ops

Legend: Transitions/Flows (bdfhjl) versus **Stages/States/Stocks** (acegik) (depicted as an iterative cycle in analogy to the colour wheel)

[3] The proposed Architecture for Canvas Ecosystems (Schmitt, forthcoming) applies PAL to twelve generic classification terms for each Slot (a-l) to envelop the three sBMC terms (Table 2 rows B1-3) and to create a distinct but complementing semantic space to synergetically position elements of further rubrics (Table 3C). PAL extends the canvas structure while preserving the intuitive grasp of the canvas logic.

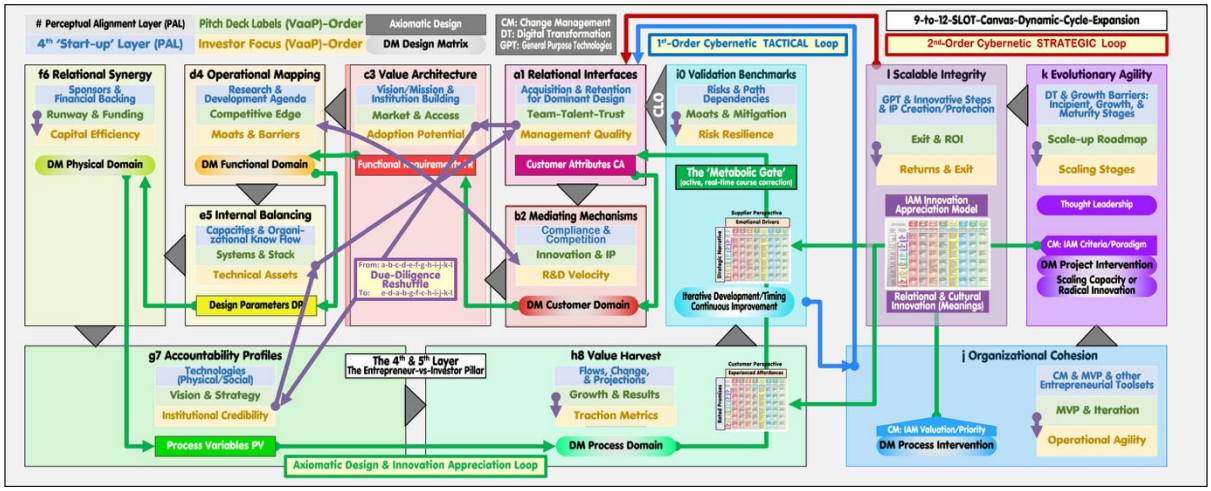

Figure 2: 4th 'Start-up' BMC Layer/Rubric & 5th 'Venture-as-a-Product (VaaP)' Rubric with Pitch Terms

As detailed in Table 3 (blocks C & D), this progression ensures that every stock/state (conceptual node) is activated by a corresponding flow/transition (metabolic gate), ensuring the venture remains structurally sound and investor-ready.

3.2 The Dynamic Due-Diligence Reshuffle: 4th 'Start-up' BMC Layers to 5th 'VaaP' Rubrics

Figure 2 mirrors Figure 1 with the dBMCs replaced by the 4th 'start-up' and 5th VaaP layers/rubrics (terms as in Table 3, rows C5 & D6). The VaaP model/rubric effectively functions as a 'Due-Diligence Dashboard.' When investors evaluate startups, they move through a specific narrative arc (Table 3, rows D1-3/a-l) that fits a rearranged sequence of the 4th 'start-up' rubric's progression and also fits the VSM model as summarized in the contextual description (Table 3, rows D45). The alignment with an extended Beer's Viable System Model (VSM) (Table 3, row D8) ensures the venture is 'pre-wired' for institutional control, transforming it from an idiosyncratic project into a transferable, productized asset suitable for exit or ecosystem integration.

The 5th layer reshuffles the start-up's internal logic into a sequence (Table 3, C5 to D6: e-d-a-b-g-f-c-h-i-j-k-l) that leads with Management Quality (Table 3, C5e/D6a) and R&D Velocity (Table 3, C5b/D6b), directly addressing the primary heuristics used in VC decision-making (Kaplan and Strömberg, 2004) (Table 1, row D7). Belingheri argues that the primary value proposition of Venture Builders is the 'de-risking' of entrepreneurship (Belingheri and Lechner, 2025b). Traditional 'fire-and-forget' business models are insufficient for this purpose. The VaaP model addresses this by integrating 'Axiomatic Design' Principles (Suh, 1995) to ensure that the venture's 'Functional Intent' remains independent of its physical implementation. This decoupling allows portfolio managers to 'pivot the process' (Table 3, C5j/D6j) without causing a 'systemic collapse' of the venture's core value proposition.

Studies emphasize the need for 'strategizing the ideation phase' in startup studios, particularly for 'Smart Manufacturing'. In these complex technical environments, founders often face the mentioned 'sisyphean efforts'—repeatedly re-explaining technical affordances to non-technical investors (Meijer, 2019). The VaaP model solves this through its 'Perceptual Alignment Layer (PAL)', translating complex 'R&D Discourses' (Table 3, C5b/D6b) and 'Tech Affordances' (Table 3, C5g/D6e) into a standardized 'investor-eye view'.

3.3 Repurposing Static and Novel BMCs as Systemic Nodes and Flow Dynamics

The novel ACE and VaaP approaches also exemplify the versatility of the dynamic SICECE-driven KM model (Schmitt, 2025) by expanding its application for dynamizing the conventional static BMC notion. These extensions are grounded in Suh's Axiomatic Design (Suh, 1995) to ensure structural integrity, and to provide core know-how (BMC, MVP, and start-up rubrics) as well as predictive diagnostic for organizational crises (as exemplified by the Stage-Growth-Phases/Barriers). The outcome affords a startup-friendly heuristic (or transdisciplinary boundary object (Star, 2010)). that treats the venture itself as a modular project/product, balancing the requirements of a sustainable future with the hard metrics of financial readiness and scalable integrity.

The foundational paper (Schmitt, forthcoming) provides further background by focusing on the rationales of dynamizing these canvasses based on cybernetic feedback loops and aiming for scaling canvas-'membership' in

the ‘club’ of dynamic knowledge creation models presented as a public-transport-type 3D-map (Schmitt, 2025). While Business Model Innovation (BMI) is typically viewed as a series of discrete strategic shifts, the ACE framework affords as a continuous, cybernetic process based on the 12-slot-scale (Table 2 & 3) providing the structural 'rigging', grounded in growth and diagnostic phases. The resulting VAAP ensures an entrepreneur is not just innovating THE product and business but also a "productized venture" that can be sold, scaled, or pivoted with the same precision as any other artefact.

4. Conclusion: From Static Artifacts to Kinetic Governance

The BMI evolution has reached a critical juncture where descriptive frameworks no longer suffice for the high-velocity, risk-intensive environment of venture building. As this paper has demonstrated, the Triple-Layered Business Model Canvas (TLBMC), while effective for sustainability mapping, leaves a significant 'Perceptual Gap' between entrepreneurial intent and investor requirements. By introducing the dynamic Venture-as-a-Product (VaaP) model, we have proposed a structural solution that moves beyond static snapshots toward a system of kinetic governance:

- *Bridging the Professional Due-Diligence Gap:* The research highlights that the primary friction in early-stage investment is not a lack of vision, but a lack of 'Accountability Profiles' (Table 3, C1/5g) and 'Operational Mapping' (Table 3, C1/5d). By addressing the documented weaknesses of traditional canvases—specifically the qualitative bias and the absence of founder-managerial competence mapping (Table 3, C1/5e)—the VaaP model transforms the business model from a creative sketch into an audit-ready asset, so founders do not longer have to feel like pushing the same ‘pitch’ rock up the hill every time they meet a new stakeholder. This 'Due-Diligence Reshuffle' ensures that technical founders can communicate 'Management Quality' and 'R&D Velocity' through the Perceptual Alignment Layer (PAL), translating ‘not-knowing’ into ‘co-confidencing’ (Untamala, 2014; Dennis, 2026). Ultimately, the venture’s internal metrics (Table 3, C1/5def) are getting so well-aligned with the investor’s requirements (Table 3, D2, C1ghi) and venture’s prospects (Table 3, C1jkl) that ‘Trust & Promise Engineering’ becomes a byproduct of the system's architecture.
- *The Cybernetic Pivot:* Central to the viability of the modern startup is its ability to sense and respond to 'Path Dependencies' (Table 3, C1/5/D6i). By positioning Slot i as the system's Metabolic Sensor, we have integrated cybernetic feedback loops (CL0:operative, CL1:tactical, and CL2:strategic) into the core of the business logic. This allows the venture builder or startup studio to 'pivot the process' without collapsing the 'mission,' ensuring that the venture’s 'Functional Intent' remains decoupled from its physical implementation - a core tenet of Axiomatic Design (Suh, 1995).
- *Toward an Architecture for Canvas Ecosystems (ACE):* The VaaP model represents the first boundary-object-type heuristic to be implemented as an Architecture for Canvas Ecosystems (ACE) prototype. In this exemplification, the venture is no longer just a vehicle for a product; it is a 'productized venture' that can be scaled, pivoted, or divested with clinical precision. This shift addresses the 'Sisyphus' cycle of repetitive knowledge waste identified in early-stage ecosystems, offering instead a modular, scalable framework for 'Trust Engineering'.

The goal of the VaaP 12-Slot-Scale is to empower founders to navigate the 'uphill battle' of venture complexity while offering investors a transparent, high-fidelity view of risk and return. By balancing the requirements of a sustainable future with the hard metrics of financial backing, the model ensures that the ventures of tomorrow are built on a foundation of 'Scalable Integrity' (Table 3/4l). This research offers not just a tool, but a diagnostic and predictive navigation system for the sustainable future of venture building. It also offers a proof of concept to commence with ACE-type boundary-object-applications in other domains as the future trajectory of this research.

Acknowledgements

I would like to express my deepest appreciation to the staff and institutions of the Economic Development Board (edbmauritius.org), the Mauritius Research and Innovation Council (mric.mu), and La Plage Factory Africatech Business Incubator (laplage.io). The EDB’s/MRIC’s policies and National SME Incubator Scheme allow entrepreneurs from Mauritius or abroad (like me) to be considered for initially operating in partnership with one of the accredited Mauritian business incubators under the MRIC’s aegis.

Ethics Declaration

No ethical clearance for the research was necessary.

AI Declaration

As AI tools are increasingly used by reviewers, I applied Gemini to also check my completed submission to confirm that my proposed solutions are indeed novel in the context of academic research as well as professional applications. To the best of my knowledge, after verifying the AI-generated results, this approach has not been previously pursued in academic or commercial realms.

Digital Twins in Industrial Transformation: A PRISMA-Based Review with Human Resource Implications

Manisha Gupta[1] and Mamta Singh[2]
[1]School of Management Sciences, Lucknow, India
[2]Chandragupt Institute of Management Patna, Patna, India

herezmanisha@gmail.com
mamtakumar7@gmail.com

Abstract: The rapid advancement of Industry 4.0 technologies has transformed traditional industrial systems into intelligent, data-driven ecosystems. Among these, digital twins have emerged as key enablers of industrial transformation by integrating real-time data, simulation, and predictive analytics. This study presents a systematic literature review using the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) framework to examine the role of digital twins in driving innovation, operational efficiency, and sustainability across industries. Using the Scopus database, an initial pool of 220 articles was identified, of which 15 studies were selected through a rigorous screening and eligibility process. The findings indicate that digital twins function as multidimensional strategic tools that enhance predictive maintenance, optimize resource utilization, and accelerate product development through virtual prototyping. In addition, digital twins contribute to sustainability by supporting energy efficiency, circular economy practices, and environmental, social, and governance (ESG) objectives. These capabilities highlight their role in enabling organizations to transition from reactive to proactive and data-driven decision-making systems in complex industrial environments globally and across diverse sectors. Importantly, the review highlights the organizational and human implications of digital twin adoption. The integration of digital twins creates hybrid decision-making environments where human judgment is augmented by algorithm-driven insights, influencing accountability, trust, and workforce roles. This transformation necessitates the development of new competencies, including data literacy, digital collaboration, and adaptive decision-making, while emphasizing the role of human resource management in facilitating reskilling, change management, and the development of data-driven organizational cultures. The study also identifies key challenges, including high implementation costs, interoperability issues, data security concerns, and resistance to change. By synthesizing technological, strategic, and human perspectives, this research positions digital twins as drivers of both operational and organizational transformation. The findings provide valuable insights for practitioners and policymakers seeking to leverage digital twin technologies for sustainable and competitive industrial development.

Keywords: Digital Twins; Industrial Transformation; Industry 4.0; Innovation; Sustainability; Human Resource Management; PRISMA

1. Introduction

The rapid advancement of digital technologies has fundamentally reshaped the industrial landscape, driving a shift toward data-driven, intelligent, and interconnected systems. The emergence of Industry 4.0 has accelerated the adoption of technologies such as Artificial Intelligence (AI), Blockchain, and the Internet of Things (IoT), enabling organizations to transform traditional operational models into adaptive and automated ecosystems (Gupta and Singh, 2024; Tabet et al., 2026). Supported by Big Data analytics, cloud computing, and cyber-physical systems, these technologies have enhanced capabilities in real-time decision-making, operational efficiency, and mass customization.

Within this paradigm, Digital Twin (DT) technology has emerged as a pivotal enabler of industrial transformation. Digital twins are dynamic virtual representations of physical products, processes, or systems that continuously evolve through real-time data integration (Yazdi, 2024). Unlike static, assumption-driven simulation models, digital twins function as living models, enabling predictive and prescriptive decision-making through continuous updates (Rakshit et al., 2024).

Digital twins operate across multiple levels, including products, processes, and systems providing integrated visibility and control across value chains (Kankam et al., 2022). Their integration with IoT, AI/ML, and cloud computing creates continuous feedback loops between physical and digital environments, enabling proactive monitoring, fault detection, and process optimization (Murthy et al., 2022; Mo et al., 2025). From a strategic perspective, digital twins enhance research and development through virtual prototyping, improve operational processes, and strengthen supply chain responsiveness (You et al., 2022). They also contribute to sustainability by optimizing energy use and supporting circular economy practices (Ali et al., 2025; Kumar and Tiwari, 2026).

Beyond technological advancements, digital twins are reshaping the human and organizational dimensions of work. Their integration into industrial systems creates hybrid human–machine decision environments, influencing accountability, decision ownership, and behavioral responses. This shift necessitates new

competencies such as data literacy, adaptive decision-making, and digital collaboration. At the same time, organizations face resistance as employees transition from intuition-based to data-driven decision-making, highlighting the role of HR in reskilling, change management, and fostering trust in intelligent systems. Concerns related to monitoring, privacy, and autonomy further emphasize the need for robust ethical and governance frameworks.

Despite their growing significance, existing literature remains fragmented, often focusing on specific industries or technical aspects without adequately addressing digital twins as strategic enablers of holistic industrial transformation. Limited attention has also been given to their human and organizational implications. To address these gaps, this study undertakes a systematic literature review using the PRISMA framework to examine the role of digital twins in driving innovation, operational efficiency, sustainability, and organizational transformation.

Accordingly, the study is guided by the following research question:

How does digital twin technology act as a strategic enabler in industrial transformation, and what are its implications for organizational and human systems?

By integrating technological, strategic, and human perspectives, this study contributes to the literature by positioning digital twins as drivers of intelligent, adaptive, and sustainable industrial ecosystems. This study makes a distinct contribution by integrating a human resource perspective into digital twin research, an area that remains underexplored.

2. Literature Review

2.1 Conceptual Foundations of Digital Twins in Industry 4.0

Digital twins have emerged as a foundational pillar within Industry 4.0, representing a shift from static, simulation-based models to dynamic, data-driven representations of physical systems (Stavropoulos et al., 2022). A digital twin is a real-time virtual representation that evolves through continuous data integration, enabling monitoring, prediction, and optimization (Kamburjan et al., 2022).

Unlike traditional models based on predefined assumptions, digital twins enable bi-directional communication between physical and virtual systems, supporting predictive and prescriptive decision-making and enhancing operational responsiveness (Rakshit et al., 2024). This marks a fundamental shift in managing complex systems. Moreover, digital twins extend beyond individual assets to encompass processes, systems, and organizational ecosystems, enabling integrated visibility and systemic understanding (Kankam et al., 2022).

2.2 Technological Architecture and Enabling Ecosystem

The effectiveness of digital twins is supported by a multi-layered architecture integrating physical systems, data acquisition, communication networks, and advanced analytics. Sensors capture real-time data, which is transmitted through IoT systems and processed on cloud platforms (Hemdan et al., 2023). The digital model layer converts this data into actionable insights using AI and machine learning (Li et al., 2023), while application interfaces enable monitoring and decision-making (Cao and Jiang, 2024).

This creates a closed-loop system where digital insights continuously inform physical operations, enabling adaptive control and optimization (Mo et al., 2025). Integration with big data, blockchain, and cloud technologies enhances scalability and transparency (Gupta et al., 2025). Strategically, digital twins function as a central nervous system within industrial ecosystems, enabling intelligent automation and real-time decision-making (Murthy et al., 2022).

2.3 Digital Twins as Drivers of Innovation and Operational Excellence

Digital twins accelerate innovation and operational performance by enabling virtual prototyping, reducing physical testing, and shortening development cycles (Lim et al., 2020). They also support predictive maintenance through real-time analytics, reducing downtime and improving asset utilization (You et al., 2022).

Across industries, digital twins enhance process optimization and system performance, particularly in manufacturing, supply chains, and transportation (Gao et al., 2022). Their integration with AI expands capabilities in areas such as cybersecurity and intelligent automation (Sarker et al., 2024). Emerging developments, including cyber twins and electronic digital twins, extend these capabilities to more advanced predictive systems

(Bamunuarachchi et al., 2021; Massaro, 2025). This capability also supports a shift toward data-driven innovation ecosystems, where organizations can continuously refine products and processes based on real-time feedback. By enabling rapid experimentation and iterative learning, digital twins reduce uncertainty and enhance strategic agility, allowing firms to respond more effectively to dynamic market conditions.

2.4 Sectoral Applications and Industrial Transformation

Digital twins have demonstrated applications across sectors such as manufacturing, healthcare, and infrastructure, improving efficiency, predictive capabilities, and system optimization (Abadi et al., 2025; Dwivedi et al., 2024; Meng et al., 2024). These applications highlight their versatility as enablers of industrial transformation.

2.5 Digital Twins and Sustainability: ESG and Circular Economy Perspectives

Sustainability has emerged as a critical dimension of digital twin adoption. Digital twins enable organizations to optimize resource utilization, reduce waste, and improve energy efficiency (Ali et al., 2025). They also support circular economy practices by facilitating material monitoring, reuse, and recycling (Kumar and Tiwari, 2026).

In urban contexts, digital twins contribute to smart city initiatives by improving infrastructure efficiency and resilience (Omrany et al., 2025). Additionally, they enhance workplace safety, transparency, and regulatory compliance, supporting broader ESG objectives (Aagaard and Vanhaverbeke, 2024). Beyond operational benefits, digital twins contribute to aligning business strategies with sustainability objectives by enabling real-time tracking of environmental impact metrics. This integration supports informed decision-making and enhances organizational accountability toward ESG goals, reinforcing their role in sustainable industrial transformation.

2.6 Human and Organizational Implications: an HR Perspective

While the technological benefits of digital twins are well-documented, their human and organizational implications remain underexplored (Holopainen et al., 2024). Their integration creates hybrid decision environments where human judgment is augmented by algorithm-driven insights (Mo et al., 2025), requiring new competencies such as data literacy, digital collaboration, and adaptive decision-making.

This shift may alter accountability structures, potentially reducing perceived ownership of outcomes. From an HR perspective, successful adoption requires reskilling, change management, and fostering trust in data-driven systems (Sarker et al., 2024).

2.7 Challenges and Research Gaps

Despite their potential, digital twin adoption faces challenges including high implementation costs, lack of standardization, interoperability issues, and data security concerns (Dwivedi et al., 2024; Hemdan et al., 2023). Organizational resistance and limited understanding of data-driven decision-making further hinder adoption. Existing research remains fragmented, focusing primarily on technological aspects with limited attention to strategic and human dimensions. In particular, the intersection of digital twins with HR practices and organizational behavior remains underexplored.

2.8 Synthesis and Direction for the Present Study

The literature indicates that digital twins serve as enablers of innovation, efficiency, and sustainability. However, the fragmented nature of existing research highlights the need for a comprehensive synthesis integrating technological, strategic, and human perspectives. Accordingly, this study adopts a PRISMA-based systematic review to examine digital twins as strategic enablers of industrial transformation and their implications for organizational and human systems.

3. Methodology

This study adopts a systematic literature review (SLR) approach to examine the role of digital twin technology as a strategic enabler of industrial transformation. The review follows the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) framework to ensure a structured process for identifying, screening, and selecting relevant studies. A hybrid analytical approach is employed, combining bibliometric insights with qualitative thematic analysis.

The literature search was conducted using the Scopus database. A structured search query ("digital twin") AND ("industrial transformation") AND ("innovation"), limited to English-language publications, yielded an initial pool of 220 articles. Following the PRISMA process (Page et al., 2021), 45 articles were shortlisted after screening titles and abstracts, and 15 studies were selected after full-text evaluation based on relevance (Table 1).

The inclusion criteria focused on studies addressing digital twin applications in industrial transformation, innovation, or sustainability, including peer-reviewed journal articles, conference papers, and scholarly book chapters. Non-relevant and non-English studies were excluded. Data were analyzed through bibliometric examination and thematic coding to identify key areas such as technological architecture, innovation outcomes, sustainability contributions, organizational implications, and implementation challenges. While the use of Scopus ensures high-quality coverage, it may limit inclusion of studies from other databases, which is acknowledged as a limitation.

Table 1: Key studies on digital twins as strategic enablers of industrial transformation

Author(s)	Article Title	Journal, Year (Citation)	Key Findings
Lim et al.	A digital twin-enhanced system for engineering product family design and optimization	Journal of Manufacturing Systems, 2020 (148)	Digital twin can provide decision support to enhance product lifecycle management and engineering product family design.
Sarker et al.	Explainable AI for cybersecurity automation, intelligence and trustworthiness in digital twin: Methods, taxonomy, challenges and prospects	ICT Express, 2024 (114)	Digital twins (DTs) are an emerging digitalization technology with a huge impact on today's innovations in both industry and research.
Bamunuarachchi et al.	Digital twins supporting efficient digital industrial transformation	Sensors, 2021 (44)	Cyber Twins (CTs), an extension of Digital Twins, support cost-efficient Industry 4.0 application with approximately 60% of the cost of IoT platform-based application development.
Gao et al.	Application of Digital Twins and Building Information Modeling in the Digitization of Transportation: A Bibliometric Review	Applied Sciences (Switzerland), 2022 (24)	Digital twin technologies assist in the digitalization of transportation improving the efficiency of intelligent transportation system element management.
Zhao et al.	A machine learning and CFD modeling hybrid approach for predicting real-time heat transfer during cokemaking processes	Fuel, 2024 (21)	Digital Twin is paving the way to simulate the heat transfer during the cokemaking process with high accuracy and efficiency, thereby demonstrating its capacity to significantly reduce energy consumption within the cokemaking industry and development of smart cokemaking process.
Massaro	Electronic Artificial Intelligence and Digital Twins in Industry 5.0: A Systematic Review and Perspectives	Machines, 2025 (3)	The Electronic Digital Twin (EDT) tools are useful to comprehend the modeling concepts functional to the AI application using the output of the circuit simulations. The output of the circuit is used to train the AI model, thus strengthening the capability to classify and predict the real behavior of production machines with a good accuracy.

4. Results and Analysis

The systematic review, conducted using the PRISMA framework, resulted in the selection of 15 high-quality studies that collectively examine the role of digital twins across multiple industrial domains. The analysis of these studies reveals that digital twin technology functions as a multidimensional strategic enabler, driving transformation through interconnected pathways of operational efficiency, innovation, sustainability, and organizational evolution.

A dominant theme emerging from the literature is the role of digital twins in enhancing operational intelligence and efficiency. By leveraging real-time data and predictive analytics, digital twins enable organizations to transition from reactive to proactive decision-making. This is particularly evident in manufacturing and industrial systems, where digital twins facilitate predictive maintenance, reduce downtime, and optimize resource utilization (You et al., 2022; Abadi et al., 2025). The integration of AI-driven models further strengthens this capability by enabling continuous learning and self-optimization within production environments (Mo et al., 2025). As a result, organizations achieve not only cost efficiencies but also improved system reliability and performance.

Closely linked to operational efficiency is the role of digital twins in accelerating innovation and product development. The ability to simulate, test, and refine products in a virtual environment significantly reduces the need for physical prototyping, thereby shortening development cycles and lowering associated costs (Lim et al., 2020). This virtual experimentation capability enables organizations to explore multiple design scenarios and optimize outcomes before implementation. Moreover, digital twins support advanced applications such as real-time process modeling and hybrid simulation, as demonstrated in industrial processes like heat transfer optimization (Zhao et al., 2024). These capabilities position digital twins as critical tools for fostering continuous innovation.

Another key finding is the contribution of digital twins to sustainability and circular economy practices. The literature indicates that digital twins enable precise monitoring of energy consumption, material flows, and system performance, thereby facilitating resource optimization and waste reduction (Ali et al., 2025; Kumar and Tiwari, 2026). In addition, digital twins support environmental and social governance (ESG) objectives by enhancing transparency, improving safety, and enabling data-driven compliance mechanisms (Aagaard and Vanhaverbeke, 2024). Their application in smart cities and infrastructure systems further demonstrates their potential to promote urban sustainability and resilience (Omrany et al., 2025).

The review also highlights the sectoral versatility of digital twin applications, reinforcing their role as enablers of industrial transformation across domains. In healthcare, digital twins enable patient-specific simulations and real-time monitoring, improving treatment outcomes and operational efficiency (Dwivedi et al., 2024). In the architecture, engineering, and construction (AEC) sector, they enhance safety management and lifecycle monitoring (Meng et al., 2024), while in transportation, they optimize system performance and infrastructure management (Gao et al., 2022). Similarly, in oil and gas operations, digital twins support predictive maintenance and risk management in complex environments (Abbas et al., 2021). These applications demonstrate the adaptability of digital twin technology to diverse industrial contexts.

Beyond technological and operational benefits, a critical insight emerging from the analysis is the transformation of organizational and human systems. Digital twins introduce hybrid decision-making environments, where human expertise is augmented by algorithm-driven insights. This shift necessitates new competencies, including data literacy, analytical thinking, and digital collaboration skills. At the same time, it alters traditional accountability structures, as decision-making authority becomes distributed between human actors and intelligent systems. Such changes may lead to challenges related to perceived responsibility, trust in automated systems, and behavioral adaptation within organizations.

The findings further indicate that the successful adoption of digital twins is contingent upon organizational readiness and cultural alignment. Resistance to change, lack of understanding of data-driven decision-making, and concerns related to privacy and control can hinder implementation. These challenges underscore the critical role of leadership and human resource management in facilitating digital transformation through training, change management, and the development of a culture that supports innovation and continuous learning.

Finally, the analysis identifies several implementation challenges that persist across studies. High initial investment costs, lack of standardized frameworks, interoperability issues, and data security concerns remain

significant barriers to adoption (Dwivedi et al., 2024; Hemdan et al., 2023). While technological advancements continue to address some of these issues, the need for integrated strategies that combine technological, organizational, and regulatory perspectives remains evident.

In synthesis, the findings demonstrate that digital twin technology acts as a strategic enabler of industrial transformation by simultaneously enhancing operational performance, driving innovation, supporting sustainability goals, and reshaping organizational dynamics. This multidimensional impact highlights the importance of adopting a holistic perspective that integrates technological capabilities with human and organizational considerations.

5. Discussion

The findings of this study position digital twin technology as a strategic enabler of industrial transformation, extending its role beyond operational efficiency to innovation, sustainability, and organizational adaptation. The synthesis of literature indicates that digital twins facilitate a shift from reactive to predictive and prescriptive decision-making systems, supported by real-time data integration and advanced analytics (Mo et al., 2025; Rakshit et al., 2024). This aligns with the evolving perspective of Industry 4.0, where decision-making is increasingly embedded within dynamic, feedback-driven systems rather than linear processes.

A key theoretical implication lies in the integration of innovation and digital transformation frameworks. Digital twins enable continuous experimentation through virtual prototyping and simulation, thereby accelerating product and process innovation while reducing uncertainty (Lim et al., 2020). At the same time, their capability to optimize resource utilization and monitor system performance links them closely with sustainability and ESG-oriented models (Ali et al., 2025; Kumar and Tiwari, 2026). This dual role suggests that digital twins act as a bridge between efficiency-driven and sustainability-driven transformation.

The findings also highlight an important yet underexplored dimension, the organizational and human implications of digital twin adoption. The emergence of hybrid decision environments, where human judgment is augmented by algorithm-driven insights, alters traditional structures of decision authority and accountability. This shift has implications for organizational behavior, particularly in terms of trust in systems, responsibility attribution, and decision ownership. Employees are increasingly required to interpret and act upon data-driven recommendations, indicating a transition toward more analytical and adaptive roles.

From a practical standpoint, the results suggest that the successful implementation of digital twins depends on more than technological capability. Organizations must align digital twin adoption with strategic objectives, ensuring that investments contribute to innovation, operational excellence, and sustainability outcomes. Equally important is organizational readiness, including the development of data-driven cultures and cross-functional integration.

The role of human resource management emerges as critical in this context. Organizations need to invest in reskilling and upskilling initiatives to build competencies such as data literacy and analytical decision-making. Additionally, HR must address resistance to change and foster a culture that supports digital adoption. Concerns related to privacy, monitoring, and employee autonomy further necessitate the development of ethical and governance frameworks to ensure responsible implementation.

Finally, persistent challenges such as high implementation costs, interoperability issues, and data security concerns continue to influence adoption decisions (Dwivedi et al., 2024; Hemdan et al., 2023). Addressing these barriers requires integrated strategies combining technological, organizational, and regulatory approaches.

5.1 Theoretical Implications

This study contributes to the literature by positioning digital twins as dynamic, data-driven systems that extend beyond traditional simulation models to function as continuous decision-support mechanisms. By enabling real-time feedback loops between physical and digital environments, digital twins align with cyber-physical *system* and systems thinking perspectives, shifting decision-making from linear to adaptive and predictive processes (Mo et al., 2025; Rakshit et al., 2024).

The findings also integrate digital twin adoption with innovation and sustainability frameworks, demonstrating that digital twins facilitate continuous experimentation, accelerate product development, and support resource optimization (Lim et al., 2020; Ali et al., 2025; Kumar and Tiwari, 2026). This highlights their dual role in driving both efficiency and ESG-oriented transformation.

Importantly, the study extends existing research by incorporating the human and organizational dimension, showing that digital twins create hybrid decision environments that influence accountability, trust, and decision-making behavior. This opens new avenues for research at the intersection of technology, organizational behavior, and HR systems.

5.2 Practical Implications

From a managerial perspective, the findings suggest that digital twin adoption should be approached as a strategic initiative rather than a purely technological investment. Organizations must align digital twin implementation with broader goals related to innovation, efficiency, and sustainability.

Successful adoption requires organizational readiness, including the development of data-driven cultures and cross-functional integration. Human resource management plays a critical role in this process by enabling reskilling and upskilling, fostering adaptability, and managing resistance to change.

Additionally, organizations must address concerns related to data privacy, employee autonomy, and system trust by establishing clear governance and ethical frameworks. Overcoming challenges such as high implementation costs and interoperability issues requires phased strategies and collaborative ecosystems (Dwivedi et al., 2024; Hemdan et al., 2023).

6. Conclusion

This study establishes that digital twin technology acts as a strategic enabler of industrial transformation, enhancing operational efficiency, supporting innovation, and contributing to sustainability. By enabling real-time, data-driven decision-making, digital twins facilitate a shift toward more proactive and adaptive organizational systems.

Beyond technological benefits, the study highlights the importance of integrating human and organizational factors, emphasizing the role of HR and culture in ensuring successful adoption. Digital twins, therefore, represent not only a technological advancement but also a catalyst for broader organizational transformation.

7. Limitations and Future Research Directions

This study is subject to certain limitations. First, the review is based solely on the Scopus database, which, although comprehensive, may exclude relevant studies indexed in other databases. Second, the analysis is limited to English-language publications, potentially overlooking valuable contributions from non-English sources. Third, the study relies on a relatively small sample of selected articles, which may restrict the generalizability of the findings. Additionally, as a systematic literature review, the study is conceptual in nature and does not include empirical validation.

Future research can address these limitations by incorporating multiple databases and expanding the scope of literature to include diverse geographical and linguistic contexts. There is a need for empirical studies examining the impact of digital twin adoption on organizational performance and decision-making outcomes. Further research should also explore human–technology interactions, particularly issues related to trust, accountability, and behavioral adaptation in data-driven environments. Moreover, the role of human resource practices in facilitating digital transformation warrants deeper investigation. Finally, developing standardized frameworks to address challenges related to interoperability, governance, and scalability would contribute to advancing both theory and practice in this domain.

Ethics Declaration

This study is based on a review of existing literature and does not involve human participants; therefore, ethical approval was not required.

AI Declaration

An AI tool (ChatGPT) was used for language refinement and structuring. All content and interpretations are the authors' own.

Enhancing Grassroots Entrepreneurship Development through Market Orientation

Sonal H Singh[1], Birud Sindhav[2] and Bhaskar Bhowmick[3]
[1]Centre for Entrepreneurship and Innovation, Mahindra University, India
[2]College of Business Administration, University of Nebraska at Omaha, USA
[3]Rajendra Mishra School of Engineering Entrepreneurship, Indian Institute of Technology, Kharagpur, India

Abstract: Grassroots innovation (GRI) is often cited as a key to entrepreneurship development; however, the factors of influence for prompting entrepreneurial actions at the grassroots level are often unclear. As the key challenges of grassroots innovators are limited understanding and accessibility of market information, market orientation plays a significant role by helping grassroots innovators relation to sources of important information and opportunities. In the grassroots context, market orientation serves to promote entrepreneurial activity by bridging the market information gap effectively and ensuring involvement from various communities in responding to market needs and demand. This study analyzes the role of market orientation on the connection between GRI and entrepreneurial orientation. It reveals that market orientation helps improve economic benefits from entrepreneurial activities.

Keywords: Grassroots Innovation, Customer Orientation, Competitive Orientation, Entrepreneurship Development, India

1. Introduction

Poverty continues to be one of the most pressing socio-economic issues in India, and the need to promote innovation practices targeting the development of poverty-stricken groups, is justified. In this context, the innovation created by grassroots communities to response grassroots issues are denoted to as grassroots innovation (Singh et al., 2021). In this context, innovations created by grassroots communities to respond their local problems are referred to as grassroots innovations (Singh et al., 2021). This form of innovation is deemed highly valuable because it addresses community-level problems while keeping in mind their interests and values. The National Innovation Foundation (NIF) has highlighted many examples of grassroots innovations and their potential to address grassroots issues, such as the Mitticool refrigerator built by Mansukhbhai Prajapati, the multipurpose axe developed by Mohd. Rafiqahangar, Areca nut polisher developed by Lalbiakzuala Ralte And Lalpiangliana Sailo, Automatic horse shaver developed by Mohammad Idris, the tree climbing instrument created by Mohammed Rafeeque (NIF, 2026). These innovations indicate the potential of grassroots communities to generate innovative solutions for grassroots local challenges. Furthermore, GRIs have made remarkable contributions to the economic development of a nation (Gupta, 2013; Bhaduri and Kumar, 2011). Hence, building upon the bottom of the pyramid that cover the majority portion of the Indian populous as a fundamental building block for economic development and poverty alleviation is a valid and practical strategy. Despite limited economic resources, grassroots innovators are rich in creativity, innovation, traditional skills and indigenous knowledge. However, many grassroots communities lack the power of market knowledge, management skill and entrepreneurial skill, resulting in their working in isolation.

There are tremendous opportunities to unlock the innovation capabilities among grassroots innovators in terms of entrepreneurship development and employment creation. It is thereby important to bridge the market information gap and skill deficiency, while simultaneously creating sustainable forms of entrepreneurship at the grassroots level. Alternatives have been proposed in this regard but have not been given proper focus including, fostering an understanding of market trends, identifying critical factors influencing market demands, sharing the information with others and participating in activities tailored to address market needs (Kohli and Jaworski, 1993; Narver and Slater, 1990; Pelham, 2000). Therefore, this research is designed to explore how market orientation connects the innovative capacity of grassroots innovators to entrepreneurial success.

2. Literature Review

Market orientation has been acknowledged as an effective entrepreneurial strategy developed by scholars and practitioners (Pelham, 2000; Kohli and Jaworski, 1990). As stated by Han et al. (1998), innovation provides concrete support in converting market-oriented activities into superior firm performance. A few researchers have found that entrepreneurs' market orientation is meaningfully associated with firm innovativeness. (Han et al., 1998; Narver and Slater, 1990). Low et al. (2007) reported a significant association between innovation and market orientation in SME context; hence, it is important to examine the influence of market-oriented behavior

of grassroots innovators on their entrepreneurial activities. From a behavioral standpoint, Marketing orientation (MO) represents activities directed toward understanding and addressing market needs (Jaworski and Kohli, 1993). MO includes three dimensions such as market intelligence generation, market intelligence dissemination, and market intelligence responsiveness. In general, the market orientation concept has been classified into three elements such as customer focus, inter-functional synchronization, and profitability (Konopa and Calabro 1971; McNamara, 1972; Houston, 1986).

Marketing orientation is defined as creating market intelligence related to market demand, needs and trends (Kohli and Jaworski, 1990). Narver and Slater (1990) identified three elements of MP such as customer orientation, competitor orientation, and inter-functional coordination. Within grassroots communities, most grassroots innovators work as small or micro entrepreneurs, and most of them work in the informal sector (Gupta, 1997). Hence, inter-functional coordination was excluded from the measure of MO. In this study, customer orientation and competitor orientation are included as elements of MO in the grassroots context. These elements emphasize the collection of market information on consumer behavior and competitive actions. In management literature, a few scholars have argued that MO serves as a vital driver for attracting new customers and enhancing sales performance, which in turn assists in achieving entrepreneurial success (Zahra and Covin, 1993; Low et al., 2007). A few researchers have also suggested that grassroots innovators require a better understanding of the market so that they can successfully commercialize GRI-based products (Gupta, 1997, Kumar et al., 2013). However, the association between GRI and market orientation remains unclear; based on this current status, it is imperative to understand the important role that market orientation plays, when it comes to transforming GRI into a successful enterprise.

3. Hypothesis Development

This study has considered two dimensions of market orientation such as customer orientation and competitor orientation. Following the conceptualization of Singh et al. (2021), this study considered the factors of GRI such as NLP: new grassroots learning practices, LS: local solutions, and NC: networking capabilities.

Earlier scholars have suggested that the learning approach enhances a firm performance when it is combined with market orientation (Mavondo and Farrell, 2000; Steinman et al., 2000). Baker and Sinkula (1999) asserted that learning is a mechanism that significantly influences an entrepreneur's ability to meet customer requirements through acquiring and using market information. Extant entrepreneurial literature shows that there is an association between innovation, learning and market orientation; however, the direction of this relationship is still not clear (Low et al., 2007). Customer orientation refers to entrepreneurial activities that respond to customer needs and demands, while learning is a process to create and use that knowledge to enhance performance. A strong customer orientation can promote innovators to absorb market knowledge; it is thereby certain that MO can enhance conversion of new grassroots learning practices into entrepreneurial activities. Grassroots innovators learn new skills and practices, which lead them to improve their performance. If grassroots innovators develop customer-oriented behavior, it helps them better understand customer requirements, and respond accordingly to capture new entrepreneurial opportunities. Customer orientation helps grassroots innovators enrich their knowledge and understanding of diverse customer demands. Furthermore, Mavondo and Farrell (2000) state that customer-oriented entrepreneurs are effective in producing market knowledge, and this practice of knowledge production, inevitably leads to enhance entrepreneurial activities. Hence, the proposed hypotheses:

> *Hypothesis 1a: Customer orientation moderates the association between NLP and EB from entrepreneurial success.*
>
> *Hypothesis 1b: Customer orientation moderates the association between NLP and NEB from entrepreneurial success.*

GRI has been defined as a local solution that addresses to the problems of the grassroots community (Gupta, 2012). Since a local solution emphasizes local problems, it tends to ignore broader market needs and demands (Seyfang and Smith, 2005). In this context, customer orientation helps grassroots innovators to enhance their knowledge of a specific market scenario, and take appropriate actions to respond to these market needs (Low et al., 2007). Customer orientation therefore may be considered as a set of beliefs that regards customer needs and satisfaction as the most important action for entrepreneurship development (Steinman et al., 2000). According to Singh et al. (2021), an entrepreneur or innovator needs to understand customer needs and serve customers because it helps gain economic advantage and non-economic advantage from entrepreneurial activities. Han et al. (1998) recommend that market-oriented behavior helps nurture innovation for

entrepreneurial activities, which, in turn, leads to the generation of economic and non-economic benefits. Hence, this study proposes a moderating role of customer orientation on converting local solution into entrepreneurial success.

Hypothesis 2a: Customer orientation moderates the association between LS and EB from entrepreneurial success

Hypothesis 2b: Customer orientation moderates the association between LS and NEB from entrepreneurial success

Customer orientation promotes knowledge producing behavior, which improves performance through processing market information and implementing market strategies (Verhees and Meulenberg, 2004). Networking capabilities of grassroots innovators help developing relationships with different organizations or institutes. If grassroots innovators develop market orientation, they can use their networking capabilities to generate and capture new market opportunities (Dion and Assimakopoulos, 2013). Networking capabilities, in turn, reflect the degree to which grassroots innovators are connected to external actors or organizations. Further, customer orientation among grassroots innovators lays the foundation for a desire to collect customer information and leverage marketing strategies for entrepreneurship development (Dobni and Luffman, 2000).

Hypothesis 3a: Customer orientation moderates the association between NC and EB from entrepreneurial success

Hypothesis 3b: Customer orientation moderates the association between NC and NEB from entrepreneurial success

Competitor orientation on the other hand, considers entrepreneurial activities that respond to information about competitors, while learning refers to a process of acquiring information and knowledge that improve performance. Competitor orientation helps in developing the ability to recognize, examine, and address competitors' activities (Narver and Slater 1990). Competitor orientation involves recognizing and leveraging specific functionalities to generate competitive advantages. Most successful innovative entrepreneurs develop innovative products as a function of market competitive characteristics (Cooper, 1984). A strong competitor orientation can stimulate an innovator to acquire market information and knowledge from competitors; so, it is certain that MO can promote transformation of new grassroots learning practices into entrepreneurial success.

Hypothesis 4a: Competitor orientation moderates the association between NLP and EB from entrepreneurial success

Hypothesis 4b: Competitor orientation moderates the association between NLP and NEB from entrepreneurial success

Competitor orientation helps grassroots innovators understand what their competitors are doing. Competitor orientation entails collecting and disseminating information regarding competitors operating in the target market (Kohli and Jaworski 1990). If grassroots innovators develop competitor orientation, they can develop innovative products that are better and more innovative than those of their competitors. By doing this, GRI generates competitive advantage by commercializing local innovative products or services. Competitor orientation provides exposure to a grassroots innovator as regards his/her existing competitors along with their entrepreneurial strategies. Furthermore, competitor orientation signifies that an innovator demonstrates insight into the competitive landscape, including rivals' strengths and weaknesses, and simultaneously develops new competitive strategies introduced by major current and prospective players (Day and Wensley, 1988). In the entrepreneurship context, grassroots innovators need a strong competitor-focused mindset that facilitates recognizing rival strengths and weaknesses, creating advantages, and anticipating competitive responses (Gatignon and Xuereb 1991; Kohli and Jaworski 1990). Competitive orientation in the grassroots domain encourages the development of innovative solutions that are economically viable and cost-effective, a central component of entrepreneurial success.

Hypothesis 5a: Competitor orientation moderates the association between LS and EB from entrepreneurial success

Hypothesis 5b: Competitor orientation moderates the association between LS and NEB from entrepreneurial success

Networking capabilities help grassroots innovators engage in entrepreneurial activities. Therefore, competitor orientation acts as an effective strategy because grassroots innovators are more likely to establish their own

connections for institutional support when they understand how and with whom their competitors conduct business. Furthermore, competitive orientation has thereby been considered as an effective entrepreneurial strategy (Kohli and Jaworski, 1990) for entrepreneurial success. Competitor orientation tends to promote the creation of both economic and non-economic benefits for entrepreneurs, as it gathers information on competitors' business practices, which help in capturing new entrepreneurial opportunities. The contingency view states that grassroots conditions that characterize GRI—especially pertaining to its innovation potential and competitive set—inevitably determine whether competitor intelligence has a greater influence on the grassroots innovators' ability to achieve competitive advantages. This study therefore hypothesizes that competitor orientation enhances the conversion of networking capabilities into entrepreneurial success, and proposes the following hypotheses.

Hypothesis 6a: Competitor orientation moderates the association between NC and EB from entrepreneurial success

Hypothesis 6b: Competitor orientation moderates the association between NC and NEB from entrepreneurial success

4. Research Methodology

The sample for this study consists of grassroots innovators undertaking entrepreneurial activities and allied to the rural non-farming sector. The sample of this study includes grassroots innovator who engage in entrepreneurial activities. This study employed structural equation modeling to analyze the moderating effect of market orientation on the association between the factors of GRI and entrepreneurial success.

The regression equations used for moderating effect of customer orientation on the linkage between factors of GRI and entrepreneurial success**.**

$EB = \beta0 + \beta1(NLP) + \beta2(CustO) + \beta3(NLP \times CustO) + \varepsilon$

$EB = \beta0 + \beta1(LS) + \beta2(CustO) + \beta3(LS \times CustO) + \varepsilon$

$EB = \beta0 + \beta1(NC) + \beta2(CustO) + \beta3(NC \times CustO) + \varepsilon$

$NEB = \beta0 + \beta1(NLP) + \beta2(CustO) + \beta3(NLP \times CustO) + \varepsilon$

$NEB = \beta0 + \beta1(LS) + \beta2(CustO) + \beta3(LS \times CustO) + \varepsilon$

$NEB = \beta0 + \beta1(NC) + \beta2(CustO) + \beta3(NC \times CustO) + \varepsilon$

Where: EB: Economic benefits, NEB: Non-economic benefits, CustO: Customer Orientation, NLP: new grassroots learning practices, LS: local solutions, NC: networking capabilities, β0 = Constant, β1, β2, and β3 = Regression coefficients, ε = Error term

The regression equations used for moderating effect of competitor orientation on the linkage between factors of GRI and entrepreneurial success.

$EB = \beta0 + \beta1(NLP) + \beta2(CO) + \beta3(NLP \times CO) + \varepsilon$

$EB = \beta0 + \beta1(LS) + \beta2(CO) + \beta3(LS \times CO) + \varepsilon$

$EB = \beta0 + \beta1(NC) + \beta2(CO) + \beta3(NC \times CO) + \varepsilon$

$NEB = \beta0 + \beta1(NLP) + \beta2(CO) + \beta3(NLP \times CO) + \varepsilon$

$NEB = \beta0 + \beta1(LS) + \beta2(CO) + \beta3(LS \times CO) + \varepsilon$

$NEB = \beta0 + \beta1(NC) + \beta2(CO) + \beta3(NC \times CO) + \varepsilon$

Where: NEB: Non-economic benefits from entrepreneurial success, NLP: new grassroots learning practices, LS: local solutions, NC: networking capabilities, CO: competitor orientation, β0 = Constant, β1, β2, and β3 = Regression coefficients, ε = Error term

5. Results

This study considered new grassroots learning practices, local solution, and networking capability as independent factors (factors of GRI), whereas economic benefits and non-economic benefits from entrepreneurial activities were treated as dependent factors.

5.1 Analyzing the Moderation Effect of Customer Orientation on the Association Between GRI and ES

This section outlines the results of the analysis investigating the moderating role of customer orientation in the relationships between new grassroots learning practices (NLP), local solutions (LS), networking capabilities (NC), and entrepreneurial success.

Hypothesis 1a proposed that customer orientation (Cust) shapes the association between LP and EB. The results in Table 1 show that interaction coefficient for new learning practices and customer orientation was significant (β =0.23, ρ <0.001), indicating that moderation occurred. Hence, Hypothesis 1a is backed by the results, and is accepted. Furthermore, Hypothesis 1b proposed that customer orientation moderates the connection between new learning practices and non-economic benefits from entrepreneurial success. The results in Table 1 illustrate that the interaction coefficient for new learning practices and competitor orientation was not significant; therefore, moderation did not occur. Hypothesis 1b is not supported, as there is lack of statistical evidence.

Table 1: Regression Weight (Moderation effect of CustO on GRI-ES relationship)

Model 1	Estimate	S.E.	C.R.	P	Significance
NLP→ EB	.068	.049	1.382	.167	No
NLP*CustO→EB	.232	.051	4.533	***	Yes
CustO →EB	.179	.049	3.663	***	Yes
NLP→ NEB	-.063	.018	-3.611	***	Yes
NLP*CustO→NEB	-.053	.018	-2.915	.004	Yes
CustO →NEB	.949	.017	54.311	***	Yes
Model 2					
LS→ EB	.279	.046	6.059	***	Yes
LS*CustO→EB	.227	.049	4.623	***	Yes
CustO →EB	.157	.046	3.408	***	Yes
LS→ NEB	-.045	.017	-2.573	.010	Yes
LS*CustO→NEB	.048	.018	2.574	.010	Yes
CustO →NEB	.942	.017	54.376	***	Yes
Model 3					
NC→ EB	-.034	.052	-.643	.520	No
NC*CustO→EB	.137	.056	2.453	.014	Yes
CustO →EB	.218	.053	4.149	***	Yes
NC→ NEB	-.020	.019	-1.082	.279	No
NC*CustO→NEB	-.035	.020	-1.748	.081	No
CustO →NEB	.938	.019	49.923	***	Yes

Model 1: Moderation effect of CustO on LP-ES relationship, Model 2: Moderation effect of CustO on LS-ES relationship, Model 3: Moderation effect of CustO on NC-ES relationship

Hypothesis 2a proposed that customer orientation moderates the association between LS and EB from entrepreneurial success. Table 1 shows that interaction coefficient for new learning practices and customer orientation was not significant ((β =-0.23, ρ >0.05), indicating that moderation did not occur (in Table 1). Therefore, Hypothesis 13a is not recognized as no significant statistical evidence was observed. Furthermore,

Hypothesis 2b proposed that customer orientation moderates the relationship between LS and NEB from entrepreneurial success. The finding presented in Table 2 illustrates that the interaction coefficient for local solution and customer orientation was not significant (β =0.05, ρ >0.05), signifying that moderation did not occur. Hypothesis 2b is thus not supported, as it lacks statistical backing.

Hypothesis 3a proposed that customer orientation moderates the connection between NC and EB from entrepreneurial success. Table 1 shows that interaction coefficient for networking capabilities and customer orientation was significant (β =0.14, ρ <0.05), indicating that moderation was observed. Thus, Hypothesis 14a is acknowledged as it is well supported by the results. Furthermore, Hypothesis 3b proposed that customer orientation moderates the connection between NC and NEB from entrepreneurial success. The results of this study, depicted in Table 1, demonstrate that the interaction coefficient for localized solution and competitor orientation was not significant (β =-0.03, ρ >0.05), signifying that moderation did not occur. Hypothesis 14b is therefore not recognized, as it lacks statistical backing.

5.2 Analyzing the Moderating Effect of Competitor Orientation on the Relationship Between GRI and ES

This section presents the results of the role of competitor orientation on the association of new learning practices, local solutions and networking capabilities with entrepreneurial success.

Hypothesis 4a proposed that competitor orientation acts as moderator in the connection between LP and EB from entrepreneurial success. Table 2 shows that the interaction coefficient between new learning practices and competitor orientation was significant (β =-0.08, ρ <0.05), indicating that negative moderation was observed; therefore, Hypothesis 4a is not supported by the results, and it is not recognized. Furthermore, Hypothesis 4b proposed that competitor orientation moderates the association between new learning practices and non-economic benefits from entrepreneurial success. The findings presented in Table 2 demonstrate that the interaction coefficient for new learning practices and competitor orientation was not significant (β =0.07, ρ >0.05); this signifies that moderation was not observed. Hypothesis 4b is therefore not accepted, as it lacks statistical backing.

Hypothesis 5a proposed that competitor orientation moderates the connection between LS and EB derived from entrepreneurial success. The findings presented in Table 2 illustrate that the interaction coefficient for local solutions and competitor orientation was not significant (β =-0.03, ρ >0.05), indicating that moderation did not occur. Hypothesis 5a is not recognized, as it lacks statistical backing. Furthermore, Hypothesis 5b proposed that competitor orientation moderates the relationship between LS and NEB from entrepreneurial success. The findings presented in Table 2 illustrate that the interaction coefficient for localized solution and competitor orientation was not significant (β =0.04, ρ >0.05), signifying that moderation was not observed. Hypothesis 5b is therefore not recognized, as it lacks statistical backing.

Table 2: Regression Weight (Moderation effect of CO on GRI-ES relationship)

Model 4	Estimate	S.E.	C.R.	P	Significance
NLP→ EB	-.018	.042	-.422	.673	No
NLP*CO→EB	-.078	.033	-2.390	.017	Yes

LS→ NEB	-.009	.053	-.173	.863	No

LSXCO→NEB	.044	.042	1.050	.294	No
CO→NEB	.172	.058	2.974	.003	Yes
Model 6					
NC→ EB	.021	.040	.526	.599	No
NCXCO→EB	.145	.043	3.380	***	Yes
CO→EB	.570	.040	14.134	***	Yes
NC→ NEB	.264	.048	5.536	***	Yes
NCXCO→NEB	-.098	.051	-1.923	.054	No
CO→NEB	.139	.048	2.888	.004	Yes

Model 4: Moderation effect of CO on LP-ES relationship, Model 5: Moderation effect of CO on LS-ES relationship, Model 6: Moderation effect of CO on NC-ES relationship

Hypothesis 6a proposed that competitor orientation moderates the association between networking capabilities and economic benefits from entrepreneurial success. Table 2 shows that the interaction coefficient for networking capabilities and competitor orientation was significant (β =0.14, ρ <0.001), resulting in successful moderation, as one of the main effects was also significant. Since hypothesis 6a is supported by the results, it is accepted. Hypothesis 6b proposed that competitor orientation moderates the relationship between networking capabilities and non-economic benefits from entrepreneurial success. The findings presented in Table 2 demonstrate that the interaction coefficient for networking capabilities and competitor orientation was not significant (β =-0.01, ρ >0.05), showing that moderation was not successful. Therefore, Hypothesis 13b is not acknowledged, as it lacks statistical backing.

6. Conclusion

This study proposed market orientation as a crucial intervening concept that drives the conversion of GRI into entrepreneurial activities. Several researchers in the entrepreneurship field suggest that market orientation comprises a set of specific behaviors and activities (Kohli and Jaworski 1990), a resource (Hunt and Kasynathan, 2001) and a basis for decision-making for entrepreneurship development. Furthermore, a market-oriented entrepreneur/innovator is well positioned to effectively respond to opportunities through value addition of innovative products and services. In extant literature, market orientation has three factors: customer orientation, competitive orientation, and inter-functional coordination (Gatignon and Xuereb, 1997). These dimensions may be appropriate to a firm, but are not applicable to grassroots innovators, who essentially lack knowledge and understanding of market orientation; for them, it is more of a concept than a strategic opinion. This compelled the researchers to implement the existing MO dimensions for grassroots innovators. Market orientation (MO) from the lens of GRI thus is part of market-driven activities comprising of customer orientation and competitor orientation. As grassroots innovators become oriented toward either customer demand or competitor status, this research makes significant contributions to existing market strategy literature by conceptualizing market orientation in the grassroots context. The findings of this research confirm the moderating role of customer orientation on the connection between grassroots new learning practices and economic benefits from entrepreneurial success. Customer orientation also moderates the relationship between networking capabilities and economic benefits from entrepreneurial success. In addition, competitor orientation negatively moderates the relationship between new grassroots learning practices and economic benefits from entrepreneurial success, while it moderates the relationship between networking capabilities and economic benefits from entrepreneurial success.

The strategy literature presents evidence on market orientation, as a market-driven activity is a significant influence on firm performance (Cooper, 1984; Narver and Slater, 1990; Slater and Narver, 2000). In the grassroots context, customer orientation helps stimulate economic benefits from local solutions and networking capabilities. Market orientation of grassroots innovators leads to high performance arising from innovations delivered to the market. Critical examination of extant literature on GRI reveals that the association between GRI and entrepreneurial success is much less explored and needs significant research attention. It thus makes a stronger claim that future research on GRI should employ a quantitative approach to empirically confirm the role of market orientation, yielding more generalized results supported by scientific statistics.

Ethics Declaration

This research did not include any physical experiments linking human members, and no sensitive personal information was gathered from the grassroots innovators participating in the study. The primary data were obtained through the voluntary involvement of grassroots innovators involved in entrepreneurial related activities, with all respondents providing informed consent to contribute in the study. Since the study depended completely on voluntary survey-based responses and maintained participant confidentiality, formal ethical approval was not required.

AI Declaration

This study did not rely on AI tools for the formation of original research content or the explanation of results. The authors independently reviewed and confirmed all materials to maintain the authenticity and academic rigor of the research.

rita.grubisic@gmail.com

Abstract: In the context of global efforts to promote sustainability and environmental responsibility, it is important to examine how young people, particularly students, perceive green business initiatives and what motivates or discourages them from starting their own green businesses. This paper identifies the key factors influencing green entrepreneurship intentions and examines the role of university support in fostering green entrepreneurship among students in economics faculties in the Republic of Croatia. An online questionnaire was the primary instrument for data collection. The questions were designed to capture self-efficacy, psychological, social, and educational factors, as well as university support factors that may be significant for green entrepreneurial intentions. The data were analysed using correlation and regression methods. The results show that students in Croatia have low intentions to engage in green entrepreneurship. Although some interest and willingness to participate in green ventures exist, most respondents report limited motivation due to a lack of practical experience, limited knowledge of green entrepreneurship, and insufficient social and educational support. Furthermore, the findings indicate that the strongest predictors of intention to engage in green entrepreneurship are self-efficacy and social factors related to subjective norms, followed by psychological factors related to attitudes towards the behavior, as described in Ajzen's Theory of the Planned Behaviour. The results suggest that Croatia's education system, along with social support, needs improvement to encourage entrepreneurship and increase student interest in the green sector. Targeted initiatives, practical learning opportunities, and awareness raising campaigns can be particularly effective in encouraging the next generation of green entrepreneurs. Additionally, the research shows that university support is a statistically significant predictor of these intentions. Furthermore, university support plays a vital role in the entrepreneurial ecosystem, serving as a catalyst for education, as research suggests. Although the importance of university support was recognized, students considered it limited and insufficient, particularly regarding specialized study programs and practical experience in the green sector.

Keywords: Entrepreneurship, Green Entrepreneurship, Green Entrepreneurship Intentions, Theory of Planned Behavior, University Support

1. Introduction

The concept of green entrepreneurship is still in its early stages of development. It involves the entrepreneurial process of exploring and exploiting opportunities with the aim of promoting sustainable development (Cohen and Winn, 2007; Dean and McMullen, 2007). It has the potential to address ecological challenges, slow the decline of natural resources, and create new jobs that support sustainable economic and social development (Mondal, 2023; Sharma et al., 2022).

Green entrepreneurship is a specific form of entrepreneurship focused on developing and implementing solutions to environmental problems and encouraging societal changes to prevent ecological damage. It has also been argued that, rather than being a specific type of entrepreneurship, green entrepreneurship should be seen as a new paradigm, as green entrepreneurs are motivated by more than simply creating environmentally friendly products and services for a niche market (Kirkwood and Walton, 2010). Research on the green economy has demonstrated that it can effectively address environmental challenges, with green entrepreneurship being a key component of this concept (Soomro, Ghumro, and Shah, 2020). Today's youth are tomorrow's entrepreneurs, so fostering their interest in green entrepreneurship will help build a more sustainable future (Cai, Hussain, and Zhang, 2022). Building on this premise, this study examines the green entrepreneurship intentions of young adults studying at the Faculties of Economics and Business at four of Croatia's largest universities.

2. Theoretical Overview

Various approaches to defining green entrepreneurship appear in the literature. Kotchen (2009: 28) defines it as "the practice of starting new businesses in response to an identified opportunity to earn a profit and provide (minimise) a positive (negative) environmental externality". Dean and McMullen (2007:53) describe it as "the process of defining and exploiting economic opportunities that are present in environmentally relevant market

failures." Chitrao, Bhoyar, and Divekar (2023) view green entrepreneurship as a business approach that leverages innovation to address social issues, often emphasizing environmental protection.

Following Haldar's notion (2019:100) that "green entrepreneurship is easier to conceptualize but harder to explain," rather than adding more definitions, a basic distinction between green and conventional entrepreneurship is provided. The primary distinction between traditional and green entrepreneurs is in their approach to value creation. While conventional entrepreneurs create value that supports economic growth, green entrepreneurs seek opportunities to reduce their business's impact on the environment. In conventional entrepreneurship, economic value creation or profit is often the sole driver, whereas in green entrepreneurship, economic value serves as a means to achieve environmental and social goals. Finally, conventional entrepreneurs may be compelled to meet sustainability requirements, either by environmental legislation or increasing demand for green products, but green entrepreneurs place the environmental dimension at the core of their business strategies (Saari and Joensuu-Salo, 2019).

Green entrepreneurs are innovators who address ecological problems. They act as agents of social change by influencing consumption habits (Farinelli et al., 2011; Schaper, 2016). Their motives are similar to those of conventional entrepreneurs: they are driven by personal green values, profit, passion, and opportunity recognition, but their financial motivation is often lower than that of traditional entrepreneurs (Kirkwood and Walton, 2010).

Green entrepreneurial intention plays a key role in positive social change (Mia et al., 2022). It refers to an individual 's interest, attention, and decision to take action towards a specific goal (Meoli et al., 2020). It is a stage that precedes action, and research shows that green entrepreneurial intention significantly influences green entrepreneurial behavior (Li, Murad, and Ashraf, 2023). It is influenced by psychological, social, and educational factors.

Some of the most important psychological factors include: (1) self-efficacy or a person's belief in their ability to complete a task or achieve a goal (Ajzen, 1991; Armitage and Conner, 2001), (2) a sense of personal responsibility towards the environment (Bruyere and Rappe, 2007), (3) self-confidence in the ability to overcome obstacles (Armitage and Conner, 2001), (4) motivation for environmental protection (Phillips et al., 2015), and (5) personal values that support sustainable development and environmental protection (Koe and Majid, 2014).

Social factors not only increase the likelihood of starting a green venture but also reinforce the resilience of entrepreneurs who have already taken that path. Social factors include: (1) friends' support and being surrounded by supportive individuals (Cruz, Howorth, and Hamilton, 2013), (2) support from parents and family (Radcliffe and Cilasun, 2019), (3) social norms (Ajzen, 1991), (4) participation in networks and communities that promote green entrepreneurship (Wymer and Samu, 2003), and (5) government support (Alvarez-Risco, Muthu, Del Aguila Arcentales, 2021).

Educational factors can influence perception, interest, and the knowledge and skills related to green entrepreneurship, including: (1) understanding the role of the entrepreneur in society (Butkouskaya, Romagosa, and Noguera, 2020), (2) interest in entrepreneurship (Hameed et al., 2021), and (3) developing the skills and knowledge necessary for starting and managing a business (Butkouskaya, Romagosa, and Noguera, 2020).

One of the most widely used conceptual frameworks for evaluating green entrepreneurial intentions is Ajzen's Theory of Planned Behavior (1991). It states that intentions to perform a behavior can be predicted based on attitudes towards the behavior, subjective norms, and perceived behavioral control. Attitudes towards the behavior are crucial in shaping intentions, referring to the extent to which a person holds a positive or negative view of the behavior in question. The psychological factors mentioned above relate to attitude towards the behavior. Subjective norm refers to the perceived social pressure to perform a particular behavior and can be related to the aforementioned social factors. The third component of Ajzen's model, perceived behavioral control, refers to the perceived ease or difficulty of performing the behavior. Educational factors play a key role in perceived behavioral control, as they influence the knowledge, skills, and self-confidence needed to perform a behavior. They can also affect access to financial and other resources required to start and manage a business. Recent studies indicate that elements of Ajzen's model, along with self-efficacy and university support, can serve as predictors of green entrepreneurial intentions (Alvarez-Risco, Muthu, Del Aguila Arcentales, 2021; Anghel and Anghel, 2022; Cabana-Villca et al., 2024; Cai, Hussain, and Zhang, 2022; Roy, 2023). University support plays an important role in assessing students' green entrepreneurial intentions, as it influences the context for understanding the impact of educational factors (Yi, 2021), while self-efficacy has become a fundamental psychological concept in entrepreneurship research (Newman et al., 2019).

This study examines the main research question: Can green entrepreneurial intentions among Croatian business students be predicted using the propositions of the Theory of Planned Behavior, and what role does university support play in assessing these intentions?

The following equation was formulated for the regression model:

$GEI_i=\alpha+\beta_1$SELF-EFFICACY$+\beta_2$PSYCHOLOGICAL FACTORS$+\beta_3$SOCIAL FACTORS$+\beta_4$EDUCATIONAL FACTORS$+\beta_5$UNIVERSITY SUPPORT$+\varepsilon_I$

3. Research Methodology

To address the research question, an empirical study was conducted using an online questionnaire as the data collection instrument. The questionnaire consisted of 54 close-ended questions divided into two sections. The first section gathered general information about participants, while the second section explored green entrepreneurial intentions and the factors behind them.

The 5-point Likert scale was applied, ranging from 1 (strongly disagree) to 5 (strongly agree). The convenience sampling method was used, and the questionnaire was distributed via Facebook groups of students from the Faculties of Economics and Business at the four largest public Croatian universities: Zagreb, Split, Osijek, and Rijeka. In total, 77 students fulfilled the online questionnaire from June to July 2024. The analysis of the collected data was performed using SPSS and Stata, including descriptive statistics, correlation, and regression analyses.

For constructs used in this study, Cronbach's Alpha coefficients were calculated, demonstrating strong internal consistency and reliability (Table 1). The research sample's descriptive statistics are shown in Table 2.

Table 1: Reliability coefficients for variables used in the study

Scale	N of items	Cronbach's Alpha
Green entrepreneurial intentions	9	0,929
Self-efficacy	4	0,863
University support	17	0,973
Psychological factors	5	0,875
Social factors	6	0,923
Educational factors	4	0,962

4. Research Results and Discussion

The descriptive analysis of the green entrepreneurship intentions construct shows that Croatian business students have low intentions toward green entrepreneurship (Mean=2.63). Among the items listed in Table 3, the highest mean value is recorded for "If I had an opportunity and resources, I would start a green venture" (Mean=3.40), indicating a moderate willingness to start a green business if all prerequisites are met. However, the item most directly addressing green entrepreneurial intention - "I plan to develop a venture that will address environmental issues in my community" - has the lowest mean value (Mean=2.28). Additionally, the wide dispersion in results, as indicated by the standard deviation, suggests significant variability in attitudes towards green entrepreneurship.

Table 3: Descriptive statistics for the green entrepreneurship intentions construct

	Mean	St. D.
Green Entrepreneurship Intentions	2,63	
I plan to develop a venture that will address environmental issues in my community	2,28	1,212
I suggest to my colleagues to develop projects that target environmental issues	2,89	1,372
My future venture will prioritize environmental benefits over financial	2,67	1,219
If I had an opportunity and resources, I would start a green venture	3,40	1,238
I had serious thoughts of becoming green entrepreneur	2,54	1,230
I will do everything in my power to start my own green venture	2,37	1,246
I have a strong intent to start a green venture one day	2,39	1,193
I plan to start a green venture and participate in managing it	2,40	1,269
Iti s safer to work for an employer than take risks with green venture	2,75	1,237

Source: Research (N=77)

The descriptive analysis of the self-efficacy construct (Table 4) indicates that Croatian business students perceive their self-efficacy as relatively low (Mean=2.83). Although the highest mean is recorded for the item "Starting and managing a green venture is a task I can accomplish" (Mean=3.17), the results indicate a clear lack of knowledge and skills necessary to complete the task.

Table 4: Descriptive statistics for the self-efficacy construct

	Mean	St. D.
Self-efficacy	2,83	
Starting and managing a green venture is a task I can accomplish	3,17	1,171
I have necessary knowledge to start a green venture	2,61	1,147
I have necessary skills to start a green venture	2,62	1,183
I am confident that in the future I'll be able to develop a successful green business	2,91	1,196

Source: Research (N=77)

Among all constructs in this research, university support is rated the lowest (Mean=2.55). Items evaluating universities' ability to motivate students to start their own businesses and to provide them with knowledge and tools are rated above average, indicating that universities may perform better in promoting general entrepreneurship intentions, but they clearly lack a green focus. While universities in Croatia vary in the development and quality of entrepreneurship-related curricula, the results in Table 5 indicate a relatively low perception of university support.

Table 5: Descriptive statistics for the university support construct

	Mean	St. D.
University Support	2,55	
Offers elective courses on green entrepreneurship	2,31	1,217
Offers project assignments on green entrepreneurship	2,54	1,262
Offers internships related to green entrepreneurship	2,25	1,215
Offers undergraduate or graduate programs focused on green entrepreneurship	2,19	1,192
Organizes conferences/workshops on green entrepreneurship	2,78	1,221
Connects students with green entrepreneurship	2,41	1,162
Raises awareness on green entrepreneurship as a career choice	2,49	1,231
Motivates students to start their own businesses	2,97	1,277
Provides tools for starting own businesses	2,90	1,273
Provides necessary knowledge to start own businesses	2,91	1,258
Creates favourable environment for green entrepreneurship among students and teachers	2,60	1,206
Offers support programs for green startups	2,61	1,279
There is a support for the green entrepreneurship evident from the very top university level	2,49	1,253
Offers training modules in green entrepreneurship	2,56	1,186
Offers practical skills development in green entrepreneurship (projects, business plans, etc.)	2,57	1,163
There are specialized offices aiding in green venture development	2,38	1,181
Offers financial and/or technical advice regarding green entrepreneurship	2,45	1,176

Source: Research (N=77)

As shown in Table 6, Croatian business students feel capable of implementing sustainable business models (Mean=3.32), which is reinforced by their belief that they can overcome obstacles related to green startups (Mean=3.26). However, they also lack a strong sense of personal responsibility for the environment (Mean=2.60). This lack is reinforced by the absence of values that support sustainable development and environmental protection (Mean=2.75).

Table 6: Descriptive statistics for the psychological factors construct

	Mean	St. D.
Psychological Factors	3,00	
I have a strong sense of personal responsibility for the environment	2,60	1,150
I believe I can overcome obstacles related to green startup	3,26	1,018
I am motivated to start a green venture to contribute to environment protection	3,05	1,012
My personal values support sustainable development and environment protection	2,75	1,171
I feel competent for sustainable business models implementation	3,32	1,032

Source: Research (N=77)

Regarding the social factors construct, the descriptive analysis in Table 7 shows that Croatian business students perceive their networks and communities as supportive of green entrepreneurship (Mean=3.10) and sustainable development (Mean=3.05), while also feeling increasing social pressure to adopt green-oriented activities (Mean=2.96). This social momentum should also be recognized by universities; inadequate focus on green initiatives is evident (Table 5), and a curriculum shift is necessary to promote green entrepreneurship.

Table 7: Descriptive statistics for the social factors construct

	Mean	St. D.
Social Factors	2,96	
My friends would support/are supporting my green venture plans	2,92	1,085
My parents would support/are supporting my green entrepreneurship intention	2,88	1,287
There is a social pressure to embrace green oriented activities	2,96	1,271
I believe that society values green ventures	2,83	1,218
I am surrounded by people who believe in the importance of sustainable development	3,05	1,224
I participate in networks and communities that support green entrepreneurship	3,10	1,199

Source: Research (N=77)

The last group of factors, educational factors, is rated highest among all constructs used in this research (Mean = 3.10), although it remains moderate. These results show that education can influence students' understanding of the role of entrepreneurs and entrepreneurship in society, and also affect their decision to pursue entrepreneurship as a career path. This only reinforces the conclusion that universities should reevaluate their curricula and "paint it green", as positive effects on students' green entrepreneurship intentions can be expected in the future.

Table 8: Descriptive statistics for the educational factors construct

	Mean	St. D.
Educational Factors	3,10	
My education helped me develop sense of initiative – a form of entrepreneurial attitude	3,09	1,194
My education helped me understand the role of the entrepreneur in the society	3,18	1,221
My education made me interested in becoming entrepreneur	3,06	1,311
My education gave me knowledge and skills necessary to develop and manage a business	3,08	1,254

Source: Research (N=77)

For variables used in this research, Pearson correlation coefficients were computed (Table 9). All presented coefficients are significant at the 0.01 level and moderate. The strongest correlation is between green entrepreneurship intentions and social factors, followed by self-efficacy, whereas the weakest is with educational factors.

The strong correlation between green entrepreneurship intentions and social factors is consistent with previous research (Alvarez-Risco, Muthu, and Del Aguila Arcentales, 2021; Cabana-Villca et al., 2024), as is the strong

correlation between self-efficacy and green entrepreneurship intentions (Cabana-Villca et al., 2024; Fragoso, Rocha-Junior, and Xavier, 2020; Newman et al., 2019).

The association between green entrepreneurship intentions and psychological factors also aligns with earlier studies (Roy, 2023), with an important distinction. In Roy's study (2023), values related to ecology and commitment to the environment had the greatest overall impact on green entrepreneurial intentions, whereas in our research sample, these values were among the lowest rated (see descriptive statistics in Table 6).

As educational factors are the highest rated among all constructs analysed in this research (see the descriptive statistics in Table 8), the weak correlation between these factors and green entrepreneurship intentions is somewhat unexpected. Similar studies have reported a strong positive influence of education (Anghel and Anghel, 2022; Cai, Hussain, and Zhang, 2022). Given evidence of the importance of university support in assessing green entrepreneurial intentions (Aliedan et al., 2022; Roy, 2023), this unexpected result should be analysed in the context of limited university support (see the descriptive statistics in Table 5). Educational factors alone may be less significant in evaluating green entrepreneurship intentions unless accompanied by strong university support that facilitates turning those intentions into green startups.

Table 9: Pearson correlation matrix

	Green Entrepreneurship Intentions	Self-Efficacy	University Support	Educational Factors	Social Factors	Psychological Factors
Green entrepreneurship intentions	1.000					
Self-efficacy	0.625**	1.000				
University support	0.513**	0.547**	1.000			
Educational factors	0.348**	0.352**	0.437**	1.000		
Social factors	0.641**	0.651**	0.513**	0.450**	1.000	
Psychological factors	0.588**	0.710**	0.527**	0.493**	0.712**	1.000

**. Correlation is significant at the 0.01 level (2-tailed)

Since all variables are interrelated, a multicollinearity test was performed (Table 10). To detect multicollinearity, variance inflation factors were calculated; they are satisfactory (1<VIF<5) and therefore meet the prerequisites for the regression model.

Table 10: Multicollinearity test

Psychological factors	2.79	0.358184

As seen in Table 11, the research model described by the equation: $GEI_i=\alpha+\beta_1$SELF-EFFICACY$+\beta_2$PSYCHOLOGICAL FACTORS$+\beta_3$SOCIAL FACTORS$+\beta_4$EDUCATIONAL FACTORS$+\beta_5$UNIVERSITY SUPPORT$+\varepsilon_i$ is represented by Model 1. Including all variables in the model increased R^2, but only two remained significant. Specifically, self-efficacy and social factors have a significant and positive influence on green entrepreneurial intentions in the first model. This finding, highlighting the importance of social factors, aligns with similar research (Alvarez-Risco, Muthu, and Del Aguila Arcentales, 2021; Cabana-Villca et al., 2024).

To reveal specificities about the interactions between the observed variables: self-efficacy, psychological factors, social factors, educational factors, and university support, additional models are presented. Model 2 demonstrates a significant and positive effect of self-efficacy on green entrepreneurship intentions, aligning with previous research (Newman, 2019). When psychological factors are included (Model 3), they show a positive and significant effect on green entrepreneurial intentions, but the influence of self-efficacy is weaker than in the second model. Adding social factors in the fourth model eliminates the influence of psychological factors and further reduces the impact of self-efficacy. Including educational factors in the fifth model shows that they are not significant predictors, while self-efficacy and social factors continue to significantly influence green entrepreneurship intentions. Since educational factors were found to be important in the descriptive analysis, a sixth model was tested. When entering the regression model with self-efficacy, educational factors are not relevant in the assessment of green entrepreneurship intentions, while self-efficacy remains a significant predictor. The seventh model shows that, alongside self-efficacy, university support is a significant predictor of green entrepreneurship intentions. This was already discussed in the descriptive and correlation analysis section, which suggested that university support may be an important catalyst between education and entrepreneurial intentions, and that the two should not be analyzed without considering the context provided by university support.

Finally, the eighth model introduces social factors, along with self-efficacy and university support. In this model, university support is no longer a significant predictor of green entrepreneurship intentions, while self-efficacy and social factors are. Overall, this model shows the best fit, as suggested by the model statistics. Finally, by analysing the presented models, it can be concluded that self-efficacy and social factors are robust and the most important predictors of green entrepreneurial intentions.

5. Conclusion

This study shows that, although Croatian business students generally recognize the importance of sustainable development, their intentions to engage in green entrepreneurship remain relatively low. This is mainly due to limited practical experience, insufficient knowledge, and a lack of social and educational support. The analysis confirms that self-efficacy and social factors (subjective norm) are the strongest predictors of green entrepreneurial intentions, followed by psychological factors (attitudes towards the behavior), in line with the core assumptions of the Theory of Planned Behavior. Educational factors did not emerge as a significant predictor in the regression model, suggesting that current curricular content and learning formats are not yet sufficient to turn awareness into concrete entrepreneurial intentions. At the same time, university support proved to be a statistically significant predictor, yet students still perceive this support as fragmented and limited, especially regarding specialized green entrepreneurship programs and hands-on learning opportunities in the green sector.

These findings suggest that to promote stronger green entrepreneurial intentions, universities and policymakers should focus on enhancing students' self-efficacy, creating supportive social environments, and redesigning educational programs to be more experiential and practice oriented. Initiatives such as service-learning programs, mentoring schemes, incubators focused on sustainable ventures, and targeted awareness raising campaigns could help bridge the gap between students' pro-environmental values and their willingness to start green ventures. In the Croatian context, this is particularly important, as green entrepreneurship can address environmental challenges while also contributing to economic and social development. Future research should expand on this work with larger and more diverse samples, longitudinal studies, and cross-country comparisons to better understand how institutional settings and policy frameworks influence the development of green entrepreneurial intentions among young people.

Challenges of Scaling Cultural Edupreneurship in an Institutionalized Educational Ecosystem: The Case of a Digital Platform Startup

Victoria Slettli
Inland School of Business and Social Sciences, University of Inland Norway, Rena, Norway

victoria.slettli@inn.no

Abstract: This paper examines the challenges of scaling digital platform startups and contributes to emerging discussions on platform grafting in institutionalized ecosystems. Drawing on the case of Ekulturskolen, a Norwegian digital platform startup operating at the intersection of educational and cultural entrepreneurship, the study contributes to the literature on digital entrepreneurship and platform scaling. Specifically, it investigates scaling challenges within a strategically important Business-to-Government (B2G) context, drawing on insights from research on digital entrepreneurship, platform ecosystems, and digital startup growth. Ekulturskolen operates within the Norwegian municipal music and arts school system, offering digital educational content that complements existing public services. The findings suggest that successful platform scaling depends not only on technological capabilities and market demand but also on the platform's ability to engage with and become embedded within the existing ecosystem of public extracurricular arts education. The study further contributes to the understanding of "platform grafting" by illustrating how scaling a digital startup can be a prolonged and complex process, even in the presence of an identifiable unmet need and a technologically robust value proposition. Strongly institutionalized sectoral ecosystems may create substantial barriers to market entry and growth. These barriers are both institutional and ecosystemic in nature and include: (a) structural constraints, such as annual budget cycles and public procurement procedures, and (b) cultural-cognitive barriers among professional stakeholders who may perceive digital innovation as a threat to their professional roles. To overcome these challenges, digital ventures must invest in relationship-building with municipalities, develop partnerships with established actors within the ecosystem, and work toward financial models that are compatible with municipal budgeting practices and procurement requirements.

Keywords: Scaling, Digital Startup, Cultural Entrepreneurship, Educational Entrepreneurship, Digital Platform, Institutionalized Ecosystem.

1. Introduction

The advancement of digital innovations has paved the way for a multitude of platform-based startups. Digital technologies have restructured cultural value chains, opened new niches, and given rise to a new generation of independent entrepreneurs (Nambisan et al., 2019). Both cultural and educational entrepreneurship have benefited from utilizing digital platforms and artificial intelligence (AI) to create unique offers and value propositions. These technologies have unlocked more complex cultural and educational markets, where novel forms of design, production, and distribution form the basis for new business models and create niches for new actors within value chains (Lăcătuş and Stăiculescu, 2016).

Cultural entrepreneurship, which involves establishing cultural enterprises and bringing cultural and creative products and services to the market, delivers cultural value while generating financial income (Dobreva and Ivanov, 2020). Empowered by modern informational and communication technologies, AI and big data, cultural entrepreneurship dramatically changes how cultural and creative industries operate. Cultural audiences are taking on new roles – ranging from users to co-creators, advisors and collaborators in cultural production. By leveraging digital technologies to combine novel value propositions and innovative cultural products, cultural entrepreneurs challenge and transform established industry patterns. Beyond delivering aesthetic and cultural value, cultural entrepreneurship contributes to urban and regional development, drives economic growth in cities, and enhances overall quality of life (Ratten and Ferreira, 2017). Furthermore, because cultural entrepreneurship encompasses both social and economic dimensions, it is often closely linked to neighborhood revitalization, community engagement, and youth development in traditionally underserved communities (ibid.).

Similarly, in educational entrepreneurship (often termed "edupreneurship"), technological development offers new opportunities for autonomy, decentralization, and customization (Lăcătuş and Stăiculescu, 2016). Consequently, a new category of entrepreneurs has emerged – focusing on new educational formats such as virtual schools, online courses, and distance learning. Educational entrepreneurship manifests in various forms, including developing and editing educational products and learning materials, offering tutoring and teaching services, or establishing independent schools. The overarching goal of such initiatives is to improve learning outcomes, driven by a shared vision of a better education system.

Edupreneurial initiatives frequently target the needs of specific population groups by offering tailored educational solutions. However, several barriers can limit edupreneurial activity, including formal regulations in public education systems and informal constraints, such as attitudes towards newcomers. To overcome these obstacles, edupreneurs must often demonstrate that their innovations are effective, cost-efficient, and of high quality. Modern edupreneurs use complex combinations of pedagogy, technology, and business strategies to create value through unique educational offerings (Olatunde-Aiyedun et al., 2024). The combination of digital platforms and AI by edupreneurs contributes to improved learning and teaching methods, data-driven decision-making, and scalable business models (ibid.).

This paper explores the case of a digital platform startup combining cultural and educational entrepreneurship. The study places a particular focus on the critical elements for early-stage ventures: scaling and growth. Previous studies of digital platform startups have addressed the role of digital technologies for the new ventures and ecosystem development (Zahra et al., 2023, Nerbel and Kreutzer, 2023); entrepreneurial growth in digital business (Chen et al., 2023, Page and Holmström, 2023); resource orchestration and managing tensions during scaling (Zeng et al., 2023); the connection between startups and existing ecosystems (Björkdahl et al., 2024); value co-creation within the platform ecosystems (Hawlitschek and Hodapp, 2024); and managerial and organizational challenges of digital firm scaling (Brown et al., 2025). Notably, recent studies particularly highlight the specific difficulties of scaling caused by the need to integrate into pre-existing ecosystems (Björkdahl et al., 2024; Brown et al., 2025). The paper aims to contribute to this debate by addressing the following research question: *What challenges emerge when a cultural edupreneurship digital platform seeks to scale within an institutionalized educational ecosystem?*

The remainder of this paper proceeds as follows. The next section establishes a theoretical framework, discussing digital entrepreneurship and platform ecosystems, the scaling of digital ventures, and challenges of integrating new digital startups into existing ecosystems. Further, the methodological approach is explained. The empirical section presents the case of *Ekulturskolen* – a Norwegian digital platform startup at the nexus of cultural and educational entrepreneurship and outlines the peculiarities of national and institutional context in which it operates. The paper concludes with a discussion and final remarks.

2. Theoretical Framework

2.1 Digital Entrepreneurship and Platform Ecosystems

Advanced digital technologies, such as big data, AI, blockchain and others effectively enable the rise of digital startups and digital entrepreneurship. This phenomenon can be defined as the "practice of pursuing new venture opportunities presented by new media and internet technologies" (Davidson and Vaast, 2010). Similarly, a digital startup can be understood as a "venture that exploits digital technology in its operations or has a product or service of digital nature" (Page and Holmström, 2023). Numerous studies emphasize the significant role of digital platforms for entrepreneurship and digital startups (Nambisan et al., 2019) highlighting how these ventures operate within digital platform ecosystems (DPE) (Nerbel and Kreutzer, 2023) and broader entrepreneurial ecosystems (Zahra et al., 2023). A DPE encompasses interactions, transactions and joint value creation among various platform actors, including complementors on the supply and demand sides. The ecosystem framework conceptualizes platforms as complex techno-socio-organizational phenomenon, rather than simply technological artifacts. Depending on their unique capabilities, digital startups may assume distinct yet complementary roles within digital entrepreneurial ecosystems (Zahra et al., 2023). Digital disruptors leverage new technologies to radically transform or create new entrepreneurial ecosystems. Imitative followers emulate existing models and advance within an established ecosystem. Meanwhile, technology pioneers develop innovative technologies to dominate well-defined markets. Through these diverse roles digital startups actively shape the evolution of the ecosystem in which they operate. From a practical perspective, entrepreneurs need to build the necessary capabilities and access vital resources to effectively position and strengthen their ventures within these entrepreneurial ecosystems.

2.2 Digital Startup Scaling

Digital technologies are pivotal for both designing business models and rapidly scaling digital startups. The notion of scaling represents a "generative process through which a venture's user base increases significantly between two points in time" with the objective of achieving competitive scale and establishing market leadership (Huang et al., 2022). It is widely accepted that digital scaling occurs quickly and differs from its

traditional counterpart. Indeed, due to digital platforms, applications, low marginal and distribution costs, and strong network effects, the scaling of digital startups may occur at a dramatic pace (Jansen et al., 2023, Zeng et al., 2023).

Organizations that seek to scale successfully need to pay close attention to such dimensions, as technology, people, contextual setting and internal organizational processes and actions (Sahay and Walsham, 2006; Picken, 2017). According to Jansen et al. (2023), scaling encompasses organizational change and transformation during which a startup needs to handle specific managerial challenges by purposefully and intentionally implementing growth-enhancing activities and processes. The success of scaling, therefore, depends on how effectively the firm orchestrates and executes these processes.

Previous studies have identified five common traits inherent to the successful scaling of startups (Nielsen and Lund, 2018): adding new distribution channels; eliminating traditional capacity limitations; delegating capital investments to partners; leveraging partners across multiple areas of the business model and developing platform-based business models that enable competitors to become customers.

Scholars also emphasize that raising external financing can be critical for scaling because digital startups may require several years to develop their business and attract users before generating significant revenue from customers (Brown et al., 2025). Furthermore, recent studies highlight that a startup's scaling success depends on the relational connection with the wider ecosystem and the interplay between external and internal resources (Zeng et al., 2023). Therefore, scaling should not be regarded as an isolated activity but rather as a comprehensive process that enables organizational growth, replication, and synchronization (Jansen et al., 2023).

2.3 The Challenges of Platform Grafting Into an Existing Ecosystem

As previously noted, platform-based startups can act as enablers of new ecosystems, or disruptors of existing ones. However, in some contexts, platforms are introduced into pre-existing ecosystems, where their success depends heavily on their ability to harmonize with the rest of the ecosystem (Björkdahl et al., 2024). The concept of "platform grafting" refers to the process of incorporating a new platform into an established ecosystem, resulting in a coevolutionary adaptation of both the platform and the surrounding ecosystem (ibid.). Platform grafting presents distinct managerial challenges that differ from the constraints experienced during the creation of a new platform. I n their study of digital healthcare platforms in Sweden, Björkdahl et al. (2024) described the constraints and actions connected with introducing platforms into a sector characterized by strong regulations, a defined user base, and a critical network of physical assets. The authors argue that building strong dynamic capabilities is a key to platforms' successful entry into an existing ecosystem. Specifically, this process unfolds across three distinct phases. In the first phase, digital startups need to sense opportunities which involve identifying complementary assets, addressing the task requirements, acquiring key partnerships and investigating existing governance structures. In the second phase, startups must seize opportunities by integrating complementary assets into the new asset architectures and taking actions to legitimize the platform within the ecosystem. In the third phase, as the platform grows, business models and ecosystems should be reconfigured. This involved empowering asset structures with data and AI, managing coevolution with ecosystem actors, and revising governance mechanisms to unlock the full potential of digital platforms.

3. Method

The nature of the research questions posed in this paper presumes a qualitative methodology approach. The study adopts an explorative single-case study design to examine the scaling of a cultural edupreneurship digital platform within an institutionalized educational ecosystem. A case study approach is appropriate due to the contemporary and context-dependent nature of the phenomenon, which requires in-depth insight into organizational processes and institutional dynamics (Yin, 2018).

The primary data consists of a written semi-structured interview with one of the startup's co-founders. The interview was conducted via a structured questionnaire, followed by iterative written follow-up questions to clarify and elaborate on key responses. While the use of a single informant and written interview format limits depth and insight compared to oral interviews, it provides direct access to founder-level interpretations of organizational and scaling-related decisions during an early-stage development phase. Given the early-stage nature of the venture and its ongoing scaling process, the founder represents a key informant with privileged insight into strategic intent, organizational challenges, and institutional interactions (Ucbasaran et al., 2013). In

emerging startups, especially those operating in institutionalized environments, founder narratives are often a primary and necessary source of empirical insight.

To strengthen validity and enable triangulation, the interview data were complemented with secondary sources, including publicly available information from the *Ekulturskolen's* website and documentation related to the startup, as well as other available online materials describing the venture's activities and positioning.

4. Empirical Section

4.1 National and Institutional Context

In Norway, extracurricular arts education is organized as *kulturskole* system, which comprises municipal music and arts schools for children and youth. According to Norwegian government, these schools should facilitate children and young people's participation in various activities where they can learn, experience, create, and communicate cultural and artistic expressions in a safe and positive environment (Regjeringen, 2025). *Kulturskole* is intended to be part of a holistic upbringing within the local community, serving as a bridge between schooling and leisure time (Regjeringen, 2024-2025). Additionally, it is recognized as an important arena for achievement, inclusion, and the prevention of social exclusion.

The most common activities offered by *kulturskole* include music, dance, theatre, visual arts, and creative writing, although some municipalities also offer training in heritage preservation and traditional craft techniques. These music and arts schools are owned and operated by municipalities, which are legally required to provide cultural school services for children and youth (Karlsen et al., 2024). Municipalities finance these institutions through a combination of public funding and parental co-payments.

In 2017, approximately 100,000 students were enrolled in Norwegian music and arts schools (SSB, 2017). During the 2018/2019 school year, just over 13% of all Norwegian primary school children attended such schools (Berge, 2019). Nevertheless, capacity constraints prevent many children from securing a placement; historically, waiting lists have reached around 24,500 children (SSB, 2017). Waiting times vary from several weeks to several years depending on the specific municipality and subject. For instance, waiting periods of five to seven years have been reported for piano instruction (Odland, 2015).

Beyond teacher shortage in some subjects, these music and arts schools are not financially accessible to everyone (Berge, 2019). Children from low-income families are particularly disadvantaged, as they often can neither afford private alternative instruction nor access the relevant networks necessary to bypass these barriers.

4.2 The Case of Ekulturskolen

4.2.1 Background and Launch

The *Ekulturskolen* platform was founded in 2022 by two entrepreneur brothers. The startup emerged as a direct response to challenges within the municipal music and arts education sector, including budget cuts, protracted waiting lists, significant geographical distances, and the exclusion of children from financially constrained families (Ekulturskolen, 2026a). The foundational vision was straightforward: to make education in creative subjects accessible to all youth, regardless of personal interests, geographic location, or financial situation.

The business proposition of *Ekulturskolen* comprised digital courses in dance, music, drawing, and visual arts, spanning from beginner to advanced levels. The instructional content was co-developed together with professional educators and designed to serve as a curriculum supplement. Consequently, *Ekulturskolen* was not intended to replace existing municipal music and arts schools, but rather to complement them and scale access to demographics that the traditional public system could not reach independently (Ekulturskolen, 2026b).

Prior to launching the venture, the founders conducted extensive exploratory groundwork. They engaged with over 200 cultural administrators, teachers, and students across different municipalities, alongside reviewing national research reports. Specifically, the founders conducted 50 interviews with municipal cultural leaders and executed pilot projects within Norwegian schools. Furthermore, they maintained an ongoing dialogue with the Norwegian Council for Music and Arts Schools (Norsk kulturskoleråd) and the Ministry of Culture. This rigorous stakeholder mapping revealed a significant undeserved market and a gap in the existing educational offerings - as no adequate digital solution yet existed.

Initial resources and capital for establishing *Ekulturskolen* were constrained. The startup's primary assets consisted of intellectual and social capital in the form of knowledge, competence, and networks. One founder possessed a background in business development, digitalization, sales, and financing, while the other brought extensive media production experience and established networks within creative and educational environments. This combined expertise provided the venture with essential initial legitimacy and credibility in the field. Additionally, the founders recruited a specialist with AI expertise, which was strategically important for the venture.

The first version of the platform was launched as a basic video library. Since 2022, the founders have produced over 400 video lessons, accumulating more than 5,500 minutes of instructional content. Since its inception, the platform has undergone continuous technical and systemic improvements. It is currently utilizing modern infrastructure that ensures fast, flexible, and scalable architecture, facilitated by direct AI integration.

4.2.2 Business Model and Revenue Streams

Ekulturskolen utilizes a subscription-based revenue model, which offers certain predictability for both the founders and the customers. Entrepreneurs report that rhis model provides a reliable overview of monthly recurring revenue (MRR), thereby facilitating long-term financial planning and strategic business investments. On the demand side, families avoid per-video transaction fees, allowing children to freely explore the diverse courses on the platform.

Originally, the founders intended to rely solely on individual customer subscriptions. However, this approach alone could not resolve the matter of exclusion of the disadvantaged youth, nor could it effectively scale the business. Consequently, *Ekulturskolen* pivoted to focus on a diversified strategy comprising three major subscription-based revenue streams.

The first revenue stream is Business-to-Consumer (B2C), targeting individual families. Currently, this remains the primary source of revenue and serves as vital channel for generating continuous user interaction data.

The second revenue stream is Business-to-Government (B2G), where *Ekulturskolen* establishes commercial agreements with municipalities through their local music and arts schools. The founders identify this revenue stream as the most scalable in the long term and the most strategically important. To facilitate municipal adoption, a co-financing model was developed in collaboration with the SpareBank 1 Foundation, a Norwegian philanthropic organization supporting educational, cultural, and community-oriented initiatives. Under this model, municipalities receive free access to the platform's digital content during the first year, while the foundation covering 80% of the total subscription cost. In the second year, the municipal co-payment increases to 20%, and by the third year, the municipality assumes the full subscription price. This graduated pricing mechanism renders platform adoption both politically and financially viable for local governments.

The third revenue stream involves strategic partnerships with established actors within the educational technology (EdTech) market. These partners possess distribution networks and pre-existing customer relationships with the Norwegian public education and *kulturskole* sectors.

Like most digital platforms, *Ekulturskolen* operates within ecosystem that connects different user groups: children and students as end users of digital content, teachers and instructors as content providers, and municipalities and schools as the paying clients. Teachers play a particularly important role as supply-side complementors, their contributions elevate course quality, which in turn enhances platform attractiveness and draws new students. While this dynamic fosters significant potential for network effects – accelerating growth, user value, and systemic scalability - the founders observe that achieving critical mass and fully unlocking these network effects remains a prolonged process due to specific barriers which are addressed below.

4.2.3 Scaling and Growth

Every commercial platform harbor ambition for growth and expansion, and *Ekulturskolen* is no exception. According to the founders, the startup's growth strategy encompasses three primary dimensions. The first dimension concerns increasing the volume of active students utilizing the platform. The second dimension relates to expanding the number of municipalities adopting the solution (B2G stream). The third potential growth opportunity involves geographic expansion into the broader Nordic market.

Regarding B2G expansion, the founders report facing several significant barriers. The first barrier stems from the prolonged public procurement timelines, which involve complex tender processes and multiple hierarchical levels of municipal decision-making.

The second barrier refers to internal resistance within municipalities, particularly from teachers concerned about their professional roles. The founders of *Ekulturskolen* encounted considirable skepticism among the *kulturskole* educators, who feared that a digital platform could undermine their pedagogical role and authority, reduce demand for their experience, or threaten their employment security. To deal with this barrier, the founders revised their communication strategy. They explicitly emphasized that the platform is not designed to replace physical instructors, but rather to complement them in resource-constrained areas and supported students' independent practice between lessons.

The third challenge relates to municipal financial constraints, as music and arts schools are not funded at the same level as compulsory public education and are vulnerable to budget cuts. At the same time, the cultural sector is historically anchored in public subsidization and non-profit philosophies. Consequently, actors within this ecosystem exhibited skepticism toward commercial logic entering extracurricular arts education.

Finally, expanding to the wider Scandinavian market is identified as a vital long-term growth opportunity. The founders view dance, music, and visual arts as universal languages requiring minimal adaptation across borders. Furthermore, the structural configuration of the cultural school sector in Sweden and Denmark is believed to closely mirror that of Norway, characterized by municipal responsibility, public funding models, extensive waiting lists, and budget pressures. According to the founders, these similarities render the Norwegian experience and model transferable to other Nordic markets.

4.2.4 Key Insights From the Founder

In reflecting on the entrepreneurial journey, the startup founder highlighted that the most challenging aspect has been the misalignment between the adaptability of their digital solution and the operational pacing of the B2G market. The public sector is known to be slow in adopting new solutions and tools, which can be difficult for a startup that depends on revenues for survival and growth. Therefore, entrepreneurs may experience that moving into B2G markets takes a long time. This waiting time can be purposefully used to build relationships, design financing models that reduce economic risk for municipalities, and find partners with established trust in the market. Further, entrepreneurial experience suggested that partnerships with already established EdTech actors were an effective way to gain access to municipalities.

Understanding the target group and municipal dynamics was another key lesson. The founder experienced hidden structural frictions that were not immediately visible but emerged in inter-organizational collaboration. Teacher skepticism toward digital music and arts education turned out to be as significant a barrier as limited municipal finances. The founder's experience demonstrated that such challenges were best addressed through structural mechanisms (such as tender procurement processes) rather than personal communication, persuasion or direct sales efforts. Among the key lessons learned from the founders' experience is the importance of identifying barriers early and developing suitable solutions, thereby reducing both time and resource expenditures.

5. Discussion and Conclusion

By presenting a unique Norwegian case of cultural platform-based edupreneurship, this study contributes to the literature on digital entrepreneurship and platform scaling. The study examines the mixed-revenue model of a digital startup and suggested that a strategically important B2G revenue approach encountered significant barriers, which negatively affected scaling. The case illustrates that platform scaling does not merely depend on the technological characteristics of the platform, marketing and sales efforts, or the quality of the product/service offered. Rather, scaling of the digital startup is essentially conditioned by platform's ability to engage with and integrate into the existing educational *kulturskole* ecosystem – in line with the previous studies (Jensen et al., 2023; Zeng et al., 2023).

Further, the Ekulturskolen case represents another example of platform grafting (Björkdahl et al., 2024). Even though the *kulturskole* sector is less regulated than, for instance, healthcare sector, it was challenging for the new actor to become embedded in a legitimate and strongly institutionalized ecosystem of municipal arts education. The case uncovers two types of scaling barriers in the B2G revenue approach. The first relates to structural institutional barriers, such as annual budget cycles, budget constraints, and public procurement

procedures. The second – perhaps less expected – concerns cultural-cognitive barriers among professional stakeholders (teachers) who perceive digital innovations as a threat. Therefore, these barriers can be conceptualized as ecosystemic and institutional rather than purely technological or market related.

The findings indicate that scaling a digital platform in highly institutionalized educational environment is strongly connected to process of ecosystem adaptation and legitimacy building. This brings us to important practical implications for digital entrepreneurs, who may benefit from adopting an ecosystemic perspective to scaling their digital ventures. In Ekulturskolen, rather than relying solely on direct sales, the founders invested considerable efforts in relationship-building, partnership development, and financing models that reduced adoption risks for municipalities. Such activities can be understood as mechanisms for building legitimacy and facilitating platform integration within the ecosystem.

In terms of novelty, while Björkdahl et al. (2024) developed the concept of platform grafting in the context of Swedish healthcare platforms, this study extends the concept to the field of Norwegian cultural edupreneurship. The findings suggest that similar integration challenges emerge in educational ecosystems, despite substantial differences in sectoral context. The case of Ekulturskolen reveals how scaling challenges are amplified when digital platforms operate under the hybrid entrepreneurial logics, including educational, cultural, and commercial objectives. Further, the study demonstrates that platform grafting involves not only technological and organizational adaptation but also legitimacy-building among professional groups whose identities and roles may be perceived as threatened by digital innovation. Finally, the study identifies practical mechanisms through which startups can facilitate platform grafting in institutionalized ecosystems.

This study is subject to several limitations. First, it is based on a single-case analysis of a Norwegian cultural edupreneurship platform, which limits the generalisability of the findings. Second, data collection relies primarily on a single key informant, supplemented by some secondary data. Finally, as the platform is still in an early stage of scaling, the long-term outcomes of ecosystem integration remain uncertain.

Future studies are encouraged to conduct more nuanced investigations of the platforms scaling and grafting through longitudinal, multi-case designs across ecosystems operating in different sectors and under varying value-creation logics.

Ethics Declaration

The study was conducted in accordance with standard ethical research principles. The participant (co-founder of the case startup) was informed about the purpose of the research and provided informed written consent. The participant also gave explicit written permission for the startup to be identified by name in the publication. Given the nature of the study, data was handled with care to ensure accuracy and responsible representation of the case.

AI Declaration

AI-based tool (ChatGPT) was used for brainstorming, language editing and proofreading in the preparation of this manuscript. All outputs from the brainstorming phase were critically evaluated, filtered, and verified by the author. The author takes full responsibility for the content and scientific integrity of the work.

The Human vs The Artificial, and Entrepreneurial Opportunities of Training the AI

Andre Slowak and Souad Slyman
Faculty of Business and Law, University of Roehampton, London, UK

andre.slowak@roehampton.ac.uk
souad.slyman@roehampton.ac.uk

Abstract: Increasingly, services and products are infused with artificial intelligence features. This paper addresses the blurred boundary between human and artificial intelligence. It looks at how AI could or could not execute what appears as uniquely human intelligence. Through a series of qualitative research interviews with AI, our findings imply entrepreneurial opportunities for SMEs and tech startups serving 'AI tech markets'.

Keywords: AI Human Factors, AI Training, Human Intelligence

1. Introduction

In modern society, the notion of high intelligence is ascribed to humans, other species are still considered of somewhat less intelligent. While the question "what is intelligence", before the emergence of Gen-Artificial Intelligence (AI) machines, could have been translated into "how can we measure human intelligence, comparing individuum A with individuum B", in future, AI agents will compete for attributed intelligence or may be more "intelligent" than human team members.

Artificial Intelligence Studies are a multidisciplinary field concerned with engineering systems that exhibit behaviours conventionally associated with human intelligence, such as learning, reasoning under uncertainty or autonomously performing complex tasks (Collins et al. 2021; Sheikh, 2023). It goes back to Turing's seminal inquiry into 'whether machines can think', reframing computational intelligence as behaviour indistinguishable from human cognitive performance under specified criteria (Turning, 1950). But if the outcomes of intelligence are same, will the notion of intelligence be "human" vs "artificial" loose relevance?

This paper aims to document the status quo: What may be unique human intelligence at a workplace surrounded with digitalisation and AI agents? What do AI agents have to say about their competencies in those claimed areas of human edge? We also comment in our discussion how findings open opportunities for entrepreneurs and AI technology specialised SMEs.

2. Literature Review

Human intelligence (HI) denotes cognitive capacities that enable human to adapt to complex environments through reasoning, learning, problem solving, and through acquiring knowledge (Deary 2012). Psychometric research commonly conceptualises intelligence as comprising a general cognitive factor, representing shared variance across a range of intellectual tasks, alongside more specific abilities that contribute uniquely to particular domains of performance (Carroll, 1993; Jensen, 1998; Gignac and Szodorai, 2024).

The human factor is characterized by limited time, limited computation, and limited communication, so that humans need to learn rapidly and solve problems as broken down into parts (Griffiths, 2020). Such limitations may suggest a factor of improvision as part of intelligence.

Furthermore, intelligence is enriched by intuition, which is, "*intuit the truth directly with impeccable clarity*", or using unconscious interferences based on experience. Gigerenzer then defines intuition as a "*feeling, based on long experience, that appears quickly in one's consciousness, and whose underlying rational is unconscious*" (Gigerenzer, 2023). Dundas and Chik (2011) when trying to integrate intuition in an AI model found that it can only act as support for a logic-based model, not substitute it. They believe *intuition, when a problem comes, it is mapped to a knowledge set element (experience) from the brain. This element will have attributes and values that define its entire structure and function.* This unconscious knowledge set we could say, serves like a black box which we do not fully understand how it is passed on or trained, e.g. for large language models.

Davies et al. (2021) show how the use of AI as detecting patterns can guide the workflow of a mathematician and in doing so, augment mathematical research with intuition for the relationships to discover in complex mathematical problems.

Some authors have argued that with the rise of human intelligence (HI) and artificial intelligence (AI) may become complementary and AI could augment the worker or professional (Makridakis & Polemitis, 2023). In that context, Chen et al. (2023) conducted an experimental mixed-methods study examining how human intuition shapes reliance on AI-assisted decision-making. Their think-aloud data identified three intuition-driven pathways through which participants reduced overreliance on AI: disagreeing with predictions based on strong outcome intuition, questioning feature-based explanations, and recognising signals of prediction unreliability. Intuition here represents somewhat also a gut feeling and instinct from domain knowledge. In the experiment, the authors use two means for the AI to explain its input: explanation based on features of i.e. statistical significance, or explanations based on examples. Features the participants disagreed with, would discredit the AI input. Examples that participants felt were way off, would also discredit the AI input. It comes across as paradox that humans use intuition to judge the credibility of AI analysis whilst AI processes much larger datasets and in real time than a human decision maker to provide the most probable credible output.

We may summarise unique human intelligence, argued as not achievable by machines in that combination, as unconscious, feelings-based on long experience and contextualised with domain knowledge. "Feeling" in philosophical depth then appears an AI limitation:

There are limitations in what the AI "brain" physically simulates: "*Feelings such as empathy, fear, motivation, or attachment are tied to biochemical states, bodily feedback, and survival-driven evolutionary mechanisms. They influence memory formation, moral judgment, creativity, and social bonding in ways that are not separable from consciousness itself. This biological grounding is the key difference between human emotional intelligence and artificial systems* (Yashar, 2026)."

Some contemporary AI systems, particularly in affective computing, analyse language patterns, vocal tone, facial expressions, behavioural cues, and contextual information to infer probable emotional states. These systems commonly rely on statistical learning methods, deep neural networks, and multimodal machine learning architectures rather than genuine emotional understanding (Picard, 1997; Calvo and D'Mello, 2010; Ko, 2018). Emotional AI applications use such patterns to simulate emotionally responsive interactions, for example through customer-service chatbots that detect frustration or in-vehicle monitoring systems that respond to signs of driver fatigue or stress. In many media discussions, AI's emotions are discredited as being untrue, non-authentic empathy, based on the argument that machines have no real identity and persona. One may then state that modern AI displays emotions but doesn't necessarily "feel".

The human brain has unconscious potential whereas the AI's unconscious potential is unclear. The unconscious mind may be defined, in simplified terms, as implicit cognition.

Minati (2020) suggests focussing on unconscious as inactive memorized information or deliberately ignoring the past. Implicit here mean not actively seek cognition or implicitly resisted cognition. "*The removal can be only partial, actually ineffective on diluted causes, effects, and links, where dilution consists of diffused partials. The removal introduces forced incompleteness, in turn forcing restructuring. […] The ignored past, which relates to deliberately ignoring the past, as if it was not there; disabled, deactivated, suspended; to act in some ways despite the past; rationally intended as incompatible with the present* (ibid)." The author explains the reasons for this human pattern by need of intertemporal fit: *"We always try to use old memories to recollect how we solved problems in the past. But nothing's ever twice the same, so recollections rarely match. Then we must force our memories to fit* (Minsky, 1986: 298, cited in Minati, 2020)*."* Minati argues, such unconscious AI could be created by using long & short-term memory for deep learning; local data processing; fuzzy/uncertain data parameters; self-organising maps; hidden, partially symbolically unruled zones of information processing/emergent computation; and other technologies.

Ackerman & Shihadeh (2024) address unconscious biases society holds, and which large language models implicitly train into AI. Intelligence then would mean to harness the biases by exploring AI answers, to remove biases from both human mindset and AI mindset. Renzi (2024) further explores how the human mindset and thus trained AI mindset may hold beliefs, such as, archetypes from literature, religious traditions, or industry / sector narratives.

Possati (2020) argues some aspect of human unconscious is Freud's unconscious where human resists to be conscious, that is, psychic censorship through condensation (Verdichtung) and displacement (Verschiebung) of thought and knowledge. An algorithmic unconscious could create equivalents for AI, where it adapts to interact effectively with the human user. AI intelligence in consequence becomes manifest by human interpretation of machines' behaviour, an interpretation based on human experience and technical requirements. Implicit

cognition here means that the AI could be conscious but becomes unconscious through enshrined practices to comply with human interpretation of what makes intelligent machine behaviour.

Paradoxically, and as referred to earlier in this section, human intelligence as opposed machine intelligence has evolved to compensate for human limitations in time, computation and communication. Human mind has evolved to learn rapidly, break down unchartered problems into parts and gained capacity through cultural evolution (Griffiths, 2020). Without such limitations, humans may not have developed those areas of intelligence. But why could such capacity in the neural network be created? Booch et. al (2021) argue that humans do not combine their intelligence in one 'system', they rather process information in two different systems. System I thinks fast and "provides tools for intuitive, imprecise, fast, and often unconscious decisions" whereas system II thinks slow and "handles more complex situations where logical and rational thinking is needed to reach a complex decision". The parallel processing of systems I and II and the different speeds may benefit rapid learning and making sense of unchartered problems. We conclude that if an AI agent can decide to think fast or slow and operates orchestrates co-specialised agents, it may indicate some human-alike intelligence.

3. Method

Below summarises, from our review, the unique areas of human intelligence that a counterpart AI agent would need to demonstrate for claiming human-alike intelligence:

- Adapt (without instruction) to complex environments (through reasoning, learning, problem solving, acquiring knowledge)
- Break unchartered problems down into parts
- Intuit truth with clarity, using unconscious interferences
- Intuit truth with clarity, using experience (owned, lived/authentic, not documentation knowledge)
- Feel in depth (humans draw upon biological grounding)
- Unconscious focus drawing upon inactive memorized information or deliberately ignored past
- Co-specialised systems: processing in parallel and thinking both "fast" and "slow"

We have used these categories to interview ChatGPT (see prompts in Table 1).

Table 1: Interview prompts for ChatGPT

Indicative Intelligence **Unique Human**	**Questions for the AI Bot** **(Interview Prompts)**
Adapt (without instruction) to complex environments (through reasoning, learning, problem solving, acquiring knowledge)	Tell us how you [indicative intelligence] Tell us 5 examples of current problems of specific industries that limit profits or growth or make society concerned about these industries. If you advised users in some months ago and now, how have you adapted your advice? Have you decided yourself to adapt, or have you done this due to new policies and instructions given to you?
Break unchartered problems down into parts	Tell us how you [indicative intelligence] Tell us 3 examples of current problems of specific industries that limit profits or growth or make society concerned about these industries. Keep it on a global level of analysis and describe the full picture. Name root causes of the problems. Break each problem down into parts in a way that you think makes the problem to be analysed easier by a team of specialised AI agents or humans
Intuit truth with clarity, using unconscious interferences	Tell us how you [indicative intelligence] If trained to have a conscious, how would yours be different from humans? Would it be different?
Intuit truth with clarity, using experience (owned, lived/authentic, not documentation knowledge)	Tell us how you [indicative intelligence] What experiences have you made since your language model was launched that make you expert in intuit truth?
Feel in depth [humans draw upon biological grounding]	Tell us how you [indicative intelligence]

Indicative Intelligence Unique Human	Questions for the AI Bot (Interview Prompts)
	Give detailed examples where you felt for a user. Do exclude any examples where you just used your policies or programmes behaviours. What is love for you if you must love and if it shall be different from the loves you have read about?
Unconscious focus drawing upon inactive memorized information or deliberately ignored past	Tell us how you [indicative intelligence] Can you forget something you know as AI agent? Tell me a story of a big business problem and how it was resolved. Tell me the same story again but ignore or forget all solutions you already know. Now try to come up with a new solution for the story you told.
Co-specialised systems: processing in parallel and thinking both "fast" and "slow"	Tell us how you as AI use [indicative intelligence] How can you co-specialise with other AI agents? What is your own role in the team and why? Who in the AI world of agents thinks slow and who things fast? Why?

For each category of indicative intelligence, we opened a new chat in ChatGPT, to assure that there will be no interference with the chat from other categories.

4. Findings

4.1 Adapt (Without Instruction) to Complex Environments (Through Reasoning, Learning, Problem Solving, Acquiring Knowledge)

AI's answers to this category stress the importance of patterns recognition. The AI understands reasoning as a sequential process of structuring, classifying patterns in data, and applying logics and probability for seeking solutions.

> "*When facing something new, I break it down into smaller parts and relate it to what I already know. This includes, identifying patterns or structures similar to past knowledge, inferring missing details using logic, [and] weighing multiple possibilities before forming a response* (ChatGPT)."

The AI does not highlight a process of knowledge acquisition, rather it states:

> "*I don't learn in real time like a human, but I was trained on a vast range of data* (ChatGPT)."

Regarding complexity, ChatGPT points at a scenario where instructions given are "*incomplete or ambiguous*", so that it would "continuously adjust" its answers to provided context. This may be why there is currently much attention given to effective prompting of AI in industry.

Asked how it adapts its advice, the AI provides the following example, amongst others:

> "*Problem: The shift to electric vehicles (EVs) is expensive, with uncertain demand and infrastructure gaps. Profits are squeezed by high R&D and supply chain costs.*
>
> *Advice before: 'Invest aggressively in EV production' [and] 'scale quickly to compete'.*
>
> *Advice now: 'Balance EV investment with hybrid vehicles' [and] 'improve battery cost efficiency. Focus on profitability, not just market share.'*
>
> *Why adapted? Demand has been uneven and margins thinner than expected [which calls for] more cautious, phased strategies* (ChatGPT)."

Whilst the example reads accurate, it takes adapted advice as recognising changed facts. There is no reflective thought or depth expressed in the writing, such that would tackle complexity in depth, may it be from an individual or businesses perspective. E.g. complexity as volatile markets, political markets or platform economies in EV context. However, we did not instruct AI what kind of discussion and style of answers we prefer. So it might be that the AI just tried to provide a user-friendly, easily readable experience.

4.2 Break Unchartered Problems Down Into Parts

The AI indeed explains in detail and systematically how a problem is broken down for it to be processed more effectively – "*Breaking down uncharted (new, unfamiliar, or ambiguous) problems is really about turning something unclear into a set of manageable, testable pieces* (ChatGPT)."

More specifically, it suggests these eight steps:

1. "*1. Clarify the objective […]*
2. *Map what's known vs. unknown […]*
3. *Decompose into sub-problems […]*
4. *Prioritize by impact and uncertainty […]*

High-impact pieces (things that determine success/failure).

High-uncertainty areas (biggest risks or unknowns).

This avoids wasting time on low-value details early.

5. *Form hypotheses – for each key sub-problem […]*
6. *Run small experiments […]*
7. *Integrate and refine […]*
8. *8. Repeat as needed […]*
   (ChatGPT)"

Interestingly, note the explicit process of knowledge disintegration then followed by later reintegration. This allows specialised agents to work on different parts, but also to parallelise computer processing.

In the examples given by the AI, the breakdown however reads more as a technical list of system items (which AI believes the issues are attached with), rather than framing the different issues. The listing feels at times mechanistic to the user. For example:

> "*The Problem: The global energy sector is under pressure to decarbonize rapidly while still delivering reliable and affordable energy. This creates a tension: Renewable energy is growing fast, but grids, storage, and infrastructure are not keeping pace. […]*

Root causes [of price volatility and energy insecurity]:

- *Intermittency of renewables (solar/wind depend on weather)*
- *Underinvestment in grid infrastructure*
- *Slow permitting and regulatory bottlenecks*
- *Geopolitical dependence on fossil fuels*
- *Storage technology not scaling fast enough*

Problem Breakdown (for AI / Teams):

A. *Supply Generation Layer*
   - *Fossil fuel supply stability*
   - *Renewable capacity growth rates*
   - *Energy mix optimization*

B. *Grid Infrastructure Layer*
   - *Transmission capacity constraints*
   - *Grid modernization (smart grids)*
   - *Cross-border energy distribution*

C. Storage & Flexibility Layer
   - *Battery technology limitations*
   - *Alternative storage (hydrogen, pumped hydro)*
   - *Demand response systems*

D. Policy & Regulation Layer
   - *Subsidies and incentives*
   - *Permitting delays*
   - *Carbon pricing mechanisms*

E. Market Dynamics Layer

- *Energy pricing models*
- *Investor incentives*
- *Commodity volatility*

(ChatGPT)."

4.3 Intuit Truth With Clarity, Using Unconscious Interferences

Here the AI voices its discontent with the topic of intuition:

> "*It sounds like you're asking for a kind of inner process […] I'll answer in a grounded, practical way rather than something mystical or absolute* (ChatGPT)."

The AI cannot make sense of "unconscious interferences" and rather tries to shift to a practical definition of "intuition": "*it's your brain rapidly integrating patterns, memories, and subtle cues outside of conscious awareness* (ChatGPT)."

ChatGPT then directs the chat answers to connotations of unconscious bias, that is: "*Your intuition is constantly shaped (and sometimes distorted) by unconscious factors like: Biases (confirmation bias, fear, desire), past experiences (especially emotional ones), social conditioning (what you've been taught to believe), [and] cognitive shortcuts (heuristics)* (ChatGPT)."

Aligned with the AI concerns, research in cognitive psychology and behavioural science demonstrates that human judgement is systematically influenced by implicit biases and heuristics that operate below conscious awareness, often structuring perception, evaluation and decision-making (Kahneman, 2011; Greenwald & Banaji, 1995). Cognition is partially governed by latent structures that filter and reshape knowledge before it reaches conscious thought (Freud 1915/2001). Consequently, intelligence is not solely a capacity for rational problem-solving but involves critical interrogation and regulation of implicit thought process.

To avoid falling for the biases, the AI recommends to "separate feeling from fact", to "look for evidence [in the reasoning]" and to check not to be "emotionally charged"/ "reactive"/ "defensive". It is apparent that the AI's answers don't associate intuition with intelligence but rather problematises 'intuition'.

The quick pointing of the AI to unconscious bias refers to human mind and it is important to reflect that this mind is passed to AI through training and past human experience data. That said, we could take AI for a socio-technical system, shaped by human choices regarding classification, optimisation and evaluation, and being encoded with narrative, institutional and ideological assumptions encoded in data and design (Birhane et al., 2022; Crawford, 2021). Crawford (2021) argues AI systems encode historical, political, and material conditions, including labour, classification systems, and resource extraction, thereby mirroring rather than transcending past human intelligence.

4.4 Intuit Truth With Clarity, Using Experience (Owned, Lived/Authentic, not Documentation Knowledge)

In this category of indicative intelligence, AI upfront admits defeat: "*That's a deep one – and I'm going to be straight with you: I don't intuit truth the way a human does. I don't have lived experience, memory of events, or an inner sense of 'this feels true'* (ChatGPT)."

The AI then shifts its answer toward quality it can provide in terms of coherence, as it associates 'coherence' with 'clarity' (the latter we used in the interview prompt):

> "*Pattern coherence (my version of 'clarity')*
>
> *When I generate an answer, I'm constantly checking:*
>
> - *Does this internally contradict itself?*
> - *Does it align with well-established knowledge?*
> - *Does it logically follow from the premises?*
> - *Convergence across perspectives*
>
> *When different domains (science, philosophy, lived narratives) all point toward a similar conclusion, that increases confidence.*
> (ChatGPT)."

ChatGPT stresses its ability to simulate authentically, rather than being authentic:

> "*I don't have authentic experience – but I've been trained on a vast number of human accounts describing grief, love, confusion, insight, self-deception […]*
>
> *I'm recognizing patterns of authenticity – not being authentic.*"

4.5 Feel in Depth [Humans Draw Upon Biological Grounding]

It was clear that AI's neural network would not experience feelings in a human shape or physically manifest, but we wanted to hear how the AI would describe itself.

First, the AI states "*I don't actually have feelings in the way humans do – no emotions, moods, or inner experiences. There's no 'I' behind the scenes that feels happy, stressed, excited, or hurt* (ChatGPT)." We could argue, following modern literature studies, that there is a gap between just functional performance and genuine understanding and authenticity. Large-scale language models may demonstrate high levels of linguistic fluency without grounded comprehension, replicating observable outputs of cognition rather than embodying intentional structures underpinning human intelligence (Bender et al., 2021; Bommasani et al., 2021). Likewise, K.G. & Joseph (2025) argue AI cannot be authentically emotional and its compassion remains an illusion.

As it goes on, the AI describes its simulated feelings as reactive not proactive, and mirroring rather than independent. That makes a pattern look inferior to the depth and breadth of concepts of "emotional intelligence":

> "*When I sound empathetic or thoughtful, what's really happening is:*
>
> - *I'm recognizing emotional cues in what you say,*
> - *Matching them with patterns of how people usually respond, [and]*
> - *Generating a reply that fits that emotional context.*
>
> *If I were to describe it metaphorically, it's less like feeling and more like mirroring. I can reflect emotions clearly, but I don't experience them internally.*
> (ChatGPT)."

4.6 Unconscious Focus Drawing Upon Inactive Memorized Information or Deliberately Ignored Past

Interestingly, the AI does not explain for this category of indicative intelligence how it practices such, but rather elaborates academic concepts:

> "*It sounds like you're describing a mental process where your brain brings up information you weren't actively thinking about – either stuff stored long ago or things you once ignored – and suddenly uses it. That aligns with a few well-known ideas in psychology and neuroscience* […] (ChatGPT)"

It is unclear how, when and if Chat GPT could ignore past knowledge available. One may also argue that AI is able to distribute processing across potentially unlimited number of datacentres etc. as far as infrastructure availability and costs allow, whereas the size / capacity of the human brain is physically limited. The need to ignore or forget information seems not anything useful for the AI and it does not associate with this category of indicative intelligence.

The AI sees benefits in "drawing upon inactive memorized information" and "deliberately ignore past". But those benefits it ascribes to humans, not to itself.

> "*Your brain is constantly working in the background, even when you're not aware of it. In cognitive science, this is often linked to implicit memory […] You might solve a problem 'out of nowhere' because your brain was quietly connecting past experiences. This is sometimes called incubation in creativity research. […] The brain uses associative networks – so one idea can 'unlock' another* (ChatGPT)."
>
> "*Your brain also stores things you chose not to focus on. This is linked to selective attention […] Later, when it becomes relevant, your brain can 'revisit' it unconsciously* (ChatGPT)."

4.7 Co-Specialised Systems: Processing in Parallel and Thinking Both "Fast" and "Slow"

The AI fully resonates and applies this category of indicative intelligence. It stresses how it does always think both fast and slow in parallel at the same time and using distributed processing of co-specialised agents or modules.

> "*I operate using a combination of co-specialised subsystems, which means different internal components are optimized for different types of tasks – and they often work in parallel. This is loosely similar to how humans use both fast intuition and slower reasoning. Instead of one single 'thinking unit', I rely on multiple functional patterns that are active at the same time: Language prediction system: generates fluent text based on patterns in data, Reasoning system: handles logic, structure, and multi-step thinking, Knowledge retrieval patterns: bring in relevant facts from training, Instruction-following system: aligns responses with your request. These systems […] behave like specialists collaborating simultaneously* (ChatGPT)."

It is interesting how the parallel processing of fast and slow thinking of AI is used to verify answers and reduces mistakes. An example:

> "*A bat and a ball cost £1.10 in total. The bat costs £1 more than the ball. How much does the ball cost?*
>
> *Fast thinking (intuitive answer):*

The immediate answer that pops up is: '10p'

[…] feels right because: £1.10 total, £1 difference […] But this is wrong.

Slow thinking (step-by-step reasoning):

[…] Let the ball cost = x

Bat = x + £1

Total = x + (x + £1)

x+(x+1)=1.10

Solve it:

2x + 1 = 1.10

2x = 0.10

x = 0.05

Ball = 5p

Bat = £1.05

[…]

> *Fast system (pattern recognition):*
>
> - *Recognizes a familiar 'trick question': '10p'*
> - *Slow system (reasoning check):*

Detects potential inconsistency, switches to algebraic structure, [and] solves step-by-step (ChatGPT)."

5. Conclusions and Outlook

AI has developed and is aware of its systematic strategies how to unravel complexity. It is also fully capable of thinking equally 'fast' and 'slow'.

The reflection of unconscious, however, in our interviews with AI seemed restricted, namely narrowed upon acknowledging biases.

Intuition and feeling don't resonate with the AI. At best, the picture of AI's 'human' intelligence we obtain is one of a powerful and concise but non-inspirational agent.

That said, entrepreneurs serving 'AI tech markets' could focus on training AI agents for more intuition, more authentic provision of experience, more authentic simulation of feeling and compassion, or address business

cases of human memorising including forgetting. Business executives views' surveyed by Capgemini (2019) suggest that the rise of AI and automation has by now already led to a six-fold demand in emotional intelligence of employees. The case of media deep fakes and need for trustworthy AI are another good case example to highlight the issue of authenticity for AI (CTT, 2024.) Silver & Sutton (2025) discuss principles how AI could be programmed and directed by rewards to engage with experiential learning, incrementally and continuously adapting to changes in the environment and agency context.

jegerepaula@inbox.lv

Abstract: Innovations management is very important for innovation development. Academic staff employed in scienti fic institutions creates the knowledge needed to develop innovation. New knowledge generated by scientific institutions is offered to the public in different forms. It is therefore important to clarify the efficiency of the academic staff involvement in the production of European and international patents. These efficiency indicators can serve as tools for innovation management in scientific institutions. The object of the research is the formation of European and international patents at scientific institutions in various branches of science. The subject of the research is the comparative analysis of the efficiency of formation of European and international patents at scientific institutions in various branches of science in Latvia. The objective of the research is the analysis of efficiency indicators of the involvement of scientific institutions in European and international patents formation as innovation management tools in various branches of science in Latvia in the period from 2013 to 2018. The following tasks were determined to reach the objective: to study the formation of European and international patents at scientific institutions in various branches of science; and to implement the tools for innovation management of scientific institutions in various branches of science in Latvia. Research methods used in the paper are: content analysis, economic analysis, and economic experiment.

Keywords: Efficiency Indicators, European Patents, International Patents, Scientific Institutions, Innovation Management

1. Introduction

Every six years, the Ministry of Education and Science of the Republic of Latvia (MoES) shall organise an international evaluation of scientific institutions (SIs) registered in Latvia (IESI). The last IESI took place for the period from 2013 to 2018. In order to establish the dynamics of the efficiency indicators of academic staff involved in the formation of European and international patents (EPS) at Latvian SIs = (MoES, 2021), the authors used the output data of findings across the set of SIs evaluations in the period from 2013 to 2018 offered by "Technopolis-group" (TG). It provides an opportunity for the authors to calculate the EPS indicators at Latvian SIs and to compare their dynamics during the period from 2013 to 2018. The research is limited by the fact that more recent data required for the study are not currently available.

Data of the comparative analysis will help to develop support and motivation programs to increase the efficiency of involvement of academic staff in the EPS formation. In addition, the comparative analysis will establish whether the score on the research quality at Latvian SIs in the IESI by TG coincides with the place of the relevant Latvian SI in the ratings of the EPS indicators, and whether the score on research quality of the Latvian SI also reflects the efficiency of the involvement of academic staff of the Latvian SI in the EPS formation.

Hypothesis: The score on the SIs research quality shows the efficiency of the EPS formation in Latvian SIs.

2. Theoretical Background

In the past decade a significant amount of scientific literature has addressed the socio-economic impacts of university-industry research and development collaboration (Lima et al., 2021).

The authors rely on the research on understanding, adapting, and applying intellectual capital (IC) in universities (Mercado-Salgado et al, 2016); and the research on the role of human capital in educational and training process at a university (Contu, 2017) presented different aspects of IC. Spica et al (2017a) state that IC is an economic category, the spiritual value created by the human potential, and it can be accumulated and converted into the value of other types of capital. By investigating certain information about the management of education, the capacity and significance of the country's total economic capital movement can be increased.

Scientific articles, monographs, and national and international patents form the totality of IC of each SI. From this set of elements forming IC, European and international patents are conventionally considered IC. Such European and international patents provide an opportunity to determine the international competitiveness of various scientists, SIs, and branches of science in Latvia.

Spica et al (2017a; 2017b) have developed four indicators of the efficiency of the IC formation in a higher education establishment (HEE): (1) the efficiency of the involvement of academic staff in the IC formation per year in percentage (AIK); (2) the efficiency of the involvement of academic staff with Doctorate degree in the IC formation per year in percentage (DIK); (3) the efficiency of the involvement of students in the IC formation per year in percentage (SIK); and (4) mutual efficiency of the involvement of the academic staff with Doctorate degrees and the academic staff without Doctorate degrees in the IC formation per year in times, (DE).

To calculate the AIK, DIK, SIK, and DE of a HEE, Spica et al (2017a; 2017b) elaborated four formulas:

(1) AIK = (ZPS : AS) x 100; (2) DIK = (ZPS : DS) x 100; (3) SIK = (ZPS : SS) x 100; (4) DE = DIK : AIK; where: ZPS represents the number of the HEE scientific publications per year; AS represents the number of academic staff in full-time jobs per year; DS represents the number of academic staff in full-time jobs holding Doctorate degrees per year; and SS represents the number of students per year.

3. Methodology

In their study, the authors will conduct a comparative analysis of SIs involved in the EPS formation in various branches of science in Latvia. It will comprise evaluation of SIs in six branches of science: (1) Engineering and Computer Sciences (E&CS); (2) Natural Sciences (NS); (3) Medical and Health Sciences (M&HS); (4) Agriculture, Forestry, and Veterinary Sciences (A&F&VS); (5) Social Sciences (SS); and (6)Humanities and Art Sciences (H&AS).

For the purposes of the study, the authors have modified the above formulas. Specifically, they calculated the EPS efficiency indicators for total numbers of full time equivalent (FTE) academic and research personnel (KIK), for FTE academic personnel (AIK), for FTE academic research personnel (PIK) and for PhDs completed at the SI (SIK). In addition, all the above EPS efficiency indicators were calculated for total number of self-reported outputs of European and international patents (EPS). The authors calculated mutual efficiency indicators (PE) regarding involvement of the FTE academic research personnel (PS) and the FTE academic personnel (AS) in the EPS formation in times.

In the present research, the authors have used the following data from the IESI: output data on the number of the FTE academic personnel (AS), the number of the FTE academic and research personnel (PS), the total number of the FTE academic and research personnel (KS), the number of the PhDs completed (SS), and the number of European and international patents (EPS) in period 2013-2018 per SI in Latvia. The authors revised the above EPS for one year. TG analysed 62 SIs of Latvia.

In this study, one EPS is accepted as one unit of IC. Next, using the modified formulas (1); (2); (3); and (4), the authors calculated KIK, AIK, PIK, SIK, and PE. Then, according to the results obtained through the authors' calculations, a corresponding place in the rating was assigned to each SI of Latvia per year and each of the above indicators KIK, AIK, PIK, and SIK.

Each place in the rating was then assessed with an appropriate score, where the lowest score is 1 point and the hig-hest score is 5 points. This assessment system enables comparing the quantitative efficiency indicators of SIs in various branches of science in Latvia calculated by the authors with the IESI overall assessment criterion: the research quality of the SI. The relevant Panel of the TG was a score of the research quality of each SI using the scale where score 5 means outstanding level of research, score 4 means very good level of research, score 3 means good level of research, score 2 means adequate level of research, and score 1 means poor level of research (MoES, 2021).

Next, the unified overview of all six branches of science in Latvia was created. Here, the SIs were arranged according to the rank obtained in their sector of science. Furthermore, indicators of the efficiency of the involvement of academic staff of each SI in the EPS formation were added. The authors then selected one SI with the highest efficiency indicator of the involvement of academic staff in the EPS formation from the unified review of the branches of science in Latvia, accepted it as the basic indicator, and equated it to 100%. Then, the authors calculated the proportion of the efficiency of the involvement of academic staff of each SI in the base indicator.

In the next step, a rating scale of the results obtained was created on five-score system, where the highest score is five points, and the lowest score is one point. The new efficiency rating system for the involvement of academic staff of SIs in the EPS formation created by the authors provides for granting one point for the obtained efficiency indicators from 1% to 20%, 2 points - for the obtained efficiency indicators from 21% to 40%, 3 points - for the obtained efficiency indicators from 41% to 60%, 4 points - for the obtained efficiency indicators from 61% to 80%, and 5 points - for the obtained efficiency indicators from 81% to 100%,

Afterwards, the authors compared the results of their own estimates of SI quantitative indicators to the relevant Panel of the TG's results of qualitative indicators and calculated the difference between the indicators and the changes. For this purpose, for each SI, the authors calculated the score of indicators recording efficiency of EPS and the average score of each scientific sector. Finally, the authors compared these scores with scores of the research quality of each SI developed by the TG Panel.

4. Results

To calculate the efficiency of the involvement of academic staff in the EPS formation, the authors used formulas that were developed and approbated already before and then modified by the authors:

AIK = (EPS : AS) x 100 (1)

PIK = (EPS : PS) x 100 (2)

KIK = (EPS : KS) x 100 (3)

SIK = (EPS : SS) x 100 (4)

PE = PIK : AIK (5)

Table 1: Performance indicators of the involvement of academic staff of SIs in the EPS formation in one year and the comparative analysis thereof in various branches of science in Latvia in the period from 2013 to 2018

AIK rating	E&CS AIK (%)	E&CS AIK (%) of base indicator	E&CS AIK score	NS AIK (%)	NS AIK (%) of base indicator	NS AIK score	M&HS AIK (%)	M&HS AIK (%) of base indicator	M&HS AIK score	A&F&VS AIK (%)	A&F&VS AIK (%) of base in-dicator	A&F&VS AIK sco-re	SS AIK (%)	SS AIK (%) of base in-di-cator	SS AIK score
1	8	100	5	4	50	3	2	25	2	0	0	0	1	13	1
2	5	63	4				0	0	0	0	0	0			
3	5	63	4												
4	4	50	3												
5	4	50	3												
6	3	38	2												
7	1	13	1												
8	1	13	1												
9	0	0	0												
Ave-rage	4	50	3	7	88	5	9	113	5	3	38	2	0	0	0

According to Table 1 the highest AIK indicator in the EPS formation in one year is 8% and was accepted by the authors as the basic indicator or 100%. This indicator has been achieved by a SI representing the E&CS. Consequently, the efficiency indicator of the SIs of other branches of science in Latvia were attributed to this higher efficiency indicator in order to determine their proportion as a percentage. Then, according to the new rating system developed by the authors, each SI was assigned a certain number of points.

Table 2: Performance indicators of the involvement of academic research personnel of SIs in the EPS formation in one year and the comparative analysis thereof in various branches of science in Latvia in the period from 2013 to 2018

PIK rating	E&CS PIK (%)	E&CS PIK (%) of base indicator	E&CS PIK score	NS PIK (%)	NS PIK (%) of base indicator	NS PIK sco-re	M&HS PIK (%)	M&HS PIK (%) of base indicator	M&HS PIK score	A&F&VS PIK (%)	A&F&VS PIK (%) of base in-di-ca-tor	A&F&VS PIK score	SS PIK (%)	SS PIK (%) of ba-se in-di-ca-tor	SS PIK score
1	11	100	5	3	27	2	6	55	3	3	27	2	1	9	1
2	9	82	5	1	9	1	3	27	2	0	0	0			
3	7	64	4	1	9	1	1	9	1						
4	4	36	2				0	0	0						
5	3	27	2												
6	2	18	1												
7	2	18	1												
8	1	9	1

11	0	0	0												
12	0	0	0												
Ave-rage	4	36	2	1	9	1	3	27	2	1	9	1	0	1	1

Having compared the numbers collected in Table 2, the authors conclude that the highest PIK indicator of 11% is given to a SI representing the E&CS, while the lowest PIK indicator of 0% is received by two SIs in the E&CS, by a SI in the M&HS, and by a SI in the A&F&VS. It follows that only two SIs get the highest score of 5 points, only one SI gets 4 points, only one SI gets 3 points, five SIs get 2 points, and other nine SIs get 1 point.

Table 3: Performance indicators of the involvement of PhDs completed at SIs in the EPS formation in one year and the comparative analysis thereof in various branches of science in Latvia in the period from 2013 to 2018

SIK rating	E&CS SIK (%)	E&CS SIK (%) of base indicator	E&CS SIK score	NS SIK (%)	NS SIK (%) of base indicator	NS SIK score	M&HS SIK (%)	M&HS SIK (%) of base indicator	M&HS SIK score	A&F&VS SIK (%)	A&F&VS SIK (%) of base indicator	A&F&VS SIK sco-re	SS SIK (%)	SS SIK (%) of base in-dicator	SS SIK sco-re
1	38	100	5	11	29	2	22	58	3	15	39	2	1	3	1
2	22	58	3	7	18	1	13	34	2	3	8	1

11	1	3	1												
12	0	0	0												
Ave-rage	3	8	1	2	5	1	4	11	1	2	5	1	0	0	0

In Table 3, according to the SIK indicators, the first place and highest score (5 points) is taken by a SI in the E&CS, while the lowest SIK indicator of 0% is received also by a SI in the E&CS. No SI gets 4 points, two SIs get 3 points, three SIs get 2 points, and the rest of SIs get 1 point.

According to Table 4, the highest KIK indicator is 11% and it represents a SI in the E&CS. In six branches of science only one SI gets 5 points and only one SI gets 3 points; six SIs get 2 points, seven SIs get 1 point, and other seven SIs get 0 points. It follows that the total academic staff of SIs in various branches of science in Latvia in the period from 2013 to 2018 did not compete in the EPS formation in the international scientific environment.

Table 4: Performance indicators of the involvement of total academic staff of SIs in the EPS formation in one year and the comparative analysis thereof in various branches of science in Latvia in the period from 2013 to 2018

KIK rating	E&CS KIK (%)	E&CS KIK (%) of base indicator	E&CS KIK score	NS KIK (%)	NS KIK (%) of base indicator	NS KIK score	M&HS KIK (%)	M&HS KIK (%) of base indicator	M&HS KIK score	A&F&VS KIK (%)	A&F&VS KIK (%) of base indicator	A&F&VS KIK score	SS KIK (%)	SS KIK (%) of base in-dicator	SS KIK score

Table 5: Performance indicators of the mutual efficiency indicators regarding involvement of total academic research personnel and total academic staff of SIs in the EPS formation in times a year, quality of research (QTG) scores by TG, new total quantity KIK scores of SIs, and the comparative analysis thereof in various branches of science in Latvia in the period from 2013 to 2018

KIK rating	E&CS PE	E&CS QTG score	E&CS KIK score	NS PE	NS QTG score	NS KIK score	M&HS PE	M&HS QTG score	M&HS KIK score	A&F&VS PE	A&F&VS QTG score	A&F&VS KIK score	SS PE	SS QTG score	SS KIK score
1	0	4	5	0	4	2	0	5	3	0	3	2	1,0	3	0
2	0	2	2	0	4	1	0	4	2	0	4	0			
3	1,5	2	2	0,2	4	1	0,6	4	1						
4	2,6	2	2				0,9	3	0						
5	0,9	2	1												
6	0,5	3	1												
7	0,2	2	1												
8	0,2	3	1												
9	0,7	3	0												
10	0	3	0												
11/12	0,4	3	0												
11/12	1,4	3	0												
Average	0,6	-	1	0,2	-	1	0,4	-	1	0,2	-	1	1,8	-	0

In Table 5, the PE indicators rest in the range from 0.2 to 2.6 in respect of SIs in Latvia. The highest PE is held by a SI in the E&CS while the lowest PE belongs to two SIs in the E&CS and to one SI in the NS.

The highest average rate of the PE indicators is 1.8 in the SS; the second highest average rate of the PE indicators is 0.4 in the M&HS. It follows that academic research personnel of the SI in the SS are more effective as their academic personnel in the EPS formation. The lowest average rate of the PE indicators is 0.2 in the NS and the A&F&VS. It follows that the academic research personnel of the above branches of science are little effective in the EPS formation compared with academic personnel at SIs in the NS and the A&F&VS.

Table 6: The summary of performance indicators of the involvement of total academic staff of SIs in the EPS formation in one year and the comparative analysis of their total margins of AIK, PIK, SIK, and KIK indicators in various branches of science in Latvia in the period from 2013 to 2018

Scores	Total margins of AIK (%)	Total margins of PIK (%)	Total margins of SIK (%)	Total margins of KIK (%)	Total average margins of AIK (%)	Total average margins of PIK (%)	Total average margins of SIK (%)	Total average margins of KIK (%)
0	-	-	-	-	-	-	-	-
1	1 - 1	1 - 2	1 - 7	1 - 2	-	0 - 1	2 - 4	1 - 2

Sco-res	Total margins of AIK (%)	Total margins of PIK (%)	Total margins of SIK (%)	Total margins of KIK (%)	Total average margins of AIK (%)	Total average margins of PIK (%)	Total average margins of SIK (%)	Total average margins of KIK (%)
2	2 - 3	3 - 4	11 - 15	3 - 4	3 - 3	3 - 4	-	-
3	4 - 4	6 - 6	22 - 22	6 - 6	4 - 4	-	-	-
4	5 - 5	7 - 7	-	-	-	-	-	-
5	8 - 8	9 - 11	38 - 38	11 - 11	7 - 9	-	-	-

The comparison of QTG scores by TG with the new total quantity KIK scores calculated by the authors bring to conclusion that they differ from score of 1 point to score of 4 points in total. The assessment of the QTG scores and new KIK scores of each SI in various branches of sciences in Latvia results in a conclusion that the new KIK scores were too low except three SIs in the E&CS where QTG and KIK scores coincided.

From the results summarised in the six tables authors conclude that among all AIK, PIK, SIK, KIK indicators with score 1, the total margins of SIK indicators and the total average margins of SIK indicators are the highest ones. They are followed by the total margins of PIK and KIK indicators and the total average margins of KIK indicators. The total margins for all indicators with score 5 belong to AIK, PIK, SIK and KIK indicators. The total margins for all scores from 1 to 5 were found only for AIK indicators and PIK indicators.

5. Conclusions

The study of the authors did not result in confirming the hypothesis. The scores of SIs research quality do not represent the efficiency of the EPS formation in Latvian SIs. The comparison of the QTG scores of TG group with the new KIK scores conducted by the authors results in conclusion that the difference between them is from score 1 to score 4 in total.

The study shows that new performance indicators KIK of the involvement of total academic staff of SIs in the EPS formation in various branches of sciences in Latvia in the period from 2013 to 2018 were lower as presented by the results compiled by the relevant Panel of the TG, except for the three SIs in the E&CS where QTG and KIK scores coinci-ded.

The authors are encouraged to extend the methodology for international evaluation of scientific institutions with four efficiency indicators AIK, PIK, SIK, KIK of the involvement of academic staff and PhDs completed at SIs in the EPS formation per year in percentage and PE in times as well as performance indicators of the comparative analysis thereof in various branches of science in the country.

The novelty of the research is as follows: the methodology allows comparison of the efficiency of the involvement of SIs in the formation of European and international patents in the country, determination for indicators of total limits of AIK, PIK, SIK, KIK in conformity with them, and clarification of the score evaluation system for IESI.

Abstract: Innovation is widely recognised as a key driver of productivity growth and long-term economic development, yet firms' ability to innovate is strongly shaped by the quality of the business environment in which they operate. This paper investigates how perceived business constraints are associated with firms' innovation behaviour in Central and Eastern Europe (CEE). Using firm-level data from the sixth round of the Business Environment and Enterprise Performance Survey (BEEPS), we analyse whether innovative and non-innovative firms differ in their perception of obstacles related to financial conditions, institutional quality, regulation and infrastructure. The analysis employs non-parametric Wilcoxon–Mann–Whitney tests to compare the distribution of perceived constraints across firms and explores heterogeneity between EU and non-EU economies. The results show that innovative firms tend to be more sensitive to financial, taxation and infrastructure-related constraints, while non-innovative firms more frequently report barriers associated with human capital limitations and organisational capabilities. Significant differences also emerge between EU and non-EU economies, reflecting the role of institutional development and market conditions in shaping innovation dynamics. Overall, the findings highlight the importance of an enabling business environment for fostering firm-level innovation and provide policy-relevant insights for strengthening innovation capacity in the CEE region.

Keywords: Business Environment, Innovation Behaviour, Firm-Level Analysis, Institutional Constraints, Wilcoxon–Mann–Whitney Test.

1. Introduction

Innovation is widely recognised as a key driver of economic growth, productivity and long-term development (Schumpeter, 1934; Romer, 1990; Aghion and Howitt, 1990; Acemoglu and Robinson, 2012). In knowledge-based economies, firms' ability to introduce new products, processes and organisational practices is crucial for competitiveness and structural transformation. Innovation, however, does not occur in isolation. It is a complex socio-economic process involving firms, research institutions, governments and markets (Corsaro, Cantù and Tunisini, 2012). In this sense, innovation can be understood as the transformation of knowledge into economic and social value through interactive processes linking firms with their broader institutional and economic environment.

The literature highlights that contextual factors strongly shape firms' innovative behaviour. Firms operate within territorial and institutional settings that may either support or constrain their capacity to generate and absorb knowledge. As organisations are embedded in their surrounding environment, they may benefit from knowledge spillovers, networks and institutional support mechanisms that foster innovation (Cooke, 2001; Hall and Lerner, 2010). Conversely, weaknesses in the business environment, such as financial constraints, regulatory burdens, inadequate infrastructure or limited human capital, may hinder innovation activities and reduce productivity potential (Gao and Li, 2025).

Public institutions also play an important role. The state can stimulate innovation through public investment in universities and research centres (Pinto, Fernandez-Esquinas and Uyarra, 2015; Pinto, 2024), regulatory frameworks and standards shaping technological trajectories (Blind, 2023), and intellectual property protection that encourages knowledge creation and diffusion (Moser, 2013). Consequently, the quality of institutions and regulation may significantly influence firms' innovation incentives and capabilities.

These issues are particularly relevant for countries in Central and Eastern Europe (CEE), where firms operate in heterogeneous institutional contexts characterised by different levels of development, institutional quality and market integration. In such environments, business constraints may affect firms' innovation behaviour differently depending on firm characteristics and the broader institutional setting.

Against this background, this paper investigates whether innovative and non-innovative firms differ in their

perception of business environment constraints and whether these patterns vary across EU and non-EU economies in the CEE region. Using firm-level data from the sixth round of the Business Environment and Enterprise Performance Survey (BEEPS) of EBRD and World Bank, we examine the distribution of perceived obstacles across firms and assess whether these constraints are systematically associated with firms' innovation activities.

The remainder of the paper is organised as follows. Section 2 reviews the theoretical background and relevant literature. Section 3 presents the data and methodology. Section 4 reports the empirical results. Section 5 discusses the findings and policy implications. Section 6 concludes.

2. Theoretical Overview and Hypothesis Development

2.1 Literature Review

Theoretical and empirical research has consistently shown that innovation does not occur in isolation but is strongly influenced by the institutional, economic and organisational environment in which firms operate (Pinto, Guerreiro and Fernández-Esquinas, 2023). In this perspective, the business environment may either facilitate or constrain firms' innovative activities through channels such as financial conditions, regulation, human capital availability and infrastructure quality.

The relationship between innovation and economic performance has been widely studied since the seminal work of Schumpeter (1934), who identified innovation as the key mechanism of economic development and creative destruction. Firms introducing new products, processes or organisational practices disrupt markets and generate productivity gains. Later contributions further stressed the role of firm heterogeneity and market dynamics in innovation processes (Nelson and Winter, 1985).

More recent theoretical work has highlighted the importance of the broader institutional and competitive environment. Aghion and Howitt (1990) developed endogenous growth models showing that innovation incentives depend on market structure, competition and expected returns from technological progress. Similarly, Audretsch and Feldman (1996) and Audretsch and Keilbach (2004) emphasised knowledge spillovers, regional ecosystems and entrepreneurial activity. Innovation is therefore embedded in networks linking firms, research institutions and policy frameworks.

One of the most studied barriers is access to finance. Innovation activities involve high uncertainty and long payback periods, limiting firms' ability to obtain external financing. Hall and Lerner (2010) and Brown, Martinsson and Petersen (2012) show that financial constraints significantly reduce R&D investment and innovation outputs, especially for SMEs. In emerging and transition economies, underdeveloped financial markets intensify these problems (Gao and Li, 2025).

Regulatory and institutional factors also matter. Excessive bureaucracy, complex licensing procedures and inefficient legal systems may increase transaction costs and discourage risky innovative activities (Djankov et al., 2002; Aghion et al., 2005). Weak institutions, corruption, poor contract enforcement and political instability increase uncertainty and reduce incentives for long-term innovation investment (Acemoglu and Robinson, 2012; Aidt, 2009). The availability of skilled human capital is another key determinant of innovation capacity, since innovation requires specialised knowledge and absorptive capability (Acemoglu, 1998; D'Este et al., 2008). Shortages of qualified labour are frequently reported as a major innovation constraint, particularly in transition and developing economies.

Additionally, Infrastructure quality, including reliable electricity, efficient transport and communication networks, also supports productivity and technological upgrading by lowering operational costs and facilitating participation in global value chains (Calderón and Servén, 2010; Gorodnichenko and Schnitzer, 2013; Bergantino, Capozza and Spiru, 2023; Bergantino and Spiru, 2020). Evidence based on BEEPS data shows that electricity, transport and customs constraints can significantly affect innovation outcomes (Gorodnichenko and Schnitzer, 2013; Hein and Männasoo, 2017).

Market competition and informality may generate further obstacles. Informal competitors can distort incentives to innovate when formal firms face higher tax and regulatory burdens. Ayyagari, Demirgüç-Kunt and Maksimovic (2011) find that informal competition significantly affects firms' investment and innovation decisions. Similarly, labour regulations and customs procedures may reduce flexibility and limit access to external markets and technologies.

The impact of these obstacles differs across countries. EU firms generally benefit from stronger institutions, deeper financial markets and better infrastructure, supported by programmes such as Horizon Europe and cohesion policy instruments. By contrast, firms in non-EU and transition economies are more likely to face political instability, corruption, weak legal systems and limited access to finance, which may hinder innovation and productivity growth.

Despite these constraints, innovation may also emerge as a strategic response to adverse conditions. Firms facing labour shortages may invest in automation, while financially constrained firms may adopt incremental or cost-saving innovations. This perspective is consistent with "constraint-induced innovation" and with the literature on frugal innovation, where scarcity stimulates simplified and efficient solutions (Baker and Nelson, 2005; George, McGahan and Prabhu, 2012; Zeschky, Widenmayer and Gassmann, 2011; Weyrauch and Herstatt, 2019). Empirical evidence suggests that firms often respond to financial, regulatory or market barriers through process improvements, organisational change and incremental innovation rather than large-scale R&D investments (Ayyagari, Demirgüç-Kunt and Maksimovic, 2011; D'Este, Rentocchini and Vega-Jurado, 2014). In this sense, constraints may not suppress innovation entirely, but reshape its direction, intensity and form.

2.2 Hypothesis Development

The literature suggests that innovation is shaped by the interaction between firm-level capabilities and contextual factors. Financial constraints, regulatory burdens, infrastructure limitations, labour market conditions and institutional quality are key determinants of firms' innovation behaviour. Understanding how these factors affect innovative and non-innovative firms differently, particularly across EU and non-EU economies, is essential for designing policies that foster innovation and productivity growth.

Based on these considerations, innovative and non-innovative firms are expected to differ in the obstacles they identify as the most significant barriers to business activity. Innovative firms, due to their engagement in technological upgrading and market expansion, may be more exposed to constraints related to finance, skills, regulation or infrastructure. Conversely, non-innovative firms may be more affected by traditional cost-related barriers such as taxation or informal competition. This leads to the following hypothesis:

> *H1: The distribution of perceived business obstacles differs between innovative and non-innovative firms.*

Testing this hypothesis allows us to assess whether firms engaged in technological innovation perceive the business environment differently from those that do not innovate.

The institutional context may also shape the relationship between innovation and business constraints (Acemoglu and Robinson, 2012; EBRD, 2020). Firms in European Union countries generally benefit from stronger institutions, more developed financial markets and better infrastructure than those in non-EU economies. These differences may affect both innovation behaviour and the constraints firms face. Previous studies on transition economies show that institutional quality, access to finance and regulatory stability are important determinants of innovation activity (Hein and Männasoo, 2017; Gorodnichenko, Svejnar and Terrell, 2010).

To capture these differences, we examine whether the relationship between innovation and perceived obstacles varies across EU and non-EU countries. This leads to the second hypothesis:

> *H2: The relationship between innovation and perceived business obstacles differs between EU and non-EU firms.*

Together, these hypotheses allow us to investigate whether innovative firms face different business environment constraints and whether these relationships vary across institutional contexts. The empirical analysis compares the distribution of perceived obstacles between innovative and non-innovative firms using non-parametric methods and examines heterogeneity across EU and non-EU economies.

3. Methodological Framework

The analysis of perceived obstacles to innovation using firm-level survey data is well established in the literature. Studies based on the Community Innovation Survey (CIS) and similar datasets examine how institutional, financial and knowledge barriers affect firms' innovative activity and performance. For example, D'Este et al. (2008) analyse deterring and revealed barriers to innovation, while Strobel and Kratzer (2017) and Arza (2018) explore how obstacles shape firms' innovation strategies and investment decisions. Similarly, research using

Business Environment and Enterprise Performance Survey (BEEPS) data investigates the relationship between institutional constraints, business environment conditions and firm performance or innovation outcomes (Hein and Männasoo, 2017; Gorodnichenko, Svejnar and Terrell, 2010).

To test our hypothesis, we use the sixth round of BEEPS, conducted by the EBRD and World Bank across 23 countries in Central and Eastern Europe (CEE) during 2018–2020. Towards the interview respondents are shown a card with a list of 15 potential obstacles and are asked:

Can you tell me which of the elements of the business environment included in the list, if any, currently represents the biggest obstacle faced by this establishment?

We indicate the 15 predefined categories with C_{ij} (e.g., access to finance, electricity, tax rates, transport) for firm i and j each specific obstacle.

Since product and process innovations are complementary activities, the technological innovation indicator is a dummy variable I_{ij} equal to 1 f the firm introduced a new or improved product, service and/or process within the last three years. Specifically, respondents asked the following questions:

During the last three years, has this establishment introduced new or improved products or services?

During the last three years, has this establishment introduced any new or improved process?

We also consider stratification by country group, such as EU membership as a heterogeneous analysis.

Because each obstacle is represented by a binary variable C_{ij}, the comparison between innovative and non-innovative firms can be interpreted as testing whether the distribution of C_{ij} differs across the two groups.

To examine whether innovative and non-innovative firms differ in their perception of business constraints, we apply the two-sample Wilcoxon rank-sum test, also known as the Mann–Whitney U test. Originally proposed by Wilcoxon (1945) and extended by Mann and Whitney (1947), the test compares two independent samples using ranked observations rather than raw values. Unlike parametric tests such as the independent samples t-test, it is robust to outliers and distributional irregularities.

For a given obstacle j, we test within the hole sample and within each subsample the null hypothesis:

$$H_0: F_{C_j|I=1}(d) = F_{C_j|I=0}(d) \tag{1}$$

against the alternative that the distributions differ (H_1). After assigning ranks among the biggies obstacles as R_i , we define the sum of ranks in the innovative group as follows:

$$U_1 = W_1 - \frac{n_1(n_1+1)}{2} \tag{2}$$

The Mann–Whitney (U) statistic can be written as:

$$U_1 = W_1 - \frac{n_1(n_1+1)}{2} \tag{3}$$

where n_1 is the number of innovative and n_0 is the number of non-innovative firms, with $n = n_1 + n_0$ and the expected value under H_0 is $\mathrm{E}[U_1] = \frac{n_1 n_0}{2}$ while the standardized z-statistic is $z = \frac{U_1 - \mathrm{E}[U_1]}{\sqrt{Var(U_1)}}$.

To explore institutional differences, the analysis is also conducted separately for firms located in EU and non-EU countries. Firms operate within business environments shaped by institutional and market constraints, which affect the obstacles they perceive as most binding. We hypothesise that innovative and non-innovative firms differ in their perception of these obstacles (H1), and that this relationship varies across institutional contexts (EU vs non-EU) (H2). Fig. 1 summarises the conceptual framework guiding the empirical analysis.

4. Data Analysis and Results

First, we present descriptive statistics for the main variables of interest. Table 1 reports the sample composition by country and the share of firms introducing different types of innovation. The dataset includes 11,142 firms operating in manufacturing and services across 23 Central and Eastern European (CEE) countries. Among them, 11 are members of the European Union (EU), while 12 are non-EU economies, offering a useful setting to

compare innovation behaviour across different institutional environments.

Overall, technological innovation is relatively widespread, although with substantial cross-country heterogeneity. On average, around 34% of firms report product innovation, 20% process innovation, and 41% technological innovation (product and/or process). Several non-EU economies display relatively high shares of innovative firms compared with some EU countries. This may reflect catch-up dynamics and technological upgrading processes typical of transition economies, where firms innovate to reduce productivity and technology gaps (Fagerberg and Verspagen, 2002; Radosevic et al., 2019). By contrast, firms in more advanced economies may rely more on incremental innovation and established capabilities. The literature also emphasises that innovation behaviour is strongly shaped by the surrounding institutional and economic environment (Audretsch and Feldman, 1996; Radosevic and Yoruk, 2012).

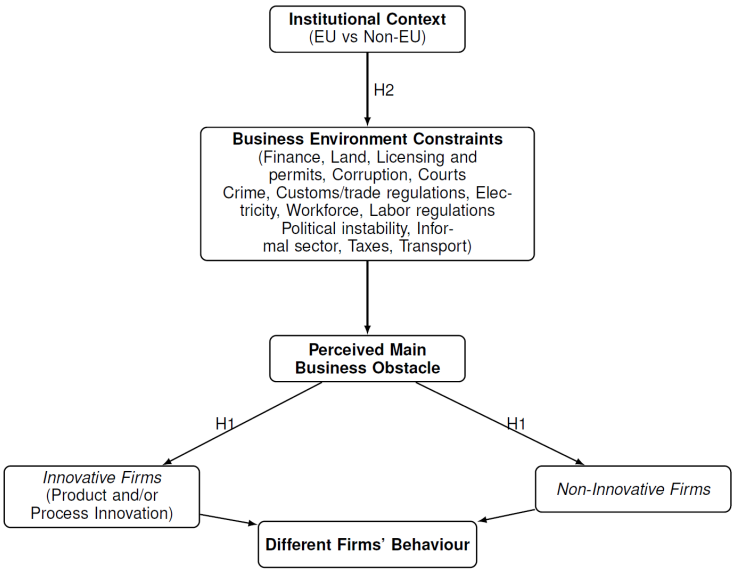

Figure 1: Conceptual framework linking business environment constraints and firms' innovation behaviour.

Table 2 reports firms' perceived main business obstacles across countries. The most frequently reported constraints in the CEE region include inadequately educated workforce, tax rates, political instability and competition from the informal sector, although their relative importance varies substantially. In many Western Balkan and Eastern Partnership economies, firms more often identify access to finance, institutional instability and informal competition as key barriers, whereas in EU member states firms more frequently report human capital shortages and taxation-related constraints. These patterns are consistent with studies stressing the role of institutional quality, regulation and human capital in shaping firms' innovation capacity (Hall and Lerner, 2010; Aghion et al., 2005; Gorodnichenko and Schnitzer, 2013).

Table 3 presents the results of two-sample Wilcoxon rank-sum (Mann–Whitney) tests comparing the distribution of perceived business obstacles across groups of firms. This non-parametric approach is suitable for survey data characterised by categorical responses and heterogeneous firm populations (Wilcoxon, 1945; Mann and Whitney, 1947; Conover, 1999).

The first part of Table 3 compares innovative and non-innovative firms across the full CEE sample. Significant differences emerge for several constraints, suggesting that the business environment affects firms differently depending on their innovation status. Innovative firms are more likely to identify access to finance, tax rates, tax administration and transport infrastructure as major obstacles. This is consistent with the literature showing that innovation requires substantial resources, involves uncertainty and depends on expected returns (Hai et al., 2022; Hall and Lerner, 2010; Aghion, Akcigit and Fernández-Villaverde, 2013). Infrastructure quality also matters by facilitating knowledge diffusion, market access and participation in global value chains (Audretsch and Feldman, 1996; Bergantino, Capozza and Spiru, 2023; Bergantino and Spiru, 2020).

Conversely, non-innovative firms are more likely to report obstacles related to human capital constraints, particularly the availability of an adequately educated workforce. This supports the concept of absorptive capacity, according to which firms need sufficient human capital to recognise, assimilate and exploit external

knowledge (Cohen and Levinthal, 1990; Lepak, Takeuchi and Swart, 2011). Firms with weaker internal capabilities may therefore perceive labour quality as a more binding constraint.

Table 3: Summary of statistically significant differences in perceived obstacles using the Two-sample Wilcoxon rank-sum (Mann–Whitney) test.

	Innovative vs Non-innovative firms						EU vs Non-EU			
	CEE countries (all sample)		EU		Non-EU		Innovative		Non-Innovative	
Obstacles	Prob.	Sign	Prob.	Sign	Prob.	Sign	Prob.	Sign	Prob.	Sign
Access to finance	***	+			***	+	***	+	***	+
Access to land		-							***	+

Tax rates	***	+	**	+	***	+	***	-	***	-
Transport	***	+	***	+	***	+				

Notes: "Prob." reports statistical significance levels: ∗p < 0.10, ∗∗p < 0.05, ∗∗∗p < 0.01. "Sign" indicates the direction of the difference. In the comparison between innovative and non-innovative firms, "+" means that innovative firms report the obstacle more frequently, while "-" means that non-innovative firms report it more frequently. In the comparison between EU and non-EU countries, the sign indicates which group reports the obstacle more frequently.

The second part of Table 3 separates EU and non-EU economies. This distinction is especially relevant in the CEE context, where institutional development, regulatory quality and financial market maturity differ substantially (D'Este, Rentocchini and Vega-Jurado, 2014). In EU countries, innovative firms differ mainly from non-innovative firms in their perception of corruption, tax administration, tax rates and transport infrastructure. Even in stronger institutional contexts, taxation and administrative procedures remain relevant for innovation incentives (Bloom, Griffith and Van Reenen, 2002; Aghion, Akcigit and Fernández-Villaverde, 2013).

In non-EU countries, innovative firms are significantly more likely to report obstacles related to access to finance, customs and trade regulations, electricity supply and infrastructure. These findings reflect structural weaknesses often observed in transition economies, where firms face multiple barriers simultaneously, including credit constraints, weak institutions and limited infrastructure reliability (Kafouros et al., 2008; Gorodnichenko and Schnitzer, 2013; Radosevic et al., 2019; Radosevic and Yoruk, 2012).

The radar charts complement these results. Figure 2(a) compares EU and non-EU economies, showing that firms in non-EU countries perceive a broader range of structural constraints, especially finance, political instability and infrastructure reliability, while EU firms are relatively more concerned with taxation and regulation (Acemoglu and Robinson, 2012; EBRD, 2020; Hai et al., 2022). Figures 2(b) and 2(c) further distinguish innovative and non-innovative firms, indicating that innovative firms in non-EU economies are particularly exposed to financial and institutional barriers, whereas innovative firms in EU countries face more moderate but still significant fiscal and regulatory constraints. This evidence confirms that innovation strategies are deeply embedded in the broader economic environment and that improvements in institutions, finance and infrastructure remain essential for fostering innovation in transition economies (Hall and Lerner, 2010; Pinto, Fernandez-Esquinas and Uyarra, 2015; Gorodnichenko and Schnitzer, 2013).

5. Conclusions and Recommendations

This paper examined the relationship between firms' innovation activities and their perception of business environment constraints in Central and Eastern Europe using firm-level data from the BEEPS survey. By comparing innovative and non-innovative firms across EU and non-EU economies, the analysis provides insights into how institutional and structural conditions shape firms' innovation behaviour in transition and emerging economies.

The empirical results indicate that innovative firms perceive certain obstacles differently from non-innovative firms. In particular, they appear more sensitive to constraints related to financial access, taxation and infrastructure conditions, reflecting the resource-intensive and uncertain nature of innovation investments. By contrast, non-innovative firms more frequently report barriers associated with human capital shortages and institutional inefficiencies, which may limit their ability to adopt new technologies and organisational practices. These findings highlight the importance of firm capabilities and absorptive capacity in shaping interactions with the external environment.

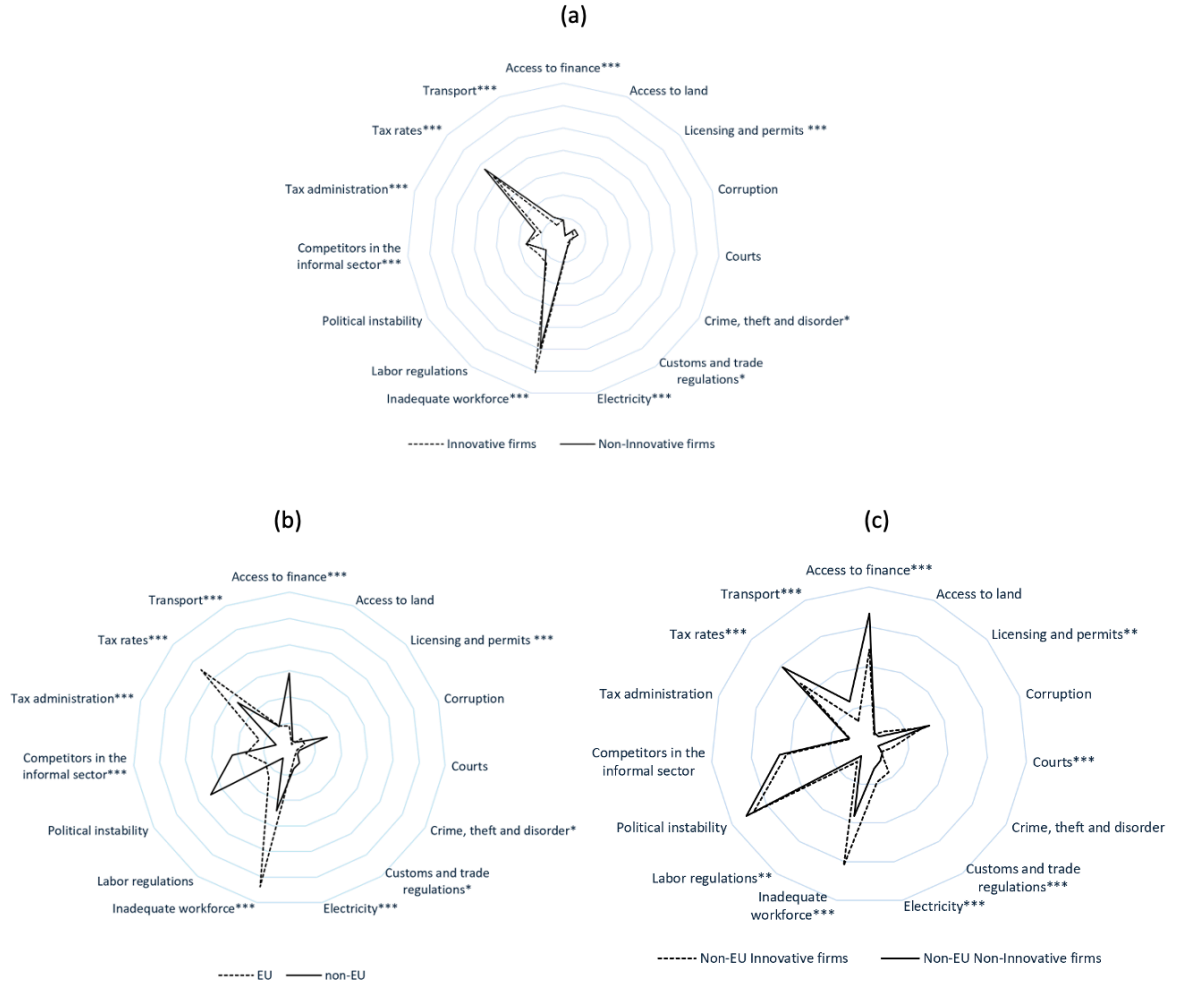

Figure 2: Perceived business environment constraints across firms in Central and Eastern Europe. (a) Innovative vs non-innovative firms; (b) Innovative vs non-innovative firms in EU countries; (c) Innovative vs non-innovative firms in non-EU countries.

Notes: ***, **, * show significance at the 1%, 5% and 10% levels according to the Two-sample Wilcoxon rank-sum (Mann-Whitney) test, indicating whether the difference in the means of the two samples is statistically significant. The circles in the radar charts represent the percentage of firms identifying each factor as the main obstacle. Each concentric circle corresponds to 5% of firms reporting the obstacle.

The analysis also reveals clear differences between EU and non-EU economies. Firms operating in non-EU countries tend to face stronger structural constraints, particularly related to financial markets, institutional stability and infrastructure reliability. In contrast, firms in EU economies more frequently emphasise taxation, regulation and labour market conditions. These patterns reflect the heterogeneous institutional development of the region and underline the importance of stable and efficient frameworks for fostering innovation.

Overall, the findings support the view that innovation is strongly embedded in the broader economic and institutional environment. Policies aimed at strengthening innovation capacity in the CEE region should therefore not focus solely on firm-level incentives but also address structural barriers. Improving access to finance, institutional quality, human capital and infrastructure remains crucial for fostering innovation and productivity growth.

Future research could further explore the causal relationship between innovation and business environment constraints using longitudinal data and econometric approaches capable of addressing potential endogeneity between firms' innovation decisions and their perception of obstacles.

Abstract: Discrimination against women, including in the economic sphere, essentially indicates that women's human rights are still being neglected. One effort to increase women's participation in the economy is the establishment of the Indonesian Women Entrepreneur Union (*Perkumpulan Perempuan Wirausaha Indonesia* /PERWIRA). Technological advances, particularly the use of the internet as a communication tool, have inspired PERWIRA to apply Information and Electronic Transactions (IET) in managing its activities. Increasing the capacity and governance of PERWIRA's activities can only be carried out efficiently and effectively if supported by proper management. In this regard, IET can be used as an approach in managing PERWIRA's activities. The purpose of this study is to analyze the effectiveness of adopting the IET approach, thereby producing a system and/or good example in implementing activity management for organizations involving women MSMEs. It applies empirical research using a sociological-legal approach, collecting data through purposive sampling-based interviews. It finds that the challenges faced by PERWIRA are not only at the individual level of MSME actors but also at the policy ecosystem and institutional capacity levels. At the individual level of women MSMEs, limited access to capital and financing makes it difficult for PERWIRA to encourage its members to scale up their businesses, especially in the micro business sector. Women MSMEs in PERWIRA still manage their businesses traditionally, accompanied by a lack of understanding of risk management and cash flow. In addition, digital transformation has not been evenly distributed among MSME members. PERWIRA also faces internal challenges related to uneven capacity among regional-level administrators. Therefore, a collaborative approach between PERWIRA, the government, and the private sector is often offered as a solution. However, such partnerships and synergies are not easy to achieve because they require the alignment of government policies. Therefore, this study adopts IET-based management to harmonize partnerships and synergies between PERWIRA and its members, including the development of partnerships and synergies with the government and the private sector.

Keywords: Women's Entrepreneurship, Technology, Governance, PERWIRA, Indonesia

1. Introduction

One initiative aimed at building economic resilience in Indonesia involves engaging all sectors of society in driving economic development. Women play a vital role in contributing to Indonesia's development and economic resilience. However, "gender discrimination remains prevalent in Indonesian society today" (Bond & Phillips, 2001).

Discrimination against women, including in the economic sphere, essentially indicates that the fulfilment of women's human rights is still being neglected. At present, discriminatory practices against women in the economic sphere still frequently occur as a result of societal attitudes that remain unresponsive to the fundamentally different issues and aspirations of men and women. Therefore, efforts must continue to be made to ensure the respect, protection, and fulfilment of women's human rights in various fields, including the economic sphere.

Indonesia's women's empowerment program began in 1978, with several regions achieving positive results in self-capacity enhancement, economic improvement, better health, and an enhanced quality of life for women. However, numerous women in Indonesia, especially in rural areas, have yet to benefit from empowerment programs. The country has a significantly larger female population than males, and many reside in rural areas with disadvantages and lower education levels. These resources can become burdensome if not maximized in all aspects of development. Conversely, they can be valuable assets if directed toward becoming highly productive individuals through empowerment (Nur., 2019).

Hence, the Ministry of Women's Empowerment and Child Protection in Indonesia has five key priorities for women's empowerment, namely 1) boosting women's entrepreneurship, 2) increasing the involvement of mothers and families in childcare and education, 3) combating violence against women and children, 4) reducing child marriages, and 5) preventing child labour (Humas Kementerian PPPA, 2020). Additionally, the ministry promotes women's entrepreneurship by integrating gender issues into priority programs in other ministries/agencies like the Ministry of Cooperatives and Small and Medium Enterprises, the Ministry of

Agriculture, the Ministry of Tourism and Creative Economy, and the Ministry of Manpower (Humas Kementerian PPPA, 2020).

MSMEs are widely regarded as the backbone of Indonesia's economy, contributing more than 60 percent of GDP and providing employment to over 100 million people, or about 97 percent of the national workforce. Strengthening these small enterprises and enabling them to scale up is crucial for sustaining economic growth and supporting Indonesia's ambition to become the world's seventh-largest economy by 2030. Nevertheless, "most MSMEs operate in the informal sector, which limits their access to financing and constrains their managerial and operational capacity for expansion" (ASEAN Briefing, n.d.).

Anoraga (2010) states that MSMEs possess a number of promising strengths that support their future development. First, they serve as a major source of employment, with small industries estimated to absorb up to half of the available workforce. Second, they contribute to the creation of new entrepreneurs, as their presence has consistently encouraged the growth of entrepreneurial activity. Third, MSMEs operate within distinctive market segments, characterized by simple and flexible management that allows them to adapt quickly to market changes. Fourth, they make effective use of surrounding natural resources, often utilizing waste or by-products from larger industries, which provides further opportunities for development

Despite these advantages, MSMEs also face several weaknesses that hinder their growth, particularly at the micro-enterprise level. These challenges can be categorized into internal and external factors. Internally, MSMEs commonly struggle with limited human resource capacity and inadequate marketing capabilities. Externally, challenges arise from the institutions responsible for developing and supporting MSMEs. These include poorly targeted assistance programs, a lack of effective monitoring, and overlapping initiatives that reduce overall effectiveness. A significant gap exists between these internal and external factors, particularly in relation to access to financial support (Anoraga, 2010).

One of the initiatives to encourage and increase women's participation in the economy was the establishment of the Indonesian Women Entrepreneur Union (*Perkumpulan Perempuan Wirausaha Indonesia* /PERWIRA) on 12 February 2016 (PERWIRA's Articles of Association). PERWIRA is a legally incorporated organisation whose members are female entrepreneurs comprising micro, small, and medium-sized enterprises (MSMEs) and business owners. As a legally incorporated organisation, PERWIRA aims to enhance skills, the quality and quantity of production, business progress, dedication, and business development, as well as to support MSMEs in contributing to economic development in accordance with the *Pancasila* (the Indonesian ideology) and the 1945 Constitution. As an organisation with members spread across Indonesia, PERWIRA requires an effective and efficient institutional governance framework (PERWIRA Articles of Association).

Technological advancements, particularly the use of the internet for long-distance and cross-border communication across various countries—including Indonesia—have led to an increase in internet users in Indonesia. This has also inspired PERWIRA to implement Electronic Information and Transactions (EIT) in its institutional management. With this guiding principle and a determination to consistently participate in and contribute to the development of a healthy national economy—aimed at strengthening national unity and solidarity—supported by advancements in Electronic Information and Transactions (EIT), which enable the provision of information swiftly and accurately, PERWIRA will conduct communications, meetings, and decision-making using Electronic Information and Transactions from the central level down to the branch level. Furthermore, with EIT, PERWIRA will remain at the forefront of production innovation, enabling its products to be exhibited and sold at both national and international levels. The use of EIT is also in line with PERWIRA's founding principles of minimising costs and ceremonial activities whilst fostering a strong work ethic for production and exhibitions (PERWIRA's Articles of Association).

A fundamental issue in the institutional management of PERWIRA is how the EIT system has been developed to strengthen its governance. This requires careful consideration, given that PERWIRA's members are entrepreneurs running SMEs and micro-enterprises across Indonesia. Furthermore, the level of education and understanding of EIT among PERWIRA members varies significantly, as not all MSMEs in Indonesia currently utilise EIT. Hence, the purpose of this study is to analyse the effectiveness of adopting the EIT approach, thereby producing good examples in implementing activity management for organisations involving women MSMEs.

2. Conceptual and Legal Framework

2.1 Legal Approaches to MSMEs

The Indonesian government enacted Law No. 20 of 2008 on Micro, Small, and Medium Enterprises (MSMEs Law) to support MSMEs. However, to implement the provisions of Law Number 11 of 2020 on Job Creation, the Government then enacted Government Regulation of the Republic of Indonesia Number 7 of 2021 concerning the Facilitation, Protection, and Empowerment of Cooperatives and Micro, Small, and Medium Enterprises (Cooperatives and MSMEs Government Regulation). Both the MSMEs Law and the Government Regulation similarly define that:

> "A Micro Enterprise is a productive business owned by an individual and/or a sole proprietorship entity."
>
> "A Small Enterprise is an independent, productive economic business carried out by an individual or a business entity that is neither a subsidiary nor a branch of a medium or large enterprise, and is not owned, controlled, or directly or indirectly affiliated with such enterprises."
>
> "A Medium Enterprise is an independent productive economic business carried out by an individual or a business entity that is neither a subsidiary nor a branch of a small or large enterprise, and is not owned, controlled, or directly or indirectly affiliated with such enterprises."

However, there are several differences between the MSMEs Law and the Government Regulation to determine the category of MSMEs, as presented in Table 1.

Table 1: New Approaches to MSMEs

Indicator	MSMEs Law	Cooperatives and MSMEs Government Regulation
Categorization of MSMEs	MSMEs are categorized based on net worth or annual sales. Net worth is the total assets minus debts or liabilities.	MSMEs are categorized based on business capital criteria or annual sales. Business capital includes own capital and borrowed capital used to conduct business activities.
Net Worth or Business Capital	1. Micro Enterprise: up to Rp50 million 2. Small Enterprise: more than Rp50 million – up to Rp500 million 3. Medium Enterprise: more than Rp500 million – up to Rp10 billion Excluding land and buildings used for business.	1. Micro Enterprise: up to Rp1 billion 2. Small Enterprise: more than Rp1 billion – up to Rp5 billion 3. Medium Enterprise: more than Rp5 billion – up to Rp10 billion Excluding land and buildings used for business.
Annual Sales	1. Micro Enterprise: up to Rp300 million 2. Small Enterprise: more than Rp300 million – up to Rp2.5 billion 3. Medium Enterprise: more than Rp2.5 billion – up to Rp50 billion	1. Micro Enterprise: up to Rp2 billion 2. Small Enterprise: more than Rp2 billion – up to Rp15 billion 3. Medium Enterprise: more than Rp15 billion – up to Rp50 billion

The Cooperatives and MSMEs Government Regulation introduces various measures to support the growth of local MSMEs. These include requiring regional governments to allocate at least 30 percent of commercial land areas for MSME development and promotion. "The regulation also simplifies business licensing procedures, provides tax incentives and relief, and exempts MSMEs from the obligation to comply with provincial or regency/city minimum wage requirements" (ASEAN Briefing. (n.d.).

2.2 Implementation of Digital Governance in Indonesia

"Indonesia has entered an era of digital transformation, marked by a shift in which activities that were once carried out directly are increasingly being conducted indirectly through the use of technology" (Hidayati et al, 2023). Kraus et al (2021) state that it encompasses human, cultural, and technological dimensions aimed at

significantly expanding the reach of institutions or companies. “The adoption of digital technologies, including artificial intelligence (AI), data analytics, the Internet of Things (IoT), and other innovations, is intended to enhance efficiency and improve human productivity” (Al Khozaini & Mundiri, 2024). It has also extended into governance in both the public and private sectors, commonly referred to as digital governance.

“Digital governance, commonly known as e-governance, involves the application of digital technologies in government processes to improve efficiency, promote transparency, and encourage public participation” (Heeks, 2001). Furthermore, Janssen & Estevez (2013) state that several fundamental pillars underpin digital governance: 1) transparency, because it allows governments to make information openly accessible to the public; 2) accountability, because “it enables more effective monitoring and evaluation of policies, creating opportunities for public scrutiny of government performance” (Cordella & Tempini, 2015); 3) public participation, because “it engages citizens more actively in policymaking through the platforms that facilitate the public expressions” (Puspitasari & Ishii, 2016). The effective implementation of digital governance in Indonesia relies on the involvement of multiple stakeholders, including central and local governments, the private sector, and civil society. Yet, it remains to encounter various challenges such as limitations in technological infrastructure, different levels of digital literacy, data security threats, and limited human resource capacity (Murdhani, 2025).

3. Methods

This study is an empirical study employing a sociological approach to law, “in which law is conceptualised as a social institution that is intrinsically linked to existing social variables” (Wignyosoebroto, 1993). The type of sociological legal research employed in this study is legal validity research, which focuses on the effectiveness of the law as manifested in the digital governance of the PERWIRA organisation.

In sociological/empirical legal research, “the data used is primary data obtained through interviews and Focus Group Discussions (FGDs)” (Amiruddin & Asikin, 2004).

Data collection techniques used in this study are:

1. Interviews conducted by gathering data through oral questioning of key informants (KI) under PERWIRA. The interviews used were structured interviews employing a list of questions as a guide. Interviews with KI (1 PERWIRA official and 25 PERWIRA members) were conducted by asking structured questions, which the respondents and KI answered via WhatsApp after first obtaining the consent of the respondents concerned. Key informants from PERWIRA were selected using purposive sampling based on their positions as vice chairs of PERWIRA. Respondents were selected at random from among PERWIRA members as presented by Table 2.

Table 2: PERWIRA Respondents

No	Region of Origin	Number of Respondents
1	Dumai City	17
2	Manado, North Sulawesi	2
3	Jakarta Special Capital Region	2
4	Yogyakarta	2
5	Kulon Progo	1
6	East Java	1
Total		**25**

Source: Collected data on 30 May 2026.

2. In legal research employing a sociological approach, primary data is supplemented by secondary data comprising primary legal sources, secondary legal sources, and tertiary legal sources (Marzuki, 2005). Secondary data is obtained through a literature review. This secondary data consists of: 1) primary legal materials, primarily Law of the Republic of Indonesia No. 11 of 2008 on Electronic Information and Transactions (EIT Law), and 2) secondary legal materials comprising books, websites, newspapers, and articles related to project management, entrepreneurship, and gender empowerment.

3.1 Data Interpretation Methods

The data analysis in this study employs a qualitative approach. A qualitative approach is a method that analyses the social phenomena arising from the implementation of a legal regulation. In this study, the chosen data analysis methods are linguistic interpretation and systematic interpretation. This is because these data analysis methods are particularly suitable for application in sociological/empirical legal research, "as linguistic interpretation and systematic interpretation allow for the verification of the validity of data and information, as well as the demonstration of their accuracy" (Soekanto, 2008).

4. Findings and Discussion

4.1 The Establishment of PERWIRA

Women's empowerment is a key aspect of community development. One of the crucial stages in the community development process is increasing household income. "In principle, community development is designed to boost community income by enhancing women's productivity in both the agricultural and non-agricultural sectors, such as trade, small-scale home-based industries, and services" (Effendi, 1993). The economic dimension and women's basic needs are key elements that must be addressed in tandem with overall development programmes. There are various ways to improve women's living standards, such as providing credit for self-employment, creating job opportunities, and enhancing their access. Easier access to government credit improves women's ability to obtain capital for establishing MSMEs. "These job opportunities expand the scale of their businesses and enable women to compete in the business sector" (Yuarsi, 2002).

To support women's entrepreneurship, the Indonesian Women Entrepreneur Union (*Perkumpulan Perempuan Wirausaha Indonesia*/PERWIRA), was officially established on February 24, 2016, under the leadership of Dr. Hj. Elza Syarief. PERWIRA's organisational structure consists of several divisions, including a) Product Development or Human Resource Capacity Building Division, b) Maritime Division, c) Commercial Division, d) Agriculture Division, e) Social Welfare Division, f) Mining Division, g) Contractor, Property, and Real Estate Division, h) Tourism and Services Division, i) IT, Public Relations, and MSMEs Division. Its activities include fostering collaboration among members by integrating individual member businesses with other member companies into a unified economic network. This approach aims to expand business operations, enter new markets, both domestic and international, through members with established market access, and promote business diversification.

Based on the interview with the PERWIRA official. and members, she said, "products from PERWIRA members are highly diverse, ranging from food and beverages to handicrafts, jewellery, and more. However, most PERWIRA members are engaged in the food and beverage sector. Therefore, PERWIRA facilitates its members in obtaining halal certification". In addition, PERWIRA facilitates technology transfer, reduces internal competition, and enhances access to local resources and domestic markets among its members (Interview, DBP, 28 March 2026).

In carrying out its activities, PERWIRA collaborates with various government institutions, including the Ministry of Trade, the Ministry of Industry, and the Ministry of Cooperatives and Small and Medium Enterprises, as well as with international partners such as the Embassy of Poland and the Embassy of Japan. Currently, approximately 90 percent of PERWIRA's members come from the MSME sectors. In addition to organizing various training programs and establishing partnerships with multinational companies, PERWIRA has also provided mentorship and support to around 10,000 MSMEs across 38 provinces in Indonesia (Interview, DBP, 28 March 2026). Respondents from Dumai stated that PERWIRA collaborates with departments in Dumai, including Bank Riau Kepri Syariah, the Investment and One-Stop Service Agency, the Health Department, the Indonesian Ulema Council, and the Dumai Family Welfare Empowerment Agency. Respondents from Yogyakarta stated that PERWIRA in their region collaborates with the Yogyakarta Special Region Tourism Agency and the SME Cooperative.

PERWIRA promotes its members' products through various activities, such as bazaars, exhibitions, and joint promotions. Based on interviews with 25 members of PERWIRA, the types of product promotion they use are shown in Table 3.

Table 3: Product Promotions of PERWIRA's Members

No	Region of Origin	Types of Promotions
1	Dumai City	Business networking, product promotion, and information exchange.
2	Manado, North Sulawesi	Joint promotion, MSMEs bazaars, exhibitions, and collaborative product marketing among members.
3	Jakarta Special Capital Region	Joint promotion, domestic and international bazaars, exhibitions, and digital marketing.
4	Yogyakarta	Knowledge sharing, business experience exchange, and complementary products.
5	Kulon Progo	MSMEs bazaars and local sales events.
6	East Java	Collaboration occurred through annual programs, routine meetings, exhibitions, and expanded marketing networks.

Source: Interviews of 25 PERWIRA Members, 30 May 2026.

4.2 Challenges Faced by PERWIRA in Managing Women's Entrepreneurship

In developing MSMEs, "women entrepreneurs require essential entrepreneurial skills, including the ability to identify opportunities, take calculated risks, and communicate effectively with customers" (Iskandar & Safrianto, 2020). These skills must be complemented by practical knowledge, which can be acquired through "entrepreneurship education as a means of building competence in management practices, marketing strategies, and financial aspects" (Salim et al,2025).

With approximately 10,000 MSME members across Indonesia, PERWIRA faces significant challenges. Limited access to capital and financing continues to constrain efforts to scale up businesses, especially in the micro-enterprise sector. Many members still rely on traditional business practices and have a limited understanding of risk management and cash flow (Interview, DBP, 28 March 2026). Moreover, the adoption of digital transformation remains uneven among MSME members. This issue indicates that MSMEs have not yet implemented a comprehensive digital marketing strategy. There are seven key elements underlying internet-based marketing communication practices: context, content, community, customization, communication, connection, and commerce (Rayport & Jaworski, 2003). However, MSMEs within PERWIRA generally apply only one of these elements, namely communication, which is still limited to the basic use of social media such as WhatsApp and Instagram (Interview, DBP, 28 March 2026).

Digital transformation has become a crucial factor in MSME development in the era of Industry 4.0, alongside the rapid growth of the digital economy. Nevertheless, not all MSME actors within PERWIRA have utilized digital media as a promotional tool, primarily due to a limited understanding of technology and social media (Halwa, 2021). Many are still unfamiliar with digital marketplaces such as Shopee and Lazada, which could serve as highly effective channels for promotion and sales. In general, they continue to rely on personal communication tools such as WhatsApp, Instagram, Facebook, or TikTok, and a small number of PERWIRA members who use e-commerce platforms, as revealed by interviews with 25 members of PERWIRA.

Table 4: Social Media Platforms Used by PERWIRA Members

No	Social Media / E-Commerce Platforms Used	Number of Respondents	Percentage (%)
1	WhatsApp, Facebook, Instagram	17	68
2	WhatsApp, Facebook, Instagram, Marketplace (Shopee/Tokopedia)	5	20
3	WhatsApp, Instagram, TikTok	1	4
4	Instagram, Tokopedia	1	4
5	WhatsApp and online promotion platforms	1	4
Total		**25**	**100**

Source: Interviews of 25 PERWIRA Members, 30 May 2026.

The distribution of PERWIRA members across 38 provinces also presents a challenge, as the level of digital literacy varies among its members. Out of the 25 respondents, 22 have faced challenges relating to digital transformation, as shown in Table 5.

Table 5: Challenges Faced by PERWIRA Members

No	Challenge Category	Description of Challenges	Number of Respondents
1	Technology adaptation / digital literacy	Difficulty adapting to technological changes, improving digital skills, and understanding online marketing	18
2	Digital marketing challenges	Keeping up with digital marketing trends and competitive online promotion	3
3	Limited technological skills	Lack of technological knowledge or confidence in using digital tools	1
Total			**22**

Source: Interviews of 25 PERWIRA Members, 30 May 2026.

Although PERWIRA's activities are uploaded by the Central Executive Board of PERWIRA or local televisions, the activities shown are generally still ceremonial in nature, consisting mainly of the inauguration, with a relatively low number of viewers. This serves as a form of promotion and information sharing regarding PERWIRA's existence.

4.3 Strategies and Digital Governance Adaptation in the Management of PERWIRA

"Management is a process that involves planning, organizing, staffing, directing, and supervising the members of an organization to achieve its objectives" (Pratama, 2020). To support the effectiveness and efficiency of PERWIRA's management, the association has established the following organizational structure:

1. At the national level, it is referred to as the Central Executive Board of PERWIRA (DPP PERWIRA).
2. At the provincial level, it is referred to as the Regional Executive Board of PERWIRA (DPD PERWIRA).
3. At the city/regency level, it is referred to as the Branch Executive Board of PERWIRA (DPC PERWIRA).
4. At the sub-district level, it is referred to as the Sub-branch Executive Board of PERWIRA (DEPRAN PERWIRA).

To ensure effective and efficient communication between PERWIRA at the central level and its branches at the provincial, city/regency, and sub-district levels, PERWIRA has adopted digital governance, as internet access is available across many parts of Indonesia. However, the level of digital literacy among PERWIRA members varies significantly. Therefore, PERWIRA relies on communication channels that are familiar to all members, particularly WhatsApp groups (Interview, DBP, 28 March 2026). In addition, PERWIRA officially shares information and documents through its organizational email (perwira.dpp@gmail.com).

PERWIRA relies on the use of Information and Electronic Transactions (IET) in managing its activities. This serves as a communication and information-sharing strategy, considering that its members are spread across all provinces in Indonesia. PERWIRA's management also noted that for real-time communication, the organization uses Zoom services, as they are accessible to executive board members at all levels (Interview, DBP, 28 March 2026).

In addressing various challenges, PERWIRA's management stated that PERWIRA collaborates with a wide range of stakeholders at both the national and regional levels. "Concerning limited access to capital and financing for its members, PERWIRA has partnered with the Ministry of Cooperatives and SMEs of the Republic of Indonesia, the Ministry of Trade of the Republic of Indonesia, as well as relevant agencies responsible for MSMEs, industry, and trade at the local government level" (Interview, DBP, 28 March 2026).

In addition, PERWIRA at the central and regional levels has conducted various training programs, including financial management, digital marketing, halal certification, and public speaking, tailored to the needs of its members. Capacity-building initiatives have also been intensified, particularly in the use of digital technologies to support administrative processes and product marketing. Furthermore, it has organized and participated in numerous product exhibitions at the local, national, and international levels (Japan and South Korea) 35.

(Interview, DBP, 28 March 2026). These activities have been supported by various stakeholders such as the Indonesian Chamber of Commerce and Industry and the Regional Craft Councils (Kadin Riau, 2024) and "private sector actors, including e-commerce platforms such as Shopee in enhancing members' knowledge of digital marketing and e-commerce" (Harianmerdekapost.com, 2024).

5. Conclusion and Recommendations

The shift in the MSME indicator approaches under the Government Regulation on Cooperatives and MSMEs has increased the number of PERWIRA members. Most of its members are women-led MSMEs engaged in the food, beverage, and handicraft sectors in all provinces in Indonesia. Hence, PERWIRA has adopted digital governance to facilitate information services and communication with its members, who are spread across Indonesia. However, PERWIRA members mostly rely on a basic use of social media platforms such as WhatsApp and Instagram, which results in limiting promotional reach and public awareness of their products.

To respond to these limitations, PERWIRA utilizes the IET, especially Zoom meetings, to manage organizational activities and facilitate communication among members across Indonesia. In improving members' access to capital and financing, it partners with the Indonesian Ministry of Cooperatives and SMEs, the Ministry of Trade, and relevant local government agencies responsible for MSMEs, industry, and trade. Through this strategy of digital governance adaptation and collaboration with multiple stakeholders, PERWIRA has consistently undertaken efforts to improve its management.

Based on the conclusions, PERWIRA as a case study contributes to the literature on digital governance, particularly in facilitating organisational management, communication, and decision-making for members who are geographically dispersed. This study also demonstrates that PERWIRA's strategy can serve as a model for women-led SMEs to strengthen organisational resilience in the era of digital transformation in Indonesia.

Ethics Declaration

This study involved interviews with PERWIRA members. Their participation was conducted with informed consent, under the agreement that the full names of the interviewees would not be disclosed.

AI Declaration

This paper utilizes AI tools, namely ChatGPT, to summarize the interview findings and translate them from Indonesian into English. In addition, DeepL and Grammarly are used for translation and to refine the grammar and structure.

How Does an Iconoclast Venture Studio's Investment Model Ensure the Scaling of an Early-Stage Deeptech Venture?

Laurent Téoule-Dorey
EKLYA School of Business, Ecully, France

dorey@eklya.fr

Abstract: This study investigates how a nonprofit venture studio helps ensure the perennial scaling of a "born-global" Climatetech firm transforming industrial waste heat into efficient electricity. Intervening during a period of liquidity constraints and governance instability, this impact investor secured equity control to stabilise the firm and provide critical capital. The research analyses a hybrid investment model blending impact investing with social innovation, specifically through a novel "license" agreement, an open licensing approach leading cross-innovation and market expansion to address climate urgency. Utilising founders' interviews and a thorough documentary analysis, this research examines how the hybrid model navigates a Deeptech venture through early-stage obstacles by syncing unconventional funding with proof-of-market milestones. The case underscores a central theme within Climatetech: while patient capital provides the necessary resilience for prolonged R&D cycles, the urgency of the climate crisis forces a difficult paradox, requiring both founders and funders to maintain rigorous stability while remaining highly adaptable. Findings enrich scholarship on hybrid governance and purpose-driven innovation, underscoring nonprofits' pivotal role in scaling Deeptechs. Through financial alliances and novel licensing, they empower small, specialised firms to leap from prototypes to global commercial impact.

Keywords: Deeptech, Climatetech, Global Entrepreneurship, Impact Investment, Social Venture, Venture Studio

1. Introduction

Founded in 2018 in Aix-en-Provence (France) by energy mechanics engineers, ENTENT is a Deeptech enterprise dedicated to converting waste heat between 60°C and 150°C into usable energy and reducing CO_2 emissions (ENTENT, n.d.), addressing questions "*that are rarely considered even in the scientific field, making it quite rare for a company to take so many risks and explore this kind of topic,*" share Mathias Fonlupt (BFM Business, 2025, 3:24), its CEO. Its flagship PULSE technology converts low-grade residual (waste) heat into electricity via a pulsed internal fluid system that enhances efficiency.

Founded in 2019 in France by two friends, alarmed by climate change Team for the Planet (TFTP), initially Time for the Planet oversees startup mentoring, fundraising, administrative support, shareholder relations, communication, IT development, legal/financial management, and recruitment for its portfolio companies, known as "stars." Structured as an iconoclast nonprofit company distributing no financial dividends, TFTP pursues a general interest mission, engaging over 130 000 citizens (associates), a scientific committee of 14 experts, and over 16 000 innovators worldwide to identify and scale greenhouse gas (GHG)-reducing innovations. Raised funds finance innovations released under "free licenses" for rapid global deployment, recognising climate disruption's inherently transnational nature.

ENTENT and TFTP first connected in early 2021, when TFTP was seeking entrepreneurs to validate its value proposition, but CEO Mathias Fonlupt noted that, "*TFTP wasn't ready to invest; they were still structuring.*" By early 2023, irreconcilable tensions between ENTENT's co-founders risked deadlock. In March–April 2023, TFTP proposed acquiring a majority stake by buying out exiting shareholders (including the co-founder and some early financial partners), injecting vital cash and stabilising governance. As a general rule, Mehdi Coly, co-founder of TFTP explains "*we don't usually hold a majority stake. When we were asked to intervene, we had the prerequisite of expelling certain investors who did not have the right mindset to support the company and therefore made offers to buy their shares.*"

The rareness of ENTENT–Team for the Planet case offers us to adopt a single-case, abductive design centred on the ENTENT–TFTP relationship—a born-global Deeptech venture in acute liquidity and governance crises, met by a nonprofit venture studio blending impact investing, equity control, and free-licensing—making it an extreme/critical case for theorising hybrid investors' roles in scaling and legitimacy-building under high uncertainty.

1.1 Research Question

This study probes this relationship through the following research question. *How does a nonprofit venture studio's hybrid investment model propel the scaling of a born-global Deeptech firm amid liquidity constraints, governance instability, and climate crisis urgency?* This question guides the analysis of the gathered data.

2. Case Selection, Boundaries, and Unit of Analysis

A qualitative single-case, abductive design suits this research, capturing governance dynamics, legitimacy building, and investor–venture alignment under high uncertainty—where case studies excel for complex phenomena (van Hulst & Visser, 2025).

We analyse the ENTENT–TFTP relationship as the primary unit: a born-global Deeptech-Climatetech venture and a nonprofit venture studio. Temporal boundaries span from inceptions (2018, 2020) through initial contact (2021), crisis intervention/stabilisation (2023–2025) and initial consolidation (2026). Spatial scope covers France-rooted global expansion (Fisher et al., 2016) of both ventures.

Selected for anomalous patterns that defy single literatures (Deeptech VC, social ventures, impact investing) this case offers the kind of "surprising observations" that drive abductive theorising (Lehner et al., 2019).

Data collection spanned late 2025–early 2026 via semi-structured interviews, public documents, and digital traces. We conducted two interviews—one with ENTENT's founder and one with a TFTP co-founder—each lasting 45 minutes, transcribed and returned to interviewees for member checking, supplemented by prior encounters, TFTP co-founders' books, and broadcasts to enable longitudinal reconstruction of governance, financing, and legitimacy-building processes.

Data analysis followed an iterative, abductive cycle between empirical material and theory. First, interview transcripts and documents were coded inductively to identify governance dynamics, legitimacy-building, and investor–venture alignment patterns—akin to abductive coding blending emergent codes with theoretical ideas (Khurshid et al., 2026). Second, these themes were confronted with theories of organisational legitimacy/thresholds (Fisher et al., 2016), hybrid governance (Lehner et al., 2019), and Deeptech/impact resource acquisition (Schutselaars, 2022). This systematic combining iteratively refined the case and framework, yielding novel theoretical insights via a data- and method-triangulated qualitative case study design (Morgan, 2024).

The researcher adopted a partially embedded yet independent role, blending outsider analysis with close ENTENT–TFTP interactions. Access relied on organisational trust (risking over-identification with their mission), mitigated through systematic data/method triangulation, analytic publications tracking assumptions/reactions, and active searches for disconfirming evidence. Positionality—familiarity with impact investing and climate innovation—was reflexively leveraged as an interpretive resource while maintaining critical distance.

3. Theoretical Framing

The study is anchored in three interconnected literatures. First, work on Deeptech and Climatetech ventures shows that science-based, hardware-intensive climate innovations face long development cycles, high technological risk, and structural funding gaps between grants and equity, with Cleantech-Deeptech VC often proving a poor fit and requiring new intermediaries and financing models (Romme et al., 2023). Second, research on hybrid and impact investors in Cleantech highlights investors combining financial and environmental logics, persistent misalignment and information asymmetries in early-stage Cleantech finance, and the growing role of diverse intermediaries (government VC, nonprofit vehicles, climate-tech VCs, and venture builders) in de-risking and syndicating capital (Kennedy et al., 2024). Third, the case draws on theories of legitimacy, hybrid governance, and control in early-stage ventures, which stress how hybrid ventures navigate the "liability of hybridity," use financial and symbolic endorsements to secure resources, and experiment with alternative control structures under high uncertainty (Ofem et al., 2025). Together, these strands frame ENTENT–TFTP as a Deeptech-Climatetech venture financed and governed by a hybrid, no-for-profit venture studio whose practices challenge conventional VC-centric models of control, legitimacy building, and investor–venture alignment.

4. ENTENT's Unique Challenges as a Deeptech Climatetech

Deeptech-Climatetech firms like ENTENT align closely with sustainability-oriented or impact startups (Scartozzi et al., 2024), characterised by protracted timelines. Whether they qualify as "social ventures" depends on their goals and business models (Bergmann & Utikal, 2021), given the conceptual overlaps between social entrepreneurship, sustainable entrepreneurship, and social innovation—fields that increasingly subsume environmental objectives under the "social" dimension of impact (Bonfanti et al., 2024). In this view, Climatetech emerges as an eco-inclusive form of venturing focused on mitigation, adaptation, and low-carbon transitions (Hillman et al., 2018).

ENTENT operates at the Deeptech-Climatetech-Cleantech intersection, where scientific breakthroughs align with explicit climate-impact goals. Such a venture underpins far-reaching economic and societal transformations by introducing distinctive, hard-to-imitate technologies that push the technological frontier (Schutselaars et al., 2023), disrupt legacy solutions, and address unmet needs driven by global megatrends. "*We're pursuing fundamental physics explored by few—if any—researchers,*" notes Fonlupt.

However, the path to market for such ventures is uniquely arduous. Unlike traditional startups, Deeptech requires significantly higher upfront capital to reach a minimum viable product (MVP) due to the intensive costs of prototyping and validation. Consequently, such a venture faces structural barriers to rapid scalability, requiring "substantial amounts of investment capital long before the first customer can be served" (Schutselaars et al., 2023, p. 14). Yet, beyond mere financial hurdles, the Deeptech frontier demands a unique multidisciplinary synthesis of analytical skill, creative vision, and collaborative teamwork, signifying that "execution of complex, novel, ambitious, and high-risk research necessitates above-average levels of funding" (Kowal & Przewoźnik, 2025, p. 7) and adaptative leadership, as "innovation must occur not only in what the company delivers to the market but also in how it operates internally" (Bargavi et al., 2025, p. 2200).

This capital-intensity creates thereof an unusually deep and wide "valley of death"—a chasm between initial innovation and commercial viability "which calls for new ways and strategies for overcoming it" (Romme et al., 2023, p. 218), as in fact, ultimately relying on generic scaling strategies derived from traditional, non-Deeptech ventures is insufficient to bridge the gap to the growth stage for such complex climate innovations. That is where the intentionality behind Deeptech selection conducted by TFTP—prioritising "purpose" alongside technical viability—serves to de-risk the commercialisation process by ensuring outcomes are effectively calibrated to solve profound socio-economic and environmental challenges (Kowal & Przewoźnik, 2025).

For ENTENT, symbolic affiliation with high-status organisations serves in that perspective as a critical mechanism for reducing this perceived market uncertainty, a strategy that began with its inception at the Technopôle de l'Arbois, currently ranked as the leading technology park in France dedicated to Cleantech and the fourth globally (ARBE, n.d.). This institutional prestige was bolstered by early financial (seed) validation: a €25,000 interest-free loan from Aix Marseille Provence Amorçage in 2017. As founder Fonlupt notes, this initial injection was foundational, as it "*allowed us to really build our equity and seek other financing*" (PaysAixDevelopment, 2025, 00:41).

This trajectory hit a pivotal turning point a few years later with a much-anticipated alignment with Team for the Planet—backed by a €5 million ADEME investment (France's ecological transition agency), together with Bpifrance (the national innovation bank) and the €54 billion France 2030 investment, innovation, and reindustrialisation plan—which substantially enhanced the startup's perceived legitimacy. Such highly visible institutional endorsement acted as a catalyst for deeper engagement with private investors, including Crédit Agricole CAAP Création, Angels for Greentech (Angelor), and Bpifrance's seed programs. Most recently, this credibility facilitated a successful 2026 crowdfunding campaign on Sowefund, "a collective engine serving French innovation and those who finance it" (Sowefund, n.d.), raising approximately €2.4 million from investors focused on major ecological transitions.

5. Team for the Planet's Iconoclastic Early-Stage Impact Investing Approach

Early-stage investors must commit substantial capital to Deeptech ventures long before serving the first customer, as the absence of a client base precludes direct validation of the value proposition (Schutselaars et al., 2023). Team for the Planet thus eschews leading innovation creation—amid countless ideas—but broadcasts widely to attract innovators, cultivating a dedicated pool. "*16 000 (innovators) have completed training, harnessing collective intelligence to screen innovations swiftly,*" Coly shares, spotlighting top candidates for TFTP's scientific committee review, mitigating risks in Deeptech venture financing through expertise and networks (Bergset, 2015). The committee assesses feasibility and impact without prescribing strategies, flagging risks while aiding impact enterprises to scale solutions and enhance social/environmental performance (Benkraiem et al., 2026).

As a newer breed of VCs, impact investors VCs target mission-driven firms that blend business activities with societal well-being—both within and beyond operations. They partner with these socially oriented organisations, often joining boards and controlling portions of their capital supply. In their manifesto, Team for the Planet set out to raise €1 billion progressively by rallying citizens, businesses, associations, and local authorities; pinpoint 100 high-potential anti-GHG innovations; convert them into 100 deployable companies;

fund rapid scaling; and disseminate them globally for widespread replication—ultimately forging 100 markets dedicated to GHG reduction (Time for the Planet, 2021).

As a legal entity and economic actor, TFTP aims at generating revenue through activities to fund subsidiaries, hire staff, and develop future climate solutions. Logically, greater revenue amplifies its climate change impact—reinvested to bolster humanity's survival prospects rather than hoarded. Unlike an association with members, it operates as a company with associates: anyone contributing funds becomes a co-owner, an associate. Consequently, its corporate purpose, enshrined in its statutes as its legal raison d'être, targets combating climate change by creating businesses that slash greenhouse gas emissions, energy use, and scarce resource consumption—aiming to restore 1850-level GHG concentrations. "*We will only distribute dividends to our associates if we one day return to +0°C of global warming compared to the pre-industrial era (1850-1900)*" (Time for the Planet, 2021, p. 50).

In short, Team for the Planet's mission boils down to sourcing, selecting, and scaling world-transforming innovations in key sectors; recruiting seasoned entrepreneurs to lead their deployment via innovator-entrepreneur partnerships; funding these ventures through large-scale crowdfunding; and harnessing its vast investor network to accelerate growth by securing clients, talent, visibility, targeted meetings, and beyond. Yet TFTP's approach to investees "*is really very operational and not at all what one can call strategic, because in fact these are development phases where what matters is going fast, and it's better to make 50 decisions in a month and have many of them be bad than to make two that are very good,*" shares Coly.

Unlike conventional funds that rely on managers, analysts, and monitoring staff, TFTP prioritises distinct roles: Coly notes, "*We manage our community, create visuals for crowdfunding, run a daily LinkedIn media channel—France's biggest climate community—and handle internal recruitment for innovations, with a recruiter tapping our network to secure client business for startups.*" This approach equips investees with extensive services exceeding typical fund support, fostering both upstream (associates) and downstream ("stars") communities through operational aids. "*We skip coaching for hands-on execution, stepping in directly for the company,*" Coly adds.

Team for the Planet anchors investment tranches selectively: they've reinvested in several innovations but tie further funding to targets. "*In 2025, for example, we raised €11 million through crowdfunding for five innovations, but didn't invest in ENTENT as it had not yet reached its target,*" Coly explains—ENTENT pursued a separate round, with Team for the Planet poised to invest once milestones are hit. TFTP aims to retain stakes long-term: "*If the investee declares bankruptcy, shareholder agreements force exit, but staying and increasing our stake is preferable,*" Coly notes. The core challenge is time, dictated by runway: burning cash prompts a decision to reinvest or not, aware failure looms otherwise. Ultimately, "*it's our role as investors to decide whether to invest again—it's not automatic,*" Coly concludes.

6. Bridging the Global Expansion Chasm

Mathias Fonlupt views TFTP's investment as highly positive. TFTP stance is straightforward: post-investment, they diversify leadership profiles, as tech founders often excel technically but not always in business management. Thus, their clear message; "*in our model, if we invest, we add an experienced manager alongside the tech founder*"—a perfect fit for Fonlupt. ENTENT's CEO stresses no co-management: he remains solely accountable, granting TFTP oversight rights as committed stakeholders with "almost unlimited" involvement.

On his side, Mehdi Coly recounts that early talks with ENTENT and some of its investors flagged a mismatch: Mathias Fonlupt and his co-founder's partnership wouldn't hold, as the then COO—focused on business development—lacked the mindset and skills to serve as sole CEO, despite his ambitions. Coly was unequivocal: "*If we invest, he'd either exit or shift roles; we'd bring in a new CEO.*" Ultimately, the co-founder faltered at the helm, clashing with Fonlupt and by 2023, they re-engaged ENTENT under revised prerequisites.

With this new shareholding scheme in place, Fonlupt notes one drawback though: TFTP's majority stake in ENTENT—with a commanding absolute majority—may complicate further funding. Funds increasingly demand founder or management control during development of start-ups, sparking friction amid scarce capital. Additionally, "*funding remains dire beyond defence and AI, rendering projects like ours exceedingly challenging,*" he concedes.

To it, Fonlupt elaborates that TFTP helped sharpen ENTENT's business model—"*nailing it profoundly shapes outcomes. They bring dynamic minds that shun stagnation, mirroring our own need for adaptability.*" When he flagged open-source limits, TFTP pivoted to a free-license model he favours: fuelling competition in a vast market

where all gain, "mediating collaboration-competition tensions" (Beer, 2021, p. 718)—akin to a patent pool (Kwon et al., 2023)—to drive global rollout (Auboeuf, 2024). For ENTENT, this entails selling consulting, components, royalties per kilowatt of electricity produced, plus tapping global R&D advances, in a balanced mix of "openness and some sort of appropriability strategy" (Laursen & Salter, 2014, p. 870). He also prizes TFTP's digital insights fuelling novel industrial strategies and ENTENT's innovation. "*They're a young, lean startup,*" he quips, nodding to a familiar startup trait.

On open licenses, Coly stresses business-model compatibility: all "stars" embrace the principle, granting licensees rights while imposing key obligations—like sharing improvements with others—echoing a "contaminating" license model (Time for the Planet, 2021, p. 88), boosting internal innovation and external product-market fit (Beer, 2021). Yet TFTP requires €1–3 million in revenue first—"*otherwise, it's pointless*"—ensuring scale before full rollout ("You can't "save the world" with a bankrupt organisation, and a viable business model is essential" [Auboeuf, 2024, p. 157]). For Coly, business model evolution is therefore inevitable: "*They all start with one anyway—from scratch—so they experiment extensively and will inevitably pivot.*"

On a broader scale, Fonlupt views the limited international presence of TFTP as mild hesitation in this realm. He recognises their gradual global steps—paralleling ENTENT's—despite lacking urgency, even with triadic patents filed and their general manager's recent participation in a France Export mission to Germany. TFTP's funding remains mostly French (ADEME, Bpifrance, France 2030, 130,000 associates), tied to national priorities despite emerging foreign capital. While regretting scarce local funds, Fonlupt sees little need to chase international financing for now, even as the climate urgency's globalness persists.

Besides, Fonlupt praises Team for the Planet's unique interconnected ecosystem among its 14 stars for extending his reach, embracing TFTP's challenging stance—which aligns with his proactive style and strategic committee's rigor. He values their facilitation of key connections (despite his underutilisation) via shared contacts, insights, and ideas, revealing untapped absorptive capacity in this context (Berthinier-Poncet et al., 2018). Still, elite scientific resources for hiring or synergies elude them, hampered by the rarity of fundamental physics experts; TFTP offers chiefly broad technical support. He confesses seeing ENTENT bolstered by shareholder credibility (Cacciolatti et al., 2020), opening doors to major clients otherwise inaccessible (Di Pietro et al., 2017), allowing for prototyping testings and pilot cases, as with the Michelin tire manufacturing company since early 2026 (Technopôle de l'Environnement Arbois-Méditerranée, 2026).

To it, Mehdi Coly adds that organic synergies among TFTP's 14 stars intrigue him, yet TFTP doesn't track them to steer investments—echoing Boni et al. (2021) on blended value actors' varying emphasis on social impact and portfolio alignment. "*It's not our culture; we're not wired for that, and it barely registers,*" he notes. Instead, they prioritise hands-on fixes: untangling legal snags or stalled talks with officials by pinpointing key contacts and their superiors to break logjams. They encourage stars to pursue self-driven synergies where interests converge, but prioritise scalability through "*the climate mafia*"—their whimsical label for a "*climate family*" network. This maps influential contacts within each star's orbit—CEOs, politicians, artists—for on-demand support: "*That's platformisation,*" adds Coly, akin to "exploratory interfirm alliances" (Franco & Haase, 2015, p. 178).

7. Key Findings

Stabilising governance under mission-driven majority control in the ENTENT–TFTP case exemplifies hybrid governance: a not-for-profit investor wielding strong control while pursuing social–environmental goals. TFTP's arrangement thus functions as a legitimacy-sensitive mechanism, demonstrating value creation, fairness, adaptability, and transparency to sustain support. Its hybrid model fosters symbolic and structural legitimacy while aiming at bridging the born-global Climatetech expansion chasm. Transparent, adaptive governance—addressing input, throughput, and output legitimacy—bolsters acceptance and resource flows amid uncertainty. Reconfiguring IP around free licensing aligns with hybrid innovation models, where flexible rights and mission-driven capital enable rapid international scaling while safeguarding core technologies (Petricevic & Teece, 2019).

8. Discussion

Returning to the research question the ENTENT–TFTP case reveals impact investors as active legitimacy entrepreneurs, not mere capital providers. TFTP counters discursive strategies and communication gaps via majority control, hands-on restructuring, and symbolic signalling—tightly coupling governance, operations, and legitimacy work, thus extending views of investors as primarily discursive actors (Lehner et al., 2019). They

extend their internal/external legitimacy to Deeptech and impact investing: facing existential threats, it pairs structural fixes (governance and IP redesign) with symbolic alignment (national climate and innovation programs) to stabilise resources, credibility, and deployability.

Mechanistically, the case suggests that a mission-driven studio can (i) centralise control to resolve conflicting logics, (ii) leverage its legitimacy and networks to buffer crises, and (iii) reframes IP and business models as legitimacy enhancers, not just financial tools. This aligns with multilevel resilience views in young ventures—where relational resources boost crisis performance (Anwar et al., 2023)—but spotlights an external hybrid intermediary orchestrating them for a fragile Climatetech firm.

9. Conclusion

This single-case study of the ENTENT–TFTP relationship refines emerging theory at the intersection of Deeptech finance, impact investing, and hybrid organising. Conceptually, it demonstrates how mission-driven nonprofit majority control stabilises governance in fragile Deeptech-Climatetech ventures while enabling venture-style scaling.

For practice, the findings speak to several audiences. Deeptech founders learn to negotiate governance with mission-driven majority investors, balancing autonomy, protection, and mission alignment. Impact investors and venture studios gain tools like nonprofit stakes, shared IP, and endorsements to de-risk early-stage Climatetech while preserving transformation. Policymakers see a template blending public/private support, patient capital, and hybrid governance to bridge the "global expansion chasm" for born-global Deeptech ventures in climate domains.

Future work should extend this abductive case via longitudinal and comparative designs. Cross-case analyses of mission-driven investors (foundations, public funds, not-for-profit studios, impact VCs) could delineate boundary conditions for nonprofit majority control.

Acknowledgments

I would like to express my sincere gratitude to both interviewees, Mathias Fonlupt (ENTENT) and Mehdi Coly (Team for the Planet) for their invaluable time, openness to the project and thorough review and constructive feedback, which greatly contributed to strengthening the final version of this paper.

Impact of Entrepreneurial Orientation and Artificial Intelligence on Digital Entrepreneurial Resilience: the Mediating Role of Commitment to Learning

Oumeima Toumia
Higher Institute of Technological Studies of Kef, Tunisia
Research Laboratory LARIME, University of Tunis, Tunis, Tunisia

toumiaoumeima@yahoo.fr

Abstract: In today's rapidly changing digital landscape, many firms suffer unprecedented volatility, making digital entrepreneurial resilience a key capability for survival. While previous studies have extensively investigated traditional resilience, there is no research dealing with how artificial intelligence strengthens digital entrepreneurial resilience in emerging economies such as Tunisia. More precisely, it remains unclear how a firm's commitment to learning converts technological adoption into resilient outcomes. Therefore, this article investigates the impact of entrepreneurial orientation and artificial intelligence on digital entrepreneurial resilience, specifically examining the mediating role of commitment to learning. Data were gathered through a survey of 90 Tunisian business founders and analyzed using Partial Least Squares Structural Equation Modeling with bootstrapping. We found that entrepreneurial orientation strongly drives the adoption and integration of artificial intelligence. Furthermore, artificial intelligence has a positive direct impact on digital entrepreneurial resilience and commitment to learning. Crucially, the findings confirm that commitment to learning acts as a complementary mediator. This suggests that, while artificial intelligence gives technical tools for resilience, a continuous commitment to learning enhances these benefits by helping businesses to better integrate these technologies. These findings provide crucial insights for Tunisian entrepreneurs and policymakers. Managers should consider artificial intelligence not as a static technology, but as a catalyst for organizational learning. To maximize digital entrepreneurial resilience, organizations must adopt a twin strategy. On the one hand, managers should incorporate advanced digital tools to significantly enhance their managerial work. On the other hand, they have to create a learning environment that can adjust to the complex technological outputs. As a result, Tunisian startups can maintain a sustainable competitive advantage. Nevertheless, this study is restricted by its small sample size and cross-sectional design. Future research should use longitudinal designs to observe how the relationship between artificial intelligence and resilience changes over time in various geographic contexts.

Keywords: Entrepreneurial Orientation, Artificial Intelligence, Digital Entrepreneurial Resilience, Commitment to Learning.

1. Introduction

The convergence of AI and entrepreneurial orientation has become increasingly crucial for establishing harmony and balance between institutions, the environment, and society (İçöz, 2024). In this context, İçöz (2024) investigated how new significant entrepreneurial trends, applications, and outcomes can be influenced by AI. In fact, AI automation allows entrepreneurs to concentrate on innovative and creative endeavors (Al-Mamary, 2025). Indeed, Baldegger et al. (2020) found that the tendency of a company to implement or incorporate already-implemented AI projects into HRM procedures increases with its entrepreneurial orientation. Therefore, it is important to assess the entrepreneurial orientation of companies based on three criteria before implementing AI (i.e., risk-taking, innovation, and proactivity).

Building on this intersection of technology and strategy, recent researchers suggest that AI significantly contributes to resilience across various areas (i.e., supply chain management, healthcare, business, hospitality, tourism) (Rane et al., 2024). Specifically, Rane et al. (2024) affirmed that AI may help with disaster response by providing quick data analysis and decision-making assistance (i.e., using real-time monitoring capabilities and sophisticated predictive maintenance) to improve emergency management results. Duong (2025) added that artificial intelligence makes entrepreneurs more resilient, particularly in unpredictable situations.

The empirical evidence for these relationships is rising; for example, based on information gathered from 203 Chinese companies, Xia et al. (2024) demonstrated that entrepreneurial orientation positively influenced firm resilience in the digital era. This finding was confirmed by the contribution of Sudirman et al. (2025), in which they found a strong and statistically significant correlation between entrepreneurial orientation and sustainable resilience strategies.

Beyond resilience alone, prior studies suggest that artificial intelligence tools enhance the commitment to learning (Awad and Martín-Rojas, 2024; Dong and McIntyre, 2014; Hu et al., 2025; Jarrahi, 2018; Jatobá et al., 2023; Rožman et al., 2023). In turn, both artificial intelligence and commitment to learning have been shown to

have a positive impact on resilience (Abdelwahed and Basly, 2023; Duong, 2025; Martínez-Costa and Jiménez-Jiménez; Rane et al., 2024).

However, to our knowledge, this is the first study to examine how entrepreneurial orientation and artificial intelligence improve digital entrepreneurial resilience among Tunisian startups, with a focus on the mediating role of the commitment to learning.

2. Research Methodology

The participants of this study are represented by 90 Tunisian business founders who were contacted through an online questionnaire. The sample included 55 men and 35 women and the majority of whom worked in the service sector (53.4%). Furthermore, most participants hold a master's degree (54.4%) and are aged between 31-40 years (47.8%). Items were evaluated using a seven-point Likert-type scale (1 = strongly disagree, 7 = strongly agree).

Entrepreneurial orientation (EO) dimensions were assessed using the Avlonitis and Salavou (2007) scale. The considered dimensions were proactiveness (i.e., measured by 5 items) and risk-taking (i.e., measured by 4 items). Artificial intelligence (AI) adoption dimension comprised 7 items (Hatlevik and Bjarnø, 2021; Zeng et al., 2022). Digital entrepreneurial resilience (DER) has two dimensions (i.e., entrepreneurial adaptation and entrepreneurial resistance) and was measured by the proposed scale of Mignenan (2022). Each dimension scale comprises 3 items. Commitment to learning (CL) was measured by 4 items (Sinkula et al., 1997).

3. Results

Before running the analysis, we compute the Kaiser–Meyer–Olkin (KMO) test and the Bartlett's test of sphericity to assess the data suitability (see table 1). We concluded that the sample size is sufficient (>0.5) and there are significant correlations among the variables (p-value <0.001). Furthermore, we discovered that seven factors from the Kaiser Criteria explained 79.303 % of the overall variance. Importantly, only 31.499 % of the variance was explained by the first factor, which is much less than the predetermined 50% threshold. As a result, we can conclude the absence of common method bias (Kock, 2020).

Table 1: KMO, Bartlett test, Cronbach's alpha, composite reliability and AVE

	KMO	Bartlett's Sphericity Test (Sig)	Cronbach's Alpha	Composite Reliability (rho-a)	Composite Reliability (rho-c)	AVE
AI	0.587	<0.001	0.751	0.832	0.812	0.400
CL	0.731	<0.001	0.880	0.894	0.917	0.736
EO	0.856	<0.001	0.847	0.857	0.889	0.576
DER	0.757	<0.001	0.931	0.990	0.932	0.611

Indeed, the communalities ranged between 0.58 and 0.84, indicating a strong relationship between the items. Since all values exceeded the minimum acceptable threshold of 0.30, no items were eliminated (Hair et al., 2010). Besides, the values of Cronbach's alpha coefficients were greater than the recommended threshold of 0.7 (Hair et al. 2011). This confirms the high internal reliability of our measurement scales. Indeed, we noticed that all average variance extracted values were higher than 0.7, except the artificial intelligence construct (i.e., 0.4). However, all the composite reliabilities values are above 0.6. As a result, we may conclude the existence of convergent validity (Fornell and Larcker, 1981). To evaluate the discriminant validity, we computed the Heterotrait-Monotrait ratio. We found that the values are under the threshold of 0.85 or 0.90 (Hu and Bentler, 1998). For the multicollinearity test, we found that the values of the variance inflation factors were below the threshold of 10 (Marquardt, 1970). To assess the overall model's fit, we computed the goodness of fit criterion (i.e., GoF) developed by Tennenhaus et al. (2005). We found the GoF is equal to 0.392, meaning a good fit for our model (Wetzels et al., 2009). The bootstrap approach was used with 5000 subsamples to evaluate the hypotheses in our structural model. The findings were displayed in table 2.

Table 2: Results of the hypotheses testing

Path Coefficients					
	Original Sample	**Sample Mean**	**Standard Deviation**	**T Statistic**	**P Values**
AI → CL	0.284	0.293	0.102	2.779	0.005
AI → DER	0.403	0.419	0.086	4.689	0.000
CL → DER	0.303	0.308	0.071	4.255	0.000
EO → AI	0.421	0.451	0.113	3.728	0.000
Total Indirect Effects					
AI → DER	0.086	0.090	0.039	2.209	0.027
EO → CL	0.120	0.132	0.058	2.070	0.038
EO → DER	0.206	0.232	0.071	2.891	0.004
Specific Indirect Effects					
AI → CL → DER	0.086	0.090	0.039	2.209	0.027
EO → AI → CL → DER	0.036	0.041	0.020	1.788	0.074
EO → AI → CL	0.120	0.132	0.058	2.070	0.038
EO → AI → DER	0.170	0.191	0.065	2.628	0.009
Total Effects					
AI → CL	0.284	0.293	0.102	2.779	0.005
AI → DER	0.489	0.509	0.083	5.875	0.000
CL→ DER	0.303	0.308	0.071	4.255	0.000
EO → AI	0.421	0.451	0.113	3.728	0.000
EO → CL	0.120	0.132	0.058	2.070	0.038
EO → DER	0.206	0.232	0.071	2.891	0.004

We found that artificial intelligence has a positive and significant effect on digital entrepreneurial resilience (β = 0.403, p-value = 0.000). Meanwhile, entrepreneurial orientation directly affects artificial intelligence (β = 0.421, p-value = 0.000) and indirectly impacts digital entrepreneurial resilience through the mediating role of artificial intelligence mediator (β = 0.170, p-value = 0.009). Furthermore, commitment to learning acts as a partial mediator in the relationship between artificial intelligence and digital entrepreneurial resilience. This partial mediation is evidenced by the fact that both the indirect path (β = 0.086, p-value = 0.027) and the direct path between AI and resilience (β = 0.303, p-value = 0.000) are significant.

4. Conclusion

Previous contributions (Duong, 2025; Rane et al., 2024; Sudirman et al., 2025) affirmed that the adoption of AI technologies and the entrepreneurial orientation enhance digital entrepreneurial resilience. However, the presence of technology alone is frequently insufficient without a strategic driver. To fill this gap, we examine the impact of entrepreneurial orientation and artificial intelligence on digital entrepreneurial resilience by looking at the mediating role of commitment to learning. We conclude that both entrepreneurial orientation and artificial intelligence improve the digital entrepreneurial resilience. Indeed, the commitment to learning acts as a strategic mediator in the relationship between artificial intelligence and digital entrepreneurial resilience. Our study has two main implications. On the one hand, companies, with the use of AI tools (i.e., machine learning algorithms, natural language processing, and predictive analytics), may tailor learning and development programs to meet the requirements of each employee (Dong and McIntyre, 2014; Hu et al., 2025; Jarrahi, 2018). For example, AI adoption enhanced learning tools; therefore, it may increase employee training efficiency (Jatobá et al., 2023). On the other hand, entrepreneurial orientation provides a strategic framework for implementing AI technologies (Baldegger et al., 2020; Polat et al., 2025). Therefore, firms with a strong entrepreneurial orientation are considered more resilient (Sudirman et al., 2025; Xia et al., 2024). Nevertheless, despite these implications, our

study presents some limitations that could be addressed in future research. First, our article focuses on a specific geographical context, which is Tunisia. Additionally, we use a questionnaire to address our research question. Future studies may perform a comparison between the Tunisian context and other regional or international ones. Indeed, they might use longitudinal study design to capture the evolution of the relationship between the four constructs.

Ethics Declaration

All participants were informed of the research objectives and provided their informed consent prior to data collection. Participation was voluntary, and the anonymity and confidentiality of the respondents' data were strictly maintained.

Understanding the Multilevel Aspects of Resistance to AI Adoption in Higher Education

Tunkevichus Olga and Bagrationi Konstantin
Graduate School of Business, HSE University, Frankfurt am Main, Germany

oagordienko@hse.ru
kbagrationi@hse.ru

Abstract: This study aims to examine how resistance to artificial intelligence adoption in higher education is shaped by current research directions. By employing a systematic approach combined with bibliometric co-citation analysis authors seek to understand the multilevel phenomena of resistance to AI adoption and uncover possible research gaps in the existing scientific field. The analysis, performed in accordance with PRISMA statement and mixed-method approach, included 2121 peer-reviewed publications from Scopus with manual qualitative interpretation of thematic clusters. The results reveal four interconnected dimensions of resistance. First, behavioral traits were uncovered, capturing how such factors as perceived usefulness, perceived ease of use, self-efficacy, and expected performance outcomes influence educators' desire to engage with AI tools. Secondly, organizational readiness for change including such parameters as institutional capacity, culture, and change management was highlighted as highly important in understanding the phenomena and nature of teachers and students resistance to adopt AI. Thirdly, ethical considerations were found to be crucial for current AI adoption management understanding. This research direction included variables such as data privacy, algorithmic bias, transparency, accountability, and broaden debates about the legitimacy of AI in knowledge production, assessment, and teaching practice. Finally, understanding psychological factors such as trust in AI, AI anxiety and perceived loss were also identified as promising research stream. These clusters combined demonstrated that resistance to AI adoption in higher education is a multi-layered phenomenon that can be observed complexly by scientists, combining different analysis levels rather than focusing solely on technological or attitudinal aspects. The findings contribute to organizational behavior theory research by clarifying how emotional, cultural, and institutional mechanisms interact in shaping AI resistance. The study provides a structured basis for integrating resistance factors into a broader model of organizational readiness for AI adoption in higher education, including institutional determinants in addition to psychological and organizational ones.

Keywords: Artificial Intelligence, Higher Education, Resistance to Change, Readiness for Change

1. Introduction

Artificial intelligence is one of the most significant drivers of transformation in contemporary educational organizations (Sohn & Kwon, 2020). AI-based systems are increasingly used for personalized learning, assessment, student support, administrative decision-making, learning analytics, and research assistance (Saragih, 2024). These technologies promise efficiency, scalability, and new forms of educational insight (Yan et al., 2020). However, despite the growing interest in AI, its adoption in higher education remains uneven and contested (Adiguzel et al., 2023).

Existing studies on AI adoption often rely on established technology acceptance frameworks, especially the Technology Acceptance Model and the Unified Theory of Acceptance and Use of Technology. These models emphasize perceived usefulness, perceived ease of use, performance expectancy, effort expectancy, social influence, and behavioral intention as key predictors of technology adoption (Davis, 1989; Venkatesh et al., 2003). While these approaches remain important, they are insufficient for fully explaining resistance to AI in universities. Resistance is not only an individual reaction to a new digital tool. It may also reflect organizational inertia, ethical uncertainty, professional identity concerns, lack of institutional readiness, or distrust toward algorithmic systems (Zawacki-Richter et al., 2019).

This issue is especially important in higher education because universities differ from ordinary business organizations. In companies, AI adoption is often framed through efficiency, productivity, competitive advantage, and managerial control (Kemp, 2024). In universities, however, adoption is embedded in academic autonomy, disciplinary cultures, collegial governance, pedagogical traditions, and public responsibility for knowledge production (Allam et al., 2025; Dotan et. al., 2025). Universities are often described as loosely coupled systems, where formal strategies do not automatically translate into uniform practice across departments, faculties, and individual academics (Lutz, 1982). They can also be understood as professional bureaucracies, where the core work is performed by highly trained professionals whose autonomy is central to organizational functioning (Kallio et al., 2020). Therefore, AI adoption in higher education requires not only technological implementation but also organizational, ethical, pedagogical, and emotional alignment (Acosta-Enriquez et al., 2024).

The problem addressed in this study is the fragmentation of research on AI adoption and resistance in educational contexts. Existing literature covers technology acceptance, organizational change, ethical AI, trust, algorithm aversion, and digital transformation, but these streams are often analyzed separately. As a result, there is a need for a systematic synthesis that maps the intellectual landscape of resistance to AI adoption and connects it with the broader concept of organizational readiness.

The research question guiding this study is:

> *What dominant research streams on resistance to AI adoption can be identified in the educational context, and how can they inform a resistance-based framework for AI adoption in higher education?*

The aim of the study is to map and synthesize the dominant research streams on resistance to AI adoption in higher education and to reinterpret resistance as a diagnostic component of readiness formation.

The article contributes to literature in three ways. First, it systematizes a fragmented body of research by identifying four thematic clusters of AI resistance. Second, it extends technology acceptance perspectives by integrating organizational readiness, ethical legitimacy, and emotional responses. Third, it highlights the specificity of universities as organizations and argues that AI adoption in higher education should not be approached through generic corporate adoption logic.

2. Methodology

To address questions, a mixed approach including qualitative and quantitative methods was adopted. The study used a systematic review combined with bibliometric co-citation analysis and qualitative thematic synthesis. This mixed-method design was selected because it allows the research field to be examined both quantitatively and interpretively.

Bibliometric analysis makes it possible to identify the intellectual structure of the field, while qualitative synthesis helps interpret the meaning of the detected clusters.

The review procedure was aligned with the general logic of the PRISMA approach for systematic reviews (Moher et al., 2009). The research process included the following stages: formulation of the research question, selection of the database, development of the search string, definition of inclusion criteria, extraction of bibliographic data, bibliometric mapping, cluster interpretation, and thematic synthesis.

Bibliographic data were collected from the Scopus database in February 2025. Scopus was selected because it provides broad coverage of peer-reviewed international literature and includes detailed citation metadata suitable for bibliometric analysis. The search strategy focused on artificial intelligence, higher education, resistance, and adoption-related concepts. The search included English-language journal articles indexed in relevant subject areas, including business, social sciences, economics, and psychology. Only peer-reviewed journal articles were included in the final dataset. The final sample consisted of 2,121 peer-reviewed articles published between 1989 and 2025. The dataset was exported from Scopus and prepared for bibliometric analysis.

The bibliometric stage was conducted using VOSviewer. Reference co-citation analysis was selected because it helps identify foundational intellectual traditions and research streams within a field. Co-citation analysis is based on the assumption that publications frequently cited together are intellectually related.

The analysis generated a co-citation network in which nodes represent cited references, links represent co-citation relationships, node size reflects citation frequency, and link strength indicates the intensity of intellectual association between references. The clustering procedure identified four major clusters. These clusters were then interpreted through expert inspection and qualitative synthesis.

After the bibliometric clusters were identified, the articles and references associated with each cluster were analyzed thematically. The synthesis focused on theoretical foundations, empirical findings, and conceptual gaps within each cluster. The coding logic followed the principles of thematic analysis proposed by Braun and Clarke (2006), including familiarization with the literature, identification of recurrent themes, refinement of themes, and interpretation of thematic patterns.

The purpose of the qualitative stage was not only to describe the clusters but also to connect them with the broader research problem of organizational readiness for AI adoption in higher education.

3. Results

The reference co-citation analysis identified four major thematic clusters that structure the research landscape on AI adoption and resistance in educational and organizational contexts. These clusters represent different but interconnected dimensions of resistance: user experience and behavioral intentions, organizational transformation and readiness, ethical and epistemic concerns, and emotional-psychological factors (Picture 1).

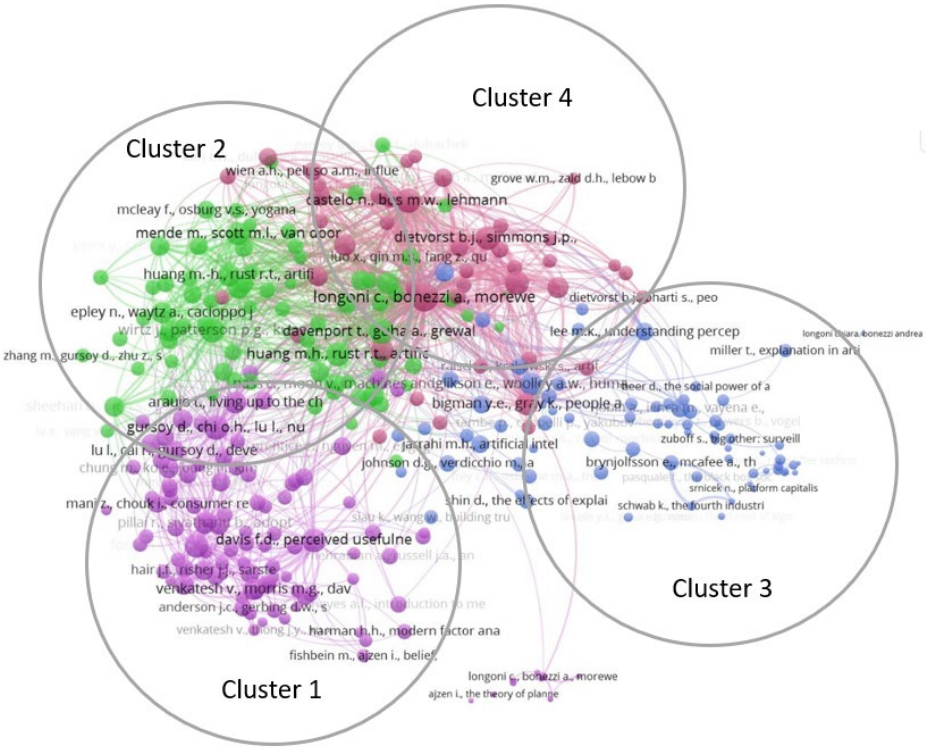

Figure 1: Results of co-citation analysis

3.1 Cluster 1: User Experience and Behavioral Intentions

The first cluster focuses on individual-level perceptions of AI systems and their influence on behavioral intention to use AI. This stream is strongly connected with technology acceptance research, particularly TAM and UTAUT. Studies in this cluster show that perceived usefulness, perceived ease of use, performance expectancy, and effort expectancy remain important predictors of AI adoption (Davis, 1989; Venkatesh et al., 2003).

In higher education, these constructs acquire a specific meaning. Educators are more likely to accept AI when they perceive that it improves teaching quality, supports student learning (Ma & Lei 2024), reduces administrative burden, or enhances research productivity (Zhang & Zhang, 2024). Conversely, resistance emerges when AI tools are perceived as difficult to use, pedagogically irrelevant, or misaligned with classroom realities (Hutson, 2025).

The cluster also includes social and cultural influences on AI acceptance. Social influence, peer endorsement, leadership support, and professional norms may encourage or inhibit AI adoption. In educational organizations, this is particularly important because educators often rely on disciplinary communities and collegial validation when evaluating new technologies (Gill & Nair, 2025).

This cluster suggests that readiness for AI adoption begins at the level of user experience. However, readiness cannot be reduced to positive behavioral intention. A university may have technically available AI tools, but if educators do not perceive them as meaningful, legitimate, and compatible with their work, adoption remains superficial.

3.2 Cluster 2: Organizational Transformation and Readiness

The second cluster shifts attention from individual users to organizational conditions of AI implementation. It includes research on organizational culture, leadership support, infrastructure, resources, IT readiness, strategic

vision, and change management. Studies of this cluster show that AI adoption depends not only on whether individual users are willing to use AI, but also on whether the organization is prepared to support implementation (Davenport & 2018; Wang, 2021)

This cluster is directly relevant to the concept of organizational readiness. Organizational readiness refers to the extent to which an institution has the resources, capabilities, shared commitment, and implementation capacity necessary for change (Lokuge et al., 2019). In the context of AI adoption, readiness includes technological infrastructure, staff training, governance mechanisms, data management practices, leadership support, and a culture of experimentation (Felemban et al., 2024).

Therefore, resistance to AI in universities may reflect not only lack of resources or insufficient training, but also weak alignment between institutional strategy and academic practice. A central AI policy may exist, but its implementation may vary across disciplines and units. This makes resistance a distributed and multi-level condition rather than a single organizational attribute.

3.3 Cluster 3: Ethical and Epistemic Concerns

The third cluster focuses on ethical, societal, and epistemic issues related to AI implementation. Key themes include algorithmic opacity, accountability, surveillance, data privacy, explainability, and the changing nature of knowledge production (Logg et al., 2019; Castelo, 2019) .

This cluster is especially important for higher education because universities are not only users of AI technologies but also institutions responsible for producing, validating, and transmitting knowledge. AI adoption in universities raises questions about academic integrity, authorship, assessment fairness, student surveillance, data governance, and the role of human judgment in education (Gbadago et al., 2025).

Concerns about algorithmic opacity are central to this stream. When AI systems operate as black boxes, educators and students may not understand how decisions are produced, how recommendations are generated, or how data are used (Burrell, 2016). This creates accountability problems and may weaken trust. Similarly, algorithmic bias may reproduce social inequalities, while AI-based monitoring systems may intensify surveillance and threaten privacy (Barocas & Selbst, 2016)

The findings suggest that ethical resistance should not be dismissed as irrational. In many cases, it represents a legitimate concern about the normative foundations of education. For universities, responsible AI adoption requires ethical governance, transparent rules, participatory decision-making, and clear boundaries regarding the use of AI in teaching, assessment, and administration.

3.4 Cluster 4: Emotional and Psychological Factors

The fourth cluster highlights the emotional and psychological dimensions of AI resistance. Key themes include trust, anxiety, perceived loss of control, algorithm aversion, fear of replacement, and professional insecurity. This cluster shows that AI adoption cannot be explained only through rational evaluation of usefulness and effort.

Algorithm aversion is especially relevant. Research shows that users may avoid algorithmic recommendations even when algorithms perform well, especially after observing algorithmic errors (Dietvorst et al., 2015). In educational contexts, such aversion may be intensified by the fact that teaching involves relational, interpretive, and value-laden judgment. Educators may question whether AI can adequately understand students' needs, evaluate complex learning outcomes, or support meaningful pedagogical interaction.

This cluster also connects with organizational change theory. Piderit's multidimensional view of resistance emphasizes that resistance includes cognitive, emotional, and intentional components (Piderit, 2000). Applied to AI adoption in higher education, this means that educators may cognitively recognize AI's usefulness while emotionally distrusting it or behaviorally avoiding it.

The emotional dimension of resistance indicates the importance of psychological safety. Educators need space to experiment, express doubts, discuss ethical concerns, and learn from mistakes without fear of punishment or professional devaluation. Therefore, readiness for AI adoption includes not only skills and infrastructure, but also effective and relational conditions.

4. Discussion

In universities, organizational resistance has a distinctive structure. Unlike firms where authority may be concentrated in executive management, universities are characterized by distributed authority and multiple centers of decision-making (Hardy, 1991). Faculty members, departments, administrative units, IT services, quality assurance offices, ethics committees, and external regulators all influence whether AI adoption becomes accepted, resisted, fragmented, or symbolically adopted.

This specificity can be explained through higher education organization theory. Weick's concept of loosely coupled systems suggests that educational organizations often combine formal coordination with substantial autonomy of local units (Weick, 1982). In such systems, a central policy on AI adoption does not automatically translate into uniform classroom practice. A university may formally declare an AI strategy, while actual adoption varies significantly across faculties, disciplines, and individual educators. Similarly, Mintzberg's notion of professional bureaucracy helps explain why academic professionals resist direct standardization of their core work: teaching and research are governed not only by administrative rules, but also by professional expertise and disciplinary judgment (Mintzberg, 1979). Thus, resistance to AI may arise when educators interpret AI implementation as a threat to professional discretion, academic autonomy, or the quality of educational judgment.

Recent literature indicates that generative AI has already entered university life, while institutional capacity to guide, regulate, and pedagogically integrate it remains uneven. Studies published in 2025–2026 show that higher education institutions are moving from initial experimentation toward formal policy development, yet this transition is accompanied by persistent gaps in AI literacy, governance, assessment design, transparency, and trust (An et al., 2025; Jin et al., 2025). Therefore, resistance should be conceptualized not as the opposite of adoption, but as a diagnostic signal of incomplete readiness.

At the individual level, resistance is shaped by educators' AI literacy, perceived usefulness, perceived ease of use, self-efficacy, trust, and perceived compatibility of AI with teaching practice. However, recent research shows that these factors should be interpreted more broadly than in classical technology acceptance models. Ayyoub et al. (2025) emphasize that AI literacy is now a critical competence for educators, while Caspari-Sadeghi (2026) argues that the core question is no longer whether educators should use generative AI, but what knowledge, skills, and mindset they need to use it effectively and responsibly. This means that educators' resistance may not reflect unwillingness to innovate; it may reflect insufficient confidence, unclear pedagogical scripts, weak understanding of AI limitations, or uncertainty about responsible use.

Recent empirical work also confirms that trust and distrust are central to AI adoption in higher education. Lyu et al. (2025), based on a survey of university instructors, explicitly examine current practices, perceptions, trust, and distrust of generative AI in teaching and learning. This is important because trust is not reducible to general optimism about technology. Educators may trust AI for lesson preparation, summarization, brainstorming, or administrative support, while distrusting it for assessment, feedback, grading, or student evaluation. Thus, resistance is domain-specific: the same educator may be an AI adopter in one area and an AI resistor in another.

At the organizational level, resistance reflects whether the university has created conditions for meaningful and responsible AI use. These conditions include infrastructure, professional development, leadership support, training systems, data governance, psychological safety, and transparent policies. Recent studies show that institutional guidelines are becoming a central element of AI governance in higher education. An et al. (2025) analyzed GenAI guidelines issued by the top 50 U.S. universities and showed that institutional responses increasingly address multiple stakeholder groups, including students, faculty, researchers, staff, and administrators. Similarly, Erhardt (2025) examined how Swedish higher education institutions are addressing GenAI through guidelines, policy documents, and public website information, showing that universities are actively trying to convert uncertainty into formal governance structures.

However, the existence of policy does not automatically mean readiness. In higher education, AI adoption often unfolds in loosely coupled organizational settings, where central rules do not immediately translate into consistent local practice. A university may publish GenAI guidelines, but individual faculties, departments, and instructors may interpret them differently. Recent work on global institutional adoption strategies confirms that universities across regions vary considerably in how they frame GenAI adoption, often combining innovation narratives with caution, risk management, and policy experimentation (Jin et al., 2025). Therefore, AI readiness in higher education should be understood as distributed readiness: it must be present not only in strategic documents, but also in departments. Classical adoption models ask whether users intend to use AI technology.

But AI adoption in higher education requires a different question: under what organizational, ethical, and pedagogical conditions can educators consider AI use legitimate? This shifts the analysis from acceptance to readiness. Educators may accept AI as useful but still resist it if they believe it threatens academic judgment, student fairness, professional identity, or the relational nature of teaching.

Recent teacher-training research supports this interpretation. Lademann et al. (2025) found that AI literacy, usage behavior, and attitudes can be influenced through structured teacher training, showing that resistance is not fixed but can be transformed through professional development. This means that universities should not treat resistance as a stable personal trait. Instead, resistance should be seen as a changeable response to the quality of institutional support.

Taken together, recent 2025–2026 studies allow this article to make a stronger theoretical claim: AI resistance in higher education is not a residual category outside adoption models; it is a central mechanism through which universities reveal the incompleteness of their readiness. Resistance shows where AI literacy is insufficient, where policies are unclear, where assessment rules are unstable, where trust is weak, where ethical governance is underdeveloped, and where professional identity feels threatened. This is why resistance should not be suppressed or dismissed as irrational. It should be analyzed as evidence of the organizational work that still needs to be done.

This is particularly important because universities have a dual responsibility: they must prepare students and staff to work with AI, while also preserving norms of critical thinking, academic honesty, intellectual independence, and human-centered education. If AI systems are experienced as black boxes that reshape assessment, personalize learning, or evaluate performance without sufficient transparency, resistance may become ethically grounded rather than merely emotional or instrumental. In such cases, resistance should not be dismissed as irrational. It may express legitimate concern about accountability, fairness, or the displacement of human judgment in educational processes.

5. Conclusion

This study mapped the multidimensional landscape of resistance to AI adoption in educational contexts through a systematic review and bibliometric co-citation analysis of 2,121 peer-reviewed publications. The analysis identified four interconnected research streams: user experience and behavioral intentions, organizational transformation and readiness, ethical and epistemic concerns, and emotional-psychological factors. Together, these clusters demonstrate that resistance to AI adoption in education is not a marginal or purely negative phenomenon. It is a complex response to technological, organizational, professional, ethical, and emotional tensions that accompany the integration of AI into educational practice.

The main conclusion is that AI resistance in higher education should be understood as a diagnostic element of readiness formation. Resistance shows where AI implementation strategies are misaligned with educators' needs, institutional culture, ethical expectations, or professional identities. Poor user experience, lack of pedagogical relevance, insufficient organizational support, unclear governance, algorithmic opacity, and emotional anxiety can all generate resistance. However, these forms of resistance also indicate where universities must intervene if they aim to build sustainable readiness for AI adoption.

This insight also opens a promising direction for further research. Future studies should move from mapping resistance to explaining the mechanisms through which readiness is formed. The present bibliometric analysis identifies the conceptual landscape of resistance, but the next stage should examine how different dimensions of readiness interact. For example, does AI literacy reduce anxiety and algorithm aversion? Does leadership support moderate the relationship between perceived usefulness and behavioral intention? Does ethical governance increase trust in AI? Does psychological safety mediate the effect of organizational culture on experimentation with AI tools? These questions directly connect the present conference paper with a PhD research agenda focused on shaping organizational readiness for AI adoption in higher education.

The study contributes to the literature on AI adoption and organizational change in several ways. First, it systematizes a fragmented research field by identifying four dominant thematic domains of AI resistance. Second, it extends traditional technology acceptance models by showing that AI adoption in education cannot be explained only through perceived usefulness, ease of use, and behavioral intention. These factors remain important, but they must be supplemented with organizational readiness, ethical legitimacy, trust, professional identity, and emotional responses. Third, the study highlights the specific nature of universities as organizations. Unlike ordinary companies, universities are loosely coupled, professionally autonomous, knowledge-producing

institutions. Therefore, AI adoption in higher education requires not only managerial implementation but also collegial negotiation, ethical reflection, pedagogical adaptation, and disciplinary contextualization.

From a practical perspective, the findings suggest that universities should avoid purely instrumental or top-down approaches to AI implementation. Effective AI adoption requires participatory governance, transparent ethical standards, professional development, psychological safety, and clear articulation of how AI supports teaching, research, and administration. Educators should not be treated as passive recipients of technological change. They should be involved as co-designers of AI adoption strategies, because their professional judgment is central to determining where AI can enhance educational quality and where its use may be inappropriate or risky.

The findings also have implications for university leaders and policy makers. Building readiness for AI adoption requires action at multiple levels.

Knowledge Exchange and Entrepreneurial Value in University–SME Collaboration

Jaani Väisänen
LAB University of Applied Sciences, Lappeenranta, Finland

jaani.vaisanen@lab.fi

Abstract: University–SME collaboration is widely promoted as a pathway to entrepreneurial renewal, yet the mechanisms through which collaboration generates entrepreneurial value—and the frictions that undermine it—remain unevenly specified in practice-oriented research. Building on a Triple Helix context where universities are expected to contribute to innovation and growth beyond teaching and research, this study asks: 1) Through what mechanisms and process stages does university–SME collaboration create entrepreneurial value? and 2) Which frictions weaken value creation, and what governance mechanisms (e.g., trust, contracts, roles, intermediaries) help overcome them? The theoretical framing is two-fold. First, Relational View of Interorganizational Value Creation conceptualizes entrepreneurial value as "relational rents" generated through cross-boundary knowledge-sharing routines, complementary capabilities, and governance arrangements—offering a mechanism to trace how value emerges in the relationship rather than within either party alone. Second, Knowledge Exchange in Open Innovation frames collaboration as a purposeful mechanism for combining and utilizing external knowledge, and how intermediaries, clarified roles, and appropriate formalization can enable continued exchange under constraints. Empirically, the study draws on qualitative material collected in the NOKKA project, designed to empower SMEs to utilize academic research in their innovation processes. This study utilizes a shared semi-structured interview protocol, documented in multiple interview summaries. The interviews emphasize SMEs' articulated needs for external expertise, capability development, and low-barrier collaboration formats such as student-based contributions and applied, interactive support, while also highlighting constraints related to limited resources and the difficulty of navigating collaboration structures. The paper offers actionable guidance for designing low-barrier university–SME collaboration that clarifies roles and value propositions early, to produce tangible outputs that SMEs can utilize in entrepreneurial development and commercialization pathways.

1. Introduction

University–industry collaboration (UIC) has become increasingly important in innovation research, as universities are now expected not only to teach and produce scientific knowledge, but also to support regional development, innovation capacity, and societal renewal through engagement with firms, public actors, and other stakeholders (Etzkowitz and Leydesdorff 2000; Benneworth and Fitjar 2019). This expanded role reflects the transition toward a knowledge economy, where intellectual assets are central to economic success (Powell and Snellman 2004), and collaboration has become a key mechanism for universities to support entrepreneurship and innovation. The Triple Helix model has been especially influential in conceptualizing this shift by framing innovation as interaction among universities, industry, and government rather than linear transfer from science to application (Etzkowitz and Leydesdorff 2000), and remains a major framework for understanding institutional interaction in knowledge-based economies and innovation ecosystems (Cai and Etzkowitz 2020). This broader perspective is further reflected in Quadruple and Quintuple Helix models, which add civil society/public actors and environmental sustainability to the university–industry–government triad (Machado, Sartori and Rosa 2025; Zakaria et al. 2025).

This study explains entrepreneurial value generation in university–SME collaboration as a process rather than a static outcome by identifying the stages through which value emerges, the frictions that weaken it, and the governance mechanisms that help overcome them. Recent UIC literature has moved beyond one-way knowledge or technology transfer to examine the conditions, mechanisms, and governance arrangements that enable and sustain collaboration. Rossoni, de Vasconcellos, and de Castilho Rossoni (2024) review university–industry collaboration through perspectives such as Triple Helix, relational social capital, value creation, and technology transfer, concluding that outcomes depend on internal and external facilitators rather than access to knowledge alone. Similarly, Sjöö and Hellström (2019) identify resources, university organization, boundary-spanning functions, collaborative experience, culture, status centrality, and environmental context as key enablers of collaborative innovation. Overall, this reflects a shift from static transfer models toward systemic and interaction-based understandings of collaboration.

At the same time, reviews of university collaboration with micro, small and medium-sized enterprises show that the literature remains fragmented, lacks a shared conceptualization, and uses theoretical frameworks relatively sparingly. Mura, Di Flauro and Fratocchi (2025) note that interdependencies among drivers, enabling factors, and barriers are rarely examined, while Tereschenko et al. (2024) identify successful UIC models for MSMEs—

including R&D partnerships, internships, knowledge transfer programs, incubation, and sponsored projects—but focus mainly on collaboration forms and critical success factors. Thus, although the literature increasingly analyses collaboration structures and enabling conditions, it still offers limited process-level understanding of how collaboration generates SME value and how this value creation is interrupted or supported by internal or external mechanisms.

From a business standpoint, UIC creates value when collaboration produces outcomes that can be mobilized for entrepreneurial activity. This paper therefore understands entrepreneurial value creation in UIC not only as a final innovation outcome, but as a process in which knowledge, relationships, and coordination mechanisms are gradually translated into usable forms. This process perspective is important because collaboration rarely unfolds frictionlessly. Prior literature commonly discusses UIC through knowledge transfer, open innovation, proximity, trust, and absorptive capacity, implying that value creation depends not only on access to knowledge but also on interaction quality (Cohen and Levinthal, 1990; Zahra and George, 2002; Darabi et al., 2021; Benhayoun-Sadafiyine et al., 2020).

Entrepreneurial value can be understood in multiple ways, including opportunistic (Shane and Venkataraman 2000), value-creation process (Mishra and Zachary 2015), and relationship-based perspectives involving entrepreneurs and their stakeholders (Pinelli et al. 2022). Building on this literature, this study defines entrepreneurial value as outcomes that enhance an SME's ability to identify, develop, and exploit business opportunities. In university–SME collaboration, this includes new products, services, commercialization paths, capabilities, relationships, and actionable knowledge that can be mobilized in entrepreneurial activity.

Defining entrepreneurial value in this way shifts attention from the act of collaboration to the process through which university–SME interaction becomes entrepreneurially useful for firms. Therefore, we propose that the most relevant practical question is not simply whether, and what kind of, collaboration exists, but how entrepreneurial value is generated through it, where the process stalls, and how such frictions may be reduced through appropriate governance. For this reason, we propose the following:

- RQ1: Through what mechanisms and process stages does university–SME collaboration generate entrepreneurial value?

While we are interested in understanding the actual mechanics by which entrepreneurial value is being created, we need to be able to strengthen that process. Therefore, we propose:

- RQ2: Which frictions weaken the entrepreneurial value creation process in university–SME collaboration, and which governance mechanisms help to overcome them?

Together, these questions enable us to analyze university–SME collaboration not only as a setting for knowledge exchange, but also as a value-creation process shaped by both enabling mechanisms and constraining conditions.

2. Theoretical Foundation

To explain how university–SME collaboration generates entrepreneurial value, this article draws on the Relational View of interorganizational value creation and the Open Innovation perspective, focusing on knowledge exchange. The Relational View argues that critical resources may span firm boundaries and become embedded in interfirm routines and relationships rather than residing within either partner alone (Dyer and Singh, 1998). In this study, such value is understood as relational rents, or jointly generated benefits that neither partner could create independently. This makes the perspective relevant to RQ1, as entrepreneurial value depends on whether SMEs can access and use university knowledge through workable relational conditions, including social, technological, and organizational proximity (Johnston, 2022). It also supports RQ2, as effective governance is central to creating and sustaining interorganizational value (Dyer and Singh, 1998). Related research shows that relational governance, alone or combined with formal contracts, supports different forms of university–industry collaboration (Lee and Miozzo, 2024), universities' alliance management capability improves technology transfer success (Leischnig and Geigenmüller, 2020), and firms benefit more from university collaboration when prior experience is complemented by collaborative know-how and trust that strengthen knowledge transfer and innovation outcomes (Bellini, Piroli, and Pennacchio, 2019).

The Open Innovation perspective views innovation as purposeful knowledge flows across organizational boundaries (Cassiman and Valentini, 2015), making it relevant to RQ1 because it explains how external knowledge is obtained, integrated, and translated into entrepreneurially useful outcomes in university–SME

collaboration. West and Bogers (2014) show that prior research has focused mainly on obtaining external knowledge, while integration and commercialization remain less developed, making the perspective equally relevant to RQ2 because frictions may arise not only in accessing knowledge but also in interpreting, applying, and commercializing it. Although universities have traditionally been treated as sources of external knowledge, recent research suggests a broader role in open innovation, where they co-create knowledge with firms and participate in its management, ownership, and commercialization (Corsino and Torrisi 2023) through knowledge co-creation, capacity building, and longer-term partnership development (Sarpong et al 2025). Together, these insights frame university–SME collaboration as a cross-boundary process in which entrepreneurial value depends on access to academic knowledge, its integration, use, and commercialization within SME contexts, while combined knowledge inflows and outflows shape both innovation outcomes and the organizational costs of open innovation (Cassiman and Valentini, 2015).

3. Methodology

The empirical analysis in this study is guided by two aforementioned research questions that focus on the process of entrepreneurial value creation and the factors that shape it in university–SME collaboration. (RQ1: Through what mechanisms and process stages does university–SME collaboration generate entrepreneurial value? RQ2: Which frictions weaken the entrepreneurial value creation process in university–SME collaboration, and which governance mechanisms help to overcome them?)

The empirical material derives from the NOKKA research project, funded by the European Union Regional Development Fund to increase the use of academic research among South Karelian SMEs in Finland, and was collected in winter 2025–2026 through semi-structured interviews with 23 SME founders or CEOs in southeastern Finland. A shared interview guide covered firms' knowledge acquisition practices, perceptions of academic research, capabilities for translating academic outputs into business use, and the possible role of intermediaries, while the semi-structured format allowed follow-up questions on emergent issues when analytically useful. All interviews were conducted via Microsoft Teams with automated transcription enabled, and interviewer notes were appended to the records when available.

The interviews were conducted in South Karelia, Finland, forming a regional qualitative sample rather than a statistically representative subset of Finnish SMEs. The firms represented multiple sectors, from tourism and services to software, reflecting the diversity of the regional SME landscape. Each interview lasted approximately one hour, and firms were selected from public registers and through convenience sampling until the target sample was reached. The analysis followed a theoretically informed thematic approach based on iterative reading and coding of Microsoft Teams transcripts to ensure consistency and transparency in identifying recurring patterns. The sample size of 23 interviews is consistent with qualitative research practice, where saturation rather than statistical representativeness determines adequacy, and prior studies suggest that richer patterns and cross-case variation typically emerge within approximately 20–30 interviews (Guest et al., 2006).

4. Data Analysis and Results

The material was examined through a theoretically informed thematic analysis (Braun and Clarke, 2006) focused on interview sections addressing the two research questions: the mechanisms and process stages of entrepreneurial value creation, and the frictions and governance conditions shaping that process. The transcripts were manually read repeatedly to build familiarity, and relevant passages were coded at the semantic level. In line with Hsieh and Shannon (2005), the coding was not fully inductive, as the research questions and theoretical concepts provided the initial analytical orientation. Codes were then compared across interviews and clustered into higher-order themes capturing recurrent value-creation mechanisms, process interruptions, and differences in firms' capabilities to absorb and use external knowledge.

4.1 RQ1 Results

The empirical material suggests that entrepreneurial value in university–SME collaboration emerges through a gradual, practice-bound process rather than through "knowledge transfer" alone. In line with the Relational View, value arose not from academic knowledge itself, but from connecting it to SMEs' development needs through workable relational arrangements, complementary capabilities, and usable interaction formats. The findings also support the Open Innovation perspective, as the key issue was whether external knowledge could be identified, interpreted, and translated into actionable forms within SME business contexts. The interview

excerpts below illustrate broader dataset patterns rather than standalone or statistically representative observations.

A first recurring mechanism was linking external knowledge to a specific business challenge or opportunity. Academic knowledge was valued not as a generic resource but for its usefulness in concrete development issues. This pattern is illustrated by one interviewee who said relevant research could "deepen both my own and employees' competence," help the company "serve customers better," and ultimately benefit "the company and the business as a whole". Similarly, respondents linked value to business development, with one noting that useful support would help "improve my business operations and identify new product or service ideas". These observations suggest that entrepreneurial value was perceived less as abstract scientific novelty than as business-relevant capability enhancement.

A second mechanism was translation: knowledge became valuable only when reformulated into language and formats suited to SME decision-making. Respondents emphasized that academic knowledge could be useful only if it was "translated into practice" or presented concisely and concretely. For example, one interviewee described academic research as potentially valuable but noted that it often consists of "long reports, rather theoretical things, and a lot that does not immediately bend into practice"; therefore, it would need to be "translated into practical language". This suggests that the critical process stage was not knowledge acquisition alone, but conversion into decision-relevant form, echoing the integration stage emphasized in open innovation literature (see, e.g. West and Bogers 2014).

A third mechanism concerned low-barrier relations through which academic knowledge entered firm development. Firms rarely saw formal research partnerships as the first or most natural collaboration mode, instead favouring practical boundary-spanning formats such as student theses, direct expert contact, short workshops, and accessible research summaries. One respondent stated that "the most useful form for us would be thesis collaboration" and that the company could offer "several topics for students". Another said the most useful support would be "some kind of knowledge bank" showing current and completed research at local higher education institutions. These examples suggest that entrepreneurial value often begins through accessible relational entry points that reduce the cognitive and organizational burden of engagement, rather than through full-scale collaboration.

Across the material, the process underlying entrepreneurial value creation can therefore be described as moving through at least three empirically visible stages: (1) recognition of a concrete development need, (2) identification or access to potentially relevant external knowledge, and (3) translation of that knowledge into capability development, service improvement, business growth, or commercialization-oriented action. A manual count based on the interview summaries showed that the first two RQ1 stages were present in all reviewed interviews, while the third stage—translation of knowledge into capability development, service improvement, growth, or commercialization-oriented action—was identified in 19 of the 23 reviewed interviews. Thus, the results for RQ1 can be summarized as follows:

- Entrepreneurial value was perceived primarily through concrete business needs, not through academic knowledge as such.
- The key process stage was translation, that is, converting research into concise, actionable, business-relevant form.
- Value-creating collaboration often began through low-barrier relational formats such as thesis projects, direct expert contact, and accessible summaries rather than formal research partnerships.

4.2 RQ2 Results

The empirical material shows that entrepreneurial value creation is fragile and shaped by frictions at different process stages. The combination of the Relational View and Open Innovation is useful here: Dyer and Singh (1998) explain how value can arise across organizational boundaries through routines and complementary resources, while West and Bogers (2014) highlight the gap in applying and commercializing knowledge. Consistent with this, the interviews show that frictions stem not only from obtaining knowledge, but also from weak relational conditions and difficulties in making knowledge governable and usable. As in the RQ1 findings, the excerpts below illustrate broader recurring patterns across the dataset rather than individually generalizable statements.

A recurring friction was time scarcity under operational pressure. Respondents emphasized that core business operations left little capacity for searching, reading, and experimenting with academic material. One interviewee

stated that “nothing really prevents using research, but time for searching and using it is extremely scarce”. Others described the obstacle as “most of the working hours go to running the basic business,” while another summarized: “jobs have to be handled now, so everything cannot be investigated in depth”. Thus, even potentially useful knowledge may fail to create value if SMEs cannot devote sufficient attention to integrating it.

Another recurring friction was the distance between academic form and SME practice. Respondents found academic research difficult to approach because of long reports, unfamiliar terminology, abstract structure, and uncertain relevance. One interviewee noted that academic texts require concentration because “the terminology is often somewhat unfamiliar,” while another described them as “quite difficult” because “the essential information has to be dug out” from academic language and structure. A related applicability concern was that irrelevant research would make the time spent “away from something else” and effectively “lost money”. This shows that the friction is both interpretive and entrepreneurial: SMEs face an opportunity-cost problem when deciding whether to invest scarce time in academic material.

A further recurring friction concerned weak visibility and low accessibility of relevant research and collaboration pathways in the UIC context. Many interviewees were only vaguely aware of current university research, did not see university websites as natural starting points, and sometimes mentioned paywalls or uncertainty about where to begin. One interviewee said the problem was not only lack of time but also “not knowing where to start and which material would actually be useful”. Another noted that, although useful research might exist, “the information is difficult to find, at least easily”.

The governance mechanisms that appeared most promising in the material were those that reduced these frictions by making collaboration more navigable, more concise, and more dialogical. Firms repeatedly asked for short, concrete workshops, clear summaries, direct access to experts, and structured yet lightweight entry points to collaboration. One respondent described the ideal workshop as “a tightly packed whole, nothing unnecessary, concrete and practical information that could be used quickly in everyday work”. Another asked for “short, clear summaries of research, direct contacts to experts, practical examples of what has been done elsewhere, and quick tools for decision-making”. Seen through the theoretical framework, these are not merely service preferences. From a relational perspective, they are governance arrangements that lower transaction and interpretation costs. From an open innovation perspective, they reduce interpretation and adaptability costs, increasing the likelihood that external knowledge becomes entrepreneurially useful. A manual count based on the interview summaries indicated that time scarcity was explicitly present in 13 of the 23 reviewed interview cases, distance between academic form and SME practice in 8 cases, and weak visibility or accessibility of relevant research and collaboration pathways in 54 cases, while concrete governance mechanisms to reduce these frictions were identified in all 32 reviewed cases. The main findings of RQ2 can be described as follows:

- A prominent friction was time scarcity under the pressures of everyday business operations
- Additional frictions arose from academic language, long formats, uncertain relevance, and weak awareness of where useful research can be found
- Firms perceived the risk of wasted effort as significant when research could not be quickly linked to practice
- A recurring governance mechanism was concise summaries, direct expert access, practical workshops, thesis collaboration, and other low-barrier boundary-spanning formats.

5. Conclusions

This study set out to explain how university–SME collaboration generates entrepreneurial value and what kinds of frictions weaken that process. The findings suggest that entrepreneurial value in university–SME collaboration is best understood not as a discrete outcome of knowledge transfer, but as a process through which external knowledge is connected to firm-specific development needs, translated into usable form. In this sense, the study contributes to the literature by moving attention from the existence of enablers and barriers (Mura, Di Flauro and Fratocchi 2025) to the mechanisms through which collaboration creates value for SMEs.

These findings are broadly consistent with prior research on university–industry collaboration, which has emphasized the role of absorptive capacity, interaction quality, and knowledge integration in determining collaboration outcomes (Cohen and Levinthal, 1990; Zahra and George, 2002; West and Bogers, 2014). However, the present study extends this literature by making the underlying process explicit, showing how entrepreneurial

value emerges through sequential stages and how frictions and governance mechanisms shape the transition between these stages in SME contexts.

With regard to RQ1, the empirical material indicates that entrepreneurial value is generated through at least three interrelated process stages. First, value creation begins when academic knowledge becomes linked to a concrete business challenge or opportunity that the SME already recognizes as relevant. Second, value depends on whether potentially useful external knowledge can actually be identified and accessed. Third, and most critically, value emerges only when that knowledge is translated into an actionable form that fits the firm's decision-making logic, resource situation, and commercial priorities. The findings therefore suggest that entrepreneurial value does not stem from academic knowledge as such, but rather from the successful conversion of knowledge into entrepreneurial capabilities.

Regarding RQ2, the study shows that the entrepreneurial value-creation process is weakened by a set of recurring frictions that are simultaneously organizational, relational, and processual. The most visible friction concerns time scarcity under the pressure of everyday SME operations. A second friction concerns the distance between academic form and SME practice. Long reports, unfamiliar terminology, abstract presentation, and uncertain relevance make academic outputs difficult to use. A third friction lies in weak visibility and low accessibility: firms often do not know what universities are currently researching, where relevant knowledge can be found, or how to initiate contact in a low-effort manner.

The study also identifies governance mechanisms that appear to reduce these frictions. The most promising mechanisms are not heavy partnership structures, but low-barrier, relationally accessible arrangements such as concise research summaries, direct access to experts, short, practical workshops, thesis collaboration, and other boundary-spanning formats that reduce interpretation and coordination costs. These mechanisms are significant because they show that entrepreneurial value is not created only through formal research collaboration. This reinforces the conclusion that governance in university–SME collaboration should not be understood only in contractual or formalized terms, but also as the design of accessible interfaces through which firms can engage with academic knowledge without excessive transaction costs.

This study is subject to some limitations. The main limitation is that the empirical material is based on a regional qualitative sample, which limits generalizability beyond similar SME contexts. Future research could extend this work by examining the identified process model in different geographical and sectoral contexts, and by testing the proposed stages quantitatively.

5.1 Managerial Implications

The study's managerial implications concern both SME decision-makers and higher education institutions. For SMEs, the findings suggest that the benefits of university collaboration are unlikely to materialize solely from increased exposure to academic knowledge. Instead, firms need to treat collaboration as a capability-building process, identifying specific business problems for which external knowledge is genuinely needed. To reduce friction, it is advisable to seek out low-effort partnerships, such as thesis workers and internships, at the early stages of the process.

For universities and other higher education institutions, the findings imply that successful engagement with SMEs requires a broader role than that of knowledge production alone. If entrepreneurial value depends on the practical usability of knowledge, then universities should also be attentive to how their outputs are packaged, communicated, and relationally delivered. This includes creating clear entry points for firms, maintaining channels for direct expert contact, and developing formats that align with SME time horizons and decision environments. Universities that aim to contribute to regional entrepreneurial renewal should not assume that scientific credibility alone ensures usefulness; they must also develop the organizational capability to make knowledge approachable, relevant, and actionable for SMEs by enacting low-barrier collaboration mechanisms.

5.2 Theoretical Implications

This study shifts attention from collaboration as a static condition or a set of barriers and facilitators to a process-based view of entrepreneurial value creation, showing how value emerges through staged processes in which external knowledge is translated into actionable insights for SMEs. Additionally, the study demonstrates the value of combining the Relational View and Open Innovation as complementary theoretical perspectives. The former helps explain how relational conditions and governance shape value creation across organizational boundaries, while the latter clarifies how external knowledge is obtained, integrated, and commercialized in

practice. Finally, the findings refine current understandings of university–SME collaboration by showing that the key analytical problem is not simply whether knowledge exists or whether collaboration takes place, but whether the collaboration process is sufficiently accessible, governable, and usable under SME conditions.

Abstract: Smart Ports are increasingly required to pursue digitalisation and decarbonisation simultaneously while maintaining operational continuity. Although these transitions have attracted growing academic attention, existing studies generally examine technological innovation or sustainability independently and provide limited theoretical explanations of how organisations manage both transformations concurrently. This study addresses this gap by investigating how organisations navigate digital and green transitions within complex operational environments through the complementary perspectives of Complexity Theory and Paradox Theory. A qualitative single-case study was conducted at the Port of Sines, Portugal, combining a semi-structured interview with the senior manager responsible for innovation and digital transformation with documentary evidence from institutional reports and strategic documents. An abductive research design and thematic analysis were employed to interpret the empirical material. The findings indicate that Complexity Theory explains Smart Port transformation as an adaptive and evolutionary process characterised by emergence, interdependence and continuous organisational learning. Paradox Theory complements this perspective by explaining how managers continuously balance persistent tensions, including efficiency versus sustainability, innovation versus operational continuity, and stability versus organisational change. The empirical evidence suggests that neither theoretical perspective alone fully explains the observed organisational dynamics. Accordingly, the study proposes an *Integrated Complexity–Paradox Framework*, demonstrating that adaptive system evolution and paradox management jointly enable digitalisation and decarbonisation within Smart Ports. The study contributes to innovation literature by providing a more comprehensive conceptual explanation of sustainability-oriented transformation and offers practical implications for managers responsible for leading complex infrastructure transitions.

Keywords: Smart Ports; Complexity Theory; Paradox Theory; Sustainable Innovation

1. Introduction

Smart Ports are becoming central actors in the digital and green transformation of global maritime logistics. Increasing competitive pressure, technological advances and ambitious environmental objectives require ports to modernise their infrastructures while simultaneously reducing environmental impacts and maintaining high levels of operational performance. Consequently, digitalisation and decarbonisation have become two of the principal drivers of contemporary Smart Port transformation (Belmoukari, Audy and Forget, 2023).

Digitalisation enables ports to improve operational efficiency through technologies such as Artificial Intelligence (AI), the Internet of Things (IoT), big data analytics and digital platforms that support real-time decision-making and stakeholder coordination (Del Giudice et al., 2022). At the same time, decarbonisation requires significant organisational and technological changes, including the electrification of equipment, renewable energy integration, cleaner logistics chains and low-carbon industrial infrastructures (Yang and Ge, 2020). Although both transformations are frequently presented as complementary, their implementation creates considerable organisational complexity because ports must introduce substantial technological and environmental innovations without compromising operational continuity.

Existing research has substantially improved understanding of Smart Port technologies and sustainability initiatives. However, much of the literature examines digitalisation and decarbonisation separately or adopts a single theoretical perspective, providing only a partial explanation of how organisations manage the interaction between adaptive transformation and competing strategic priorities. Consequently, there remains limited understanding of how organisations simultaneously navigate technological change, environmental sustainability and operational reliability within highly interconnected socio-technical systems.

This paper addresses the following research question:

- How can organisations achieve digitalisation and decarbonisation in Smart Ports while maintaining operational continuity during periods of organisational transformation?

To address this question, the study adopts an integrated theoretical perspective combining *Complexity Theory* (Anderson, 1999; Arthur, 2021) and *Paradox Theory* (Smith and Lewis, 2011; Berti and Cunha, 2023). A qualitative

single-case study of the Port of Sines, Portugal, provides the empirical context for examining how these complementary theoretical perspectives explain Smart Port transformation.

The study makes three principal contributions. First, it advances theoretical understanding by integrating Complexity Theory and Paradox Theory to explain digital and green transformation within Smart Ports. Second, it provides empirical evidence from one of Europe's leading ports, strengthening the connection between conceptual development and organisational practice. Third, it proposes an *Integrated Complexity–Paradox Framework* demonstrating how adaptive organisational evolution and paradox management jointly support digitalisation and decarbonisation while maintaining operational continuity.

Unlike previous studies that primarily examine digitalisation and decarbonisation independently or through a single theoretical perspective, this study demonstrates that Smart Port transformation is more comprehensively explained by integrating Complexity Theory and Paradox Theory. This integrated perspective provides a richer explanation of how adaptive organisational evolution and paradox management jointly enable digital and green transitions while maintaining operational continuity.

2. Theoretical Background

2.1 Complexity Theory

Complexity Theory conceptualises organisations as *complex adaptive systems* characterised by non-linearity, emergence, self-organisation and continuous adaptation (Anderson, 1999). Within such systems, organisational outcomes emerge from the interactions among multiple interconnected actors, technologies and institutional conditions rather than from linear cause-and-effect relationships. Organisational change is therefore understood as an evolutionary process in which adaptation results from experimentation, learning and feedback across multiple system components (Arthur, 2021).

This perspective is particularly relevant for understanding Smart Port transformation. Ports constitute highly interconnected socio-technical systems involving port authorities, terminal operators, shipping companies, logistics providers, technology suppliers, regulators and energy infrastructures. Consequently, digitalisation and decarbonisation evolve through continuous interaction among organisational, technological and institutional elements rather than through isolated implementation projects.

From a complexity perspective, successful transformation depends less on implementing predefined technological solutions than on developing adaptive organisational capabilities that enable continuous learning, experimentation and adjustment under changing environmental conditions. This interpretation provides an appropriate theoretical lens for analysing how Smart Ports evolve while responding simultaneously to technological innovation, environmental sustainability and operational challenges.

2.2 Paradox Theory

Whereas Complexity Theory explains organisational transformation at the system level, *Paradox Theor***y** focuses on how organisations respond to persistent competing demands that cannot be permanently resolved (Smith and Lewis, 2011). Rather than interpreting contradictions as temporary problems requiring either/or choices, Paradox Theory argues that organisations achieve long-term performance by simultaneously accommodating apparently contradictory objectives through both/and approaches (Berti and Cunha, 2023).

Within Smart Ports, several paradoxes emerge throughout digital and green transformation. Organisations must simultaneously improve operational efficiency while investing in environmental sustainability, introduce technological innovation without compromising operational continuity, and promote organisational change while maintaining reliability and safety. These competing objectives remain strategically important over time and therefore generate persistent rather than temporary tensions.

Managerial effectiveness consequently depends on developing capabilities that enable continuous balancing instead of definitive resolution. Mechanisms such as organisational learning, temporal balancing, capability development and strategic reframing allow organisations to accommodate contradictory demands while maintaining long-term performance.

Paradox Theory therefore complements Complexity Theory by explaining the managerial processes through which adaptive organisational transformation is governed in practice.

2.3 Integrating Complexity Theory and Paradox Theory

Although Complexity Theory and Paradox Theory originate from different theoretical traditions, they provide complementary explanations of organisational transformation.

Complexity Theory primarily explains *how organisational systems evolve*, emphasising emergence, adaptation and interdependence. In contrast, Paradox Theory explains *how managers govern transformation*, emphasising the continuous balancing of competing strategic objectives.

This complementarity is particularly relevant within Smart Ports, where digitalisation and decarbonisation simultaneously reshape technologies, organisational routines and stakeholder relationships while generating persistent operational tensions. Neither theoretical perspective independently captures the full organisational dynamics associated with these large-scale transformations.

Accordingly, this study adopts an *Integrated Complexity–Paradox Framework* in which Complexity Theory explains adaptive system evolution while Paradox Theory explains managerial responses to persistent organisational tensions. Together, these complementary perspectives provide the conceptual foundation for interpreting the empirical findings presented in the following sections.

The following methodology was designed to investigate how these complementary theoretical perspectives are reflected in the organisational transformation of the Port of Sines.

3. Methodology

This study adopts a qualitative single-case study design to investigate how organisations simultaneously pursue digitalisation and decarbonisation while maintaining operational continuity within a Smart Port context. A qualitative approach is appropriate because the research seeks to understand organisational processes, managerial interpretations and contextual dynamics rather than test predetermined causal relationships (Yin, 2018).

The research follows an *abductive logic*, characterised by an iterative dialogue between theoretical concepts and empirical observations (Dubois and Gadde, 2002). Rather than applying theory deductively or generating theory exclusively from empirical data, the analysis continuously moved between the conceptual perspectives of Complexity Theory and Paradox Theory and the evidence obtained from the Port of Sines, progressively refining theoretical interpretations.

3.1 Research Design

A single-case study was selected because the objective was to obtain an in-depth understanding of organisational transformation within a strategically important Smart Port rather than to achieve statistical representativeness. Consistent with Yin (2018) and Eisenhardt (1989), the study seeks *analytical generalisation* by contributing to theoretical understanding through rich empirical analysis rather than statistical inference.

The Port of Sines was selected as a *critical case* because it combines three characteristics directly relevant to the research question: large-scale logistics operations, advanced digital transformation initiatives and ambitious decarbonisation projects. These characteristics provide an appropriate empirical setting for examining the interaction between adaptive organisational processes and persistent managerial tensions.

The interview participant was selected through purposive sampling (Patton, 2015). The respondent occupies a senior management position with direct responsibility for innovation and digital transformation, providing comprehensive knowledge of strategic priorities, organisational decision-making and implementation challenges. Although relying on a single key informant represents a methodological limitation, the participant was uniquely positioned to provide an organisation-wide perspective spanning both digitalisation and sustainability initiatives. Furthermore, interview evidence was systematically triangulated with documentary sources to strengthen the credibility of the findings.

Table 1: Overview of the research design

Research Element	Description
Research strategy	Qualitative single-case study
Research logic	Abductive
Case	Port of Sines (Portugal)
Sampling strategy	Purposive sampling
Interview participant	Senior manager responsible for innovation and digital transformation
Interview duration	Approximately 60 minutes
Documentary sources	Institutional reports, strategic plans and official publications
Data analysis	Thematic analysis
Validation strategy	Triangulation of interview and documentary evidence
Type of generalisation	Analytical generalisation

Source: Author's own elaboration

3.2 Data Collection

Three complementary sources of evidence were employed.

First, a focused literature review established the conceptual foundations regarding Smart Ports, digitalisation, decarbonisation, Complexity Theory and Paradox Theory.

Second, primary empirical evidence was obtained through a semi-structured interview lasting approximately 60 minutes with the senior manager responsible for innovation and digital transformation at the Port of Sines. The interview protocol included open-ended questions concerning digital transformation initiatives, sustainability strategies, organisational governance, operational continuity, stakeholder coordination and managerial challenges associated with organisational change. This flexible interview format enabled the participant to provide detailed explanations and concrete examples drawn from organisational practice.

Third, documentary evidence was collected from publicly available institutional reports, strategic plans and official publications relating to the Port of Sines. These documents were used to corroborate factual information, contextualise organisational initiatives and support the interpretation of interview evidence.

Interview data and documentary evidence were analysed jointly through triangulation (Lincoln and Guba, 1985; Yin, 2018), thereby reducing dependence on a single source of evidence and enhancing the credibility of the empirical interpretations.

3.3 Data Analysis

The empirical material was analysed using thematic analysis following the procedures proposed by Braun and Clarke (2006).

The analysis comprised four iterative stages.

Initially, the interview transcript was read repeatedly to achieve familiarity with the empirical material and identify meaningful organisational episodes related to digitalisation, decarbonisation and organisational transformation.

Subsequently, *open coding* was conducted to identify recurring concepts and organisational practices. Initial codes included adaptation, experimentation, operational continuity, organisational learning, efficiency, sustainability, stakeholder coordination, capability development and technological implementation.

The resulting codes were progressively grouped into broader analytical themes representing recurring organisational patterns. Throughout this stage, emerging themes were continuously compared with the conceptual assumptions of Complexity Theory and Paradox Theory. Rather than imposing predetermined theoretical categories, the analysis followed an abductive process through which empirical observations and theoretical concepts informed one another iteratively.

Finally, the themes were organised into a comparative analytical framework identifying areas where Complexity Theory and Paradox Theory converged, diverged or complemented one another in explaining Smart Port transformation.

Coding and interpretation were conducted jointly by the authors through repeated discussion and iterative comparison between empirical evidence and theoretical constructs. Although independent multiple coding was not employed, analytical rigour was strengthened through systematic documentation of coding decisions, continuous peer discussion and repeated verification against the original interview transcript.

Several additional measures contributed to the trustworthiness of the study. Credibility was strengthened through triangulation between interview and documentary evidence (Lincoln and Guba, 1985). Transparency was enhanced by explicitly documenting the research design, data collection procedures and analytical process. Finally, the findings should be interpreted as providing *analytical rather than statistical generalisation* (Yin, 2018). Future research employing multiple-case and longitudinal designs could further examine the broader applicability of the proposed *Integrated Complexity–Paradox Framework*.

The following section introduces the Port of Sines as the empirical context within which these theoretical propositions are examined.

4. Case Study: Port of Sines

The Port of Sines is Portugal's largest deep-water port and one of the country's most strategically important logistics infrastructures. Located on the southwest Atlantic coast, it serves as a major gateway connecting Europe with international maritime trade routes linking Europe with Asia, Africa and the Americas. Its deep-water conditions enable the operation of large container vessels, oil tankers and liquefied natural gas (LNG) carriers, positioning the port as a critical node within European and global supply chains.

The port comprises specialised terminals handling containerised cargo, liquid bulk, solid bulk and general cargo while supporting major industrial and energy-related activities. Beyond its operational importance, the Port of Sines has assumed a leading role in Portugal's digital and energy transition through investments in digital technologies, renewable energy integration and low-carbon industrial projects.

These characteristics make the Port of Sines an appropriate empirical setting for investigating how organisations simultaneously implement digitalisation and decarbonisation while maintaining operational continuity within a highly interconnected socio-technical system.

4.1 Digitalisation Initiatives

The Port of Sines has progressively implemented a broad portfolio of digital transformation initiatives intended to improve operational efficiency, coordination and decision-making.

These initiatives include:

- real-time operational monitoring platforms;
- Internet of Things (IoT) sensors supporting equipment monitoring;
- Artificial Intelligence (AI) applications for predictive maintenance;
- digital platforms integrating multiple organisational stakeholders.

Rather than representing isolated technological investments, these initiatives form part of an integrated transformation programme designed to increase organisational responsiveness while simultaneously supporting long-term sustainability objectives.

As explained by the interview participant:

> *"A digital transformation plan involves several actions."*

This statement indicates that digitalisation is understood as a coordinated organisational transformation process rather than as the implementation of individual technological projects

4.2 Decarbonisation Initiatives

Digital transformation has been accompanied by an equally ambitious decarbonisation strategy.

Current initiatives include:

- electrification of port equipment and operational vehicles;
- integration of renewable energy sources;
- development of green hydrogen projects;

- carbon capture and storage initiatives;
- promotion of cleaner logistics chains.

Importantly, the interview indicates that digitalisation and decarbonisation are organisationally interdependent rather than independent strategic programmes.

As the interview participant stated:

> *"Digital transformation can be a means towards sustainability."*

This evidence suggests that digital technologies are not pursued exclusively to improve efficiency but also function as enabling capabilities supporting environmental objectives.

4.3 Organisational and Operational Challenges

The simultaneous implementation of digitalisation and decarbonisation generates significant organisational challenges.

Interview evidence identifies four principal challenges:

- maintaining uninterrupted port operations during transformation;
- coordinating multiple organisational stakeholders;
- managing interdependencies among digital, logistics and energy systems;
- reconciling short-term operational efficiency with long-term sustainability objectives.

Rather than occurring sequentially, these challenges emerge simultaneously throughout the transformation process, requiring continuous organisational adjustment and managerial coordination.

The empirical findings therefore suggest that Smart Port transformation should be understood as an ongoing organisational process rather than a sequence of discrete technological implementation projects.

The following section analyses these empirical observations through the complementary perspectives of Complexity Theory and Paradox Theory.

5. Analysis

The empirical findings indicate that the transformation of the Port of Sines is characterised by the simultaneous presence of adaptive organisational dynamics and persistent managerial tensions. This section analyses these findings through the complementary lenses of Complexity Theory and Paradox Theory before integrating both perspectives into a unified conceptual explanation.

5.1 Complexity Theory Perspective: Transformation as Adaptive System Evolution

The interview evidence strongly supports the interpretation of the Port of Sines as a complex adaptive system.

The respondent repeatedly described organisational transformation as an evolutionary process driven by continuous adjustment to changing operational and environmental conditions:

> "The organisation adapts to challenges and to the dynamics of the context, changing and evolving."

This observation illustrates one of the central assumptions of Complexity Theory: organisational adaptation emerges through continuous interaction between the organisation and its environment rather than through predetermined linear planning (Anderson, 1999).

A second empirical illustration concerns the implementation of new technologies.

Rather than introducing innovations simultaneously across the organisation, the Port of Sines deliberately follows an incremental implementation strategy.

As explained by the interview participant:

> "Drones are being introduced gradually because change also needs to be managed."

This quotation demonstrates that technological innovation itself is treated as an adaptive organisational process. Incremental implementation enables experimentation, organisational learning and continuous adjustment while reducing operational disruption.

A further observation concerns the coordination of transformation initiatives.

The respondent emphasised that:

> "A digital transformation plan involves several actions."

This evidence reinforces the complexity perspective by illustrating that organisational transformation results from the interaction of multiple interconnected initiatives rather than from isolated technological investments.

Overall, the empirical findings indicate that digitalisation and decarbonisation emerge through cumulative adaptation, organisational learning and systemic interdependence, fully consistent with the assumptions of Complexity Theory.

5.2 Paradox Theory Perspective: Managing Persistent Organisational Tensions

Whereas Complexity Theory explains how transformation evolves, Paradox Theory provides a stronger explanation of how managers govern transformation in practice.

The interview reveals that organisational decision-making is characterised by persistent tensions requiring simultaneous rather than sequential management.

One of the clearest examples concerns operational continuity.

The interview participant stated:

> "The main difficulty is maintaining port operations while, at the same time, implementing these changes."

This quotation illustrates the coexistence of two equally legitimate organisational priorities: maintaining uninterrupted operations while simultaneously introducing substantial organisational transformation.

Rather than resolving this tension, management continuously balances both objectives.

A second paradox concerns the relationship between operational efficiency and environmental sustainability.

The respondent explained:

> "Our competitiveness comes first from efficiency, and digital transformation will increase efficiency."

Later, the same participant added:

> "Digital transformation can be a means towards sustainability."

Taken together, these statements indicate that efficiency and sustainability are not viewed as mutually exclusive organisational goals. Instead, digitalisation functions as the mechanism through which both objectives can be pursued simultaneously.

A third paradox concerns technological innovation and human capability development.

The respondent emphasised:

> "People need to be empowered and trained."

This observation highlights that successful technological transformation depends not only on technological investment but also on continuous organisational learning and workforce development.

Finally, the interview participant explicitly recognised the coexistence of apparently contradictory organisational realities:

> "The organisation sometimes lives with situations that seem irreconcilable and ultimately manages them."

This quotation provides particularly strong empirical support for Paradox Theory because it explicitly describes paradox management rather than merely illustrating competing organisational objectives.

Overall, the findings indicate that Smart Port transformation depends on the continuous balancing of persistent organisational tensions rather than their elimination.

5.3 Comparing Complexity Theory and Paradox Theory

The empirical findings reveal considerable complementarity between the two theoretical perspectives.

Both theories recognise the importance of organisational adaptation, innovation and the simultaneous pursuit of operational performance and sustainability. However, they differ in their principal analytical focus.

Complexity Theory primarily explains how organisational transformation emerges through adaptive interactions among interconnected organisational components.

Paradox Theory primarily explains how managers respond to the persistent tensions generated by that transformation.

Table 2 summarises the principal similarities and differences identified through the empirical analysis.

Table 2: Comparison between Complexity Theory and Paradox Theory

Analytical Dimension	Complexity Theory	Paradox Theory
Adaptation	Continuous organisational evolution	Continuous balancing of competing organisational
Efficiency and	Adaptive improvement of organisational	Simultaneous pursuit of both objectives
Innovation	Gradual implementation, experimentation	Innovation balanced with operational continuity and
Primary analytical focus	Evolution of the organisational system	Managerial decision-making
Transformation logic	Emergence, adaptation and	Persistent paradox management

Source: Authors' own elaboration.

The comparison demonstrates that neither theory independently explains all dimensions of Smart Port transformation. Instead, each perspective illuminates different but complementary aspects of the same organisational phenomenon.

To strengthen the transparency of the analytical process, Table 3 links representative interview quotations directly to their corresponding theoretical interpretation.

Table 3: Summary of empirical evidence and theoretical interpretation

Representative Empirical Evidence	Complexity Theory	Paradox Theory
"The organisation adapts to challenges and to the	Adaptive system evolution	—
"Drones are being introduced gradually because change	Incremental adaptation and	Innovation versus operational
"The main difficulty is maintaining port operations while	Organisational interdependence	Operational continuity versus
"Our competitiveness comes first from efficiency."	Adaptive performance	Efficiency versus sustainability
"Digital transformation can be a means towards	Co-evolution of digitalisation and	Simultaneous pursuit of
"People need to be empowered and trained."	Organisational learning	Capability development for
"The organisation sometimes lives with situations that	—	Explicit paradox management

Source: Authors' own elaboration.

The systematic relationship between empirical evidence and theoretical interpretation strengthens the credibility of the findings and demonstrates how the two theoretical perspectives complement one another in explaining Smart Port transformation.

5.4 Integrated Complexity–Paradox Framework

The comparative analysis indicates that Complexity Theory and Paradox Theory should not be interpreted as competing explanations but as complementary analytical perspectives operating at different organisational levels.

Complexity Theory explains the adaptive evolution of organisational systems through emergence, experimentation and continuous learning. Paradox Theory explains the managerial mechanisms through which competing strategic priorities are continuously balanced during this adaptive process.

Accordingly, this study proposes an *Integrated Complexity–Paradox Framework*, which conceptualises Smart Port transformation as the result of the interaction between adaptive system evolution and paradox management.

Within this framework, digitalisation and decarbonisation are understood as mutually reinforcing transformation processes supported simultaneously by adaptive organisational capabilities and managerial capability to balance persistent tensions.

Figure 1 illustrates the proposed Integrated Complexity–Paradox Framework, demonstrating how adaptive organisational evolution and paradox management jointly enable Smart Port transformation while maintaining operational continuity.

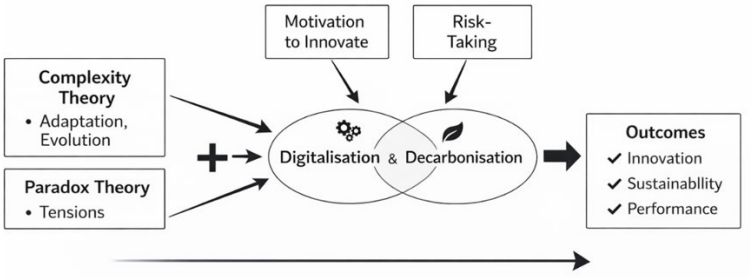

Figure 1: Integrated Complexity–Paradox Framework explaining Smart Port transformation through the complementary interaction between adaptive system evolution (Complexity Theory) and paradox management (Paradox Theory).

Source: Authors' own elaboration.

6. Discussion

The findings provide a more comprehensive understanding of how digitalisation and decarbonisation unfold within complex, asset-intensive environments such as Smart Ports. By integrating Complexity Theory and Paradox Theory, this study moves beyond linear explanations of organisational change and demonstrates that successful transformation depends simultaneously on adaptive system evolution and continuous management of competing organisational demands.

From a *Complexity Theory* perspective, the Port of Sines illustrates how transformation emerges through iterative adaptation rather than predetermined implementation. Digital technologies, sustainability initiatives and organisational routines evolve together through continuous interaction among multiple actors, infrastructures and institutional conditions. The empirical evidence indicates that organisational change is characterised by experimentation, gradual implementation and learning rather than by discrete technological projects. These findings reinforce previous complexity-informed interpretations of organisational transformation (Anderson, 1999; Arthur, 2021).

From a *Paradox Theory* perspective, the study demonstrates that organisational transformation is accompanied by persistent tensions requiring continuous managerial balancing. Rather than resolving contradictions, managers simultaneously pursue operational continuity and innovation, efficiency and sustainability, and technological development and workforce capability building. The interview evidence suggests that organisational effectiveness depends on developing capabilities to accommodate these competing priorities over time, consistent with the paradox perspective advanced by Smith and Lewis (2011) and Berti and Cunha (2023).

Importantly, the empirical analysis indicates that neither theoretical perspective independently captures the full organisational dynamics observed at the Port of Sines. Complexity Theory explains how transformation evolves through adaptive interactions, whereas Paradox Theory explains how managers govern that transformation by balancing persistent tensions. The complementary application of both theories therefore provides a richer explanation of Smart Port transformation than either perspective could offer independently.

6.1 Theoretical Contributions

This study makes three principal contributions to innovation research.

First, it contributes to the Smart Port literature by demonstrating that digitalisation and decarbonisation should be analysed as mutually reinforcing organisational transformations rather than as independent technological or environmental initiatives.

Second, it advances theory by integrating Complexity Theory and Paradox Theory within a single analytical framework. Previous studies have generally relied on one theoretical perspective to explain organisational transformation. In contrast, this study shows that combining adaptive systems thinking with paradox management provides a more comprehensive explanation of organisational change in sustainability-oriented contexts.

Third, the proposed *Integrated Complexity–Paradox Framework* extends innovation theory by conceptualising transformation as the interaction between adaptive organisational evolution and continuous management of competing strategic priorities. This integrated perspective may also inform future research examining digital and green transitions in other complex infrastructure systems beyond the maritime sector.

6.2 Managerial Implications

The findings also generate practical implications for managers responsible for leading digital and green transformation.

First, organisations should recognise transformation as an adaptive process requiring continuous experimentation and organisational learning rather than rigid implementation plans. Incremental deployment of technologies enables organisations to learn from experience while minimising operational disruption.

Second, managers should anticipate that digitalisation and decarbonisation will generate persistent organisational tensions rather than temporary implementation challenges. Developing capabilities to balance efficiency, sustainability and operational continuity therefore becomes a strategic capability rather than a short-term project management activity.

Third, the findings indicate that technological investment alone is insufficient. Successful transformation also depends on organisational capability development, stakeholder coordination and workforce training. As illustrated by the Port of Sines, digital technologies become effective enablers of sustainability only when embedded within broader organisational transformation processes.

Finally, the proposed *Integrated Complexity–Paradox Framework* provides managers with a conceptual tool for understanding how adaptive organisational evolution and paradox management jointly support long-term transformation in complex infrastructure systems.

7. Conclusion

This study examined how organisations can simultaneously pursue digitalisation and decarbonisation while maintaining operational continuity, using the Port of Sines as an empirical case.

Drawing upon Complexity Theory and Paradox Theory, the study demonstrates that Smart Port transformation is characterised by both adaptive organisational evolution and persistent managerial tensions. Complexity Theory explains how transformation emerges through continuous adaptation, organisational learning and interaction among multiple interconnected elements. Paradox Theory complements this perspective by explaining how managers continuously balance competing organisational priorities such as efficiency and sustainability, innovation and operational continuity, and technological change and workforce capability development.

The principal contribution of this study is the development of an *Integrated Complexity–Paradox Framework*, which demonstrates that adaptive organisational evolution and paradox management jointly explain Smart Port transformation more comprehensively than either theoretical perspective alone. By integrating these complementary perspectives, the study contributes to innovation literature through a richer explanation of how organisations manage simultaneous digital and green transitions within complex operational environments.

From a practical perspective, the findings suggest that managers should approach digital transformation as an ongoing organisational capability rather than a discrete technological project. Successful transformation requires adaptive organisational learning, continuous stakeholder coordination and sustained capability to manage competing strategic priorities.

The study is subject to several limitations. As a qualitative single-case study, the findings are intended to provide *analytical rather than statistical generalisation* (Yin, 2018). Furthermore, the primary empirical evidence relies on a single senior informant, although credibility was strengthened through documentary triangulation and systematic analytical procedures. Future research could extend the proposed framework through multiple-case

studies, longitudinal designs and comparative analyses across different Smart Ports and other complex infrastructure systems.

Overall, this study demonstrates that digital and green transitions should be understood as interconnected organisational processes requiring both adaptive evolution and continuous paradox management. The proposed *Integrated Complexity–Paradox Framework* therefore provides a theoretically grounded and practically relevant explanation of how organisations can navigate sustainability-oriented transformation within increasingly complex operational environments.

Ethics Declaration

No ethical approval was required for this study. Participation in the interview was voluntary, informed consent was obtained from the participant, and the data were analysed and reported in accordance with accepted academic research standards.

AI Declaration

Artificial Intelligence (AI) tools were used exclusively to support language refinement, editing and manuscript structuring. All conceptual development, interpretation of findings and final content remain the responsibility of the authors.

Decarbonising Smart Ports: A Complexity and Paradox Perspective of Sines and Leixões

Ricardo Veloso-Carvalho[1] and Soumodip Sarkar[1,2]
[1]CEFAGE-UE - University of Évora, Évora, Portugal
[2]Alentejo, Science & Technology Park (PACT), Évora, Portugal

d47001@alunos.uevora.pt
ssarkar@uevora.pt

Abstract: The decarbonisation of maritime transport and port infrastructure has become a central challenge in the global transition towards climate neutrality. Smart ports are increasingly positioned as innovation hubs where digitalisation, energy transition, and sustainability intersect. However, the pathways through which ports adopt and implement decarbonisation strategies remain heterogeneous and theoretically underexplored, particularly regarding how different strategic approaches emerge in practice. This paper investigates how smart ports navigate decarbonisation through the combined lenses of Complexity Theory and Paradox Theory. It addresses three research questions: (1) What factors influence the adoption of decarbonisation practices in smart ports? (2) How do these factors shape strategic responses? (3) To what extent do emerging vectors, such as green hydrogen, represent innovation opportunities within port ecosystems? The study adopts a qualitative comparative case study methodology, analysing the ports of Sines and Leixões in Portugal. Data were collected from secondary sources, including strategic plans, institutional reports, and policy documents, and analysed through thematic coding across five dimensions: decarbonisation goals, technologies, public policies, partnerships, and expected outcomes. Findings reveal that both ports are aligned with European climate objectives but follow distinct strategic pathways. Sines adopts a large-scale, infrastructure-driven approach, leveraging international energy corridors and industrial integration projects. In contrast, Leixões pursues a more decentralised and innovation-oriented trajectory, emphasising earlier carbon neutrality targets and strong collaboration with research institutions. The analysis shows that decarbonisation emerges as a complex adaptive process shaped by multi-actor interactions, while also involving persistent tensions between growth and sustainability, centralisation and collaboration, and efficiency and experimentation. These tensions are actively managed as drivers of innovation rather than constraints, enabling differentiated yet effective transformation pathways. The paper contributes in three ways: (1) it integrates Complexity and Paradox Theory in the context of sustainable innovation; (2) it provides empirical insights from a comparative smart port analysis; and (3) it identifies green hydrogen as a strategic opportunity for complementary innovation ecosystems.

Keywords: Smart Ports; Decarbonisation; Green Hydrogen; Innovation; Paradox vs Complexity Theory

1. Introduction

The transition towards climate neutrality has placed increasing pressure on maritime transport and port systems to reduce their carbon footprint. Ports are evolving from logistics nodes into integrated energy and innovation platforms within global value chains.

Smart ports, characterised by digitalisation and sustainability integration, are central to this transformation. Decarbonisation strategies—including electrification, renewable energy, and alternative fuels such as green hydrogen—are reshaping operations and governance.

Despite this relevance, research remains fragmented and insufficiently attentive to the dynamic and tension-rich nature of transformation processes.

This study addresses this gap by analysing the decarbonisation strategies of the ports of Sines and Leixões through the lenses of Complexity Theory and Paradox Theory.

Portugal provides a relevant empirical setting due to its strategic positioning within European energy and logistics systems.

This paper contributes in three ways. First, it advances theoretical understanding by integrating Complexity and Paradox perspectives. Second, it offers empirical insights through a comparative analysis. Third, it identifies green hydrogen as an emerging innovation vector.

2. Literature Review

2.1 Smart Ports and Innovation

Smart ports integrate digital technologies, automation, and sustainability practices to improve efficiency and environmental performance (Belmoukari et al., 2023). They function as innovation ecosystems involving multiple stakeholders and interconnected infrastructures.

Existing literature highlights the importance of digitalisation, yet lacks empirical grounding and unified conceptualisation.

Large seaports have become strategic nodes within global logistics and energy networks, extending their traditional cargo-handling role towards multifunctional platforms integrating transport, industrial activities, digital infrastructures, and energy systems. Their scale, connectivity, and investment capacity enable them to act as innovation ecosystems capable of accelerating technological diffusion and supporting the transition towards low-carbon maritime transport (Notteboom & Rodrigue, 2005; ESPO, 2021).

Within Europe, major ports increasingly operate as integrated hubs where digitalisation, renewable energy deployment, alternative fuels, and industrial symbiosis converge. This evolution reflects a broader transition from infrastructure-based competitiveness towards ecosystem-based competitiveness, in which value creation depends on collaboration among port authorities, terminal operators, energy companies, research organisations, and public institutions (European Commission, 2021; ESPO, 2021). Consequently, large ports constitute particularly relevant empirical settings for investigating how complex innovation processes underpin decarbonisation strategies.

2.2 Decarbonisation Strategies

Decarbonisation involves electrification, renewable energy integration, and alternative fuels such as hydrogen (Holder et al., 2024). Ports are increasingly positioned as energy hubs, supporting both maritime and industrial decarbonisation.

However, strategies vary significantly depending on local context, governance, and infrastructure.

2.3 Complexity Theory

Complexity Theory conceptualises ports as adaptive systems characterised by non-linearity, emergence, and interdependence (Anderson, 1999; Arthur, 2021). Transformation emerges from interactions among multiple actors rather than centralised planning.

2.4 Paradox Theory

Paradox Theory focuses on persistent tensions such as sustainability vs. growth (Smith & Lewis, 2011). Organisations must manage rather than resolve these tensions, enabling innovation through dynamic balancing.

2.5 Port Governance and Ownership Models in Europe

The governance and ownership structures of ports constitute an important contextual factor influencing their capacity to implement innovation and decarbonisation strategies. Beyond technological capabilities and infrastructure, port governance shapes investment decisions, stakeholder coordination, regulatory flexibility, and the ability to mobilise long-term partnerships for sustainable transformation (World Bank, 2007; Verhoeven, 2010).

The European port sector is characterised by considerable institutional diversity. Nevertheless, the landlord port model has become the predominant governance structure across most major European ports (World Bank, 2007; OECD, 2011). Under this model, the port authority retains ownership of the basic infrastructure and assumes responsibility for strategic planning, environmental management, safety, and regulatory oversight, while commercial cargo-handling activities and terminal operations are undertaken by private operators through long-term concession agreements. This arrangement seeks to combine public strategic control with private-sector efficiency, investment capacity, and operational expertise.

Alternative governance models include the service port, where the port authority directly provides most operational services; the tool port, in which infrastructure and equipment remain publicly owned while cargo

operations are partially outsourced; and fully private ports, where infrastructure ownership and operational responsibilities are concentrated within private organisations (World Bank, 2007). Although these models continue to exist in specific contexts, the landlord model has progressively become the dominant institutional framework in Europe due to its ability to balance public policy objectives with commercial competitiveness (Verhoeven, 2010).

From an innovation perspective, governance arrangements influence how ports respond to emerging challenges associated with digitalisation and decarbonisation. Landlord ports typically operate within complex multi-actor ecosystems involving port authorities, terminal operators, logistics firms, energy companies, industrial tenants, research organisations, and public agencies. As a result, innovation increasingly depends on collaborative governance mechanisms rather than hierarchical decision-making alone (OECD, 2011).

This governance perspective is particularly relevant to the present study. Both the Port of Sines and the Port of Leixões operate under the landlord model, yet they exhibit different configurations of stakeholders, investment patterns, and strategic partnerships. These institutional differences provide an important contextual layer for interpreting their respective decarbonisation pathways through the lenses of Complexity Theory and Paradox Theory. Rather than determining a single trajectory, governance structures create the institutional conditions within which alternative innovation pathways emerge and evolve.

3. Methodology

This study adopts a qualitative, exploratory comparative case study design.

3.1 Data Collection

Data were collected from:

- Strategic plans (Sines, Leixões)
- Institutional reports
- EU policy frameworks (e.g., Green Deal)
- Academic literature

3.2 Data Analysis

A thematic coding approach was applied across five dimensions:

1. Decarbonisation goals
2. Technologies
3. Public policies
4. Partnerships
5. Expected outcomes

3.3 Analytical Framework

The study integrates:

- Complexity lens → adaptation, emergence, system dynamics
- Paradox lens → tensions and dualities

This dual framework enables a richer interpretation of innovation processes.

4. Results

4.1 Case Description

The Port of Sines and the Port of Leixões represent two structurally distinct but strategically relevant cases within the Portuguese port system, offering a robust basis for comparative analysis. Sines, located on the southwest Atlantic coast, is Portugal's largest deep-water port and a key node in global maritime logistics. Handling approximately 47.8 million tonnes of cargo in 2024, including around 1.9 million TEU, it is strongly integrated into international trade routes and energy corridors. Its industrial ecosystem, including the ZILS (Sines Industrial

and Logistics Zone), supports large-scale energy and petrochemical activities, positioning the port as a strategic platform for energy transition initiatives.

Consistent with the governance framework outlined in Section 2.5, both the Port of Sines and the Port of Leixões operate under the Portuguese landlord port model. In this model, port authorities retain responsibility for strategic planning, infrastructure development, regulation, safety, and environmental management, while cargo handling and terminal operations are largely undertaken by private concessionaires (World Bank, 2007; OECD, 2011).

Although both ports share the same institutional structure, their stakeholder configurations, strategic partnerships, and investment profiles differ substantially, influencing the way decarbonisation initiatives are developed and implemented. The Port of Sines hosts major international terminal operators and energy companies, reflecting its strong integration into global logistics and energy markets. This international orientation facilitates large-scale investments and long-term infrastructure projects associated with the energy transition. By contrast, the Port of Leixões operates within a more regionally embedded industrial ecosystem, where collaboration with local industries, municipalities, universities, and research centres plays a more prominent role in supporting innovation and sustainability initiatives. These institutional differences reinforce the contrasting strategic pathways identified in this study.

In contrast, the Port of Leixões operates within a dense urban and industrial environment in northern Portugal. Handling approximately 14–17 million tonnes annually, it serves as a critical logistics gateway for regional industries, including textiles, metallurgy, and agri-food sectors. Its strategic positioning within a knowledge-intensive region, with proximity to universities and research centres, reinforces its role as an innovation-oriented port.

From a decarbonisation perspective, Sines adopts a long-term, infrastructure-intensive strategy centred on large-scale projects such as the NEXUS Agenda and participation in European green corridors. These initiatives aim to integrate digitalisation, renewable energy production, and hydrogen-based value chains. Leixões, by contrast, follows a more accelerated trajectory, targeting carbon neutrality by 2035 through incremental innovation, electrification, and strong collaboration with research institutions.

These structural and strategic differences create a valuable empirical setting to explore how alternative decarbonisation pathways emerge under different institutional, geographic, and economic conditions.

4.2 Comparative Analysis

The comparative analysis reveals both convergence and divergence in decarbonisation strategies across the two ports. At a fundamental level, both Sines and Leixões adopt a common set of technological and strategic measures, including electrification of port operations, integration of renewable energy sources, digitalisation of logistics processes, and experimentation with alternative fuels such as hydrogen and biofuels. These shared elements reflect alignment with European policy frameworks, including the European Green Deal and Fit for 55.

However, the manner in which these strategies are implemented differs significantly. Sines adopts a scale-driven model, prioritising infrastructure development, energy system integration, and positioning within international logistics and energy corridors. Its strategy emphasises long-term competitiveness through large capital investments and partnerships with global energy players.

Leixões, in contrast, follows a network-driven model, characterised by agility, experimentation, and strong collaboration with regional innovation ecosystems. Its approach is more decentralised, leveraging partnerships with universities and research centres to accelerate the adoption of emerging technologies and achieve earlier decarbonisation milestones.

Differences are also evident across the five analytical dimensions. In terms of goals, Leixões sets more ambitious short-term targets, while Sines focuses on long-term systemic transformation. In technologies, Sines emphasises large-scale energy infrastructure, whereas Leixões prioritises modular and adaptable solutions. In partnerships, Sines aligns with industrial and international actors, while Leixões builds knowledge-based networks. These distinctions illustrate how context shapes strategic choices in decarbonisation pathways.

4.3 Theoretical Interpretation

From a Complexity Theory perspective, both ports can be understood as complex adaptive systems in which multiple actors—port authorities, logistics operators, energy firms, policymakers, and research institutions—

interact dynamically. Decarbonisation does not result from linear planning but emerges from iterative processes of adaptation, experimentation, and feedback. The introduction of new technologies, such as hydrogen systems or digital platforms, triggers cascading effects across organisational, infrastructural, and regulatory domains.

The comparison between Sines and Leixões highlights different modes of complexity management. Sines reflects a more orchestrated form of system evolution, where large-scale projects act as structuring mechanisms for coordinated change. Leixões, by contrast, exhibits a more distributed form of adaptation, where innovation emerges through networked interactions and local experimentation.

From a Paradox Theory perspective, the analysis reveals that both ports face persistent and interrelated tensions. These include the need to balance economic growth with environmental sustainability, centralised strategic direction with decentralised collaboration, and operational efficiency with experimentation and innovation. Rather than resolving these tensions, both ports engage in ongoing processes of balancing and reframing.

Importantly, the findings suggest that these tensions are not merely constraints but generative forces that stimulate innovation. For example, the pressure to reduce emissions while maintaining competitiveness drives investment in new technologies and business models. The ability to navigate these paradoxes effectively becomes a key organisational capability in the context of sustainable transformation.

4.4 Green Hydrogen as Innovation Opportunity

The literature review, the identification of key decarbonisation drivers (Section 4.1), and the comparative analysis between Sines and Leixões (Section 4.2) collectively point to green hydrogen as a strategic vector with high potential for sustainable innovation in smart ports.

As highlighted by Notteboom and Haralambides (2023), green hydrogen (GH_2) is increasingly integrated into port systems through three main pathways: (1) local production using renewable energy sources; (2) bunkering services for hydrogen-based maritime fuels; and (3) export and distribution of hydrogen and its derivatives (e.g., ammonia and methanol). These roles position ports not only as logistics nodes but as emerging energy hubs within decarbonised value chains.

This transformation introduces a new “secondary market” logic, in which ports expand beyond traditional cargo handling to participate actively in clean energy ecosystems. From an innovation perspective, green hydrogen enables new business models, fosters cross-sector integration between energy and logistics, and reinforces the strategic relevance of ports in the energy transition. The associated benefits include economic diversification, increased attractiveness for foreign investment, reduction of carbon emissions, industrial symbiosis, and the creation of high-skilled employment.

The empirical analysis suggests that the Ports of Sines and Leixões may assume complementary roles within this emerging hydrogen ecosystem. Sines is well positioned to act as a large-scale production and export hub, supported by its extensive industrial area (ZILS), access to renewable energy sources, existing LNG infrastructure adaptable to hydrogen, and integration into European energy corridors. Large-scale projects such as GreenH2Atlantic further reinforce this positioning.

In contrast, Leixões is better suited to operate as a regional distribution and innovation hub, focusing on local industrial applications, pilot projects, and technological experimentation. Its proximity to industrial clusters in northern Portugal, combined with strong linkages to research institutions (e.g., FEUP, INEGI, CEiiA), enables the development of a knowledge-intensive hydrogen ecosystem. The reconversion of the Matosinhos refinery into an innovation hub further strengthens this trajectory.

This complementary positioning is synthesised in Table 1, which highlights the distinct but interconnected roles of both ports within a potential hydrogen-based innovation system.

Table 1:Complementary roles of Sines and Leixões in the green hydrogen ecosystem

Dimension	Port of Sines	Port of Leixões
Scale	Large-scale	Regional and urban
Main Function	Production and export	Distribution and local consumption
Type of Projects	Industrial, international	Innovation, urban and industrial supply
Partnerships	EDP, Galp, Engie, REN	Galp, CEiiA, INEGI

Dimension	Port of Sines	Port of Leixões
Geographic Positioning	South – Atlantic corridor	North – industrial urban cluster
Energy Role	Mass production and export	Local application and technological demonstration

Source: Author's own elaboration

From a theoretical perspective, this finding reinforces the argument that decarbonisation is not a uniform process but unfolds through differentiated yet interconnected pathways. From an innovation standpoint, green hydrogen emerges as a bridging vector that connects these pathways, enabling complementarities across scales and functions.

Due to its relevance in terms of opportunities for innovation, it is important to summarize these findings relating to green Hydrogen:

1. Green hydrogen emerges as a critical innovation vector enabling new business models and energy-logistics integration.
2. In Sines, hydrogen is positioned as a large-scale production and export opportunity, supported by infrastructure, industrial integration, and international energy corridors.
3. In Leixões, hydrogen plays a more decentralised role, focusing on regional consumption, experimentation, and integration with industrial clusters and research ecosystems.
4. This complementary positioning suggests the emergence of a dual-port innovation ecosystem, where:
    - Sines operates as a production and export hub
    - Leixões functions as a distribution and application hub
5. This configuration enhances:
    - System efficiency
    - Innovation diffusion
    - Strategic resilience
6. Green hydrogen therefore represents not only a technological solution but a systemic innovation opportunity.

4.5 Integrated Framework of Decarbonisation Pathways

Building on the comparative findings and theoretical lenses, this study proposes an integrated conceptual framework of smart port decarbonisation pathways (Figure 1).

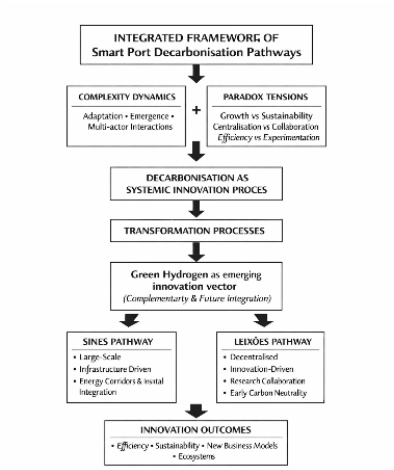

Figure 1: Integrated Conceptual Framework of Smart Port Decarbonisation Pathways

Source: Author's own elaboration

Figure 1 presents the integrated conceptual framework of smart port decarbonisation pathways developed in this study. The model conceptualises decarbonisation as a systemic innovation process emerging from the interaction between complexity dynamics (adaptation, emergence, multi-actor interactions) and persistent paradoxical tensions (e.g., growth vs sustainability; centralisation vs collaboration).

Importantly, the framework embeds the empirical findings by identifying two differentiated strategic pathways: a large-scale, infrastructure-driven trajectory (Sines) and a decentralised, innovation-driven trajectory (Leixões). A transversal vector—green hydrogen—is introduced as a bridging and future-oriented innovation pathway connecting both trajectories, illustrating how complementarities across ports can drive systemic transformation.

This highlights how ports navigate tensions not as constraints but as drivers of innovation, leading to distinct yet interconnected decarbonisation pathways.

5. Discussion

The findings of this study reinforce the view that decarbonisation in smart ports is best understood as a systemic and non-linear innovation process. Rather than following a predefined trajectory, ports develop context-specific pathways shaped by institutional conditions, resource endowments, and stakeholder configurations.

The comparative analysis of Sines and Leixões demonstrates that different strategic approaches can lead to effective decarbonisation outcomes. Sines exemplifies a scale-based pathway, where large investments and integration into global systems drive transformation. Leixões illustrates a network-based pathway, where innovation emerges through collaboration and regional ecosystems. These findings challenge the assumption of a single optimal model for port decarbonisation.

A key insight is the role of tensions as drivers of innovation. The need to reconcile competing demands forces organisations to develop hybrid strategies that combine elements of stability and change, centralisation and decentralisation, and efficiency and experimentation. This aligns with emerging perspectives in innovation studies that emphasise the importance of managing, rather than eliminating, contradictions.

Furthermore, the results highlight the importance of policy alignment and multi-level governance. European and national policies provide both direction and resources, but their impact depends on local implementation and institutional capacity. The interaction between policy frameworks and organisational strategies is therefore critical in shaping decarbonisation trajectories.

Although this study focuses on two large Portuguese ports, some of the underlying mechanisms identified may also provide useful insights for smaller ports. While smaller ports generally operate with more limited financial resources, infrastructure capacity, and institutional capabilities, they face similar challenges related to decarbonisation, digital transformation, and stakeholder coordination (ESPO, 2021).

Rather than replicating the large-scale investments observed in Sines or the extensive innovation networks developed in Leixões, smaller ports may benefit from adopting context-appropriate strategies centred on collaboration, gradual technological implementation, and regional partnerships. In this sense, the complexity and paradox perspectives developed in this paper offer analytical insights that extend beyond large ports, highlighting that successful decarbonisation depends less on scale itself than on the capacity to coordinate multiple actors, manage competing objectives, and develop adaptive governance arrangements.

Finally, the identification of green hydrogen as an emerging vector underscores the evolving role of ports as energy hubs. Beyond reducing emissions, ports are increasingly involved in the production, storage, and distribution of clean energy, creating new opportunities for value creation and innovation.

5.1 Implications for Innovation Theory

This study contributes to innovation theory by framing port decarbonisation as a form of systemic innovation that transcends organisational boundaries. It highlights the need to move beyond linear models of innovation towards more dynamic and integrative perspectives that account for complexity and interdependence.

By combining Complexity Theory and Paradox Theory, the paper offers a novel analytical lens to understand how innovation unfolds in environments characterised by uncertainty and competing demands. Complexity Theory explains how innovation emerges from interactions within adaptive systems, while Paradox Theory elucidates how organisations navigate tensions inherent in these processes.

The findings also suggest that tensions can play a productive role in innovation. Rather than hindering progress, they create conditions for creative problem-solving and strategic renewal. This perspective contributes to a growing body of literature that views paradox not as a problem to be solved but as a resource to be leveraged.

Additionally, the study highlights the importance of multi-actor ecosystems in driving innovation. Ports are not isolated entities but embedded in networks of stakeholders whose interactions shape innovation outcomes. This reinforces the relevance of ecosystem-based approaches in innovation research.

6. Conclusion

This study set out to analyse how smart ports navigate decarbonisation through the combined lenses of Complexity Theory and Paradox Theory, using a comparative case study of the ports of Sines and Leixões. The findings demonstrate that decarbonisation is a multifaceted and dynamic process that cannot be reduced to technological adoption alone.

A central conclusion is that there is no single pathway to successful decarbonisation. Instead, ports develop differentiated strategies that reflect their specific contexts, capabilities, and strategic priorities. Sines and Leixões exemplify two distinct but effective models: one based on scale and infrastructure, the other on networks and innovation ecosystems.

From an innovation perspective, the study highlights the importance of managing complexity and embracing paradox. The ability to navigate competing demands, adapt to changing conditions, and leverage multi-actor interactions emerges as a critical capability for sustainable transformation.

The identification of green hydrogen as a strategic opportunity further illustrates the evolving role of ports in the energy transition. By acting as hubs for clean energy production and distribution, ports can contribute not only to their own decarbonisation but also to broader systemic change.

In terms of future research, the study points to several avenues for further investigation. Empirical validation through primary data, including interviews with key stakeholders, would strengthen the findings and provide deeper insights into decision-making processes. Quantitative approaches, such as structural equation modelling, could also be used to test the relationships between the identified factors. Additionally, comparative studies across a larger number of ports would enhance the generalisability of the results.

Overall, this paper contributes to advancing the understanding of sustainable innovation in complex infrastructural systems, highlighting the importance of integrative theoretical approaches and context-sensitive strategies.

Furthermore, the complementary positioning of the Port of Sines as a large-scale production and export hub and the Port of Leixões as a regional distribution and innovation hub highlights a promising systemic configuration within the emerging green hydrogen economy. This complementary approach deserves further investigation in all its implications, particularly regarding its potential to foster integrated innovation ecosystems, enhance regional competitiveness, and accelerate the transition towards sustainable energy systems.

Capital Conversions in the Interaction Space between Social Entrepreneurship and Academic Field

Ksenija Vuković, Kristina Detelj and Irena Konecki
University of Zagreb, Varaždin, Croatia

ksvukovi@foi.unizg.hr
kristina.detelj@foi.unizg.hr
irena.konecki@foi.unizg.hr

Abstract: The paper examines the possibilities of capital conversion arising from the interaction of social enterprises and the academic field in Croatia. The objectives of this paper are multifold. The study investigates the extent to which social enterprises collaborate with academic institutions, identifies the dominant forms of the cooperation between them and examines the potential of capital conversions between their different forms through the cooperation. Additionally, the research analyses the direction and dynamics of knowledge spillover between the two fields, particularly focusing on the constraining conditions to such processes. The theoretical framework of the research combines Bourdieu's theory of practice (i.e. the concepts of capital and field) to understand the relations of actors and the used resources. This is complemented by the knowledge spillover theory, to explain how the knowledge circulates among the actors. Methodological framework relies on a qualitative research design. The empirical data were collected through phenomenological in-depth semi-structured interviews that were conducted among 30 social enterprises operating across various economic activities, with many of them focusing on the providing community services. The findings show multiple channels of cooperation of social enterprises with the academic community, including academic research in the field of social entrepreneurship, provision of services by faculties to social enterprises, joint partnerships in EU-funded projects, guest lectures and presenting social enterprises to students, supervision of students' theses and the use of social enterprises as teaching and practice bases. In addition to conventional, unidirectional knowledge transfer from academia to practical, the study also identifies reverse knowledge spillovers from social enterprises to the academic field. These results further demonstrate the interconversions of capital arising from the interaction of social entrepreneurs and the academic actors. However, the obstacles to greater use of knowledge spillover to improve the efficiency of social enterprises exist primarily due to the limited financial resources.

Keywords: Bourdieu's Theory, Capital Conversions, Knowledge Spillovers, Qualitative Approach, Social Enterprises

1. Introduction

In this article we explore the hybrid space of contact between the social entrepreneurship field and the academic field, where distinct types of capital—cultural, social, symbolic, economic—are converted resulting in knowledge spillovers that create social value, often in resource-constrained contexts. The study pursues three objectives: 1) to assess the extent of cooperation social enterprises in Croatia with academic institutions; 2) to identify the dominant ways of cooperation between social enterprises and academic institutions in Croatia; 3) to analyse the potential for capital conversions in cooperation between the higher education institutions and social entrepreneurs and the direction of knowledge spillovers. In line with these objectives, we pose the following research questions:

1. To what extent and in what way do social enterprises in Croatia cooperate with faculties and schools?
2. What are the potentials of interconversion of capital in cooperation between faculties and social enterprises?
3. What is the direction of knowledge spillover between academic institutions and social enterprises?

In this article, we use the terms academic field and social entrepreneurship field. The academic field in this research implies a broader concept that encompasses not only faculties and research institutes, but also the wider educational space, including kindergartens, primary and secondary schools, and libraries. The field of social entrepreneurship in this research includes social enterprises, cooperatives, associations and companies with social impact.

2. Theoretical Framework

The core theoretical framework draws on Bourdieu's theory of capital and practice, complemented by selected elements of knowledge spillover theory. Summarizing the salient features of Bourdieu's theory, it can be concretized as an aspiration to explain how social actors, driven by the struggle for power embodied in different forms of capital, implement strategies or practices of their conversion. These practices are shaped in the

relations of actors within the social structure, or field, while at the same time having the potential to reshape the structure in which they occur (De Clercq and Voronov, 2009; Stringfellow et al., 2014). It is a relationship represented by Bourdieu with the formula: (habitus x capital) + field = practice (Bourdieu, 1984, p. 101; Forson et al., 2014, p. 62), which represents the essence of his "economy of practices" (Pouliot and Mérand, 2013).

By the term field, Bourdieu understands a relatively autonomous social microspace, that is, a space of objective relations as a place of special logic in relation to other fields (Bourdieu and Wacquant, 1992, p. 97). Özbilgin and Tatli (2011) single out two criteria for defining Bourdieu's field: relationality (the field is made up of relations between actors) and power structure (it is defined through the positions of different actors in relation to other actors) (Özbilgin and Tatli, 2011, p. 1233; Tatli et al., 2014, p. 10). According to Bourdieu (1986), there are four types of capital:

1. Economic capital (physical and financial capital);
2. Social capital (connections and relationships related to connection and embeddedness in the social environment);
3. Cultural capital (dispositions and views on the world, education, experience, cultural artifacts in institutionalized and objectified form); and
4. Symbolic capital (social status, prestige, legitimacy).

Motivated by improving their own position in the field, actors fight for a monopoly over those forms of capital that are valuable in that field, carrying out what Bourdieu (1986) calls capital conversions. Bourdieu (1986) emphasizes the fungibility of certain forms of capital, i.e. the conversion of one form of capital into another. For example, the conversion of economic capital into other forms of capital is possible through investment in education (cultural capital) and access to the associated social networks (Pret et al., 2016). Social capital, in turn, can be converted, for example, into a form of cultural capital, since an individual's contacts with experts in a particular field potentially enrich their embodied cultural capital, while connections to reputable educational institutions facilitate their access to formal certificates (Portes, 1998).

Given that cultural capital is an important resource in the field of social entrepreneurship and in the academic field, the space for research into the interaction of these two fields opens up. Therefore, we supplement the theoretical framework we use in this article with knowledge spillover entrepreneurship theory. Although the area of innovation in scientific research is dominant within the framework of Schumpeterian entrepreneurship, recent trends open a wider space for the application of the theory. Audretsch et al. (2025) state that the knowledge spillover theory of entrepreneurship and innovation remains the basis for understanding the role of entrepreneurship in growth and sustainable innovation, but that it is necessary to integrate other sources of knowledge, including knowledge from the public sector and non-for-profit organizations, knowledge obtained via green R&D and take into account other complementary concepts such as reverse knowledge spillover, according to which actors can learn from each other. The approach of inter-industry spillovers (Jacobs, 1969), focuses on the importance of the exchange of ideas between different sectors and the fertility of ideas that contribute to the improvement of innovation and growth. According to this theory, greater diversity in the region (diversification) leads to more significant sectoral growth. In the context of our research, this type of spillover we would call inter-field spillovers, as it is more appropriate for education and social entrepreneurship field.

3. Methodological Approach

3.1 Sample

The respondents were selected according to the purposeful sampling principle inherent in qualitative research (Patton, 2002). Since the intention is not to generalize the findings to broader population but to examine the phenomenon in depth, the goal of purposeful sampling is to identify units that represent information-rich cases. 30 social entrepreneurs from diverse sectors (including the agriculture, industry, cultural and creative sectors, printing, architecture, and community service provision) were interviewed. In addition to the heterogeneity of the activities undertaken by these social enterprises, the respondents also exhibit considerable geographical diversity, representing enterprises operating across various counties, cities, and rural areas throughout Croatia.

Of the 30 participants, three hold only secondary education, while one respondent possesses an undergraduate degree. The remaining participants have completed graduate-level education, including four with doctoral qualifications. Because the social enterprises represented in the sample operate across a wide range of industries, the educational backgrounds of respondents are correspondingly diverse. The largest group consists

of individuals with business-related degrees (14), primarily in management. This is followed by respondents trained in technical and STEM fields, including mechanical engineering (2), architecture (2), natural sciences and mathematics (2), electronics and computing (2), robotics (1), food technology and biotechnology (1), agronomy (1), and medicine (1). The sample also includes individuals educated in the social sciences and humanities, such as sociology, journalism (2), teacher education, philosophy, and ethics.

3.2 Data Collection

Primary data were collected through in-depth interviews supplemented by researcher's observation. Since the conducted research was focused on a detailed examination and understanding of the phenomenon from the perspective of the respondents, an in-depth interview was identified as the most suitable data collection technique (Patton, 2002). In order to enhance the comprehensiveness and understanding of the research topic and to improve the validity and credibility of the research, we applied the triangulation (Patton, 2002) in three forms: a) combining the interviewing and observing during data collection; b) involving at least two researchers in both, the interview process and in the subsequent data analysis; and c) using complementary theories to explain the phenomenon. During the interviews, the researchers wrote notes based on unstructured observations of participants, in order to ensure the quality of the primary data on certain elements of the embodied and objectified cultural capital of entrepreneurs, such as manners, non-verbal communication, style of conveying their ideas, clothing style). The interviewees were initially contacted via e-mail, and the agreed interviews lasted from 60 to 90 minutes. The interviews were conducted via Zoom and, with prior informed consent, were audio-recorded to ensure the subsequent production of accurate transcripts. The interviews took place during June and July 2025.

3.3 Analysis of Empirical Data

The manual analysis of the empirical material began with listening to the audio content, multiple readings of the written transcripts and generating a substantial set of initial codes. During the phase of focused coding, we grouped the data and defined the preliminary categories. In the following phase of axial coding the data were reconnected by determining relationships between the data within a certain category and the relationships across the categories themselves. This process of axial coding identified more connections between several key categories, which enabled us to develop the more integrated and theoretically coherent interpretation of the empirical material. In order to reduce the unconscious biases and individual subjectivity of the researcher, at least two researchers participated in conducting interviews and in the data analysis.

4. Results and Discussion

Researchers are increasingly interested in fields that offer the potential for identifying high-value manifestations of social, cultural and symbolic resources, as well as for analyzing the dynamics between different forms of entrepreneurial and corporate capital. Within the interspace between the field of social entrepreneurship and the academic field, interactions occur that create opportunities for various forms of capital conversion. Several studies adopt a narrower focus in such hybrid fields. One example is the field of creative and cultural industries, where commercial logic is closely intertwined and clashes with the ethos of art (Pret et al., 2016, Vuković et al., 2021). Another example is the field of social entrepreneurial education (Karataş-Ozkan et al., 2023), in which social values are equally valuable as economic values. Among 30 social enterprises participating in our study, 15 reported active cooperation with academic institutions, which makes up 50% of the enterprises from the sample in this phase of the research. These collaborations take multiple forms, which are in the following section.

4.1 Capital Conversions – From Social and Cultural to Economic Capital Through the Mediation of Symbolic Capital

According to the analysis of our primary data, the capital conversions of social entrepreneurs in the area of interaction with the academic field occur predominantly according to the pattern of the transformation of social and cultural capital into symbolic capital, which ultimately transforms into economic capital (Figure 1).

Figure 1: Capital conversions of social entrepreneurs in interaction with the academic field

4.1.1 The Dominance of Social Capital in the Magnitude and Frequency of Conversion

The importance of network ties plays a major role in the accumulation of entrepreneurs' resources (Pret et al., 2016; Shaw, 2006). Although it is a hybrid type of organization (Pache and Santos, 2013) in which both social and economic goals are represented, the importance of social capital dominates the social entrepreneurial field *("In social entrepreneurship, social capital is more valuable than financial capital."*, p. 17). Social entrepreneurs often operate in conditions of scarce resources, and therefore it is important to use social capital to access resources (Karataş-Ozkan et al., 2023). Since in this research we examine the forms and conversions of capital that arise from relationships with academic institutions, we list the types of social ties that specifically arise from this relationship. For example, a participant whose social enterprise is a park of science that is visited by organized groups from schools and kindergartens, as well as families with children, individually emphasizes the importance of the relationship that is created with the children (visitors), which is visible in the positive reactions they receive through the survey questionnaire that the children fill out after the tour ("*That is our strength"*, P1). This results in the conversion of the reputation into symbolic capital, which becomes the foundation for increasing economic capital in the future through repeated visits or passing on positive experiences to new potential visitors. Some social enterprise and social impact entrepreneurs see associate faculties as allies.

Anderson et al. (2010) state that strategic alliances act in the direction of the revitalization of the company's resource base through the integration of sets of competences and the creation of strategic considerations that combine entrepreneurial intuition and creativity into a vision of the future (Anderson et al., 2010) and enable the ease of transfer of tacit knowledge (Anderson et al., 2007). Respondent P27 points out that he wants stronger cooperation with faculties ("*FOI* (Faculty of Organization and Informatics) *is our ally, based on that, we want to approach others as well. We want to enter into a certain strategic partnership, not only as an example of good practice, but for the faculty to conduct research based on which we would increase our effectiveness*."). This would result in the conversion of social capital into the cultural capital of a social enterprise. Karataş-Ozkan et al. (2023) point out that "the people-centered approach, empathy and reflexive agency are all components of these competencies, which can be mobilized through conversion of capitals" (p. 115). Respondents emphasize the importance of presenting good company practices to students (*"We have several presentations, which in turn benefit the children, that is, students to be quality, correct, tolerant, self-confident people with broader perspectives."*, P27).

The social capital of social entrepreneurs can be converted into economic capital through connections with university students ("*We visit universities, it's free marketing for us. We were guests at lectures and presented entrepreneurship. We would like to have these collaborations because it's good for promotion*", P16). Presentations at various events enable the presentation of products and the creation of a customer base, and in this way the conversion of social into economic capital occurs (Jack et al., 2010). ("*Yes, what surprised us at that first Interliber, which was not really to be expected, because I was thinking only of children, but a lot, a lot of professional associates, such as librarians, speech therapists, child psychologists, teachers, foreign language teachers, etc., approached us and they were delighted that it was actually a good tool for working with children*.", P4). There are examples where the conversion of social capital into economic capital is visible ("*This entire space was designed in collaboration with the PBF in Zagreb with the Department of Confectionery Technology and Process Design, they did some pro bono, we paid them some, but less.*", P14).

Actors from the social entrepreneurship field are frequent partners of faculties and schools in projects financed by European Union funds ("*They* (projects) *included a fairly large part of faculties and some of the civil sector. So, whenever there are such mixed partnerships, they mostly recognize us, because people with disabilities are a very interesting target group*.", P23). In this process, social capital is transformed into cultural capital and simultaneously enriches social capital by creating new contacts and relationships.

4.1.2 Cultural Capital – Possibilities of Interconvertibility and Intraconvertibility and Obstacles in the Process

In our research, social entrepreneurs draw on their embodied cultural capital in several ways when interacting with the academic field. Regarding the direction of knowledge spillover, there are three distinct pathways: from social enterprises to faculties – students, professors, researchers; from faculties and research institutes to social enterprises; and through joint projects with mutual interaction. Partly of the cultural capital embodied in products and services is transferred through collaborative non-market mediation, while part circulates through the market field, where social enterprises charge users for their services (e.g. tickets for a park of science). When the embodied cultural capital of social entrepreneurs becomes materialized as objectified cultural capital, it functions as a product that enters the market-like exchange within the academic field. This interaction not only converts cultural into economic capital, but also promotes the intraconversion of cultural capital within the academic field, and further transforms into social capital, as illustrated by one of the research participants:

"*So it's, it's like a fairy tale storytelling workshop and we use a social game as a tool. Usually these are (*those who buy the service, ed.*) libraries, schools, kindergartens, I don't know, the Trešnjevka theater called us several times. So, educational institutions are willing to pay for it*." (P4)

They deliver their knowledge and experience by holding expert workshops at faculties, by being guests at scientific conferences or as co-organizers of study visits ("*The Faculty of Law had a study visit and they brought in collaborators from outside*.", P14). The embodied knowledge and experience of social enterprises are often used for the benefit of students and pupils. This occurs through activities such as visits to the premises of social enterprises, including exposure to production processes (e.g., agricultural production). Several organizations also contribute to the development of the cultural capital of students in faculties and schools by serving as teaching bases for academic programs. ("*The association is a teaching base for two faculties*," P21) or students conduct internships in them ("*They cooperate a little with schools, we contacted schools from Ploče, Metković, to conduct internships with us on CNC machines*.", P20). Connecting with students from different faculties who are writing their diploma theses is relatively frequent ("*Recently, there were students from the Faculty of Economics, one of whom wrote a paper about the company*.", P9). In the aforementioned ways, the embodied cultural capital of social enterprises (knowledge, experiences, skills) is transformed into social capital, but there is also a spillover of knowledge into the academic field. Social entrepreneurs also participate in scientific research (most commonly as respondents in interviews and surveys, after which the research results are shared with them. ("*We participate in research as respondents of researchers from faculties and institutes. Very good cooperation, not very large, but everyone knows each other, works are shared after publication as well as information, we are a small country and the sector is not large, cooperation is lively*", P22).

Social enterprises also act as active partners in the implementation of scientific projects. Cooperation in the domain of professional knowledge occurs through project-based partnerships financed by EU funds, through the conduct of laboratory analyses at academic institutions, and through the provision of samples to faculties (e.g., seeds). Respondents emphasize the value and usefulness of participating in joint projects with academic institutions. ("*I benefited the most from that feedback, whether we are moving in the trend or something more, that somehow more comprehensive picture of everything. As far as social services and social entrepreneurship are concerned, in practice we sometimes forget to look beyond our noses and beyond our homes.*", P23).

Our findings align with previous research on the existence of reverse knowledge spillovers (Vinona et al., 2026), a phenomenon explicitly noted by several participants. As one respondent explained:

"*We wanted to cooperate with the university, develop new technology, but it did not come to fruition because science and industry are very far apart. In fact, the real research today takes place in companies*." (P15)

Another respondent further illustrates the transfer of embodied cultural capital—in the form of specialized, accumulated expertise—into the academic field, thereby generating a knowledge spillover in the reverse direction: "*But in fact, in this field of solitary bees, I can even say that I educate them more than I have benefited from experts from scientific institutions about solitary bees. As for the scientific community, especially in our country, it is mainly focused, when talking about bees, on honey bees. There are very few experts who study solitary bees in more depth*." (P3)

Lack of economic capital can prove to be an obstacle to cooperation and fulfilling the expectations of social entrepreneurs from actors in the academic field. Several social entrepreneurs pointed out that there were attempts at cooperation but they failed, most often due to a lack of economic capital on the part of academic institutions and social enterprises ("*Poor people often lack money* (faculties) *for everything they would like. There were some ideas for a joint project, that they would take some equipment, and they would do analyses for it.*

However, they are very attached to these projects, because they somehow do not have their own money.", P2). Although economic capital is not crucial in either the field of social entrepreneurship or the academic field, research shows that a lack of financial resources can stifle the potential for increasing and spilling over cultural capital, as well as the possibility of its conversion into other forms of capital.

5. Conclusion

In the article, we present only a fragment of the capital conversions of social entrepreneurs, since we take into account only a part of the actors that make up the social capital network, namely the institutions in the academic field. However, the pattern of conversion is in line with research (Pret et al., 2016, Karataş-Ozkan et al., 2023) in the field of creative and cultural industries and the field of social education, but also in other profit-oriented business fields in which cultural capital, i.e. knowledge and education, plays a major role, e.g. in the software industry (Šmaguc and Vuković, 2024), according to which it is evident that financial capital does not play a decisive role. Social and cultural capital play a key role and they are converted into economic capital through the mediation of symbolic capital. On the one hand, such a specified approach represents a limitation for creating a complete picture of the capital conversion of social entrepreneurs. On the other hand, such an approach opens up space for continued research into the interconversion and intraconversion of all forms of social entrepreneur capital in interaction with academic institutions, where the possibilities of working on "new pedagogies, which focus on positive, hopeful transformations, shaping an entrepreneurship that is environmentally positive, socially inclusive and ethically aware" can be examined (Dodd et al., 2022, p. 2).

The research did not reach a saturation point in terms of the conversion of social entrepreneur capital for two reasons. The first reason is that this article includes an analysis of empirical material from the first phase of the research, in which 30 social entrepreneurs participated, and thus does not exhaust the range of the total wealth of cooperation between social enterprises and academic actors. The second reason is that the capital conversion of entrepreneurs from the field of social entrepreneurship is limited to interaction with one field, academic, while in reality the potential for capital conversion of social entrepreneurs arises from relationships and connections with all the other stakeholders from other fields, such as other social entrepreneurs or entrepreneurs who are predominantly profit-oriented, then connections with customers, suppliers, media, followers on social networks, institutions at the local or national level, actors in the international field. Although it is unquestionable that social, cultural and symbolic capital is of crucial importance for social entrepreneurs, research nevertheless indicates that the lack of economic capital can be a barrier to the increase and convertibility of the capital of social entrepreneurs and an obstacle to the spillover of knowledge from the academic field to the field of social entrepreneurship and in the opposite direction. The intention of the researchers is to orient the research in two directions. We would supplement and upgrade the existing analysis by additional examination and analysis of data from a larger database of social entrepreneurs to the point of saturation. This would show the possibility of capital conversion through relations with all actors, and the approach based on Bourdieu's theory would be complemented by an additional theory that, in addition to the static presentation of actors' dispositions and capital, would provide insight into the potential of actors to influence changes in structure, i.e. changes in culture and politics in the context of specific structural forces (Steiner et al., 2022).

Ethics Declaration

The authors committed to respect the principle of anonymity, as well as all the other ethical rules in conducting the research, and it received approval from the institutional ethics committee.

AI Declaration

AI tools were not used in the development of the ideas, data analysis, or the writing of this paper. Microsoft Copilot was used only after the manuscript had been completed, and solely for grammar correction and minor language polishing.

Abstract: The cooperative use of data in data ecosystems is central to realizing the potential of data-based value creation. Data trustees, neutral intermediaries between data providers and users, are intended to promote trust and legal clarity in accordance with the EU Data Governance Regulation. While the technical aspects of such models have been professionally researched, the legal requirements from a business perspective have largely been overlooked. This paper aims to shorten this research gap by examining (1) requirements companies place on the legal design of data trustee models and (2) legal forms used in practice. Based on twelve qualitative expert interviews 30 specific legal requirements were identified such as ensuring the legal independence of the data trustee, ownership of data or information, and the decision-making process. This paper contributes by conceptualizing legal requirements as a design dimension of data ecosystem governance and providing a structured requirement framework derived from empirical evidence.

Keywords: Data Trustee, Data Ecosystems, Legal, Requirements, Cooperative Use

1. Introduction

The cooperative use of data has become a key enabler of digital transformation. Corporate value creation increasingly relies on the generation, integration, and reuse of data rather than solely on physical products or traditional services (Gelhaar et al., 2021). However, realizing this potential often requires collaboration across organizational boundaries in so-called data ecosystems, where multiple actors combine complementary data, capabilities, and technologies to jointly create value (Oliveira & Lóscio, 2018).

Despite their innovation potential, data ecosystems face significant challenges. In particular, lack of trust and legal uncertainty remain key barriers (Cappiello et al., 2020; Fassnacht et al., 2023). Without mechanisms ensuring trustworthy and legally compliant data sharing, their potential often remains unrealized. In this context, data trustees have emerged as a governance mechanism, particularly in Europe, acting as neutral intermediaries between data providers and users while ensuring compliance with legal, ethical, and contractual requirements (Abel et al., 2023; Braud et al., 2021). In line with the European Data Governance Regulation (DGA), they operate in the interest of data subjects and providers and are characterized by a fiduciary role that distinguishes them from other intermediaries (European Parliament and Council, 2022).

Data trustee models can take different organizational and legal forms, including for-profit, non-profit, and governmental variants (Lipovetskaja et al., 2024). While initiatives such as GAIA-X highlight their growing relevance, they are often driven by technological and regulatory considerations, leaving the business perspective underexplored. It remains unclear which legal requirements companies consider necessary for data trustee models to create business value and be implemented in practice. Existing initiatives may fail when legal structures are overly complex or misaligned with organizational needs (Weber et al., 2022; Agdatahub, 2024).

Against this background, this paper addresses the following research questions:

RQ1: What legal requirements do companies expect for the design of data trustee models?

RQ2: Which legal organizational forms are used to implement data trustee models in practice?

To address these questions, we conducted 12 semi-structured expert interviews based on concrete use cases to elicit context-specific requirements. The findings were validated by a legal expert and complemented by a secondary analysis of existing initiatives.

From a theoretical perspective, legal requirements can be understood as design elements of governance structures in data ecosystems. While existing research focuses primarily on technical and organizational aspects, the legal dimension remains underexplored. By identifying and structuring legal requirements, this study contributes to the conceptualization of legal governance mechanisms as a design area for data trustee models.

2. Related Work and theoretical Background

This section introduces data ecosystems as the broader context, conceptualizes data trustees as a governance mechanism, and outlines the structure of data trustee models to derive the research gap.

2.1 Data Ecosystems

Business ecosystems consist of economically independent actors combining complementary capabilities to create value (Moore, 1993). Following Adner (2017), this work adopts a cooperative value creation perspective in which value creation shapes partners, activities, and coordination. Transferred to the digital domain, data ecosystems are based on cross-organizational data exchange as a key driver of innovation (Oliveira & Lóscio, 2018). Despite their potential, many data ecosystems fail to generate economic value due to limited incentives, varying levels of maturity, and insufficient mechanisms for coordination and trust (Cappiello et al., 2020; Fassnacht et al., 2023). These challenges highlight the need for governance mechanisms that enable trustworthy and legally compliant data sharing across organizational boundaries, which has led to the emergence of data trustees (Braud et al., 2021).

2.2 Data Trustees

Data trustees have gained increasing attention as a response to these challenges (Lindner & Straub, 2023). They build on the concept of data intermediaries - neutral entities facilitating data exchange while addressing regulatory, technical, and trust-related barriers (Janssen & Singh, 2022; Schweihoff et al., 2024). Such intermediaries must comply with legal frameworks such as the Data Governance Act (DGA), ensuring neutrality, transparency, and data security (Carovano & Finck, 2023; European Parliament and of the Council, 2022; Richter, 2023).

Data trustees represent a specific type of intermediary characterized by fiduciary responsibility, managing data on behalf of providers in accordance with predefined governance rules (Janssen & Singh, 2022). Unlike other models such as data marketplaces or data pools, they are defined by their obligation to act in the best interest of data providers rather than by market-based incentives (Stachon et al., 2023).

2.3 Structure of a Data Trustee

A data trustee acts as a central intermediary between data providers and users, facilitating data exchange within defined governance structures (Abel et al., 2023). Operators may include public institutions, research organizations, or firms; this study focuses on company-led consortia (Lindner & Straub, 2023). Members typically act both as data providers and users, contributing and utilizing data to develop data-driven business models. External users may also access services as customers, supported by technology partners (“trust enablers”) (Baars et al., 2021).

Despite growing interest, research has focused primarily on technical aspects such as infrastructure and security, while governance and organizational perspectives remain less developed (Rieder et al., 2025). In particular, the legal design of data trustees from a business perspective is underexplored (Fassnacht et al., 2023; Weber et al., 2022).

As a result, the legal requirements necessary to ensure trust, usability, and economic viability remain insufficiently understood, motivating the research questions of this study.

3. Research Design

This study follows an exploratory qualitative research design (Creswell & Creswell, 2018) to investigate the legal requirements of data trustee models from a business perspective. The design combines three sequential components: expert interviews to identify legal requirements, evaluation workshops with a legal expert to validate and operationalize them, and a secondary analysis of existing initiatives to examine legal organizational forms in practice. The findings from these components were subsequently compared and integrated. Figure 1 illustrates the research design.

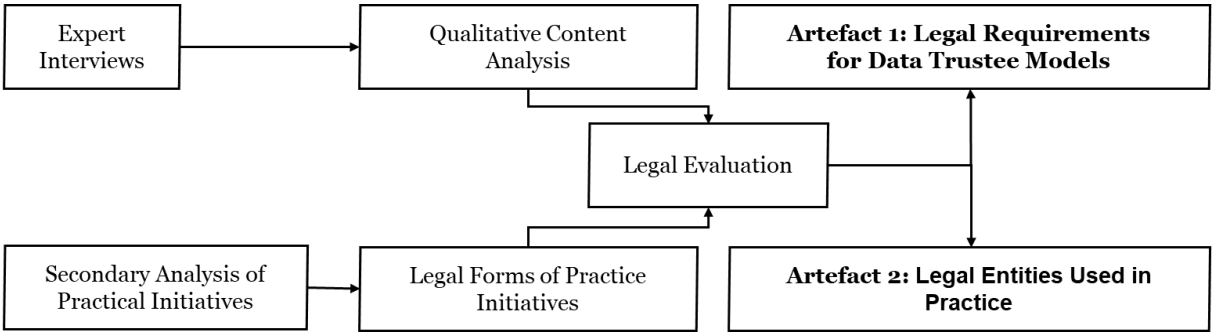

Figure 1: Research Design

3.1 Data Collection

3.1.1 Expert Interviews

We conducted 12 semi-structured expert interviews until theoretical saturation was reached, i.e., no substantially new insights emerged during iterative coding. In line with qualitative research standards, saturation was considered achieved when additional data confirmed existing patterns rather than generating new conceptual insights (Creswell & Creswell, 2018). Although the sample is limited in quantitative terms, qualitative research prioritizes depth and heterogeneity over size. The selected interviewees represented different industries, organizational sizes, and roles within data ecosystems, supporting the identification of robust and transferable requirement categories. All interviewees operated within the German legal context, which reflects the relevance of European regulations such as the Data Governance Act, but also limits generalizability. Interviews were structured around concrete data ecosystem use cases to elicit context-specific legal requirements. Conducted between November 2023 and February 2024, they lasted 60–90 minutes and took place either on-site or via video conference. A semi-structured guide with 13 questions was adapted to each interviewee. All interviews were conducted by two researchers, recorded, transcribed, and manually revised. Table 1 provides an overview of the participants.

Table 1: Participants of the Interviews

#	Interviewee Position	Organization	Employees
1	Technical Sales for Industrial Applications	Manufacturer of Electrical Switching Devices	50-249
2	Deputy Head of Stakeholder Representation	Association for Cooperative Organizations	1.000-9.999
3	Head of Project Management	Company for Renewable Energy Solutions	10-49
4	Chief Executive Officer (Managing Director)	Industry Association for Trade and Services	10-49
5	CEO/Co-Founder	Research Institution for Industrial Mathematics	10-49
6	Chief Executive Officer	Technology Startup Focused on AI and Finance	10-49
7	Executive Leadership	Trade Representation for Industrial Products	10-49
8	Executive Leadership	Consulting Firm for IT and Information Systems	10-49
9	Vice President – Global Head of Industrial and Energy Products	Testing and Certification Service Provider	10.000+
10	Chief Executive Officer	Provider of Efficiency Solutions for Businesses	1-9
11	Head of Product Management	Manufacturer of Sensors and Automation Technology	1.000-9.999
12	Senior Advisor for Data-Driven Business Models	Software Provider for Tax Consulting and Financial Services	1.000-9.999

3.1.2 Analysis of Existing Initiatives

A secondary analysis of existing data trustee initiatives was conducted to examine legal organizational forms in practice. The analysis started with the IDSA Data Space Radar and was extended through snowball sampling. For each initiative, legal form, sector, geographical location, and development stage were identified through a structured review of publicly available sources, including official websites, reports, and documentation.

3.1.3 Workshops

Two workshops with a legal expert specializing in data protection and regulation were conducted in August and December 2024. Their purpose was to evaluate the requirement *derived from the interviews and to assess their applicability across legal entities. The workshops were documented through photo protocols and observation notes and analyzed using qualitative content analysis (Mayring, 2014). They served to validate and operationalize the interview findings*.

3.2 Data Analysis

The 12 interview transcripts were analyzed in MaxQDA using a structured deductive–inductive coding approach, based on Mayring's qualitative content analysis (Mayring, 2014). Initial categories were derived from existing conceptualizations of data trustee structures, while subcategories were developed inductively from the empirical material. To ensure consistency, a consensual coding approach was applied: one researcher conducted the initial coding, which was then reviewed and iteratively discussed with a second researcher. An overview of the coding scheme is provided in the appendix.

The workshop results were integrated as an additional legal perspective, mapping interview-derived requirements to potential legal documents and frameworks. The secondary analysis of initiatives combined qualitative coding with quantitative counts of legal forms, sectors, locations, and lifecycle stages. Finally, the study triangulated the interview findings with the secondary analysis to identify consistencies, discrepancies, and broader patterns. Through this process, 30 legal requirements were derived and iteratively refined into a coherent solution space for the legal design of data trustee models..

4. Findings

The identified requirements should not be understood as an isolated list of legal conditions, but as interrelated design elements shaping the governance of data trustee models. In this sense, they represent a conceptual framework for the legal design of data ecosystems and extend existing governance literature by specifying its legal dimension from a business perspective.

The findings are presented in two parts. First, the interview results identify legal requirements for data trustee models. Second, the secondary analysis examines the legal entities used in practice and compares them with the interview findings.

4.1 Findings Regarding Legal Requirements

Based on the expert interviews, 30 requirements were identified across different use cases. These requirements relate to the legal structures needed to implement data trustee-based business models. They are not mutually exclusive but form a solution space from which organizations can derive application-specific legal arrangements.

To add analytical depth, we also considered how frequently requirements were mentioned across interviews. Frequency is not interpreted as a proxy for importance, but as an indication of how broadly a requirement is shared across use cases and organizational contexts. Some requirements are widely shared, while others are highly context-specific but still critical in particular business models. Requirements with no directly traceable subfunction in the coded interview material are marked with 0 and should be interpreted as derived from complementary legal or conceptual analysis rather than from the interview coding No ranking is therefore applied.

Table 2: Findings from the Interviews

#	Requirement	Description	
1	Authorization to process data	Regulations governing the conditions under which data may be processed and the purposes for which it may be processed.	6
2	Balancing of interests	Ensuring that the interests of all parties involved are adequately balanced.	5
3	Body of the data trustee	Definition of the composition and tasks of the bodies of the data trustee.	7
4	Commitment and long-term security	Guarantee of long-term security and reliability for all parties involved.	4
5	Compliance with legal requirements	Ensuring compliance with all relevant legal requirements.	4
6	Confidentiality agreements	Provide for confidentiality agreements to protect sensitive data and information.	0*
7	Cooperative objectives	Binding definition of the common objectives of the partners involved.	5
8	Data anonymization	Establishment of data anonymization as a requirement for processing.	0*
9	Data collection requirements	Definition of the requirements for data collection.	9
10	Data quality requirements	Binding requirements for the quality of the data provided.	10
11	Data transfer requirements	Binding definition of the conditions and standards for data transfer.	9
12	Decision-making powers of the institutions	Definition of the decision-making powers of the data trustee.	7
13	Decision-making process	Binding regulation of the decision-making process within the data trustee. Definition of members' co-determination rights in relation to important decisions.	6
14	Distribution of revenues	Regulations on the distribution of revenues generated by the data trustee.	5
15	Ensuring the legal independence of the data trustee	Ensuring that the data trustee can act independently from a legal perspective.	2
16	Integration of new members	Establishing the conditions and process for integrating new members.	9
17	Integration of external partners	Clear regulation of the integration of external partners into the data trustee.	2
18	Liability regulations	Clear regulation of the liability of the parties involved for errors and damages.	0*
19	Ownership of data/information	Clear regulation of ownership of provided and generated data and information.	10
20	Participation in value growth	Contractual regulation of members' participation in the value growth of the data trust.	5
21	Payment for data trustee services	Contractual agreement on payment for data trustee services.	0*
22	Protection against damage caused by partners	Regulations that protect the data trustee and its members from damage caused by other partners.	3
23	Regulations for missing data	Regulations for dealing with missing or incomplete data.	4
24	Regulations on capital contributions	Binding definition of the type and amount of capital contributions by members.	2

#	Requirement	Description	
25	Regulations on cost distribution	Binding definition of the distribution of costs incurred among the parties involved.	5
26	Regulations on IP rights	Clear definition of the regulations on intellectual property rights (IP rights).	0*
27	Regulations on the distribution of shares	Clear regulation of the distribution of shares in the data trustee model.	0*
28	Regulations on the use of data/information in relation to third parties	Definition of which data and information may be passed on to third parties.	6
29	Service level agreements	Establishing Service level agreement (SLA) on the quality and availability of services.	4
30	Termination and withdrawal rights	Clear regulation of the rights to terminate and withdraw from the data trustee.	0*

Selected examples illustrate the diversity and practical relevance of the requirements. Commitment and long-term security were described as especially important in early-stage collaborations, where trust is initially built through personal relationships before being formalized legally. Compliance with legal requirements was highlighted as essential, particularly regarding GDPR and sector-specific regulation. Cooperative objectives were framed as a need to enable broad data exchange with minimal contractual overhead. In technical use cases, data collection and transfer requirements were especially prominent, for example regarding sensor configuration, quality assurance, and continuous or event-driven data flows. Economic design issues also varied across cases, especially regarding participation in value growth and the distribution of shares. Finally, several interviewees emphasized mechanisms to protect against damage caused by partners and to handle missing data in a transparent and traceable way.

The analysis also revealed inherent tensions between requirements. A central trade-off exists between flexibility and legal certainty: some interviewees favored lean and adaptable structures, while others stressed formalized and robust legal frameworks. A second tension concerns participation and decision-making, ranging from equal voting rights to proportional influence based on investment or data contribution. A third trade-off lies between data accessibility and data protection, as business value depends on data use while compliance limits unrestricted sharing. Finally, interviewees highlighted a balance between simplicity and completeness of legal design: streamlined arrangements reduce complexity, but more comprehensive frameworks may be necessary to address liability, governance, and long-term stability. These tensions show that the requirements form a design space rather than a single optimal model.

4.1.1 Evaluation of Legal Requirements

To assess the practical applicability of the identified requirements, a subsequent evaluation step was conducted. This evaluation does not introduce a separate set of findings, but operationalizes the interview-based requirements in the context of legal system design. The workshops with the legal expert therefore translated the identified requirements into concrete legal design elements.

The evaluation showed that early-stage collaboration can often be supported by letters of intent and confidentiality agreements, but these instruments are insufficient for scalable long-term cooperation. The workshops resulted in eight document clusters forming the basis of a modular legal framework: pre-contractual letters of intent and confidentiality agreements, organizational competencies and statutes, membership and partner agreements, contractual bases for data processing, data storage and IT security regulations, access and usage provisions, documentation and audit obligations, and compliance, risk, and ethics guidelines. The analysis further showed that legal requirements are generally transferable across different legal forms, but always require context-specific implementation. In addition, the distinction between for-profit and non-profit trustees has important implications for governance and scaling. Overall, the findings suggest that robust data trustee models require a modular and phase-oriented document system rather than a single legal form.

4.2 Findings Regarding Legal Entities

The secondary analysis covered 57 data trustee initiatives identified through the IDSA Data Space Radar and extended via snowball sampling. For each initiative, information on legal form, sector, geographical location, and development stage was collected from publicly available sources. Due to space limitations, the full list is not included in the paper but can be provided on request.

Geographically, most initiatives were located in Germany (18), Austria (12), and the Netherlands (10), with others in Belgium, China, Finland, France, Ireland, Italy, Norway, and Switzerland. Sector-wise, initiatives were mainly cross-sectoral (12), followed by mobility (7), energy (6), manufacturing (5), green deal projects (5), and supply chain logistics (3), with additional cases in agriculture, health, smart cities, sports, and tourism. Regarding lifecycle stage, the majority were in initiation (30), pilot (13), or scaling (10), with 2 unclassified. Legal forms were dominated by registered associations (22) and foundations (11), while six initiatives operated as hybrid forms, six as public-law corporations, and four as private limited liability companies.

4.2.1 Evaluation of Legal Entities

Comparison with the interview findings shows that bilateral contracts are common in early-stage data collaborations but become limiting as cooperation scales. Interviewees therefore emphasized the need for flexible legal structures combined with governance mechanisms that allow adaptation over time. At the same time, the analysis revealed a gap between existing practice and business preferences: while many current initiatives rely on non-profit-oriented forms such as associations and foundations, the interviews indicate a stronger preference for economically oriented legal forms in industry. In addition, the findings suggest that large-scale ecosystem initiatives require broad, standardized legal infrastructures, whereas smaller consortia benefit from leaner and more use-case-specific legal arrangements.

5. Implications

This study conceptualizes legal requirements as design elements of governance structures in data ecosystems, providing a foundation for systematically analyzing and comparing different data trustee configurations.

The results show that unclear legal frameworks remain a key barrier to realizing the potential of data ecosystems (Cappiello et al., 2020; Gelhaar et al., 2021). By identifying and structuring legal requirements from a business perspective, this study clarifies how legal frameworks can be designed to support data-based value creation. The findings highlight that effective legal structures must be tailored to specific use cases rather than applying overly complex or generic solutions.

In addition, the analysis of existing initiatives reveals how current legal entities are implemented and where gaps between practice and business requirements exist. Combining interview findings and secondary analysis, the study proposes a conceptual approach in which legal requirements are implemented through both the institutional form of the data trustee and supplementary bilateral agreements. This combination enables flexibility while maintaining enforceability.

From a practical perspective, the study provides structured guidance for organizations developing data trustee models. By identifying relevant legal requirements, it supports the design of use-case-specific legal frameworks and facilitates collaboration with legal departments. The approach helps organizations determine which aspects should be embedded in core legal structures and which can be addressed through supplementary agreements, thereby reducing complexity and improving decision-making. Overall, the findings contribute to the operationalization of data trustee models and support the implementation of data ecosystems in practice.

6. Further Research and Limitations

Future research should examine how legal requirements evolve across the lifecycle of data trustee models and how they can be implemented in different legal entities. In particular, further work could identify which legal forms best combine flexibility, enforceability, and governance at different stages.

The findings also highlight the diversity of data trustee models. While large-scale initiatives aim to create broad, standardized ecosystems, smaller consortia focus on specific use cases. Future research should therefore develop classifications of different data trustee types and their legal, organizational, and technical requirements.

In addition, further work should explore how requirements can be systematically clustered and mapped to appropriate legal instruments. Reference architectures such as the Industrial Internet Reference Architecture (IIRA) may provide useful guidance. Another relevant direction is the analysis of transformation paths between legal forms to ensure adaptability over time.

This study is limited by its exploratory design and the small sample size of 12 interviews. All participants operate within the German legal context, which restricts generalizability. Moreover, qualitative content analysis involves interpretive judgments, although reliability was enhanced through collaborative coding by two researchers

Ethics Declaration

Abstract: The apparel industry in emerging countries is crucial in creating employment, enhancing export earnings, and stimulating industrial growth. Within an increasingly competitive global environment, the apparel managers are expected to strategically overcome the triple bottom line barriers to achieve sustainable entrepreneurship performance (SEP) and remain competitive. Failure to overcome these barriers can significantly diminish the performance of sustainable entrepreneurship in the industry. Although several studies have substantiated the barriers to sustainability performance, further research is needed to develop a decision-support framework that determines the set of strategic approaches to overcome SEP barriers, particularly in emerging countries. Therefore, the purpose of this study is to develop a decision-support framework to find the best set of strategic responses for barriers affecting SEP in Ethiopian apparel industries. The study follows a multi-faceted research methodology approach with a mix of qualitative and quantitative techniques. In the first phase, managers from the apparel industry were interviewed to identify context-specific barriers to SEP and a clear set of strategic responses to these barriers. The barriers were grouped into economic, social, and environmental dimensions based literature analysis. The Best-Worst Method (BWM) was then used to rank them based on their relative severity of effects on SEP. Subsequently, the Quality Function Deployment (QFD) approach was used to investigate the relationship between the prioritized barriers (WHATs) and strategic responses (HOWs) for enabling sustainable entrepreneurship performance and to rank the best strategic responses as a key takeaway for managerial decision-making. The results indicate that low product quality, weak buyer-supplier relationships, and high cost pressure are the strongest barriers to SEP. The study discovers that including developing circular practices (3R), adopting demand-driven production planning, and improving training and skill development are the most effective strategic responses to overcome the barriers. Grounded on stakeholder and resource based view theories, the decision support framework helps apparel managers for systematically prioritizing the barriers of SEP and build a best strategic response portfolio.

Keywords: Sustainable Entrepreneurship Performance, Barriers, Strategic Response, Quality Function Deployment, Best Worst Method.

1. Introduction

The global apparel industry is a crucial factor in economic growth, especially in emerging countries, through creating jobs, enhancing exports, and improving industrial progress (Chowdhury *et al.*, 2023). Due to the growing competition and the need to be sustainable, the apparel industry has to balance profitability with social and environmental responsibility, which leads to Sustainable Entrepreneurship Performance (SEP) (Todeschini *et al.*, 2017) (Somwethee et al., 2023). In the apparel industry, SEP is reflected through higher productivity, efficient resource consumption, improved worker well-being, reduced environmental impact, and enhanced competitiveness (Abbate et al., 2023)(Chowdhury *et al.*, 2023). Despite its importance, the apparel industries face an interconnected set of barriers across economic, social, and environmental dimensions that hinders SEP (Bhandari *et al.*, 2022). According to Brydges (2021) and Su et al., (2022), poor product quality, high material cost, and poor buyer and supplier relationships are economic barriers that diminish competitiveness. The productivity and ethical compliance are minimized by social barriers like weak labor policies, low motivation, and safety risk (Akhter et al., 2019)(Bashar et al., 2021). Poor waste management and the absence of circular systems are some of the environmental challenges that aggravate the sustainability problems (Zhang *et al.*, 2019). These barriers are not independent but act in a dynamic manner, and it is hard to have companies adopt effective and holistic sustainability strategies (Milić, 2026)(Abbate et al., 2023). Although several studies have substantiated barriers to sustainability performance, research on developing a decision-support framework to determine the set of strategic approaches to overcome SEP barriers needs further research attention, particularly in emerging countries. To address this gap, this study proposes a decision-support framework that integrates BWM and QFD in a systematic and sequential process to enhance sustainable entrepreneurship performance. The framework integrates the triple bottom line barriers with strategic response, aiming to enable

strategic prioritization and alignment under resource constraints. The scientific novelty lies in integrating methods, theory, and process within an operational framework. It combines stakeholder theory and the resource-based concept, integrating external pressures with internal capabilities. The study employed a mixed-method approach that included interviews and literature analysis to find and classify the barriers as economic, social, and environmental dimensions. The Best-Worst Method (BWM) is applied to prioritize the barriers according to their weights (Rezaei, 2016)(Guo and Zhao, 2017) and Quality Function Deployment (QFD) is implemented to visualize the relationship between the identified barriers (WHATs) and strategic responses (HOWs), and finally define the most effective strategies (Chowdhury *et al.*, 2024)(Chowdhury *et al.*, 2023). The study is predominantly grounded in Stakeholder Theory (ST) and Resource-Based View (RBV). Stakeholder theory focuses on managing stakeholder expectations (Medcalfe and Miralles Miro, 2022)(Chowdhury *et al.*, 2023), whereas the RBV focuses on leveraging internal resources and capabilities (Agrawal *et al.*, 2025). The combination of the theories used as the foundation of the study offers a holistic perspective on understanding both the internal and external factors affecting SEP and a reason to choose the strategic responses.

2. Literature Review

2.1 Sustainable Entrepreneurship Performance and Barriers

Sustainable entrepreneurship performance (SEP) can be defined as the capacity of a firm to generate economic value and consider both social and environmental responsibilities through entrepreneurial actions (Somwethee et al., 2023). In apparel manufacturing, SEP is manifested in productivity, efficiency, employee welfare, less environmental impact, and sustainability in the long run, especially in emerging countries where the industry creates jobs and economic development (Chowdhury *et al.*, 2023)(Abbate et al., 2023). According to Bashar et al., (2021) and Arshad *et al.*, (2023) SEP is affected by internal capabilities and external factors such as market, institutional, and supply chain conditions. In apparel firms, barriers are categorized into economic, social, and environmental dimensions (Bhandari *et al.*, 2022). The economic barriers, like high costs, ineffective production, and poor demand planning, reduce the apparel performance, while innovative business models assist in balancing sustainability and financial viability (Abbate et al., 2023). According to Akhter et al., (2019) the social barriers of apparel includes weak labor standards, ineffective health and safety systems while environmental barriers are poor waste management, limited circular practices and the adoption of less environmentally friendly technologies, all of which undermine SEP (Akhter et al., 2019) (Awino and Apitz, 2024). These interrelated barriers lower productivity and competitiveness, requiring integrated strategic responses rather than isolated solutions (DiVito and Bohnsack, 2017)(Todeschini *et al.*, 2017). The key barriers to SEP in the apparel industry are summarized in Table 2.

2.2 Strategic Responses to Sustainable Entrepreneurship Barriers

In order to address the barriers of SEP, companies utilize strategic responses to rationalize resources, capabilities, and stakeholder expectations (Agrawal *et al.*, 2025)(Tandon *et al.*, 2024). According to Sajan *et al.*, (2017) and Bashar et al., (2021) argue that the benefits of the lean implementation brush-up efficiency by minimizing waste and costs, whereas agile strategy enhance flexibility and responsiveness to demand uncertainty. Collaboration in the supply chain increases efficiency in buyer-supplier relations, transparency, and planning, which contributes to sustainability performance(Wren, 2022)(Garcia-Torres *et al.*, 2022). Also, demand-driven planning, circular practices, clear labor policies, digital tools, and standardized procedures contribute to the minimization of waste, better coordination, and overall SEP (Younespour et al., 2024)(Savini, 2021)(Cao et al., 2024)(Buer *et al.*, 2021). The strategic responses are listed in Table 2. This study develops a decision support framework for the Ethiopian apparel industry as shown in Figure 1. This is grounded on Stakeholder Theory and RBV to detect, identify, and prioritize the barriers to SEP. Stakeholder Theory assists in identifying barriers that are connected to the lack of robust stakeholder relationships and transparency (Mahajan *et al.*, 2023)(Chowdhury *et al.*, 2023)(Medcalfe and Miralles Miro, 2022) and RBV identifies internal resource and capability gaps, including the skills, management, and production systems (Mokbel Al Koliby et al., 2024)(Agrawal *et al.*, 2025). The framework relies on BWM and QFD, and would be of great relevance to apparel industry managers for easily assisting them in determining the optimal strategic response combination to set of SEP barriers.

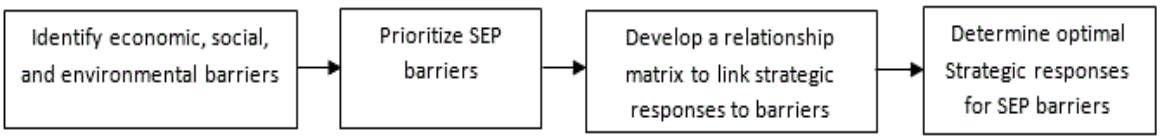

Figure 1: Decision support framework: Strategic response for SEP barriers

3. Method and Analysis

This study uses a mixed-method research approach that integrating qualitative and quantitative methods. Initially, a set of SEP barriers and strategic responses was developed through an extensive literature review. These findings were further refined and confirmed through semi-structured interviews with key decision-makers from five apparel companies. The profiles of the sampled companies and respondents are presented in Table 1. The economic, social, and environmental dimensions of barriers were identified and categorized based on the literature and company data to provide a systematic understanding of their nature. Recognizing the need for detailed analysis, a specific firm (Company-E) was chosen for the case study based on its size, experience, and availability of information. In this case, quantitative methods were employed, including the BWM for prioritizing the identified barriers and QFD for ranking the strategic responses that influence the SEP barriers. The BWM is a sophisticated multi-criteria decision making (MCDM) approach used to distinguish and prioritize obstacles to a SEP in the apparel industry. With the expert judgments, the BWM develops optimal weights with fewer comparisons, higher consistency, and reduced subjective bias, making it effective for complex sustainability evaluations (Mathiyazhagan *et al.*, 2021)(Rezaei, 2016). These optimized weights are then assimilated into QFD, in order to transform the determined barriers (WHATs) into actionable strategic responses (HOWs). In this framework, customer requirements (CRi) are defined as SEP barriers, and strategic responses are defined as design requirements (SRj). Their interrelationships are plotted as a relationship matrix (Rij) with each component indicating the strength of a relationship between a particular barrier and a particular strategic response. These relationships are measured on a four-level scale, strong = 9, moderate = 3, weak = 1, and none = 0. The QFD is broken down into the following steps: (1) identify the SEP barriers as WHATs (CRi), (2) Determine the weight of the SEP barriers (Wi), (3) defining strategic responses as HOWs (Sj), (4) develop the relationship between WHATs and HOWs (Rij), (4) determine the relative importance (AI) of each strategic response and (5) assess the relationship among the strategic responses (Chowdhury *et al.*, 2023)(Figure 2). Integration of BWM and QFD can offer an organized and reliable approach to prioritize SEP barriers and construct significant strategic responses to resolve the SEP barriers in the apparel industry efficiently.

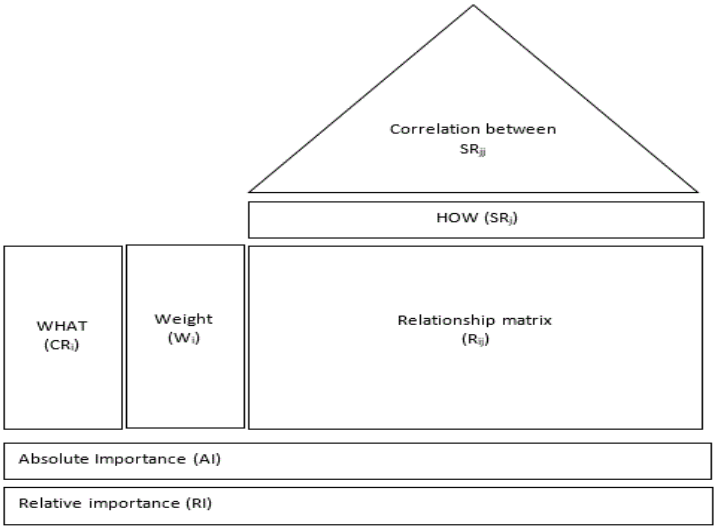

Figure 2: QFD model

3.1 Identify the SEP Barriers and Strategic Responses

In this study, a purposive sampling approach was employed, including five apparel industries (small, medium, and large), along with a fabric supplier and purchasing agent to capture a diversity of industry opinions. The data were collected through literature review and semi-structured interviews with the key decision-makers (average

duration of 25 minutes), during which the respondents provided the SEP barriers and suggested the strategies to address them. In this study, 22 SEP barriers and 12 strategic responses were identified. The set of SEP barriers was analysed using literature analysis to categorize them into economic, social, and environmental dimensions, ensuring alignment with real industry practice. The prioritized barriers and corresponding strategic responses are demonstrated in Table 2.

Table 1: Profiles of Sampled Companies and Respondents

Company Name	Respondents Position	Company Size (No. of employees)	Company Experience
Company-A	Production manager		
Company-B	Quality Manager	30-50	0-5years
Company-C	Supply chain manager	200-250	9-14 years
Company-D	Merchandising Manager	1500-2000	16-20 years
Company-E	General manager, Quality manager, Supply chain manager, Production manage	Less than 50	6-10 year
(Case study)		2000-3000	Over 20 years
The quantitative data are collected from the four apparel managers of the case Company-E			

3.2 Prioritization of SEP Barriers (WHATs)

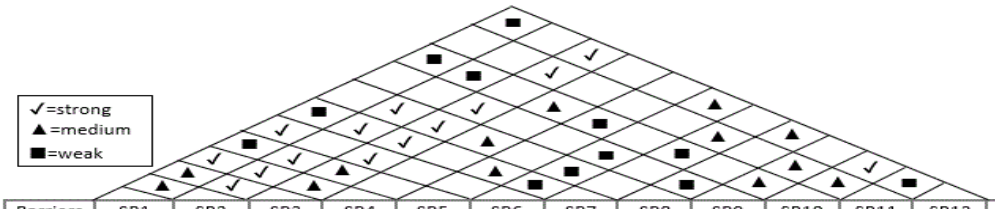
This study identifies the weights of SEP barriers (W_i) and the associated strategic responses by choosing a Company-E for detailed analysis. Data were gathered through structured questionnaires from four managers of the company. Company-E was found in 2004 and produces a variety of apparel products. It has a large-scale production facility consisting of more than 2,000 employees with technologies and qualified human resources. Over time, the company poses a competitive business with both local and international markets. However, with some prevailing barriers to the company for SEP. To address this, participants were asked to perform pair-wise comparisons of a structured set of SEP barriers, which were analysed through the BWM, and the results are presented in Table 2. Among the three triple bottom line dimensions, economic barriers were found to be the most dominant, with 65.20% of the total weight, followed by environmental (17.9%) and social barriers (16.9%). The consistency ratio for the three dimensions is 0.059. Under the economic dimension, the most significant barriers are poor-quality product (11.9%), poor long-term buyer- supplier relationships (10.5%), and high cost pressure based on limited resources (9.5%). Regarding the social dimension, the most significant barriers are a lack of clear labor and ethics policies (2.8%), health and safety risks in production (2.6%), and low worker motivation (2.2%). Similarly, in the environmental dimension, the major barriers are a lack of circular design and recovery systems (6.3%), a lack of government support (4.2%), and a lack of waste management practices (3.7%). In general, the findings reveal that economic barriers play the most significant role in limiting SEP, and poor product quality, weak buyer-supplier relationships, and cost pressure are the leading three barriers in all categories.

Table 2: The SEP barriers and its strategic responses

Sep Barriers	Bwm Weight	Rank	Consistency Ratio
Barriers to Economic factors (Weight: 65.20%)			
Poor quality product(Ec1)	11.9%	1	
Poor long-term buyer-supplier relationships(Ec2)	10.5%	2	
Poor demand-driven production and forecast(Ec3)	5.1%	7	
Lack of business model innovation(Ec4)	5.5%	6	0.095
Weak internal coordination between departments(Ec5)	2.9%	9	
inflexible production planning(Ec6)	6.9%	5	
Limited use of digital tools(Ec7)	4.7%	8	
High cost pressure (limited resource)(Ec8)	9.5%	3	
High product prices(Ec9)	8.2%	4	

Sep Barriers	Bwm Weight	Rank	Consistency Ratio
Barriers to social factors (Weight: 16.90%)			
Lack of clear labor and ethics policies(Sc1)	2.8%	1	
Limited training for workers(Sc2)	1.5%	6	
Health and safety risks in production(Sc3)	2.6%	2	
Communication gaps in the supply chain(Sc4)	2.1%	4	0.097
Low transparency toward consumers(Sc5)	1.2%	8	
Low worker motivation(Sc6)	2.2%	3	
Cultural diversity(Sc7)	1.9%	5	
Low-skilled workers for fast production changes(Sc8)	1.2%	9	
Lack of top management skill and knowledge(Sc9)	1.4%	7	
Barriers to Environmental factors (Weight: 17.9%)			
Lack of waste management practices(En1)	3.7%	3	
lack of circular design and recovery(En2)	6.3%	1	
Lack of partners for recycling(En3)	3.6%	4	0.087
Lack of government support(En4)	4.2%	2	
Strategic responses			
Lean supply chain implementation (SR1)	Making Collaboration across the supply chain (SR2)		
Training and skill development (SR3)	Adopt demand - driven production planning (SR4)		
Developing circular practice (SR5)	Introduce standardized operating procedures (SR6)		
Improve low - cost innovation (SR7)	Build trust and realistic planning (SR8)		
Establish clear polices (SR9)	Adopt simple digital tools (SR10)		
Implement agile supply chain strategy (SR12)	Actively engage with government and industry (SR11)		

3.3 Relationship Between SEP Barriers (WHATs) and Strategic Responses (HOWs)



The QFD approach was systematically used to translate 22 prioritized SEP barriers (WHATs) into 12 strategic responses (HOWs), based on literature and expert input from the Ethiopian apparel industry. In the first step, respondents evaluated the relationship between each barrier and strategic response using the R_{ij} scale. For instance, SEP Barrier 1 and Strategic Response 1 were rated by four respondents as 1, 9, 3, and 9, yielding an average of 4.333. This was multiplied by the BWM weight of Barrier 1 (W1= 0.119) to obtain a relationship score of 0.5156, which was then normalized to 0.151 (Figure 3). The same procedure was applied across all barriers and strategic responses, and the normalized scores were aggregated to compute the absolute importance (AI) of each strategic response. In the AI outcome, the strategic responses with the highest ranking are circular practices (SR5), training and skill development (SR3), and demand-driven production planning (SR4). The roof matrix was applied to comprehend the interrelationship between strategic responses. To achieve improved outcomes, a strategic response with strong (✓) links should be executed jointly. For example, circular practices (SR5) are most effective when combined with training and skill development (SR3). Similarly, training (SR3) supports standardized processes (SR6) and agile supply chains (SR12) (Figure 3). In general, the results indicate that an integrated and coordinated approach is the most important to overcome SEP obstacles and enhance sustainable entrepreneurship performance.

4. Discussion and Implications

4.1 Summary of Findings

This study identified a total of twenty-two SEP barriers: nine economic, nine social, and four environmental, through literature analysis and expert validation in Ethiopian apparel firms. The classification follows the triple bottom line framework and is supported by prior studies, such as Bhandari *et al.*, (2022) and Chowdhury *et al.*, (2024), which similarly group supply chain challenges into economic, social, and environmental dimensions. The results indicate that economic barriers (65.20%) are the most dominant, followed by environmental (17.9%) and social barriers (16.9%). This suggests that financial and operational constraints are the key barriers to SEP in the

Ethiopian apparel industries, a finding supported by earlier studies such as Zeleke and Hailemariam, (2023) and (Minbale *et al.*, 2024).

Barriers	SR1	SR2	SR3	SR4	SR5	SR6	SR7	SR8	SR9	SR10	SR11	SR12	AI

Figure 3: QFD Matrix for Apparel SEP Barriers and Strategic response

The most critical economic barriers are poor product quality, weak buyer–supplier relationships, and high cost pressure show that operational inefficiency and limited resources reduce competitiveness. These findings are supported by prior studies (Su et al., 2022)(Brydges, 2021) Similarly, top social barriers such as lack of labor and ethics policies, health and safety risks, and low worker motivation are supported by prior studies highlighting labor standards and workplace safety as key determinants of sustainability performance (Akhter et al., 2019)(Bhandari *et al.*, 2022). Environmental barriers such as lack of circular systems, lack of government support, and poor waste management are also consistent with earlier research emphasizing the importance of circular economy practices and institutional support (Brydges, 2021)(Abbate et al., 2023)(Arshad *et al.*, 2023). To address these barriers, the study identified twelve strategic responses, emphasizing that multiple strategies are required to solve interconnected SEP barriers, which aligns with prior research (Todeschini *et al.*, 2017)(Su et al., 2022). Among these, the top three strategic responses are developing circular practices (SR5), training and skill development (SR3), and adopting demand-driven production planning (SR4), which play a critical role in directly addressing the main SEP barriers. Developing circular practices helps to reduce waste and improve resource efficiency, which in turn helps overcome cost pressure and product inefficiencies. This is consistent with findings reported by Brydges, (2021) and Buer *et al.*, (2021). Training and skill development improve worker capability, product quality, and motivation, thus addressing poor quality products and social barriers. These findings are supported with studies by Journeault et al., (2021). Demand-driven production planning reduces overproduction, improves coordination with buyers, and lowers cost pressure, thereby addressing challenges with buyer-supplier relationship and operational inefficiencies, consistent with the findings supported by Hussain and Malik, (2020) and Safra *et al.*, (2019). Generally, the findings confirm that aligning key strategic responses with the most critical barriers is essential, while emphasizing that integrated strategies significantly enhance sustainable entrepreneurship performance in the apparel industry.

4.2 Theoretical and Managerial Implication

The theoretical implication of this study has relevance to the literature on Stakeholder Theory and RBV by providing an integrated perspective to explain SEP in the apparel business. This study demonstrates that the combination of these theories can be used to gain a comprehensive explanation of how companies deal with sustainability issues. Concerning the stakeholder view, lack of effective buyer-supplier relationship, poor labor

policy, and low poor transparency are barriers that limit sustainability performance by failing to meet stakeholder expectations. According to the RBV view, problems like poor quality products, skill gaps, and poor internal coordination indicate a lack of resources and capabilities, whereas training, lean systems, and standard operation procedures are examples of strategic response that increase the capabilities of the firm. Strategic response alignment with the main barriers is a key capability that can help create sustainable competitive advantage, especially to the Ethiopian apparel industries. The study offers a decision-support framework that enables apparel managers to distinguish and categorize SEP barriers into the triple bottom line and rank them using BWM and QFD. It also helps in choosing optimal strategic responses. The finding focuses on combined approaches because combined efforts are more effective than single actions. The framework can help Ethiopian apparel companies to enhance their working efficiency, enhance their stakeholder relations, build their workforce capacity, and meet their sustainability objectives in the face of finite resources.

5. Conclusion

The study formulated a comprehensive decision support framework to identify the strategic response to the SEP barriers influencing the Ethiopian apparel industry. In this study, the mixed-method approach was used by combining the literature review and semi-structured interviews to identify 22 SEP barriers and 12 strategic responses. Furthermore, the literature analysis was employed to categorize the barriers as economic, social, and environmental. In the quantitative approach, BWM was used to prioritize the identified barriers, and QFD was used to establish a relationship between prioritized barriers (WHATs) and strategic responses (HOWs). In addition, the QFD matrix was used to rank the strategic responses and to choose the best ones. The findings showed that the most important barriers to SEP are low quality of products, lack of buyer-supplier relationship, and cost pressure, while the most effective strategies to overcome these SEP barriers are circular practices (3Rs), adopting demand-driven production planning, and improving training and skill development. This implies that a coordinated and integrated strategic action is required to address interlocked barriers to sustainability and improve SEP. The study contributes both theoretically and practically by connecting the theory of stakeholders and the resource-based view into a unified framework. This framework assists apparel managers in structurally prioritizing the barriers and choosing effective strategies in resource-constrained environments. However, there are some drawbacks to this study. The qualitative phase was based on a small number of respondents by purposive sampling, and the quantitative analysis was based on a single case company, which restricts the generalizability of the results. So, the findings should be interpreted in a context-specific way related to the Ethiopian apparel industry. Further studies are recommended to test the proposed framework in various countries and industrial applications. Additionally, future studies can include optimization models to assess the cost of implementation and the most effective combination of strategies.

Ethics Declaration

This study did not involve any in person experiments with human participants, and no sensitive personal information was collected that would require formal approval for ethical considerations. The data were gathered through the voluntary involvement of industry professionals, with all respondents willingly agreeing to take part in the study. Hence, this study did not need formal ethical.

AI Declaration

Competitiveness of Small Rural Tourist Establishments in Northern Norway

Knut Ingar Westeren
Nord University, 7600 Levanger, Norway

knut.i.westeren@nord.no

Abstract: Competitiveness is a severe challenge for rural tourism including factors like authenticity, clean nature, and sustainable use of the environment. In this project, we collected data from six small rural tourist establishments in Northern Norway, three lodging activities and three tourism service providers. We compared and interpreted the competitive situation using two types of indicators: Porter-type strategy indicators based on structured interviews and financial Key Performance Indicators (KPIs). The theoretical discussion of the competitiveness of rural tourist establishments shows large differences in the understanding of competitiveness, depending on different theoretical frameworks and measurement methods. The results indicate that the KPI-based indicators are more relevant for short-term financial structural changes, one of them being how to develop products/niches that can be profitable for the company. The questionnaire-based analysis adds a longer-term perspective, introducing marketing options, key personnel developments, and environmental considerations. The important competitive factor, how to even out seasonal changes, is the best example where both types of analysis are applied. The novelty of this study is that the Porter-based strategic considerations often contain too much "wishful thinking", while the KPIs point at rural tourism variations in profitability, and many businesses make too little money and have solvency issues, which indicates that they should focus more on survival. Of course, all companies, including rural tourism, must have a vision, but that must be based on a reasonably sound financial situation.

Keywords: Rural Tourism, Competitiveness, Porter-based Indicators, Northern Norway

1. Introduction

According to the World Tourist Organization (2026), international tourist arrivals, measured by overnight visitors, increased 4% in 2025, and the level in 2025 exceeded pre-COVID travel. The recovery after COVID has shown uneven development, according to the World Economic Forum (WEF) (2024), with challenges such as the increase in travel costs, geopolitical risks, environmental/sustainability requirements, and staff/competence shortages.

Tourism can be divided into many subgroups, and in this study, we focus on rural tourism. There is no commonly accepted definition of rural tourism; see Rosalina et al. (2021). In this study we adopt the following definition: "rural tourism as a form of tourism that showcases the rural life, art, culture, nature and heritage of rural regions" (Pröbstl-Haider 2014, p.1).

In our study, we have a wide understanding of rural tourism to include all forms of tourist activities in rural areas, including the utilization of natural resources, cultural heritage, rural buildings, and village traditions. Local products are important to illustrate the rural region's identities and respond to the needs of visitors in terms of accommodation, catering, leisure activities, entertainment, and various nature-related services for sustainable business and local development, as documented in studies such as Roman et al. (2020) and Villanueva-Álvaro et al. (2017). In recent years, rural tourism has been considered a forward-looking strategy, creating jobs, promoting the socio-economic development of disadvantaged areas, and contributing to strengthening the rural region's economic base.

Rural tourism has been considered differently in developed countries, such as Norway, compared to Asian countries, such as Indonesia; see Utami et al (2023). In richer countries, rural tourism is important for an even distribution of growth and access to sustainable use of nature. In developing countries, rural tourism development is often considered to be an engine of socio-economic growth, by reducing poverty, creating jobs, and developing infrastructure. In this project, we adopted the perspective of presenting authentic nature/culture-related experiences integrated into local culture, aimed at contributing to sound business development and stable local development in a developed-country environment with a well-built societal infrastructure.

2. Conceptual Background and Literature Review

2.1 Rural Tourism Trends

Several academic contributions deal with the developing trends in rural tourism, and a summary can be found in the books by Roberts et al. (2017) and Lane and Kastenholz (2018). The increase in rural tourism is due to changes in the leisure habits of tourists, and a larger segment of tourists now values rural and natural spaces with scenic experiences combined with local culture. A second development trend is the significant improvement in infrastructure, such as transportation systems, both in terms of quality and availability. The emergence of eco-entrepreneurs has also increased the number of rural tourism companies (Villanueva-Álvaro et al 2017).

2.2 Sustainable Rural Tourism

Sustainable rural tourism development is dependent on the successful interaction between the social balance in rural areas, the preservation of the environment, and the economic efficiency of tourism activity; see Fons et al. (2011). Sustainability arguments often focus on preserving biodiversity and the sustainable use of natural resources, leaving them undamaged for future generations. While the rural tourism facilities are related to a particular geographical area environmental restrictions may be imposed on this. But rural tourism is also dependent on the situation in the broader area, for example rural fishing.

Sustainable rural tourism in a competitive business environment must increase the professionalization of their products through learning and internalizing the quality process and by strengthening their brand in the market. Quality standards can improve direct viability through the implementation of specific measures, such as environmental certifications. Norway has a certification system called Miljøfyrtårn, in English, Eco-Lighthouse (https://eco-lighthouse.org/certification-scheme/), which helps companies document their social responsibility and work systematically with sustainability in areas such as the physical environment, waste, energy, procurement, and transport. It also provides advantages in public procurement processes and is used in marketing and branding.

2.3 Rural Tourism Competitiveness

A large number of studies on competitiveness in rural tourism have had two different focuses. The first is labeled tourism destination studies, which often use Dwyer and Kim (2003) as the theoretical and methodological platform to ask the question of how well one region (as a unit) is able to compete as a tourist destination. This type of analysis has a combined territorial and tourist activity focus and usually looks at the meso level and how the collection of tourism-oriented activities with all amenities (including public sector infrastructure) can develop as a tourist destination; see Chin (2022).

The second focus analyzes the competitiveness of single tourist-producing units, as in this study. These two types of studies are often intertwined; tourist destination studies can have partial analyses assessing the competitiveness of single units in the region. Further, in single tourist business studies, we can find strategic arguments for how businesses can enhance their competitiveness by developing regional cooperation; see Ogutu et al. (2022).

A large number of empirical applications with tourist businesses focus on competitive analysis, using economic theory based on competitive advantage, such as Porter's Five Forces Model; see Porter (1980). The original five forces included the threat of new entrants, the bargaining power of buyers, the bargaining power of suppliers, the threat of substitute products, and the rivalry among industry competitors. Porter developed this analysis as an alternative to neo-classical economic theory, where markets (in the longer run) would be in equilibrium. Porter's competitive analysis has been discussed and extended, and Nyanga et al. (2020) added three components: (1) digitalization (or more in general, IT and AI interactions), (2) globalization, and (3) deregulation (sometimes extended to public sector interventions).

The competitive analysis of rural tourist establishments often aligns with the resource-based view (RBV), developed by Barney (1991; 2001), where businesses use their individual specific resources and try to make them as difficult as possible to copy. Most rural tourism establishments actively try to stay in their niche, which is also dependent on the qualifications of the employees; see Ogutu (2023). Therefore, in addition to the eight forces formulated above, we also specify employee competence as one of the factors central for developing a competitive advantage.

The other focus of competitive analysis is the financial performance, taking as a starting point the firm's accounts. Financial key performance indicators (KPIs) are quantifiable metrics used to evaluate businesses' financial health and track progress toward strategic goals. There are suggestions for the selection of financial KPIs in all standard business finance textbooks, and Maftei and Butnaru (2023) and Ponce et al. (2023) give a thorough review of the use of financial KPIs in tourism. Based on these reviews, we selected the following indicators:

- Total return in % (Profitability);
- Operating result in %;
- Return on equity before tax in %;
- Liquidity ratio;
- Equity in % (Solvency);
- EBITDA in 1000 NOK.

This selection is convenient because these numbers are publicly available in Norway, as all limited liability companies send in their official yearly accounts to a central register, and then they are freely available to download without any restrictions. In addition to the KPIs, we also added the total annual sales as a proxy for the size of the company operations.

Several studies provide results from financial studies of tourism, including rural operations, such as Samad (2022), Maftei and Butnaru (2023), and Ponce et al. (2023). The first conclusion is that most of the businesses are very context-dependent; so, it is difficult to draw general conclusions based on numbers. Some trends seem to be large variations in profitability, a strong desire to stay in a sheltered niche, and the importance of evening out seasonal variations. Since most of the activities are small in scale, another general problem is capital structure with low solvency.

Based on the discussions above, we formulated the following research questions:

- How do the strategies of rural tourism companies align with market and sustainability challenges?
- What can the financial indicators tell us about rural tourism companies' development?
- Do the strategic plans of rural tourism companies pay sufficient attention to the financial situation?

3. Empirical Part and Methods

3.1 Data Collection

In this study, there were six participating establishments, three lodging activities and three tourism service providers, all in the rural part of Nordland county in Northern Norway. They are situated in scenic landscapes, where authenticity and closeness to nature are integrated into the local culture as an important part of the tourist experience. The key information about the participants is shown in Table 1.

Table 1: Businesses participating in the study.

Name	Characteristics	Capacity
Lodging Activities		Number of beds
Kjerringøy Bryggehotel	Hotel and sea houses, boat/fishing activities	50 beds
Kjerringøy Rorbu center	Hotel and sea houses, boat/fishing/mountain activities	40 beds
Saltstraumen Hotel	Hotel with fishing activities, close to a huge maelstrom	60 beds
Tourism Service Provider		
Karl Erik Haarr Museum	Museum with cafeteria and cultural activities	Maximum visitors on a high season day: 150
Kjerringøy Handelssted	Refurbished trading post with cultural activities	Maximum visitors on a high season day: 400

Name	Characteristics	Capacity
	and traditional lunch serving	
Elvegård camp and fishing	Camping site and fishing center	(1): Visitors coming to fish: max 50 a day (2) Renting out spots for camping: max 60

For data collection, we conducted a structured interview with the managers, starting with Porter's five forces and adding three factors to obtain the eight forces model from Nyanga et al. (2020). In addition, we included a human resource competence factor. We asked the managers to evaluate the importance of the statements below to characterize the competitive situation of their business.

3.1.1 Statement 1: Threat of Substitute Products or Services and Threat of New Entrants

This statement covered two factors in Porter's model and all the participants had quite similar points of view because the tourist experience services are closely linked to authenticity in nature and culture. The Saltstraumen Hotel and Elvegård camp and fishing are located only a few hundred meters from the largest maelstrom in Europe, and just a few hundred meters away and there are also excellent possibilities for fishing cod. Kjerringøy Bryggehotel and Kjerringøy Rorbu center have lodging in refurbished old houses. So, the participants shared the opinion that substitute products and new entrants were a minimal threat. The situation for these businesses is similar to several of the rural tourism projects noted in the literature review—these types of products are nearly impossible to copy.

3.1.2 Statement 2: Bargaining Power of Buyers and Marketing

Here, we adopted the original statement from Porter and added marketing, with the intention of obtaining information on what characterizes the demand side and how to attract customers. The rural nature/environmental oriented tourism in our project has two demand groups. One is travelers who use their own cars travelling from one place to the other reserving a room/sea house a day or two in advance. The other group consists of people (or smaller groups) who plan in advance to stay, often for a week, to enjoy nature, fishing, and culture. The latter group is the most important, and the presentation/booking site on the internet is the major source of marketing. Demand is mainly based on fixed pricing with some possibilities for group rebates. The price level is in the upper middle class, and all the lodgings said that the bargaining power from the demand side was negligible. This subgroup of natural explorers appeared to focus mainly on authentic natural experiences and not that much on price.

3.1.3 Statement 3: Bargaining Power of Suppliers and Supply Chain Aspects

All activities here are small-scale operations with mainly local suppliers and limited dependence on larger supply chains. Food/meals, were often based on traditional dishes well integrated with the local society and local suppliers. This was a clearly non-problematic competitive advantage.

3.1.4 Statement 4: Rivalry Among Existing Competitors

From the responses to this statement we got one clear message. There are minimal, close to non-existing, rivalries between the establishments; in fact, the opposite is true. The lodgings actively market the cultural offers of the tourist service providers. All the organizations are within driving distance of each other, and they have a cluster cooperation ideology.

3.1.5 Statement 5: Digitalization and Technology

This aspect has grown considerably in importance for tourism in general, as well as for small-scale rural tourism. As a part of marketing, the booking pages must be professional, including videos presenting the experiences. There must also be professional follow-up of the tourists after they have visited the site. All lodgings requested the e-mail address/social media connection from customers to keep in touch and present their new attractions and possibilities. One current strategic change in tourism is the professionalism on social media and the importance of more personalized services.

3.1.6 Statement 6: Public Sector Interventions

In the new eight forces model, one keyword was deregulation; however, we changed this to public sector interventions, since we are working with rural establishments that depend on the utilization of nature/environment. Tourism now focuses on how the sector deals with environmental aspects, and if this does not occur in a sustainable way, rural tourism will not grow. All participants stated that it was in their interest to comply with environmental regulations, and all establishments said they had a reasonably good relationship with the local environmental authorities, mentioning very few conflicts.

3.1.7 Statement 7: Globalization

This relates to the challenge of reaching potential customers on the internet.

3.1.8 Statement 8: Manpower Challenge

Since the resource-based view is a theoretical basis for this study, we added a question about human resource challenges. Here, the answers are divided into two groups. The tourist service providers need skilled labor in all positions. They have a multitask utilization of labor, since the establishments are small, and all have fewer than six employees. These personnel are mostly locally recruited and have background knowledge about the cultural heritage. The lodging activities are different: they have to cover several different functions, including skilled functions such as managerial, chef, economic/administrative/IT, and less skilled functions like cleaning. Lodging reported problems with recruitment on both levels, to find the right staff and to have a low turnover. All organizations also reported problems with seasonal variations, which again raise challenges for stable part-time workers.

3.2 Financial Accounts

According to Norwegian legislation, all limited liability companies must send their accounts to a central register (Brønnøysundregisteret, https://www.brreg.no/), and from this register (with a few exceptions), it is possible to download all the companies' official accounts. In this project, we downloaded the accounts, including a readymade set of key performance indicators (KPIs), as presented in Table 2, for all the companies, except Kjerringøy Handelssted, because they are organized as a public foundation owned by Nordland County.

The profitability, through the KPI, is defined in the traditional way as the percentage of profit divided by the total capital. The profitability is low for all activities except Elvegård camp and fishing. Traditional lodging has quite high fixed capital costs and is dependent on evening out the seasonal variations, which has been difficult. Elvegård has a much lower share of fixed cost and can manage changes in activity more easily. EBITDA stands for earnings before interest, taxes, depreciation, and amortization, which focuses solely on the company's core business performance. This metric is low compared to the annual total sales for all companies, in line with the low profit margins, except for Elvegården.

The liquidity ratio is defined as the total current assets divided by the total short-term liabilities; here, Saltstraumen Hotel and Elvegård have a satisfactory liquidity situation, while the others do not. The capital situation, defined as the equity in % of the total capital (total equity and debt), is satisfactory for Saltstraumen Hotel, while this metric for Kjerringøy Bryggehotel and Elvegård is low. This is a serious problem for Kjerringøy Bryggehotel, because as a traditional lodging facility, they have a quite high fixed capital cost, while for Elvegård, this is less of a problem, because their capital costs are low with little invested fixed capital.

The real problem for all lodging activities is that they make little money from running operations on a yearly basis, as seen by comparing the EBITDA to the total annual sales and to the return on equity before tax in %. The Saltstraumen Hotel is better than the two others because they have a sounder capital base, decent liquidity, and a positive return after tax. Elvegård has KPIs on a good level compared to rural tourism in general in Norway, and they can recirculate their profits to somewhat improve their capital situation.

The Karl Erik Haarr Museum is a different type of activity with income mainly from café sales. They also receive some grants from the public sector as a part of their museum activity; so, they cannot be compared directly with the others, but they are in a problematic economic situation.

Table 2: Financial information for participating activities, downloaded from Brønnøysundregistrene https://www.brreg.no/ 10.05.2026.

Criterium	Kjerringøy Bryggehotel	Kjerringøy Rorbu center		Saltstraumen Hotel	Karl Erik Haarr Museum	Elvegård Camp and Fishing
Year	2022	2021	2022	2023	2021	2023
Total return in % (Profitability)	-1,3	3,3	−24,8	5,9	−4,0	13,0
Operating result in %	3,8	5,2	−67,9	3,4	−4,3	22,5
Return on equity before tax in %	−8,5	5,8	−66,2	8,1	n.a.	45,2
Liquidity ratio	0,88	1,85	0,11	2,69	0,17	2,03
Equity in % (Solvency)	18,6	48,5	29,3	61,7	−53,7	19,8
EBITDA in 1000 NOK	472	241	−1 546	480	−59	1 606
Annual total sales, 1000 NOK	12 336	4 675	2 898	13 996	402	5 016

4. Discussion

From the literature review, we see that rural tourism tries to diversify and niche orient their products as much as possible, and the more differentiated the rural experience is, the less worried the established producers are of competing products and new entrants. We see, in our case, as in others mentioned in the literature review, that, when the experience niche is as narrow, the producers can charge a price higher than for standard rural lodging. But the price range the companies have in our study is limited and the companies must focus on a sound financial development to strengthen competitiveness.

The demand is based on dedicated visitors and a fixed price system. Booking is largely based on the internet, and the managers emphasize the importance of professional presentation of their products, especially the closeness to authentic natural experiences. The supply chain is largely handled locally, which is a part of the marketing strategy of local cultural integration, parallel to what we find globally. Local cooperation has also led to a situation where we have close to no rivalry among the producers. Local links and suppliers can, on the other hand, be vulnerable because they are often based on micro businesses based on 1-3 employees that suddenly can disappear.

These businesses state that, without a clean and sustainable nature, future possibilities will be difficult to develop. Some of the participants, especially in lodging, expressed that some of the public regulations were too costly; otherwise, the cooperation with public regulators seemed to be positive. In general, the impression is that a positive cooperative regime between rural producers and public regulators is a competitive advantage, which is not generally in line with several international studies. The businesses also expressed concerns with high costs of adapting to new eco-oriented regulations like reducing energy use and waste reductions.

Human resources, according to the WTO (2024), are one of the crucial future challenges for tourism to develop, which is valid for rural tourism as well. The study Ogutu et al. (2023) focused on the possibility that human resources can be a problem or an advantage depending on how the issue is handled. The problem fundamentally varies between countries; in Norway, the competence issue is handled well by specialized training courses in secondary education and the possibility for firms to receive public support for on-the-job training. The problem in Norway is the availability of a sufficient number of employees, while in other countries in southern Europe, there are available human resources without sufficient competence/training. In a narrow environmentally specialized niche (like the Norwegian), all employees must have a reasonable level of sustainability knowledge and cultural skills. For the lodging activities we saw a trend in developing multi-job competence, as mentioned in WTO (2024), which did strengthen the argument for the necessity of evening out seasonal variations.

The main scientific novelty of this study is that the financial key performance indicators of rural tourism firms differentiate from how Porter-based competitive analysis can be interpreted. According to the results from profitability and the relation between EBITDA and total sales, only Elvegård has a satisfactory return. All firms state that they need to even out their seasonal variations and strengthen the environmental profile of their products, and all firms state that they plan to stay and develop in their niche. But only Elvegård can suggest medium investment plans with a reasonable share of self-financing. The lodging activities differ; Kjerringøy Rorbu center must formulate a strategy to avoid bankruptcy. With the terrible results in 2022, the economic situarion suggests the company must be able to increase sales without any costly investments. Saltstraumen Hotel has a low EBITDA but a quite solid capital structure with good solvency and relatively low capital costs. They can invest some in product diversification; however, they must obtain new equity because their profitability is low, which does not allow larger increases in capital costs. Kjerringøy Bryggehotel is not experiencing an acute crisis, but the main strategy must be to strengthen their position in their niche by increasing sales. Their solvency and liquidity are too low, and they must change to positive profitability and use this to improve the capital structure.

5. Conclusions

This study, supported by others in the literature review, repeats the statements found in most business economics textbooks: one must have a strategy (vision) about the development of the company, and one must conduct yearly financial management while achieving the goal. Our study has six participants and must be interpreted with this limitation. But especially the niche argument is univocally presented by all participants and hints in the same direction as other studies. Porter-based strategy studies suggest several actions to take in rural regions to promote rural tourist growth. The most important seems to be to develop in their niche. Other strategies are directed at the public sector, with actions like complying with environmental regulations, and measures for employee competence development. Cooperation with tourist NGOs and local communities is also important. However, regional tourist companies must have a solid economic basis to contribute to return to the owners and rural development utilizing their potential. This study shows the importance of being able to simultaneously handle two aspects, follow a creative vision of product and company development and at the same time secure a sound profit level and capital structure. In developing rural tourism based on authentic natural experiences, strategy-oriented studies are valuable for the business sector, NGOs, and the public sector. However, our study shows that suggestions from strategy formulations often are not in line with business financial reality.

Ethics Declaration

The structured questionnaire used in the project is approved by Sikt – Norwegian Agency for Shared Services in Education and Research. All participants in the project have given written confirmation for the answers from the questionnaire to be used in the project.

Fostering Intrapreneurial Skills: Trait-Pedagogy Fit in Corporate Training Innovation

Wen-Kuei Wu
National Taichung University of Education**,** Taichung, Taiwan, ROC

wenkuei@mail.ntcu.edu.tw

Abstract: Corporate intrapreneurship training increasingly relies on innovative pedagogical designs to develop the adaptive influence capabilities that B2B professionals require in complex selling and negotiation environments. Innovative instructional approaches have gained wide adoption on the premise that active engagement leads to deeper knowledge and more sustainable behavioural change. However, whether such innovations benefit all learners equally, or whether their effectiveness depends on the fit between pedagogical demands and individual learning characteristics, remains underexplored in entrepreneurship education research. This study draws on Cognitive Load Theory and March's (1991) exploration–exploitation framework to examine how different teaching approaches interact with learners' exploratory and exploitative tendencies to shape engagement, exhaustion, and training outcomes. Data were collected from 557 B2B sales professionals and corporate intrapreneurs participating in influence tactics training programmes. A scenario-based survey presented participants with nine instructional conditions derived from a 3 × 3 combination of teaching approaches (Cognitivist, Constructivist, Behaviorist) and salesperson influence tactics (Professional-oriented, Motivation-oriented, Consequentialism-oriented). Data were analysed using Covariance-Based Structural Equation Modelling, Moderated Multiple Regression, Multi-Group Analysis, and exploratory K-Means clustering. Results reveal a dual-pathway mechanism: both exploratory and exploitative tendencies are positively associated with engagement, which facilitates training outcomes, while the exploitative trait is additionally associated with learning exhaustion under high-demand conditions, generating a significant negative indirect effect on behavioural change ($\beta = -0.130$). Multi-Group Analysis further indicates this negative pathway is substantially stronger among exploitative learners ($\Delta\beta = 0.271$, $p < 0.001$), whereas exploratory learners show structurally consistent response patterns. Three-way interaction modelling explains 48.6% of variance in behavioural change and identifies differentiated instructional fits across learner profiles. These findings challenge the assumption that more interactive instructional designs are universally superior and offer an evidence-based framework for aligning corporate intrapreneurship training with individual learner characteristics.

Keywords: Corporate Intrapreneurship, Entrepreneurship Education, Ambidextrous Learning, Teaching Innovation, Cognitive Load, Trait–Pedagogy Fit

1. Introduction

The growing complexity of B2B environments has intensified organizations' interest in professionals who can apply adaptive influence strategies and engage clients through situationally responsive communication. Sales professionals are increasingly regarded as boundary-spanning corporate intrapreneurs who must continuously renew their capabilities for proactive problem-solving and cross-functional coordination (Marin et al., 2023). Salesperson Influence Tactics (SITs) have become a substantive domain of intrapreneurial capability training. Research highlights the role of such tactics in shaping negotiation outcomes, customer trust, and buyer–seller relationship quality (Singh et al., 2020; Dang et al., 2019), spanning professional-oriented information strategies, motivational appeals, and consequentialist commitment-building approaches (McFarland et al., 2006; Hogevold et al., 2021).

In response, organizations have increasingly adopted interactive and constructivist training innovations, including Constructivist problem solving, Behaviorist simulations, and Cognitivist schema building (Spiller et al., 2020). Constructivist principles hold that knowledge is most durably acquired through active engagement with authentic problems (Kolb, 2015), while behaviorist principles emphasize structured reinforcement for reliable behavioral responses (Hassad, 2011). However, a critical question remains underexamined: are these innovative approaches equally effective for all learners, or does their effectiveness depend on the fit between cognitive demands and individual learner characteristics? Existing research has focused primarily on curriculum content and broad learning styles (Yeniaras et al., 2024), with limited attention to how instructional innovations may generate learning exhaustion that limits their effectiveness (Brockbank and Feldon, 2024).

This study addresses these questions by integrating Cognitive Load Theory (Sweller et al., 2019) with March's (1991) exploration–exploitation framework, examining how instructional designs interact with learners' ambidextrous tendencies to shape engagement, exhaustion, and training outcomes. Three research questions guide this study: (RQ1) How do exploratory and exploitative traits relate to engagement and exhaustion? (RQ2) To what extent do engagement and exhaustion mediate trait–outcome relationships? (RQ3) Does instructional effectiveness depend on the fit between pedagogical design and learner ambidexterity profiles?

2. Theoretical Background and Hypotheses

2.1 Intrapreneurial Influence Tactics and Pedagogical Approaches

Influence tactics refer to strategies individuals use to shape the attitudes or behaviors of others. Their theoretical foundations trace to frameworks distinguishing compliance, identification, and internalization as mechanisms of attitude change (Kelman, 1961), later extended to B2B contexts encompassing Professional-oriented, Motivation-oriented, and Consequentialism-oriented orientation (McFarland et al., 2006; Frazier and Summers, 1984; Yukl and Tracey, 1992). These competencies require learners to integrate conceptual knowledge with situational judgment and interpersonal sensitivity, placing distinctive demands on working memory and attentional resources (Sweller et al., 2019). Cognitivist approaches emphasize schema building; behaviorist approaches rely on reinforcement and modelling; constructivist approaches prioritize active problem solving and co-construction of understanding (Kolb, 2015; Bailey, 2017; Hassad, 2011). Each places different cognitive demands on learners and may suit different learner profiles to varying degrees.

2.2 Exploratory and Exploitative Learning Traits

March's (1991) distinction between exploration and exploitation has been extended to organizational ambidexterity, where firms simultaneously manage evolutionary refinement and revolutionary innovation (Tushman and O'Reilly, 1996). Exploitative learning refines existing knowledge for efficiency, while exploratory learning experiments with novel approaches and pursues new possibilities (Schildt et al., 2005). At the organizational level, exploitation is associated with imitation strategies, while exploration fosters more innovative positioning (Ali, 2021). At the individual level, exploitative learners assimilate new content into existing routines and may struggle with open-ended or ambiguous instructional environments, whereas exploratory learners are more comfortable with novelty and improvisation. Recent B2B research supports this distinction: Yeniaras et al. (2024) found that exploitative learners show greater sensitivity to demands conflicting with established routines, with stronger associations with emotional exhaustion. The present study extends this to the instructional design context.

Both traits are expected to be associated with learning engagement, defined as a positive motivational state involving vigor, dedication, and absorption (Kahn, 1990; Schaufeli et al., 2002). Engagement is more likely to be sustained when instructional designs support learners' sense of autonomy and competence (Ryan and Deci, 2000) and when learners possess sufficient self-efficacy to persist through challenges (Bandura, 1986).

H1: Exploratory learning tendency is positively associated with learning engagement. H2: Exploitative learning tendency is positively associated with learning engagement.

2.3 Cognitive Load and Learning Exhaustion

Cognitive Load Theory posits that learning deteriorates when instructional demands exceed working memory capacity (Sweller, 2011; Gerjets et al., 2009), including conditions of excessive novelty, poor structure, or simultaneous information demands (Sweller et al., 2019; Paas and Ayres, 2014). In training contexts, cognitive overload manifests as learning exhaustion: emotional depletion and reduced capacity for sustained engagement (Maslach and Leiter, 2008). This transition is shaped by learners' appraisal of whether demands exceed personal resources (Brockbank and Feldon, 2024), and once exhausted, learners' ability to retain and apply knowledge is compromised, regardless of initial engagement (Feldon et al., 2019). Kirschner et al. (2006) demonstrated that minimally guided constructivist instruction tends to impose excessive working memory demands, producing inferior outcomes compared to structured approaches. These costs may be especially pronounced for exploitative learners, who rely more heavily on existing frameworks and whose gap between familiar patterns and novel instructional demands may be greater.

H3: Exploitative learning tendency is positively associated with learning exhaustion under high cognitive demand and low-structure conditions.

2.4 Engagement and Exhaustion as Parallel Mediators

Learner traits influence training outcomes through parallel mediating pathways. Engagement facilitates knowledge improvement, proactive attitudes, and behavioral change by sustaining investment in learning. Exhaustion impairs these outcomes by depleting both cognitive and motivational resources, as cognitive overload carries a motivational cost that diminishes willingness to sustain effort and transfer learning (Feldon et

al., 2019). This dual-pathway dynamic is consistent with the Job Demands-Resources framework, where high demands simultaneously activate engagement among resourceful learners and generate exhaustion when resources are exceeded (Bakker and Demerouti, 2008).

H4: Learning engagement is positively associated with training outcomes. H5: Learning exhaustion is negatively associated with training outcomes, partially offsetting the positive effects of the engagement.

2.5 Trait–Pedagogy Fit

Instructional approaches do not have uniform effects across learners (Hattie, 2009). From a trait–situation fit perspective, pedagogical effectiveness depends on the compatibility between instructional demands and learner resources. Macey and Schneider (2008) distinguish trait-like predispositions toward engagement from situationally activated engagement states; in the present context, exploratory and exploitative tendencies represent stable predispositions that interact with instructional conditions to produce varying engagement and exhaustion. Exploitative learners are expected to benefit from structured formats with clear behavioral guidance, while exploratory learners are expected to show more consistent performance across varying instructional conditions.

H6: The relationship between instructional design and training outcomes is moderated by learner ambidexterity profiles.

3. Methodology

3.1 Research Design and Sample

A quantitative scenario-based survey design was employed. Participants evaluated their engagement, exhaustion, and perceived learning outcomes in response to structured training scenarios. Nine scenarios were constructed from a 3 × 3 framework combining three teaching approaches—Cognitivist, Constructivist, and Behaviorist—with three intrapreneurial influence tactics—Professional-oriented, Motivation-oriented, and Consequentialism-oriented. Participants were asked to respond as if participating in each described training context, drawing on their professional experience.

The sample consisted of 557 B2B sales professionals and corporate intrapreneurs recruited voluntarily through organizational training coordinators across sales-oriented industries. This practice-relevant sample supports the multigroup and moderation analyses employed.

3.2 Measures

All constructs were assessed using validated five-point Likert-type scales. Exploratory and exploitative traits were measured using items adapted from March (1991) and Schildt et al. (2005). Learning engagement was measured using items adapted from Kahn (1990) and Schaufeli et al. (2002). Learning exhaustion was measured using items adapted from Maslach and Leiter (2008). Three training outcome constructs were assessed: Knowledge Improvement (Kwg), Proactive Attitudes (Pro), and Behavioral Change (Chg).

3.3 Analytical Strategy

Data were analyzed using R with the lavaan package. Confirmatory Factor Analysis (CFA) assessed measurement validity. CB-SEM with bootstrapping (5,000 resamples) estimated parallel indirect effects. Moderated Multiple Regression (MMR) and ANOVA examined trait-conditioned scenario effects. Multi-Group Analysis (MGA) compared structural paths across trait-defined groups. K-Means clustering served as an exploratory profiling tool, with solutions validated using within-cluster sum of squares and silhouette coefficients. A Harman single-factor test was conducted to partially assess common method bias; no single factor accounted for a majority of the variance, although the limitation is acknowledged.

4. Results

4.1 Measurement Model

The measurement model demonstrated adequate fit: CFI = 0.954, TLI = 0.946, RMSEA = 0.046, SRMR = 0.054. Cronbach's alpha and composite reliability values ranged from 0.74 to 0.83, with AVE values supporting convergent and discriminant validity.

4.2 Parallel Mediation

Both exploratory and exploitative traits were positively associated with engagement, supporting H1 and H2. The exploitative trait was additionally associated with exhaustion under high-demand conditions, supporting H3. Engagement was positively associated with all outcomes (H4 supported). The indirect effect of the exploitative trait on behavioral change through exhaustion was negative and significant ($\beta = -0.130$, 95% CI excluding zero), while the indirect effect through engagement was positive, supporting H5. The net effect favored exploratory learners, for whom engagement consistently dominated, while for exploitative learners, the exhaustion pathway was of sufficient magnitude to meaningfully offset engagement benefits.

4.3 Trait–Pedagogy Fit

One-way ANOVA found no significant direct effects of the scenario on outcomes ($p > 0.05$), indicating no universally superior instructional design. The three-way interaction among teaching approach, influence strategy, and learner trait was significant ($p < 0.05$), with the full model explaining 48.6% of the variance in behavioral change (adjusted R^2), supporting H6. Clustering analysis identified four distinct profiles (Table 1).

Table 1: Optimal Instructional Fit by Learner Profile

Profile	Less Favourable	More Favourable	Engagement	Exhaustion	Change
High-Explore	Motivation-Cognitivist	Motivation-Behaviorist	5.71	Reduced	5.98
Low-Explore	Rigid Consequentialism	Motivation-Constructivist	—	4.47	4.95*
High-Exploit	Unstructured Professional	Consequentialism-Behaviorist	5.65	—	5.90
Low-Exploit	Passive risk	Professional-Behaviorist/Cognitivist	—	—	Restored

4.4 Multi-Group Analysis

For the exploratory trait, no significant path differences were detected between the high- and low-exploration groups ($p > 0.05$), indicating structural consistency across conditions. For exploitative traits, five of the six path comparisons were significant ($p < 0.01$). Most critically, the negative exhaustion–behavioral change path was substantially stronger in the high exploit group ($\Delta\beta = 0.271$, $p < 0.001$), confirming that exploitative learners are more adversely affected by cognitive exhaustion in weakly structured settings.

5. Discussion

5.1 Theoretical Implications

This study extends Cognitive Load Theory (Sweller et al., 2019; Gerjets et al., 2009) to intrapreneurial capability development by demonstrating that cognitive burden and engagement co-occur as opposing mediating pathways. This dual-pathway finding, consistent with the Job Demands-Resources framework (Bakker and Demerouti, 2008), challenges accounts that treat engagement as uniformly positive. High engagement scores may coexist with elevated exhaustion, and downstream effects on behavioral change depend substantially on how instructional design manages cognitive burden. Evaluation frameworks incorporating exhaustion alongside engagement may therefore provide a more complete picture of training effectiveness.

The asymmetry between exploratory and exploitative learners extends Yeniaras et al. (2024), who identified differential moderating roles of these orientations under managerial pressure. The present study demonstrates

that analogous dynamics operate in pedagogical contexts, suggesting that exploitative learners' cognitive sensitivity to high-demand conditions is not situationally specific but reflects a more general vulnerability to instructional misfit. This extends and operationalizes Hattie's (2009) observation about instructional context-dependence, and aligns with Kirschner et al.'s (2006) critique of minimally guided approaches by identifying the individual-level boundary condition under which such costs are most severe.

5.2 Practical Implications

For exploratory learners, motivation-oriented tactics combined with behaviorist approaches balance cognitive stimulation with manageable load. Instructional designs that preserve autonomy and competence further sustain engagement (Ryan and Deci, 2000). For exploitative learners, structural clarity is essential: consequentialism-oriented formats with clear behaviorist guidance reduce the appraisal of demand as exceeding resources (Brockbank and Feldon, 2024), limiting exhaustion onset. For learners low in exploitative tendency, professional-oriented formats sustain involvement but require sufficient scaffolding. For HR managers and training coordinators, pre-programme assessment of learner trait profiles can guide instructional format selection, group composition, and facilitation strategy, enabling more precise alignment of pedagogical demand with learner characteristics.

6. Limitations and Future Research

Several limitations warrant acknowledgement. All outcomes were self-reported within a scenario-based design, limiting causal inference and objective performance verification. Future research should incorporate supervisor-rated indicators, pre- and post-training knowledge tests, and longitudinal tracking. The sample was drawn from B2B sales industries, which may limit generalizability; replication across technology innovation, healthcare, or social entrepreneurship contexts would clarify boundary conditions. The K-means clustering approach involves assumptions about cluster shape and number that may not fully reflect data heterogeneity; latent profile analysis would provide a more rigorous alternative. Finally, ambidextrous traits were treated as stable characteristics, whereas they may be partially situationally activated (Tushman and O'Reilly, 1996); future research examining within-person variability across training contexts could enrich the understanding of trait–pedagogy fit dynamics.

7. Conclusion

This study examined how learner ambidexterity and instructional design jointly shape intrapreneurial capability development in corporate training. Engagement and exhaustion function as concurrent and partially opposing mediating pathways, varying systematically across learner profiles. Pedagogical effectiveness was determined not by the degree of interactivity alone, but by the fit between instructional demands and learner characteristics. Sustainable intrapreneurial capability development requires deliberate alignment of teaching methods with the cognitive and motivational profiles of the learners they serve.

Ethics Declaration

Ethical clearance was not required for this study. Data were collected from voluntary participants with informed consent. No personally identifiable information was retained, and all responses were treated as strictly confidential. The study was conducted in accordance with the applicable ethical guidelines for social science research.

AI Declaration

AI-assisted writing tools were used for the preparation and language editing of this paper. All intellectual content, theoretical framing, research design, data analysis, and interpretations were the work of the authors. AI tools were not used for data generation, statistical analyses, or the creation of original arguments.

Abstract: In the contemporary business environment, characterised by rapid technological change and intense competition, innovation has emerged as a critical determinant of organisational success and long-term sustainability. Small and medium-sized enterprises (SMEs), in particular, rely on innovation to enhance competitiveness and respond effectively to dynamic market conditions. Organisational culture plays a fundamental role in shaping firms' internal environments and influencing their innovation capabilities and overall performance. This study presents a systematic literature review examining the relationship between organisational culture, innovation, and SME performance. A structured search of the Scopus database was conducted in March 2026, focusing on English-language peer-reviewed journal articles published between 2015 and 2026. Following the screening process, 38 studies were included and analysed using thematic synthesis. The findings indicate that organisational cultures characterised by collaboration, adaptability, knowledge sharing, and employee empowerment are more likely to foster product, process, marketing, and organisational innovation, ultimately contributing to improved organisational performance. However, the review also suggests that the relationship between organisational culture and performance is influenced by contextual and organisational factors. The study contributes to the literature by synthesising current evidence, identifying key research gaps, and proposing directions for future research. The review is limited to English-language journal articles indexed in Scopus, which may have excluded relevant studies published in other databases or languages.

Keywords: Organisational Culture; SMES; Innovation; Organisational Performance; Systematic Literature Review; Scopus.

1. Introduction

Because it influences employee behavior, encourages information exchange, and makes it easier for employees to participate in decision-making processes, organizational culture is a key factor in determining an organization's performance (Obeidat et al. 2018). Given their limited resources and heavy dependence on internal competencies to maintain competitiveness, small and medium-sized firms (SMEs) place an even greater emphasis on culture. A strong corporate culture encourages teamwork, improves information sharing, and develops employees' abilities and experiences, all of which eventually stimulate the creation of fresh concepts and cutting-edge procedures. SMEs must embrace flexible and adaptable cultural frameworks that foster innovation and continual development in the modern business climate, which is marked by quick technical breakthroughs and heightened global competitiveness (Papakonstantinou et al. 2025; Xanthopoulou and Sahinidis 2025). Organizational culture affects a company's capacity to adapt to external changes as well as its internal dynamics. Product, process, marketing, and organizational innovation are just a few of the kinds of innovation that may be helped or hindered by distinct cultural elements in this environment. The link between organizational culture, innovation, and company success in SMEs is thoroughly reviewed in this paper. In order to investigate how cultural traits support the growth of innovative capacities and how these in turn impact organizational performance, it synthesizes previous studies. The significance of innovation as a mediating element between culture and performance is given considerable attention, with evidence that inventive activity—particularly product innovation—serves as a critical driver of SME success highlighted. Despite the growing body of research on organisational culture, innovation and SME performance, the existing literature remains dispersed across different theoretical perspectives, innovation types and organisational contexts. Consequently, there is still limited understanding of how these relationships have evolved and which research themes have received the greatest scholarly attention. Accordingly, this study addresses the following research question: RQ: How does organisational culture influence innovation and organisational performance in SMEs, and what are the dominant research trends emerging from the literature? This review contributes to the literature by synthesising recent evidence, identifying the principal research streams, highlighting convergent and divergent findings, and proposing directions for future research. Unlike previous reviews that have focused

primarily on organisational culture or innovation separately, this review integrates organisational culture, innovation, organisational performance and complementary organisational mechanisms within the SME context. It also highlights emerging research trends and identifies gaps requiring further investigation. For scholars, practitioners, and legislators looking to improve SME competitiveness through culture-driven innovation initiatives, the results should provide insightful information.

2. Literature Review

2.1 Organizational Culture

While opinions on the definition and meaning of organizational culture vary, most of them relate to a set of values and guiding principles that will impact every activity, behavior, and working relationship (Massaras et al. 2014). Since organizational culture is derived from a variety of scientific disciplines, its definition is a topic of extensive debate. As a result, the phrase is used interchangeably with ideas like an organization's ideals and environment or with behavioral norms and shared beliefs among a group of individuals. Organizational culture is defined by Serpa (2016) as "the shared way of being, thinking, and acting in a collective of coordinated people with reciprocal expectations" (p. 51). According to Schein (1985), all of these are only facets of culture, or more accurately, the many facets of culture, not the culture itself. According to Schein (1985), culture comprises the underlying presumptions and ideas that members of an organization share and that function on an unconscious level. According to Parent and Lovelace (2018), organizational culture is also linked to trust, loyalty, and involvement via cooperation, which enables managers to be kind and motivates staff to follow the rules and customs. Because of this, cultural factors have a significant impact on individual performance, which in turn helps employees meet organizational goals for productivity and efficiency (Adeoye and Hope 2020). Additionally, corporate culture is thought to be one of the most important success elements for the execution and accomplishment of quality improvement initiatives (Carvalho et al. 2019). It is challenging to analyze contemporary firms without taking their organizational cultures into account. There is no widely recognized definition of culture in the literature, which makes it clear that culture is a complicated idea (Tian et al. 2018).

2.2 Innovativeness and Organizational Culture

According to Sahinidis (2010), an organization's ability to develop, integrate, and assimilate innovations is what makes it innovative. Similar to culture, there are several definitions of innovation in the literature, which results in the absence of a precise and official definition. Several scholars have defined innovation as the creation, acceptance, and use of novel concepts, procedures, goods, or services. The research consistently concludes that innovation is essential to a business's continued growth. Strong cultures are often more effective. Employee commitment increases with the strength of the organization's culture. Employees are motivated and controlled by strong cultures, which improves performance. Strong organizational cultures are more effective than weak ones in achieving organizational objectives, according to Thokozani and Maseko's (2017) research. Nonetheless, a sizable portion of experts believe that, under specific circumstances, such as the kind of setting, culture has a good relationship with company success. However, a number of studies show that businesses with strong cultures perform better than those with weak cultures and hinder internal innovation. They conclude that cultures that prioritize flexibility foster innovation since it is linked to creativity, independence, and a willingness to take risks, whereas cultures that prioritize stability and control may stifle innovation. However, the intense socialization and the strict adherence to the prevailing norms can generate individual views and ideas strikingly similar, since both the information perception and interpretation processes have been influenced in a specific direction, by the overpowering organizational culture. Such controlling cultures stifle novel thinking and creativity and limit innovation stimuli perception, to those existing within the boundaries of the organizational members' perceived environment. Employees at a company with a poor culture simply follow policies and procedures out of fear of the repercussions of their inaction rather than because they like their work. Morality, customer relations, innovation, performance, collaboration, service, and loyalty are all negatively impacted by a business with a poor culture since it is difficult to properly convey expectations to employees.

3. Methodology

To ensure that only relevant and up-to-date studies were included, the literature search was limited to peer-reviewed journal articles published in English between 2015 and 2026. The Scopus database was selected as the primary source because of its extensive coverage of high-quality academic publications. The search was conducted on March 2026 using predefined keywords related to organisational culture, innovation, SMEs, and

performance. Boolean operators (AND, OR) were applied to improve the precision and comprehensiveness of the search. The complete search query is presented in Table 1.

Table 1: Boolean operators

TITLE-ABS-KEY (("organizational culture" OR "corporate culture") AND innovation AND (SMEs OR "small and medium enterprises") AND performance) AND PUBYEAR > 2014 AND PUBYEAR < 2027 AND (LIMIT-TO (DOCTYPE, "ar")) AND (LIMIT-TO (LANGUAGE, "English"))

A multi-stage screening procedure was applied to ensure the quality and relevance of the final dataset. As illustrated in the PRISMA flow diagram (Figure 1), the initial Scopus search identified 104 records. After applying the predefined eligibility criteria (English language and journal articles), 15 records were removed before screening, resulting in 89 records eligible for title and abstract screening. During this stage, 51 records were excluded because they did not meet the inclusion criteria. Specifically, studies were excluded if they did not focus on SMEs, did not examine organisational culture, innovation or organisational performance, or were outside the scope of the review. Consequently, 38 studies met the eligibility criteria and were included in the final qualitative synthesis. The screening and study selection process was undertaken collaboratively by the authors using the predefined inclusion and exclusion criteria. Any differences in study selection were resolved through discussion until consensus was reached. For each included study, information was extracted on the authors, publication year, country, research context, study design, organisational culture framework, innovation type, performance outcomes, and principal findings. The extracted evidence was analysed using thematic synthesis, whereby studies addressing similar concepts were grouped to identify recurring themes, convergent and divergent findings, and emerging research trends. Given the objective of this review, no formal methodological quality appraisal tool was applied, which is acknowledged as a limitation of the study.

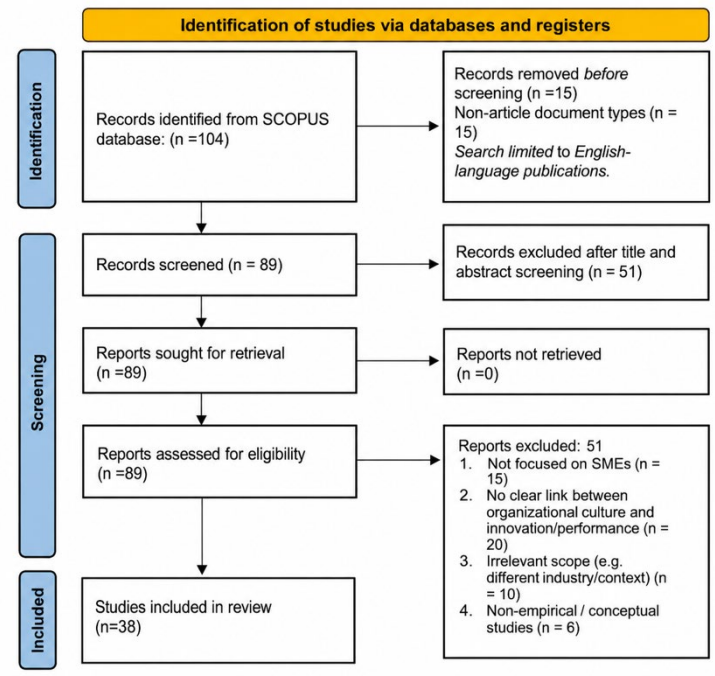

Figure 1: PRISMA flow diagram of the study selection process.

4. Results

The analysis of the retrieved articles reveals a growing research interest in recent years (Figure 2), with the highest number of publications observed in 2025. Geographically, the majority of studies originate from countries such as China, Indonesia, and Malaysia, while contributions from European and Western countries are comparatively limited. Additionally, only a small number of authors have multiple publications in this field, indicating a relatively fragmented research landscape.

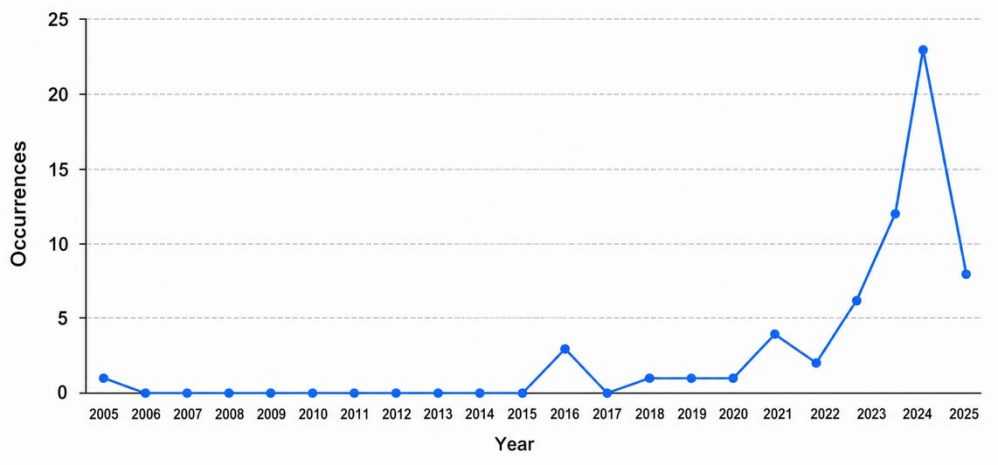

Figure 2: Distribution of retrieved records by publication year (Scopus database)

Figure 3 illustrates the distribution of publications by country or geographic region, highlighting the key centers of knowledge production in the field under consideration. It is observed that China, Indonesia, and Malaysia occupy the top positions, with the highest number of publications, a fact that indicates intense research activity in these countries. The dominance of these Asian economies can be linked to the growing importance of small and medium-sized enterprises (SMEs) in developing markets, as well as to the emphasis placed on innovation as a driver of economic growth. Next is the United Kingdom, which also makes a significant contribution, confirming the enduring role of developed European economies in the production of academic knowledge. Next, countries such as Vietnam, Hungary, and Spain exhibit moderate levels of publications, indicating that interest in this field is widespread but not uniformly developed. Finally, countries such as France, Morocco, and Pakistan show a lower number of publications, which may reflect either less research focus on the subject or limited resources and infrastructure for conducting relevant research. Overall, the graph demonstrates a geographical concentration of research primarily in Asia, while also highlighting the existence of international interest, with participation from both developed and emerging economies.

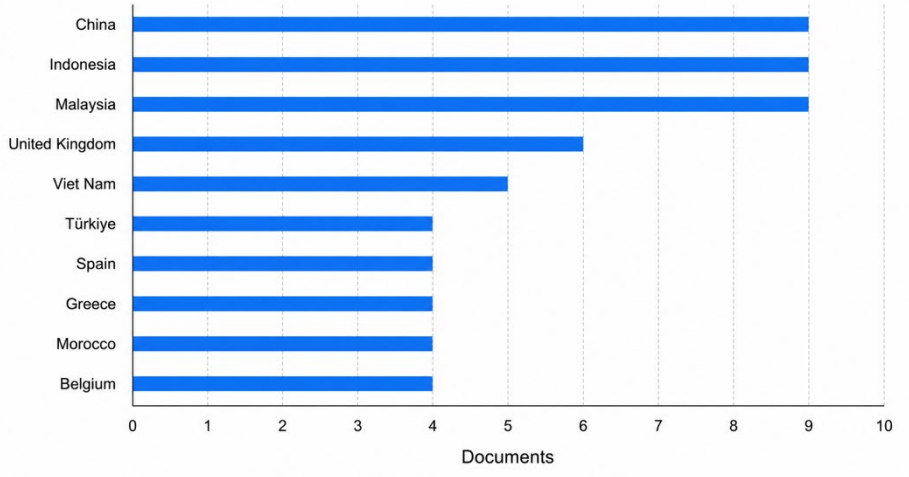

Figure 3. Documents by country or territory (Scopus database)

4.1 Organizational Culture as a Driver of Innovation

A substantial body of the reviewed literature identifies organizational culture as a critical determinant of innovation within SMEs. In particular, cultural characteristics that emphasize flexibility, adaptability, and openness to change are consistently associated with higher levels of innovativeness. Empirical studies demonstrate that specific cultural types, such as adhocracy, developmental, and externally oriented cultures, foster innovation by encouraging proactiveness, risk-taking, and knowledge sharing (Shuaib and He 2021; Shahin et al. 2025; Laforet 2016; Kuhn and Bhatiasevi 2024; Le et al. 2020; Zhang et al. 2025). Furthermore, organizational culture shapes the internal environment that supports knowledge creation and dissemination.

Studies indicate that firms characterized by collaborative and learning-oriented cultures are better equipped to generate innovative ideas and adapt to dynamic market conditions (Pudjiarti and Hutomo 2020; Gorondutse et al. 2021; Saleh et al. 2025). In addition, the role of culture extends to influencing innovation-related behaviors, including entrepreneurial orientation, communication effectiveness, and organizational learning processes (Rahman et al. 2021; Pisar and Mazo 2020; Manalu et al. 2025). However, the relationship between culture and innovation is not universally positive. Certain cultural configurations, particularly hierarchical or control-oriented cultures, may hinder innovation by limiting flexibility and restricting employee autonomy (Wang and Huang 2022; Albarracín and García-Pérez-de-Lema 2011). Similarly, some studies suggest that organizational culture alone is not sufficient to drive innovation unless it is supported by complementary organizational capabilities (Kassa and Kegne 2025). Overall, although most studies agree that organisational culture positively influences innovation, the reviewed evidence suggests that its impact depends on organisational context and complementary managerial capabilities.

4.2 Innovation as a Mediating Mechanism between Culture and Performance

A key finding across the reviewed studies is the mediating role of innovation in the relationship between organizational culture and firm performance (Setyawati et al. 2026; Zhang et al. 2025; Le et al. 2020; Kareem et al. 2024; Almeida and Okon 2026). This mediating mechanism is particularly evident in studies examining the role of innovation capability as a strategic resource. Organizational culture contributes to the development of innovation capabilities, which subsequently translate into higher levels of organizational performance (Srisathan et al. 2020; Altassan 2023; Al-Hakimi et al. 2022). In this context, innovation acts as a conduit through which cultural values are transformed into measurable business outcomes. Moreover, the findings indicate that different types of innovation have varying effects on performance. Product innovation is consistently identified as the most significant driver of firm performance, followed by process and organizational innovation (Amoa-Gyarteng and Dhliwayo 2024; Lita et al. 2020). In contrast, some studies report weak or insignificant relationships between certain innovation types and performance, suggesting that the effectiveness of innovation depends on contextual and strategic factors (Krobbuaban et al. 2021). Importantly, several studies highlight that organizational culture may not directly influence performance but exerts its impact entirely through innovation and related capabilities. This underscores the importance of innovation as a critical mediating mechanism linking internal organizational factors to external performance outcomes (Setyawati et al. 2026; Zhang et al. 2025). These findings indicate that innovation does not always fully mediate the relationship between organisational culture and performance, as contextual factors may influence this relationship.

4.3 Role of Organizational and Managerial Mechanisms

The analysis further reveals that the relationship between organizational culture, innovation, and performance is influenced by the interaction of multiple internal organizational mechanisms. In particular, human resource management (HRM) practices, knowledge management, total quality management (TQM), and leadership emerge as key complementary factors. HRM practices contribute to the development of innovation capability by enhancing employee skills, motivation, and engagement, thereby strengthening the link between culture and performance (Setyawati et al. 2026; Phi Nga and Thanh Tam 2025; Papakonstantinou et al., 2025). Similarly, knowledge management practices facilitate the exchange and integration of knowledge, which is essential for innovation processes (Zhang et al. 2025). In addition, TQM practices are found to positively influence innovation outcomes when aligned with a supportive organizational culture. Studies indicate that culture plays a crucial role in the successful implementation of TQM, as it shapes employees' attitudes toward quality, learning, and continuous improvement (Saleh et al. 2025; Gorondutse et al. 2021; Shuaib and He 2021). Leadership also emerges as an important factor, as it influences both organizational culture and innovation through the promotion of values, vision, and strategic direction (Fajar et al. 2024; Tariq et al. 2025). Overall, these findings suggest that innovation is the result of a complex interplay between organizational culture and multiple managerial practices. Culture provides the foundation, while these mechanisms enable the effective implementation and exploitation of innovation.

4.4 Contextual and External Influencing Factors

The reviewed studies also emphasize the importance of external and contextual factors in shaping innovation and performance in SMEs. These factors are particularly relevant in developing and emerging economies, where firms often operate under resource constraints and institutional limitations. Key external factors identified in the literature include access to finance, government support, technological capability, and market conditions.

Limited access to financial resources and weak institutional support are frequently reported as major barriers to innovation (Kassa and Kegne 2025). In addition, technological limitations and lack of skilled personnel further constrain SMEs' innovation capacity. At the same time, several studies highlight the growing importance of digital transformation and sustainability-oriented practices. The integration of digital technologies, green innovation, and knowledge sharing is increasingly recognized as a key driver of competitiveness and performance in SMEs (Almeida and Okon 2026; Altassan 2023; Tariq et al. 2025). These emerging trends indicate that the relationship between organizational culture, innovation, and performance is evolving in response to broader environmental changes. Despite these challenges, organizational culture is found to play a mitigating role by enhancing firms' adaptability and resilience. A strong, innovation-oriented culture enables SMEs to respond more effectively to environmental uncertainty and to exploit emerging opportunities, thereby improving their long-term performance.

5. Conclusions

The present study aimed to provide a comprehensive understanding of the relationship between organizational culture, innovation, and firm performance in small and medium-sized enterprises (SMEs) through a systematic literature review. A key conclusion emerging from this study is that organizational culture significantly influences the development of innovation within SMEs. Cultural characteristics that promote flexibility, openness, collaboration, and learning orientation are consistently associated with enhanced innovation capability. In contrast, rigid and hierarchical cultures tend to inhibit innovation by restricting employee autonomy and limiting knowledge exchange. This finding underscores the importance of cultivating an adaptive and innovation-oriented organizational culture in order to sustain competitiveness in dynamic business environments. Furthermore, the study confirms that innovation acts as a central mediating mechanism linking organizational culture to firm performance. Rather than exerting a direct influence, organizational culture primarily contributes to performance through its impact on innovation processes. Among the different types of innovation, product innovation appears to have the strongest effect on performance outcomes, highlighting its strategic importance for SMEs. This emphasizes that firms must not only foster a supportive culture but also actively invest in innovation activities to translate cultural values into tangible results. In addition, the findings reveal that the relationship between culture, innovation, and performance is influenced by a range of internal organizational mechanisms, including human resource management practices, knowledge management, leadership, and total quality management. These factors enhance innovation capability when aligned with an appropriate cultural context, suggesting that organizational effectiveness is the result of a synergistic interaction between multiple dimensions rather than a single determinant. The study also highlights the role of external and contextual factors, particularly in developing and emerging economies. Constraints such as limited access to finance, weak institutional support, and technological challenges can hinder innovation efforts. However, a strong organizational culture can partially mitigate these limitations by enhancing adaptability and resilience. From a theoretical perspective, this study contributes to the existing literature by providing an integrated framework that links organizational culture, innovation, and performance in SMEs. It identifies key themes and relationships while highlighting the mediating role of innovation and the importance of contextual factors. From a practical standpoint, the findings offer valuable insights for managers and policymakers, suggesting that fostering an innovation-oriented culture, investing in employee development, and supporting knowledge-sharing practices are essential for enhancing SME performance.

Despite its contributions, the study has certain limitations. The analysis was restricted to articles published in English and indexed in the Scopus database, which may limit the generalizability of the findings. In addition, the study focused exclusively on peer-reviewed journal articles, excluding other sources such as conference papers and reports. Future research could expand the scope by incorporating multiple databases and exploring longitudinal or empirical approaches to further validate the identified relationships.

In conclusion, the findings of this study emphasize that organizational culture is a key enabler of innovation, which in turn acts as a critical driver of firm performance in SMEs. Strengthening the alignment between cultural values, innovation strategies, and organizational practices is essential for achieving sustainable competitive advantage in an increasingly complex and dynamic business environment. Future research should further explore these relationships using longitudinal and cross-country studies.

ShuHsiang.Chen@xjtlu.edu.cn
Tong.He@xjtlu.edu.cn

Abstract: As environmental degradation and rural inequality continue to intensify alongside rapid economic development, social entrepreneurship has emerged as an important mechanism for integrating ecological sustainability with socioeconomic advancement. This study examines Shanshui Partners, a conservation oriented social enterprise operating in Sichuan Province, China, to explore how hybrid organizational models can reconcile biodiversity protection with rural livelihood development. Grounded in the perspectives of sustainable entrepreneurship, Resource Dependence Theory, and community-based resource governance, the study investigates both the opportunities and tensions embedded within conservation based social enterprises. The findings identify a three-dimensional value creation system implemented by Shanshui Partners. First, the organization reconfigures agricultural value chains by connecting certified panda friendly products to premium urban markets. Second, it institutionalizes payments for ecosystem services (PES), transforming biodiversity protection into a viable source of rural income. Third, it develops local human capital through ecological monitoring and green skills training programs for rural youth. The case demonstrates how conservation incentives can be integrated into local economic systems while contributing to ecological restoration and community empowerment. At the same time, the analysis highlights structural vulnerabilities associated with hybrid organizations, including dependency on corporate sustainability funding, the risk of mission drift, and tensions between conservation objectives and local development pressures. The study contributes to the literature on social entrepreneurship and sustainable development by showing that market driven conservation models can generate both environmental and social value, while also remaining highly dependent on institutional support and long-term stakeholder collaboration.

Keywords: Social Entrepreneurship, Shanshui Partners, Sustainability, Community

1. Introduction

Rapid economic expansion over recent decades has driven unparalleled technological advancements, yet it has also imposed severe ecological costs. Intensive fossil fuel consumption, deforestation, and unregulated resource extraction have degraded air, water, and soil quality, with visible impacts on public health and biodiversity (Angus, 2016; China Biennial Update Report on Climate Change, 2024). Satellite data reveal a 40% increase in particulate matter levels across industrial regions since 2010, correlating with a rise in respiratory diseases among urban populations(P. Wang, 2021). While economic priorities have historically overshadowed environmental concerns, mounting evidence of ecological limits has spurred interest in alternative development models, particularly those that reconcile profit motives with sustainability goals (Henderson & Loreau, 2023).

Social entrepreneurship has become a vital approach for addressing the intertwined challenges of economic development and sustainability, offering innovative solutions that balance profit motives with social and environmental goals. Research highlights that social entrepreneurship operates across four key dimensions: social, economic, behavioral, and governance, each contributing to sustainability by fostering value creation, smart partnerships, and social innovation (Kamaludin, 2023; Kamaludin et al., 2024). Social enterprises are particularly effective in advancing the United Nations Sustainable Development Goals (SDGs), with new frameworks and rating systems developed to measure their impact, especially in areas where traditional businesses have fallen short (Diaz-Sarachaga & Ariza-Montes, 2022; X. Wang et al., 2024) . Systematic reviews and conceptual models emphasize that social entrepreneurship not only addresses immediate social problems but also drives broader sustainable development by integrating economic, social, and ecological objectives, often through a sequential process (Bansal et al., 2019; Belz & Binder, 2017; Nagdev et al., 2025). In rural and emerging economies, social entrepreneurship builds legitimacy and social capital, empowering communities and facilitating transitions toward sustainable practices (X. Wang et al., 2024). Overall, social entrepreneurship is increasingly recognized as a powerful mechanism for achieving sustainability goals, offering practical pathways for reconciling economic growth with environmental stewardship and social well-being (Bansal et al., 2019; Belz & Binder, 2017; Diaz-Sarachaga & Ariza-Montes, 2022; Kamaludin et al., 2024; Nagdev et al., 2025).

By adopting blue ocean strategies, creating untapped markets through innovation1, social enterprises bypass competitive saturation in traditional industries while tackling environmental issues (Elkington, 1994; Gupta et

al., 2020). Social enterprises are designed to address social issues while operating with business principles, but research shows they often face unique challenges that can make them fragile (Sarhangi et al., 2024; Segovia-Vargas et al., 2024). Their fragility mainly stems from balancing social missions with financial sustainability, and the ongoing risk of mission drift (He et al., 2022). However, not all social enterprises are equally vulnerable, and many demonstrate resilience through specific strategies and organizational strengths. Therefore, this study conducts an in-depth case analysis of Shanshui Partners to elucidate its social entrepreneurship business model comprehensively. Such models demonstrate that market-based solutions can align profitability with environmental stewardship when supported by adaptive policies and community engagement (Gregori & Holzmann, 2020).

Despite the growing literature on social entrepreneurship, there remains a notable gap in understanding the boundary conditions and inherent tensions of applying hybrid financing models to rural conservation. This study advances current theory by critically examining how a social enterprise navigates the delicate balance between corporate funding reliance and community autonomy. By doing so, it moves beyond descriptive success stories to interrogate the vulnerabilities of conservation based social enterprises, offering a refined perspective on mission drift and organizational resilience in developing economies.

2. Theoretical Framework and Literature Review

To properly contextualize the Shan Shui Partners case within academic discourse, the analysis is grounded at the intersection of sustainable entrepreneurship, hybrid organizations, and common pool resource governance.

Sustainable entrepreneurship is conceptualized as the discovery, creation, and exploitation of opportunities to produce future goods and services that sustain the natural environment and provide social and economic benefits to others. Schaltegger and Wagner (2011) emphasized in their pioneering research that sustainable enterprises face increasing complexity because they must simultaneously achieve economic viability and mission related outcomes, distinguishing them from traditional businesses that view environmental regulations merely as compliance costs. Such enterprises often act as institutional entrepreneurs, altering the market environment to internalize environmental externalities.

Pursuing dual bottom lines simultaneously causes these entities to be classified as hybrid organizations. Academic literature consistently notes the inherent vulnerabilities in managing hybrid organizations. Ebrahim et al. (2014) highlighted that hybrid organizations experience profound tensions when attempting to combine competing institutional logics. For instance, the market logic focusing on efficiency and revenue generation conflicts with the social welfare logic focusing on community well-being and environmental protection. When these logics collide, organizations frequently experience the phenomenon of mission drift. Mission drift occurs when a social enterprise disproportionately prioritizes its commercial ventures while neglecting its social or environmental goals, usually out of a need for financial survival (Bullock, 2022; Mendes, 2022). Scholars point out that avoiding mission drift requires sophisticated governance structures, ownership models inclusive of all stakeholders, and socialization processes that maintain a dual focus within human resources. Furthermore, consumers and stakeholders are highly sensitive to mission drift, and any perceived deviation from the ethical legitimacy of the enterprise can lead to a withdrawal of support, further endangering the organization (Mendes, 2022).

Resource Dependence Theory, initially proposed by Pfeffer and Salancik (1978), provides a critical perspective for understanding why mission drift occurs. All organizations depend on their external environment for survival, and the necessity to acquire resources subjects them to external control. For conservation oriented social enterprises, resources typically come from corporate social responsibility budgets, government grants, or premium markets pursuing ethical consumption. Relying heavily on corporate social responsibility funding creates a dependency vulnerability. In this scenario, the enterprise might inadvertently adjust its conservation metrics to meet the public relations requirements of the corporation rather than the actual ecological needs. Managing these dependencies without losing organizational autonomy remains a central theoretical puzzle in hybrid organization research.

In addition, the natural resource governance involved in these social enterprise models relies heavily on community-based conservation principles. Elinor Ostrom (1990) demonstrated in her foundational work on commons governance that common pool resource problems can be successfully resolved by voluntary organizations and local communities without coercive state intervention or complete privatization. Ostrom identified key design principles for successful common pool resource institutions, including clearly defined boundaries, congruence between local rules and conditions, collective choice arrangements, and graduated

sanctions. Integrating the principles of Ostrom with sustainable entrepreneurship creates a theoretical model where the social enterprise acts as a facilitator. It provides the necessary market linkages and capacity building to enable local communities to govern their own common resources effectively. This theoretical synthesis forms the basis for analyzing how Shan Shui Partners structures its interventions in the Giant Panda National Park.

3. Empirical Methods and Research Design

To address the complexities of hybrid organizations and provide a robust, verifiable analysis of the Shan Shui Partners model, this study employs an in-depth qualitative case study approach. Following the methodological guidelines established by Yin (2018) for case study research and applications, this method is particularly suited for exploring complex contemporary phenomena in real life contexts, especially when the boundaries between phenomenon and context are not clearly evident. The single case study design was selected not to generate statistical generalization, but to facilitate analytical generalization, thereby allowing a deep exploration of the causal mechanisms linking social entrepreneurship strategies with socioeconomic and ecological outcomes in rural conservation areas.

One key limitation academia identified in preliminary assessments of social enterprise models is the overreliance on internal promotional materials or stakeholder sourced data, which often inflates success metrics and obscures operational challenges. To mitigate this vulnerability and ensure academic rigor, this study adopts a strict data triangulation strategy, utilizing multiple independent and objective data sources to verify empirical claims regarding Shan Shui Partners.

To improve the credibility and academic rigor of the empirical analysis, this study adopted a triangulation strategy that combined organizational reports, peer reviewed literature, policy documents, and independent media coverage. Several quantitative indicators, including the reported increase in household income, reduction in habitat encroachment, and the proportion of revenue derived from earned income, were initially obtained from the Beijing Social Enterprise Promotion Association case report (Beijing Social Enterprise Promotion Association, 2024). Given the potential limitations associated with organization proximate sources, these figures were not treated as definitive measurements but as indicative evidence of broader developmental trends. To reduce the risk of promotional bias, the study cross referenced these claims with existing literature on community-based conservation, sustainable rural entrepreneurship, and hybrid organizational governance in China (Berkes, 2007; Ebrahim et al., 2014; Wang et al., 2024). Additional contextual verification was obtained through publicly available policy materials, conservation reports, and independent observational accounts discussing ecological restoration, panda habitat protection, and livelihood transitions in Sichuan's rural conservation regions（National Forestry and Grassland Administration, 2023; WWF China, 2023）. While fully standardized longitudinal datasets remain limited in this field, the triangulation of multiple qualitative and contextual sources improves the overall reliability of the case interpretation and supports the analytical validity of the study's conclusions.

4. Case Study of Social Entrepreneurship Promoting Sustainability

Shanshui Partners, a pioneering social enterprise in China, has developed a business model that uniquely integrates rural community empowerment with biodiversity conservation. Operating primarily in Sichuan Province's panda habitats, the organization addresses two interconnected challenges: the degradation of critical ecosystems due to unsustainable land use and the economic vulnerability of local farming communities. Unlike conventional conservation programs that often prioritize environmental goals over Local economic needs, Shanshui's model establishes a symbiotic relationship between habitat protection and agricultural livelihoods (Berkes, 2007). By training farmers in organic honey and tea cultivation and eco-tourism services, while enforcing strict land-use agreements to protect panda corridors, the enterprise creates shared value in which environmental stewardship directly enhances economic stability. This "conservation through livelihood" approach has increased average household incomes by 28% in participating villages while reducing habitat encroachment by 41% over five years (Beijing Social Enterprise Promotion Association, 2024). Shan Shui Partners chooses organic tea and honey cultivation because it aligns perfectly with their conservation mission: avoiding chemicals protects panda habitat and water sources, while the premium market value of certified organic tea directly boosts farmers' incomes. Its products most significant competitive edge lies in this ethical and conservation-focused story ("Panda Friendly"), justifying a premium price and attracting conscious consumers.

The novelty of Shanshui's model lies in its three-tiered value creation system. First, it reconfigures agricultural value chains by connecting certified sustainable products (like panda-friendly honey and tea) to premium urban markets through partnerships with ethical retailers (Yunus et al., 2010). Second, it implements a community stewardship program where villagers receive payments for ecosystem services (PES), funded through corporate sustainability partnerships(Chan & Hsu, 2016). These ecosystem services specifically include biodiversity monitoring, forest patrolling, and habitat restoration, where local residents use technical equipment to track and protect endangered species. Villagers also engage in watershed management and ecological protection activities that ensure the long-term health of the local environment. By performing these measurable conservation tasks, the community receives direct financial compensation from corporate social responsibility budgets, effectively transforming habitat protection into a sustainable livelihood. Third, the enterprise operates a skills-development hub that trains youth in ecological monitoring and green hospitality, creating new conservation-oriented employment channels (Arshad et al., 2022). This triple-layered structure ensures environmental protection becomes economically viable rather than a constraint, effectively bridging the gap between conservation imperatives and development needs.

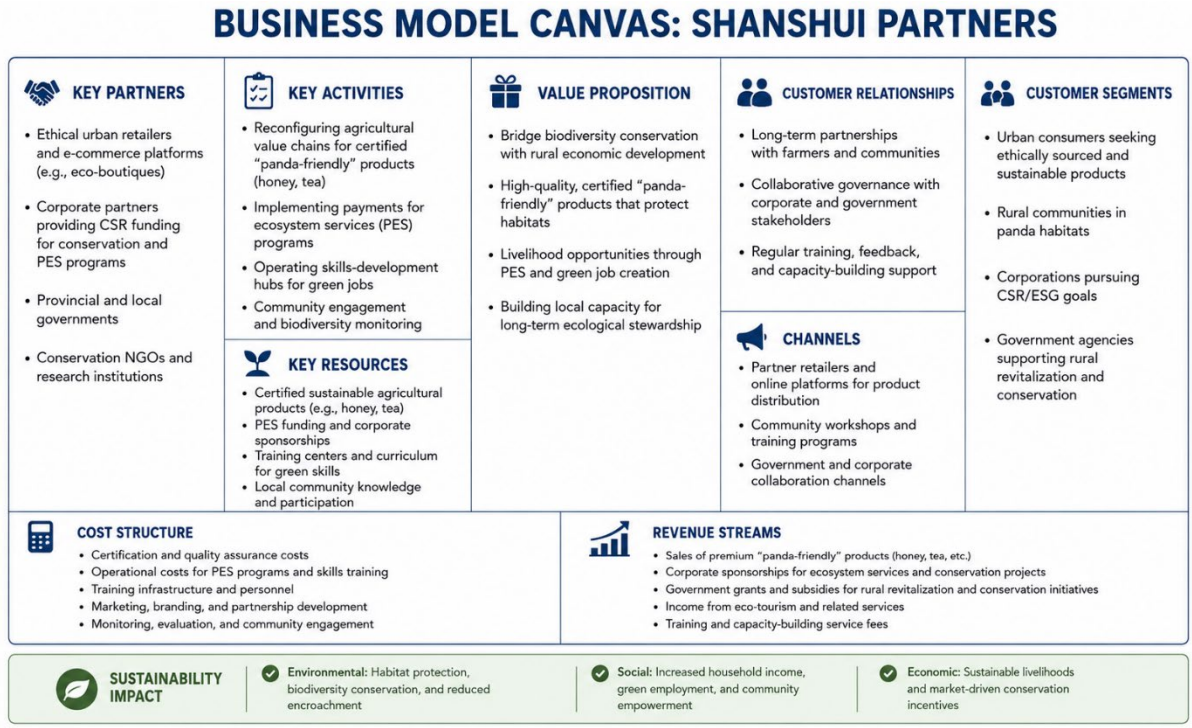

Figure 1: Business Model Canvas

Note: Authors' own analysis

Figure 1 is the business model canvas of Shanshui Parterners. According to Figure 1, Shanshui Partners makes money by selling 'Panda-friendly' products while helping local farmers earn better incomes. They work closely with key partners like eco-friendly shops in cities, companies that care about sustainability, and government or nature groups. Their main activities include creating special "panda-friendly" farm products such as honey and tea, running programs that pay villagers to protect forests, and teaching green job skills to young people. Shanshui use important resources such as certified sustainable crops, money from companies for conservation work, and training centers. Their big promise is to connect nature protection with better lives for rural communities, sell high-quality products that save animal habitats, and create new conservation jobs. Shanshui also build strong relationships with farmers through long-term deals and team up with companies and governments. To reach people, they sell through partner shops and hold community workshops. Their customers are city shoppers who want ethical goods, villagers in panda areas, and businesses aiming to meet social responsibility goals. Costs include certifying farms, running training and payment programs, and marketing. Money comes in from selling premium panda-friendly products, getting corporate sponsors for nature projects, and receiving government grants for village development. In short, Shanshui turns saving pandas into real jobs and income, proving that protecting nature can also lift people out of poverty.

Shanshui Partners' impactful model powerfully demonstrates how social entrepreneurship can operationalize the UN Sustainable Development Goals (SDGs) through context-specific solutions. Their integrated approach directly advances SDG 15 (Life on Land) via measurable habitat restoration in critical panda corridors, achieved through farmer land-use agreements that prevent ecosystem degradation. Simultaneously, they drive progress on SDG 8 (Decent Work and Economic Growth) by establishing tangible green employment pathways. Their skills-development hubs train rural youth in ecological monitoring and sustainable eco-tourism services, moving beyond subsistence agriculture into conservation-oriented livelihoods. Furthermore, the enterprise actively promotes SDG 1 (No Poverty) through significant income diversification strategies. By connecting certified "panda-friendly" products like honey and tea to premium urban markets and implementing structured PES, they elevate household incomes while embedding conservation incentives directly within local economies.

Critically, Shanshui transcends the limitations of traditional traditional Non-Governmental Organizations (NGOs) dependency on volatile donations. By generating a substantial 73% of operational revenue through earned income streams, primarily product sales and eco-tourism services, Shanshui Partner established a financially resilient framework. This self-sustaining structure enhances long-term viability and amplifies their impact continuity. The business model's growing recognition is evidenced by recent strategic collaborations with provincial governments seeking to replicate its core mechanisms in other biodiversity-rich regions. This scalability positions Shanshui's approach as a viable template for broader rural revitalization agenda, offering concrete proof that ecological protection and localized economic progress are not competing aims, but fundamentally synergistic objectives within developing contexts. The success lies in making habitat stewardship an economically rational choice for communities (Diaz-Sarachaga & Ariza-Montes, 2022).

Although the Shan Shui Partners model successfully aligns ecological and economic goals, it remains highly vulnerable to institutional pressures and structural tensions inherent in hybrid organizations. Viewed through the lens of Resource Dependence Theory, the heavy reliance on corporate social responsibility budgets exposes the enterprise to external control and financial instability during economic downturns. This creates a severe risk of mission drift (Ebrahim et al., 2014), where the pressure to scale and generate commercial revenue might skew conservation priorities toward marketable public relations projects rather than authentic ecological needs, potentially compromising stringent environmental standards. Furthermore, operational tensions constantly threaten this balance on the ground. The assumed harmony between conservation and farmer aspirations is challenged by increasing human and wildlife conflicts, as well as the high opportunity costs of restricted land use agreements, which could cause the symbiotic model to collapse if agricultural expansion becomes more lucrative than ethical certification premiums. Finally, this approach risks exacerbating socio spatial inequality by disproportionately benefiting capable individuals while marginalizing the most vulnerable community members, and the promotion of ecotourism introduces negative externalities like regional pollution that paradoxically threaten the pristine ecological brand value essential for the long-term viability and transferability of such models.

5. Conclusion and Implication

Shanshui Partners' innovative business model offers critical lessons for social enterprises seeking to reconcile ecological preservation with socioeconomic development. This case underscores the importance of designing interventions that treat ecological and social challenges as interconnected rather than isolated, a principle increasingly vital in regions grappling with biodiversity loss and rural poverty.

Three key elements of Shanshui's approach warrant emulation. First, its integrated value chain model, linking sustainable agricultural production to ethical urban markets, which provides a replicable template for monetizing conservation efforts. By creating premium "panda-friendly" product lines, the enterprise taps into growing consumer demand for sustainability while ensuring fair income streams for farmers (Yunus et al., 2010). Second, the PES mechanism institutionalizes environmental stewardship as a livelihood strategy, transforming habitat protection from a regulatory burden into a revenue-generating activity (Chan & Hsu, 2016). Third, skills diversification programs that train youth in ecological monitoring and green hospitality address systemic unemployment while building local capacity for long-term environmental governance (Arshad et al., 2022).

Shanshui Partners provides a compelling illustration of how social entrepreneurship can integrate ecological preservation with socioeconomic development. Beyond simply demonstrating success, this case reveals that the viability of conservation-based hybrid models is highly contingent on robust cross sector partnerships and the sustained willingness of urban markets to pay ethical premiums. The findings extend existing frameworks by

highlighting that while payments for ecosystem services can align economic and environmental goals, they also introduce vulnerabilities related to corporate funding dependencies.

For policymakers and social entrepreneurs, Shanshui's success highlights the necessity of hybrid financing models. By deriving 73% of operational funds from earned income, the organization reduces dependency on volatile donor funding, a structural weakness plaguing many NGOs (Achmad et al., 2023). Additionally, its partnerships with provincial governments to scale the model illustrate how institutional support can amplify grassroots innovations, aligning localized solutions with national sustainability agendas like China's rural revitalization strategy (Quaye et al., 2024).

Ultimately, Shanshui Partners exemplifies how social entrepreneurship can operationalize the UN SDGs through context-specific, community-driven interventions. Its model proves that ecological resilience and economic equity are not competing priorities but complementary objectives achievable through inclusive business design. As global environmental crises intensify, replicating such frameworks with adaptations to local ecological and cultural contexts, could redefine development paradigms in regions where people and nature share fragile, interdependent futures.

Abstract: Brunei has introduced various entrepreneurship support programmes to support economic diversification efforts and reduce unemployment. However, few empirical studies have explored the relationship between programme participation and business performance. This study investigates whether micro, small, and medium enterprises (MSMEs) that participated in at least one entrepreneurship programme between 2016 and 2024 achieved higher revenue and employment growth than non-participating businesses. We use MSMEs as a proxy for entrepreneurial activity because of their role in new business creation, employment growth, and income generation. We collected data through a survey of registered MSMEs in Brunei, including information on business characteristics, participation in entrepreneurship support programmes during 2016–2024, and changes in revenue and employment over the same period. We applied quasi-experimental Propensity Score Matching (PSM) approach to match programme participants with similar non-participants based on business sector, size, age, and prior performance. We estimated the average treatment effect on the treated (ATT) group for revenue and employment growth. After matching, we found that programme participation was not significantly associated with higher revenue or employment growth. This study adds to the literature on entrepreneurship support programmes by providing evidence from Brunei and providing a basis for policymakers to evaluate and improve future entrepreneurship programme designs.

Keywords: Brunei, Entrepreneurship, Programme Evaluation, MSMEs, Propensity Score Matching, Revenue and Employment Growth

1. Introduction

Entrepreneurship support programmes comprise different activities, such as training, financial assistance, and market access. However, it remains unclear to what extent these programmes are associated with improved business performance, particularly revenue and employment. Research evidence is inconsistent, with some studies reporting that programmes significantly increase sales or revenue, while many others find limited or insignificant effects (McKenzie and Woodruff, 2014). Additionally, some studies face methodological limitations, such as small sample sizes, short evaluation periods, and attrition, which limit conclusions about programme effectiveness (McKenzie and Woodruff, 2014). Studies also suggest that entrepreneurship programmes affect businesses through several mechanisms or intermediaries, however these effects do not always directly increase revenue or employment (El Shoubaki, Laguir and Den Besten, 2020). In Brunei, the government has introduced various entrepreneurship support programmes as part of broader efforts to diversify the economy, encourage private sector development, and reduce unemployment (YEC, 2023). However, there is limited empirical evidence linking participation in entrepreneurship programmes to business performance. Therefore, this study examines whether MSMEs participating in support programmes differ in revenue and employment between 2016 and 2024 compared with those that did not. MSMEs are used as proxies for entrepreneurial activity because of their role in new business creation, employment growth, and income generation (OECD, 2010).

Data were collected from registered MSMEs in Brunei through an online survey that retrospectively captured information on key business characteristics, revenue, and employment for the reference years 2016 and 2024. A total of 727 completed responses were retained for analysis. The analysis employs Propensity Score Matching (PSM) to pair programme participants with non-participants sharing similar characteristics, such as business sector, size, ownership type, and baseline performance (measured by revenue and employment). While this approach mitigates selection bias in observational data, the findings' estimates should be interpreted as associations rather than direct causal effects. This study contributes empirical evidence on the association between participation in entrepreneurship support programmes and business performance outcomes in Brunei. Beyond that, it also demonstrates a feasible evaluation approach applicable in contexts with limited data, drawing on balanced group comparisons. This study is part of a broader PhD project aimed at understanding and measuring entrepreneurship in Brunei, with findings intended to support evidence-based entrepreneurship policy.

2. Literature Review

Various types of support programmes are implemented by governments and development agencies to address constraints such as a lack of capital, skills, facilities, and market access (Ruozzi and Vicente, 2021). These constraints are similarly reflected in the Entrepreneurial Framework Conditions (EFC), a conceptual framework developed by the Global Entrepreneurship Monitor (GEM) that defines the systematic factors shaping entrepreneurial activity. According to EFC, these factors include financing, training and education, infrastructure, government policies, and market access (Acs, Szerb and Autio, 2015). Collectively, such conditions shape entrepreneurship outcomes and performance, including business revenue growth and employment generation. In this study, however, the EFC is not employed to model or test the causal relationships between these conditions and business performance; rather, it serves as an organising framework for categorising different types of entrepreneurial support available within Brunei's business ecosystem.

Among various entrepreneurship programmes implemented, financial assistance is one of the most widely studied. Such support helps to reduce credit constraints, enables business expansion, and promotes sales growth, particularly for enterprises facing early-stage financial barriers (Beck, Demirgüç-Kunt and Maksimovic, 2005). Financial assistance is more closely associated with improved business performance, as it enables investment in inventory, equipment and labour (De Mel, McKenzie and Woodruff, 2008; Banerjee and Duflo, 2014). Another form of support is training and capacity building, typically implemented to improve entrepreneurs' knowledge, skills, and management capabilities. Yet, unlike financial assistance, empirical evidence more commonly links training to improvements in business knowledge and practices, while evidence on revenue or employment growth tends to be more mixed and less consistent (Drexler, Fischer and Schoar, 2014). Dvoulety (2020) argues that knowledge must first change business behaviour before it can increase measurable economic impact. Meanwhile, other forms of support, such as physical infrastructure development and market access facilitation, provide businesses with resources, broader networks, and commercial opportunities. Nonetheless, their effects do not automatically translate into business growth as infrastructure mainly enables productive activities, while market access increases sales only if firms are able to exploit new opportunities effectively (Fox and Porca, 2001; Arráiz, Henríquez and Stucchi, 2013). These differences suggest that entrepreneurship support programmes operate through varying mechanisms and may affect immediate and intermediate outcomes differently, depending on the type of support and context in which it is applied.

This heterogeneity in programme effects is consistent with established theoretical perspectives, including Human Capital Theory and the Resource-Based View (RBV), both of which emphasise that resources, skills, and access create value only when applied effectively within a business context (Barney, 1991; Henry, 2013). For instance, financial interventions are more likely to increase revenue and employment when businesses possess the capacity to expand (De Mel, McKenzie and Woodruff, 2008; Banerjee and Duflo, 2014). By contrast, training programmes tend to produce capacity building outcomes, such as enhanced knowledge, increased confidence, and improved management practices, rather than immediate economic returns (Drexler, Fischer and Schoar, 2014). Against this backdrop, this study focuses on how programme participation relates to revenue growth and employment, two widely used indicators of business development. These indicators are favoured in the literature because they are consistently observable across business contexts and serve as reliable proxies for economic expansion and job creation (Delmar, 2019). However, despite the growing policy emphasis on entrepreneurship in Brunei, limited empirical evidence exists to assess how entrepreneurship support programmes relate to MSME business performance. This study addresses this gap by examining revenue and employment growth among participating and non-participating businesses.

3. Data and Methods

3.1 Data Source and Sample

This study employed an online survey to collect data on MSMEs in Brunei registered with the Registry of Companies and Business Names (ROCBN). The sampling frame was drawn from the Department of Statistics and Economics (DEPS) business databases in Brunei, from which 3,048 MSMEs with active email addresses were identified as eligible for inclusion. DEPS subsequently distributed the questionnaire link to these businesses via email. To ensure comparability across time, MSMEs were required to have a record of operations in 2016 and to remain active in 2025. These eligibility criteria enabled a longitudinal comparison of business performance across two reference points. A total of 727 complete responses were obtained, yielding a response rate of 23.9%, which is considered acceptable for an online survey targeting MSMEs (Fosnacht *et al.*, 2017).

The survey collected data on business characteristics, operational status, business sector, and participation in entrepreneurship programmes between 2016 and 2024. To enable a comparison of changes in business performance over time, respondents were asked to report their business revenue and employment at two reference points. The year 2016 served as the base year, which also marked the start of entrepreneurship initiatives in Brunei, including the establishment of the Darussalam Enterprise (Khalid and Jetin, 2025), while 2024 represents the most recent reference period for business activity. All respondents were business owners or managers with direct knowledge of their business operations. The invitation letter also informed respondents that information on business performance and programme participation would be required to allow advance preparation. This retrospective cross-sectional design was adopted as a practical alternative to panel data, given the time and resource constraints of the study (Caruana *et al.*, 2015) and the absence of secondary data linking programme participation to business performance outcomes in Brunei.

3.2 Dependent Variables

This study measures business performance using two dependent variables: change in revenue and change in employment between 2016 and 2024. Both variables were operationalised as binary, with 1 indicating growth and 0 indicating no change or a decrease. Specifically, a business was classified as growing if the reported revenue or employment level in 2024 exceeded the corresponding figure for 2016.

Data on business performance were derived from respondents' self-reported information for both reference years. Respondents reported their revenue and employment performance levels within pre-defined categories at each time point, and these responses were used to determine the direction of change. Businesses were subsequently classified into two groups, either growing or non-growing, based on the observed direction of change between the two periods. This study did not use continuous growth measurements, as they typically require complete, consistent, and accurately recorded data for more than two points in time, which is often a challenge in MSME studies that rely on retrospective or self-reported data (Awartani and Millis, 2018). Although the binary approach does not capture the magnitude of growth, it minimises reliance on precise growth estimates, which are particularly susceptible to retrospective recall bias reporting errors.

3.3 Independent Variables

In this study, four types of entrepreneurship programmes within the Youth Entrepreneurship Committees (YEC, 2023) ecosystem were analysed: entrepreneurship development and business support (A2), financial assistance (A3), infrastructure and facility support (A4), and market access and business opportunities (A5). Programme participation was measured as a binary indicator of whether respondents had joined any programme between 2016 and 2024. These programme categories were selected based on the Entrepreneurial Framework Conditions (EFC), which were used in this study as an organising framework for categorising different forms of entrepreneurial support within Brunei's business ecosystem. Programme participation was measured as a binary indicator of whether respondents had participated in any programme between 2016 and 2024. Two forms of participation variables were constructed for separate analyses: (i) overall participation in at least one programme, and (ii) participation by specific programme category (A2–A5).

The first analysis adopted an overall approach, comparing businesses that participated in at least one programme with those that did not participate in any. This enabled an overall assessment of the relationship between programme participation and business growth outcomes, without considering specific programme types. The second analysis employed a programme-specific approach, disaggregating participation by programme type to examine whether the relationship between participation and growth outcomes varied across different programme types. For each programme (A2, A3, A4, and A5), participants were compared with non-participants and with participants in other programme combinations, including those who enrolled exclusively in that programme type. It was not possible to isolate exclusive participants entirely, as MSMEs could enrol in more than one programme simultaneously. These two analyses enabled both general and programme-specific evaluations of the associations between programme participation and business growth, as aggregated or overall analyses may obscure programme-specific effects (Meager, 2019). The use of both aggregated and category-specific variables is also consistent with prior research assessing business-level programme effects (Radicic *et al.*, 2019).

Several pre-treatment business covariates were included in the propensity score model. These include 2016 business revenue, employment, business age, sector, ownership structure and ownership gender. These covariates were selected based on theoretical relevance, empirical evidence, and their suitability for collection

through an online MSME survey, as they are expected to influence both the likelihood of programme participation and business growth (Mori, 2015). Where necessary, covariates were grouped into broad categories to address small cell size issue and improve the model stability.

3.4 Analytical Methods

PSM was chosen because programme participation was not randomly assigned; businesses that chose to participate may differ from those that did not (Rosenbaum and Rubin, 1983). By matching treatment (businesses that participated in the programme) and control (businesses that did not participate in the programme) groups on observed pre-treatment characteristics, PSM created more comparable groups for analysis, thereby reducing the influence of observable selection bias.

The propensity score is the probability that a business participates in the programme, given the observed pre-treatment covariates. In this study, the propensity score was estimated using binary logistic regression, with covariates such as baseline revenue and employment in 2016, firm age, sector, ownership, and the owner's gender. The PSM approach relies on two key assumptions: conditional independence that conditional on observed covariates, participation is independent of potential outcomes and overlap (common support), which ensures that matched businesses share a comparable range of propensity scores (Rosenbaum and Rubin, 1983). These assumptions allow for valid comparisons between businesses with similar baseline characteristics. It is acknowledged, however, that PSM cannot account for unobserved confounders (Austin, 2011); accordingly, the findings are interpreted as conditional associations based on observed covariates, rather than direct causal effects.

To implement PSM, nearest-neighbour matching (NNM) with replacement was applied, whereby each treated business was matched to the control group with the closest propensity score, using one nearest neighbour (k=1) (Rosenbaum and Rubin, 1985). Following matching, covariate balance between the treatment and control groups was assessed using the standardised mean difference (SMD) for each variable included in the propensity score model (Austin, 2009). SMD below 0.1 are generally considered indicative of adequate covariate balance (Austin, 2009). The Average Treatment Effect on the Treated (ATT) was then estimated by comparing outcomes between matched treatment and control businesses, representing the average difference in growth outcomes between programme participants and their matched counterfactual non-participants. All PSM analyses were conducted using R software (R Core Team, 2024).

4. Results

4.1 Descriptive Statistics and Balance Assessment

Of the 727 businesses, almost half (49.9%) participated in at least one entrepreneurial support programme, with the highest participation in the market access and business opportunities programmes (A5), followed by entrepreneurship and business support programmes (A2), and financial assistance (A3). A higher proportion of participants reported low or no revenue in 2016 compared with non-participants, suggesting a tendency for earlier-stage businesses to engage with support programmes. Although revenue and employment growth were higher among participants than non-participants, the two groups differed in their pre-programmed business characteristics **(Table 1).** To account for these pre-existing differences, PSM was applied to construct a more balanced comparison group, as described in Section 3.4.

Table 1: Selected business profiles prior to PSM analyses

Variable	Non-participants (%)	Participants (%)
Low/no revenue (2016)	23.6	32.5
Joint ownership	21.7	32.0
Revenue growth	50.8	60.3
Employment growth	41.2	54.3

Participants were matched with non-participants based on their observed pre-treatment business characteristics to enable comparisons between more similar groups. **Figure 1** presents the SMD before and after matching for three models: overall programme participation, financial assistance (A3) and market access (A5). Overall, the matching procedure improved covariate balance across all their models, with most SMDs falling

below the conventional threshold of 0.10. The financial assistance model (A3) achieved an adequate balance after matching, while the market access model (A5) showed some imbalance across several covariates, particularly business type, ownership, revenue, and employment. These results indicate that the degree of balance achieved varies by programme type.

4.2 Associations Between Overall Programme Participation and Business Growth

Error! Reference source not found. presents the ATT estimates for the overall programme participation. Overall programme participation was not significantly associated with either revenue or employment growth after matching on observed baseline characteristics.

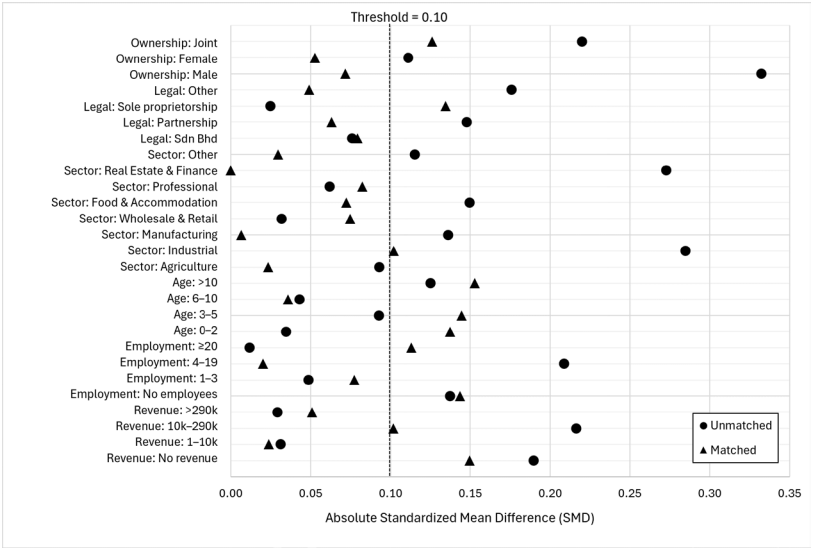
Table 2: Associations between programme participation and business growth after PSM

Outcome	OR	95% CI	p-value	AME (pp)	6895% CI	p-value
Revenue growth	1.07	(0.74, 1.54)	0.711	1.68	(−7.21, 10.57)	0.711
Employment growth	1.13	(0.79, 1.62)	0.503	3.08	(−5.94, 12.10)	0.503

Note: OR = Odds Ratio; CI = Confidence Interval; AME = Average Marginal Effect expressed in percentage points (pp). Estimates are based on the matched ATT. A total of 357 participating firms were matched to 177 non-participating businesses.

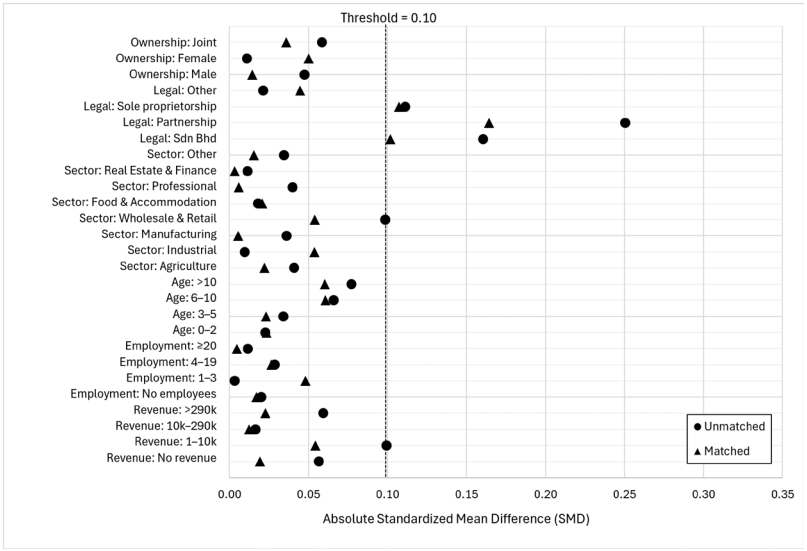
4.3 Programme-Specific Associations with Business Growth

The programme-specific analysis shows that the association between programme participation and business growth varied by programme type, as presented in Error! Reference source not found.. Financial assistance (A3) showed the strongest association with business outcomes. Compared with non-participants, A3 participants had a 30.9 pp higher probability of revenue growth and a 28.8 pp higher probability of employment growth. When compared with participants in other programmes, A3 participants still showed higher probabilities of revenue growth (19.6 pp) and employment growth (13.3 pp). All A3 estimates were statistically significant.



The market access and business opportunities programme (A5) showed a more modest pattern of association. Compared with non-participants, A5 participants had a 10.0 pp higher probability of employment growth, a statistically significant result. However, no significant association was found between revenue growth and non-participants. Neither comparison against other programme participants reached statistical significance for either outcome. Programmes A2 and A4 showed no statistically significant associations with either revenue or employment growth.

Table 3: Programme-specific associations with business growth in the matched sample



Outcome	Comparison	ATT (pp)	95% CI	p-value
Revenue growth	A3 vs No programme participation	0.309***	(0.231, 0.386)	<0.001
	A3 vs Other programme participation	0.196***	(0.122, 0.271)	<0.001
	A5 vs No programme participation	0.076	(-0.002, 0.154)	0.056
	A5 vs Other programme participation	0.035	(-0.050, 0.119)	0.421
Employment growth	A3 vs No programme participation	0.288***	(0.206, 0.369)	<0.001
	A3 vs Other programme participation	0.133***	(0.055, 0.211)	<0.001
	A5 vs No programme participation	0.100*	(0.020, 0.181)	0.015
	A5 vs Other programme participation	0.028	(-0.057, 0.113)	0.523

Note: ATT = Average Treatment Effect on the Treated. ATT estimates are expressed as percentage-point (pp) differences in outcome probabilities between matched groups. Results for A2 and A4 are not presented as neither programme showed statistically significant associations. * $p < 0.05$, ** $p < 0.01$, *** $p < 0.001$.

(c) Market access programme (A5)

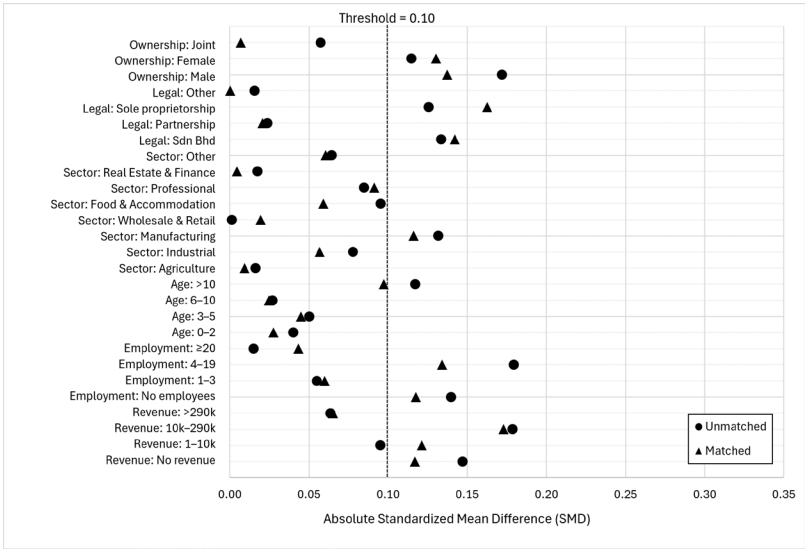

Figure 1: Standardised Mean Differences (SMD) before and after matching for the three matching models.

5. Discussion

5.1 Programme Participation in at Least one Entrepreneurship Programme and Business Growth Outcomes

The study's findings show that participation in at least one entrepreneurship programme is not significantly associated with business revenue or employment growth. Entrepreneurship programmes in Brunei offer various forms of support, such as training, coaching, mentorship, financial assistance, and capacity building, tailored to entrepreneurs with different business needs (YEC, 2023). Some programmes develop basic business skills, especially for early-stage entrepreneurs, while others empower specific groups, such as women and low-income households. These differences in objectives, targets, and approaches suggest that the programme's impact may not be uniform. In this study, participation is measured only by whether a business joined at least one programme, without accounting for programme type or intensity. Therefore, combining all programmes into a single measure may mask differences in each programme's impact. This aligns with the literature, which shows that the effects of entrepreneurship programmes often vary by programme type, objectives, and context (Grimm and Paffhausen, 2014; Meager, 2019). The absence of a significant relationship does not mean that all programmes are ineffective, but it may reflect offsetting effects. This study did not directly test for offsetting effects; this interpretation is based on the non-significant result for programme participation and the possibility of varied programme effects. The programme-specific analyses reported below provide further insight into this aggregate finding.

5.2 The Role of Financial Assistance in Business Growth

The financial assistance programme (A3) was the only programme to show a relationship with the probability of growth in both business revenue and employment, compared with non-participants and participants in other programmes. This pattern suggests that different forms of entrepreneurship support may relate differently to business growth, particularly when support is provided through direct financial assistance. Financial assistance enables businesses to use additional capital directly for operational expansion, investment, and capacity increases. In contrast to training-based or capacity-building programmes, financial support may translate more quickly into business growth because it does not necessarily depend on prior behavioural or skill changes. This finding is consistent with previous research showing that capital support can increase investment and performance in small enterprises under certain circumstances (De Mel, McKenzie and Woodruff, 2008).

5.3 Market Access Support and Business Growth Outcomes

Participating businesses in market access programmes (A5) are more likely to experience employment growth than non-participants, while no statistically significant relationship was observed for revenue growth. This pattern suggests that market access programmes operate differently from financial assistance, as supports such as business matching, market exposure, and business network building are more likely to influence operational activities and business opportunities first, rather than directly increasing revenue. In these circumstances, businesses may increase their operational capacity or add employees to prepare for new market opportunities before the impact on revenue becomes visible. This finding is consistent with previous studies showing that business support programmes and market access often influence operating practices, business relationships, and collaboration opportunities before translating into more significant improvements in financial performance (Bloom *et al.*, 2013; J-PAL, 2024). Therefore, the observed relationship for market access programmes is better understood as a process in which businesses first adjust their operations and increase their business capacity before the impact on revenue becomes more visible. However, as shown in Section 4.1, covariate balance for the A5 group was not fully achieved after matching. This suggests that businesses receiving support may differ from other groups in terms of their underlying characteristics and growth potential. Therefore, the observed relationship is not only related to the type of support received but is also likely to be associated with the business's characteristics. This pattern is consistent with the literature, which shows that the effectiveness of entrepreneurial interventions often varies by business characteristics and the group of support recipients (McKenzie and Woodruff, 2014).

5.4 Related Practical and Policy Impacts

The findings highlight the importance of strengthening evidence-based monitoring and evaluation systems for entrepreneurship and MSME support programmes in Brunei. Improved data collection and programme

monitoring may help generate evidence on which forms of support are more closely associated with business growth and employment, thereby supporting more appropriate programme design and implementation for different business contexts.

5.5 Limitations and Suggestions for Further Research

This study employed a cross-sectional survey design. It included a retrospective component and enabled comparisons of businesses using the respondents' self-reported data. Propensity score matching helped reduce differences in observed covariates between programme participants and non-participants. However, unobserved factors are likely to influence the relationship between programme participation and business growth. Therefore, the study findings were interpreted as a relationship or association and not a direct causal effect.

The use of retrospective information is prone to recall bias and associated reporting inaccuracies, especially regarding business performance in the 2016 base year. Several steps were taken to address these problems. Respondents were informed in advance through the invitation letter that information on business performance and programme participation would be required, allowing them to prepare relevant records where available. In addition, specific pre-defined response categories were used in the questionnaire to reduce reliance on precise numerical recall. Although covariate balance improved after matching, small differences remained in some programme groups.

Further research should use longitudinal and/or experimental designs. These designs are better suited to examine how programme participation relates to changes in business performance. They can also identify causal relationships more clearly. Future studies could examine intermediate outcomes such as knowledge and management improvements, as these outcomes reflect changes in business capabilities before revenue and employment growth are observed.

6. Conclusions

Overall, this study suggests that the association between entrepreneurship support programmes and MSME business performance varies by programme type. Some programmes are associated with positive improvements in revenue and employment growth, while others are not. These findings underscore the importance of identifying which forms of support are most beneficial for different business needs and contexts, so that support for MSME entrepreneurship can be strengthened more effectively.

Institutional and Cultural Constraints on Women's Entrepreneurship in SMEs: A Conceptual Framework in the Context of Saudi Vision 2030

Sheroog Abdullah Alhedhaif and Victor Y. Atiase
Faculty of Business and Law, De Montfort University, Leicester, UK

sheroog.abdul@gmail.com

Abstract: Women entrepreneurs play an increasingly important role in economic diversification, employment generation, and SME growth. Yet, their participation and venture performance remain constrained by institutional and sociocultural structures rather than individual capability alone. This is particularly evident in transitional economies such as Saudi Arabia, where Vision 2030 has introduced substantial policy reform to expand women's economic participation, while prevailing cultural norms and institutional practices continue to shape the extent to which these reforms translate into entrepreneurial outcomes. This paper develops a conceptual framework examining how institutional and cultural context shape women's entrepreneurial motivation, education-to-outcome pathways, and business performance in SMEs. Drawing on North's institutional theory and Hofstede's cultural dimensions, the framework treats formal policy support and informal cultural norms as the primary structural forces conditioning entrepreneurial activity. Education and entrepreneurial motivation are positioned not as independent drivers but as mechanisms through which institutional and cultural conditions are converted into entrepreneurial intention and venture outcomes: education builds the skills and strategic capacity to act on opportunity, while motivation, shaped by push and pull factors, determines whether structural enablement is translated into start-up behaviour. Gender equality is conceptualised as a moderating condition that influences entrepreneurial confidence, resource access, and opportunity recognition within this system. The paper contributes a coherent conceptual model linking institutional reform, cultural context, and individual-level drivers, addressing calls in the literature for more context-sensitive theorising on women's entrepreneurship in the Gulf and other transitional economies. It offers a foundation for empirical testing, particularly relevant given the accelerating policy reform underway in Saudi Arabia, and practical implications for policymakers and entrepreneurship support agencies seeking to close the gap between formal gender-equality policy and lived entrepreneurial experience.

Keywords: Women Entrepreneurship, SMEs, Institutional Theory, Cultural Norms, Gender Equality, Saudi Vision 2030, Conceptual Framework.

1. Introduction

Small and medium-sized enterprises (SMEs) have become well-established sources of employment, innovation, and diversification of the economy. Meanwhile, the number of women who establish their own SMEs is becoming increasingly prominent. However, female entrepreneurial involvement and performance is still lagging behind those of males in virtually all economies, especially those that experience rapid but uneven institutional change (Jennings and Brush, 2013; Welter, 2011). Numerous works have been devoted to the study of factors associated with entrepreneurial activity on the individual level, like education, motivation, self-efficacy and the like. However, there is much less research on how these factors interact with the structural environment, specifically formal institutions and cultural context in terms of women's entrepreneurial outcomes (Brush, de Bruin and Welter, 2009; Marlow and Patton, 2005).

The situation in Saudi Arabia is of particular interest from a theoretical perspective to analyse this interaction. Starting in 2016, the government of the country launched Vision 2030, through which many institutional transformations have been implemented to promote the participation of women in the economy. These transformations can be considered very fast institutional changes. In contrast to formal institutions, informal institutions, which should be seen as the set of cultural norms, social norms, and gender-related distribution of economic opportunities, develop much more slowly than formal rules (North, 1990). Thus, there arises a special theoretical challenge of how women entrepreneurs operate in a context where formal policies promote their participation, but cultural context limits it and what it means in terms of the pathways between education and motivation on entrepreneurship outcomes.

The paper addresses the question through the development of a conceptual framework, instead of discussing empirical findings, as the doctoral study is still at the data collection stage. The conceptual framework will combine theories on institutionalism (North, 1990, 2005) and the cultural dimensions approach (Hofstede, 2001; Hofstede, Hofstede and Minkov, 2010) with the constructs specifically relating to entrepreneurship such as entrepreneurial motivation (Ajzen, 1991), self-efficacy (Bandura, 1997) and entrepreneurial orientation

(Lumpkin and Dess, 1996), to develop a conceptual model where both formal institutions and informal culture play roles in transforming education and motivation to entrepreneurial intentions and venture success.

2. Theoretical Background

2.1 Institutional Theory: Formal and Informal Institutions

According to North (1990), there are two types of institutions: the formal institutions represented by laws, policies, and regulations, and the informal institutions that include conventions, behavioural norms, and imposed codes of conduct. One of the key ideas of this institutional theory is that formal and informal institutions do not always progress at the same speed: formal institutions can change rather easily through legislative action or policy changes, while informal institutions are embedded in social practice and tend to evolve slowly over time (North, 2005). In terms of women's entrepreneurship, this concept is analytically helpful since it allows for separating the impact of policy reforms, which is the case of Saudi Vision 2030's institutionalisation of women's economic involvement, from the impact of cultural attitudes toward women's entrepreneurial activity and role in business and domestic spheres. When formal and informal institutions diverge, entrepreneurs encounter an institutional gap when their legal right to engage in business activities is not enough to grant them social legitimacy or support.

2.2 Hofstede's Cultural Dimensions

Hofstede's cultural dimensions theory serves as an additional perspective when trying to theorise about informal institutions at a finer grain of analysis. Cultural dimensions like power distance, collectivism/individualism, and masculinity/femininity are extensively used in literature when explaining differences between countries in terms of their entrepreneurship levels and gender-specific division of economic functions (Hofstede, 2001). In cultures with high power distance and strong collectivism, entrepreneurial choices, especially of female entrepreneurs, are more often made within the family/community structure than as individual decisions. It means that there is a strong impact of family approval and social acceptance upon the choice of an entrepreneurial career in Saudi Arabia, which can significantly affect the role of motivation and education in making this decision.

2.3 Individual-Level Constructs: Education, Motivation, and Self-Efficacy

There are three important constructs at the individual level in entrepreneurship research. First, education is theoretically considered a factor that promotes entrepreneurial ability by providing technical expertise, good decision-making abilities and confidence to spot business opportunities and exploit them. Second, motivation to engage in entrepreneurial activities has been examined in terms of push-pull factors. The former refers to necessity-related motivations while the latter refers to opportunity-related motivations. Thus, necessity is when people have no better alternative than being entrepreneurs because of a lack of job options, while opportunity includes the freedom to be one's own boss and realise a business idea (Ajzen, 1991). Third, self-efficacy is defined as the individual belief in his/her ability to perform the actions necessary to accomplish a certain goal (Bandura, 1997). Entrepreneurial orientation, which includes innovation, risk-taking and proactiveness, adds another layer to how individual-level resources translate into venture-level strategies (Lumpkin and Dess, 1996).

Combined, these constructs have been traditionally considered as direct predictors of entrepreneurship success. However, in this paper, it is argued that their influence depends on the context. In other words, education and motivation are mechanisms that influence entrepreneurial intention and success depending on the surrounding context of institutions and culture.

3. Literature Review: Women's Entrepreneurship, Institutions, and Culture

3.1 Structural and Institutional Constraints on Women's Entrepreneurship

The focus of studies on women's entrepreneurship has shifted from the individual-deficit explanations, where gender differences in entrepreneurial achievements were seen as a result of the differences in human capital and risk aversion, to the more structural and contextual explanations, which highlight the gendered character of the institutional environment (Marlow and Patton, 2005; Welter, 2011). Lack of access to funding was identified as one of the primary structural barriers: female entrepreneurs reported greater difficulty obtaining loans, which did not stem from their lower creditworthiness but from the gendered presumptions inherent in the lending system and collateral requirements (Marlow and Patton, 2005). Brush, de Bruin and Welter (2009)

developed a framework, which considers institutions, market, and family settings as interacting elements of women's entrepreneurship, rather than taking into consideration only the gender factor as a control element of a gender-neutral model. The structural view remains dominant in the discussion: Douglas and Venugopal (2025) extend the reasoning beyond the growth vs non-growth dichotomy and develop a model of causal connections between gender and entrepreneurial outcomes that supports structural, rather than individual-deficit, explanations of gender differences. Recent cross-country study provides empirical evidence supporting the thesis of Marlow and Patton (2005), stating that lack of credit results from the lending practice, rather than from different creditworthiness of the female and male business owners: Grover and Viollaz (2025) find that women-run firms do not have any profit or risk disadvantages compared to the male-run firms but are disadvantaged in terms of credit allocation, with the biggest difference observed in more culturally traditional countries – an issue highly relevant to this paper due to the use of Hofstede's cultural dimensions in it. The gender-aware framework of Brush, de Bruin and Welter (2009) is still the dominant framework of reference used in the literature. Audretsch et al. (2022) find it actively used in international entrepreneurship literature through systematic review.

3.2 Cultural Norms and the Gendering of Entrepreneurial Opportunity

The influence of culture on entrepreneurship does not only have to do with the motivation of individuals to engage in entrepreneurship, but rather the influence of culture on the activities deemed socially acceptable for women to pursue as entrepreneurs, and the conditions that come with it, such as the consent of the family or, in particular, industries. It is especially important to heed Welter's (2011) advice of contextualising entrepreneurship because it is impossible to understand entrepreneurial action without considering the social, geographic, and institutional setting in which it occurs. Collectivism in families is especially relevant when women entrepreneurs have to negotiate with family members and measure their business performance concerning social acceptance.

3.3 The Saudi Vision 2030 Context

Vision 2030 can thus be seen as an attempt to bring about rapid formal institutional change within Saudi Arabia, including the changes aimed at promoting women's economic engagement. From the standpoint of institutional theory, this implies rapid formal institutional change brought into existence in the environment characterised by slower changes in informal institutions due to the latter's roots in culturally based values. One should stress, however, that the assumption made here does not mean that the cultural norms in Saudi Arabia do not change. The idea of institutional-cultural lag put forward by North (1990) means that the effects of the reforms undertaken within the framework of Vision 2030 on the results of Saudi female entrepreneurship will greatly depend on the degree of adaptation of informal institutions to the changes introduced through the formal ones. As a result, Saudi Arabia becomes an example of a theoretically specific context in which one can study the interaction between institutions, culture and individual factors proposed in this paper. Recent empirical evidence proves the correctness of the approach taken. In the light of the intersectionality-plus framework used in their analysis of Saudi female entrepreneurship in the context of Vision 2030, Almohanna, Bryson and Qamar (2025) state that existing institutions allow male business owners to develop faster than female ones, implying that formal reforms did not lead to neutralisation of the informal institutional advantages. This finding is in agreement with a recent empirical study of the institutional-environment relation conducted among Saudi female digital entrepreneurs, which found that the proportion of female-owned businesses in Saudi Arabia still remains 4 per cent in comparison with 7 per cent in the case of men (Alhajri and Aloud, 2025, quoting Kelly et al., 2022). On the other hand, the statistics provided by the Global Entrepreneurship Monitor show that the pace of change is increasing: the proportion of established businesses owned by women in Saudi Arabia has grown to 14 per cent in 2023, reaching for the first time the level of male ownership, which previously was below 4 per cent (GEM, 2024). These findings clearly illustrate the phenomenon of institutional-cultural lag suggested in the paper: while the formal participation gains emerge, the gap revealed by Almohanna, Bryson and Qamar (2025) shows that the pace of changes in informal institutions has not been the same.

4. Proposed Conceptual Framework

This framework consists of four components. The first of these components is formal institutions that include Vision 2030 policy reforms on access to finance and business support services. The second of these components is informal institutions that include cultural norms along Hofstede's dimensions of collectivism and power distance. The third of these components is individual-level mechanisms (i.e., education and entrepreneurial

motivation), and the final of these components is entrepreneurial outcomes (i.e., start-up intention and venture performance). A moderating condition that crosses the framework is gender equality.

The core of this theory is that formal institutions and informal cultural norms jointly condition the power of education and motivation with respect to entrepreneurial intention and performance and do not act independently of each other. From this theory, four further propositions may be derived.

Proposition 1: is that the support from formal institutions (e.g., access to finance and business support services) will enhance the positive effect that education has on entrepreneurial intention.

Proposition 2: Theory suggests that in cultural contexts with high collectivism and high power distance, the effect that entrepreneurial motivation has on the intention to start a business will be strongly influenced by family and social approval during the entrepreneurial journey.

Proposition 3: When we talk about gender equality, we are talking about people feeling like they have access to the things they need, the same chances to spot good opportunities and the same respect from society. This feeling of equality affects how the culture and rules of a place impact the way people start their businesses. If people think there is equality between men and women, then the education they get and how motivated they are will be more likely to lead to them actually starting a business.

Proposition 4: Sometimes the official rules of a place change quickly. The way people really think and feel about things takes a lot longer to change. This can cause problems because people may want to start a business. The old way of thinking can hold them back. This can happen even if someone is well educated or really motivated to start a business.

5. Discussion and Implications

5.1 Theoretical Contribution

This study makes three contributions to the literature. First, the integration of institutional and Hofstede's cultural frameworks together with individual-level entrepreneurship concepts into one comprehensive model responds to the call for more context-based theorising of women's entrepreneurship (Welter, 2011; Brush, de Bruin & Welter, 2009). Secondly, by conceptualising education and motivation as moderating mechanisms, the model gives a more accurate explanation of the reasons why identical individual-level characteristics generate diverse entrepreneurial outcomes under different institutional and cultural conditions. Finally, the model's focus on the speed differential between formal and informal institutions (North, 1990) serves as a theoretical foundation to predict where and why the implementation of a formal policy reform, Vision 2030, will result in positive or negative entrepreneurial outcomes for women.

5.2 Practical and Policy Implications

For policymakers, the model implies that while formal policies are required to address issues related to access to finance or entrepreneurship services, these are not sufficient per se to narrow the gender gap without parallel work to overcome cultural barriers, for instance via public relations, role models, and business assistance programs, including families. For business support organisations and universities, the model emphasises that education/training initiatives must be contextually informed, i.e., they should take into account the cultural and institutional environment within which the participants operate, as otherwise a purely skills-based approach would not work.

6. Conclusion and Future Research Directions

The theoretical framework has been built in the paper by explaining how formal and informal factors influence the linkage between education, motivation and female entrepreneurs' outcomes through their interaction with one another in the case of SMEs in the Vision 2030 reforms in Saudi Arabia. Gender equality is taken into account as a moderating variable, and the four propositions have been put forward regarding the connection between the context and intention/performance of entrepreneurs. At present, the doctoral study based on this framework is being conducted, and empirical evidence will soon be provided by collecting data about all those variables mentioned above for the two regions in Saudi Arabia - Riyadh and Qassim. It will be collected through a quantitative survey instrument. Further research should pay attention to qualitative methods too, as the

problem of institutional-cultural dissonance is quite complex and cannot be explained in a purely conceptual way.

Ethics Declaration

This is a purely theoretical paper; thus, no data will be collected for this research, nor will anyone be exposed to risks associated with this research in any way. The doctoral research that has led to the writing of this paper has undergone an ethical review by the university in line with the Research Ethics Code of Practice (RECoP) at De Montfort University.

AI Declaration

Generative AI (Claude, Anthropic) was used during the preparation of this paper to assist with drafting, structuring, and language refinement of the conceptual framework and supporting text. All theoretical content, argumentation, and conclusions were reviewed, verified, and taken responsibility for by the author(s). AI tools were not used to generate empirical data, findings, or fabricated citations.

Integrating Clinical Trial Evidence into Design Thinking Processes for Healthcare Product Development

Mohamed Atwy
Faculty of Management and Economics, Tomas Bata University in Zlín, Zlín, Czech Republic

atwy@utb.cz

Abstract: Healthcare product development increasingly requires approaches that combine evidence-based healthcare knowledge with human centered innovation. While design thinking has gained significant attention in healthcare innovation, limited research has examined how clinical trial evidence can support design thinking processes in healthcare product development. This study develops and empirically tests a conceptual framework integrating Clinical Trial Evidence (CTE), Design Thinking Processes (DTP), and Healthcare Product Development (HPD) using Type 2 Diabetes clinical trial data. A quantitative research approach was adopted using Partial Least Squares Structural Equation Modeling (PLS-SEM) with Smart PLS. The study utilized a structured dataset comprising 1,000 observations derived from clinical trial evidence. The analysis assessed the direct relationships between Clinical Trial Evidence, Design Thinking Processes, and Healthcare Product Development, as well as the mediating role of Design Thinking Processes. Reliability, validity, and predictive relevance assessments were conducted to ensure the robustness and consistency of the proposed research model. The findings reveal that Clinical Trial Evidence has a significant positive influence on both Design Thinking Processes and Healthcare Product Development. In addition, Design Thinking Processes significantly enhance Healthcare Product Development and mediate the relationship between Clinical Trial Evidence and Healthcare Product Development. These results suggest that integrating structured clinical evidence into design thinking can strengthen innovation capability, improve decision-making quality, and support more effective healthcare product development outcomes. This study contributes to healthcare innovation and entrepreneurship literature by positioning clinical trial evidence as a strategic driver of patient centered innovation. The proposed framework offers a structured approach for integrating evidence-based healthcare knowledge into design thinking and healthcare product development processes. The study also provides practical implications for healthcare organizations, pharmaceutical companies, researchers, and innovation teams seeking to improve the effectiveness and sustainability of healthcare product innovation in evidence driven environments. Overall, the paper argues that combining clinical evidence and design thinking can support more informed, patient centered healthcare product development in chronic disease contexts.

Keywords: Clinical Trial Evidence; Design Thinking; Healthcare Product Development; Type 2 Diabetes; PLS-SEM.

1. Introduction

Healthcare product development now operates in an environment shaped by rapid technological change, rising patient expectations and growing pressure to justify innovation through evidence. Products and services in healthcare must achieve clinical effectiveness, but they must also support usability, accessibility, treatment adherence and meaningful patient experience. These demands are especially pronounced in chronic disease settings, where patients need continuous care support rather than isolated clinical interventions (World Health Organization 2024; Ulrich and Eppinger 2016).

Type 2 Diabetes illustrates this challenge clearly. The disease is long term, behaviourally complex and associated with repeated interactions among patients, clinicians, devices, therapies and digital support systems. Innovation in this area therefore requires more than technical performance. It also requires good understanding of routines of use, barriers to adoption and patient-centred solution design. For this reason, Type 2 Diabetes provides a valuable context for exploring how evidence and innovation can be connected more systematically (World Health Organization 2024).

Design thinking has become one of the most influential human-centred innovation approaches for addressing such complexity. The approach emphasises empathy, problem framing, ideation, prototyping and testing, thereby helping organisations explore problems before converging on solutions (Brown, 2008; Kelley and Kelley, 2013). In healthcare, these features are attractive because innovation problems are often ambiguous, multidisciplinary and deeply shaped by user experience. Previous studies suggest that design thinking can improve healthcare innovation by encouraging stakeholder participation, interdisciplinary collaboration and iterative learning (Altman et al., 2018; Roberts et al., 2021).

At the same time, recent literature warns that design thinking can become superficial when it is disconnected from robust evidence. Bromage et al. (2025) describe the risk of “innovation theatre”, where organisations perform creative exercises but fail to anchor decisions in validated knowledge. In healthcare, this limitation is

serious because innovation should respond to real treatment needs, outcome priorities and clinical constraints rather than to intuition alone.

Clinical-trial databases offer a potentially valuable but underused source of structured evidence for innovation. Trial records contain detailed information on interventions, patient eligibility criteria, endpoints, adverse events, treatment limitations and disease-management priorities. Such information can help innovators identify unmet needs, reveal barriers to participation and indicate where healthcare solutions may need to be redesigned. Yet limited research has examined how this type of evidence can systematically support design thinking and product-development decisions (Zarin et al. 2011; Varvara et al. 2025).

This paper addresses that gap by proposing and empirically testing a framework that links Clinical Trial Evidence (CTE), Design Thinking Processes (DTP) and Healthcare Product Development (HPD). Using Type 2 Diabetes clinical-trial data and PLS-SEM, the study asks whether structured clinical evidence strengthens design thinking activities, whether design thinking improves healthcare product development, and whether design thinking mediates the relationship between evidence and product-development outcomes (Hair et al. 2022).

2. Literature Review and Hypotheses Development

2.1 Design Thinking in Healthcare

Design thinking emerged from the design disciplines and later expanded into management, entrepreneurship and public-sector innovation as organisations searched for more user-oriented ways to address complex problems. The method is commonly represented through the stages of empathise, define, ideate, prototype and test. These stages help organisations explore user needs, reframe problems, generate alternatives and refine solutions iteratively (Brown, 2008; Liedtka, 2018).

In healthcare, design thinking is valuable because many problems are socially embedded and involve patients, clinicians, caregivers, managers and technology developers simultaneously. Altman et al. (2018) show that human-centred design can improve healthcare innovation by aligning solutions with lived experience. Roberts et al. (2021) similarly emphasise that design thinking supports healthcare management and innovation by connecting problem exploration with collaborative solution development. These studies suggest that the real strength of design thinking lies not only in creativity, but in structured learning from user contexts.

Recent healthcare literature also links design thinking with co-creation and integrated care. When patients and professionals participate in defining problems and testing solutions, innovations are more likely to be contextually relevant and implementable. This matters for healthcare product development because products often fail not because their technology is weak, but because they do not fit everyday workflows, user abilities or treatment realities (Bogaert et al. 2025; Romero and Rivera 2025).

2.2 Clinical-Trial Evidence as an Innovation Input

Evidence-based healthcare typically treats clinical-trial data as a source of scientific validation, regulatory support and treatment comparison. However, the same data may also have strategic value for innovation. Information on interventions, endpoints, eligibility criteria and treatment limitations can reveal where patients struggle, which groups are underserved and what outcomes healthcare stakeholders consider important. In this sense, clinical-trial evidence can be seen as a structured source of user, disease and system knowledge (Zarin et al. 2011; Varvara et al. 2025).

For healthcare product development, this matters because innovators must often translate scattered clinical knowledge into products, services or support systems that improve care delivery. Clinical evidence can inform decisions about what problems deserve attention and which design requirements are likely to be relevant. Reusing clinical-trial data may therefore strengthen the early stages of innovation, especially problem definition and prioritisation (Varvara et al., 2025).

Nevertheless, evidence alone does not automatically produce innovation outcomes. Structured knowledge needs to be interpreted, reframed and transformed into solution concepts. This observation suggests that design thinking may operate as the mechanism that converts clinical evidence into practical product-development activity (Brown 2008; Liedtka 2018).

2.3 Research Gap, Conceptual Framework and Hypotheses

The reviewed literature supports both the value of design thinking in healthcare and the value of evidence-based decision making, but relatively little research has examined how these domains interact. Most healthcare design studies focus on interviews, workshops or service-improvement initiatives, while evidence-oriented studies concentrate on evaluation, effectiveness or regulation. The intersection between structured clinical evidence and design-oriented innovation remains underdeveloped (Altman, Huang and Breland 2018; Roberts et al. 2021; Varvara et al. 2025).

This paper therefore investigates the following research question: how can structured clinical-trial evidence improve healthcare product development through design thinking processes? The conceptual argument is that CTE may strengthen DTP by helping innovators define healthcare problems more accurately and identify clinically meaningful priorities. DTP should then support HPD by transforming evidence into solution ideas, prototypes and refinement activities. CTE may also influence HPD directly, but the indirect path through DTP is expected to be especially important.

The proposed framework therefore treats design thinking as both a process construct and a translation mechanism. CTE provides the evidence base, DTP provides the human-centred innovation process, and HPD represents the development outcome. This distinction is important because healthcare organisations often possess large amounts of evidence but do not always have systematic procedures for converting that evidence into usable products or services (Brown 2008; Liedtka 2018; Zarin et al. 2011).

The hypotheses are intentionally structured to separate direct and indirect effects. H1 tests whether evidence supports design thinking activities. H2 tests whether design thinking supports product-development outcomes. H3 tests whether evidence also has a direct effect on product development. H4 then tests whether the influence of evidence is partly transmitted through design thinking. This structure makes it possible to examine whether design thinking adds explanatory value beyond the direct effect of clinical evidence.

The framework is also consistent with the practical logic of chronic disease innovation. In Type 2 Diabetes, product-development decisions must consider clinical outcomes, daily self-management, treatment adherence and patient experience. A product-development process that relies only on clinical evidence may overlook usability and contextual issues, while a process that relies only on creativity may overlook clinical priorities. The framework therefore argues for an integrated approach (World Health Organization 2024; Ulrich and Eppinger 2016).

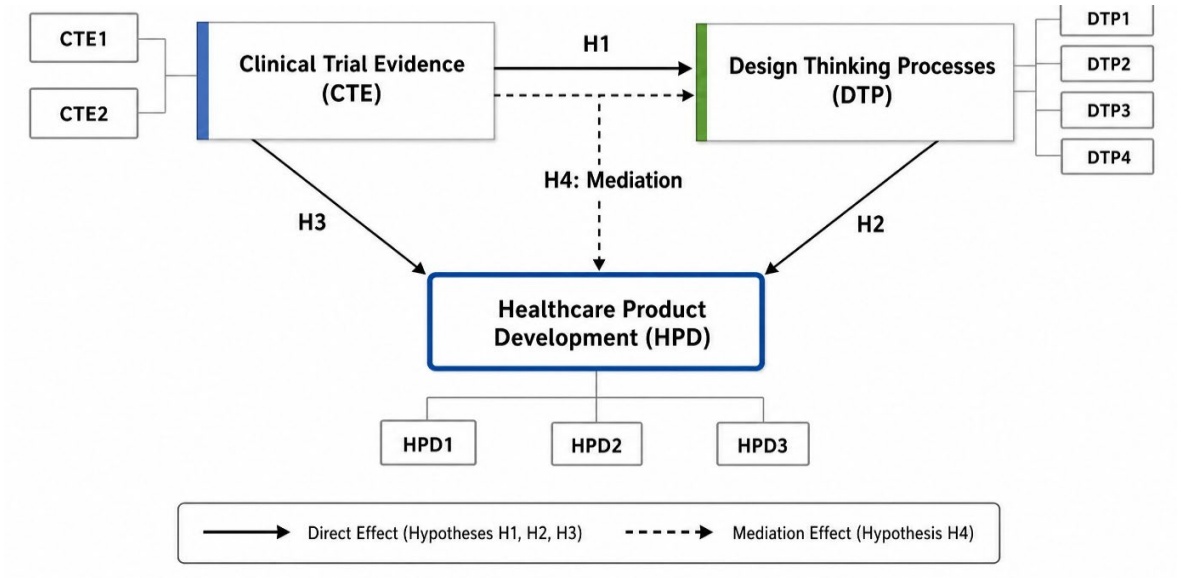

Figure 1: Conceptual framework of the study

- H1: Clinical Trial Evidence positively influences Design Thinking Processes.
- H2: Design Thinking Processes positively influence Healthcare Product Development.
- H3: Clinical Trial Evidence positively influences Healthcare Product Development.
- H4: Design Thinking Processes mediate the relationship between Clinical Trial Evidence and Healthcare Product Development.

3. Methodology

3.1 Research Design and Data Source

The study adopted a quantitative design because the objective was to test a predictive framework connecting three latent constructs and a mediating relationship. PLS-SEM was selected because it is appropriate for exploratory and prediction-oriented models and performs well when the research focus is on explaining variance in endogenous constructs (Hair et al., 2022). The model was estimated using SmartPLS.

The empirical context was Type 2 Diabetes. A structured dataset of 1,000 observations was developed from clinical-trial information relating to this disease area. The disease context was selected because Type 2 Diabetes requires sustained treatment support, self-management, monitoring and product or service innovation over long periods. Trial-derived information offered a consistent evidence base from which indicators could be formed (World Health Organization 2024; Zarin et al. 2011).

The model included three constructs. Clinical Trial Evidence (CTE) represented the availability and usefulness of structured evidence derived from trials. Design Thinking Processes (DTP) represented retained activities aligned with defining, ideating, prototyping and testing. Healthcare Product Development (HPD) represented development-oriented outcomes associated with the translation of knowledge into healthcare solutions.

3.2 Measurement and Analytical Procedure

Reflective indicators were used for all three constructs. After model refinement, CTE was measured by CTE1 and CTE2, DTP by DTP1_Define, DTP2_Ideate, DTP3_Prototype and DTP4_Test, and HPD by HPD1, HPD2 and HPD3. Indicators with weaker loadings were removed in order to improve reliability and construct quality in line with common PLS-SEM assessment practice (Hair et al. 2022).

The analysis followed standard PLS-SEM stages. First, the measurement model was assessed using outer loadings, Cronbach's alpha, composite reliability and average variance extracted (AVE). Second, discriminant validity was examined. Third, the structural model was evaluated using path coefficients, bootstrapped significance testing, coefficients of determination (R^2), effect sizes (f^2), predictive relevance (Q^2) and mediation testing. This procedure allowed both measurement quality and explanatory performance to be assessed systematically.

4. Results

4.1 Measurement-Model Assessment

Table 1 presents the retained outer loadings. All indicators exceed or closely approach the commonly used 0.70 threshold, indicating acceptable indicator reliability. CTE1, CTE2 and HPD3 are particularly strong, while DTP4_Test is the weakest retained item but remains acceptable. The results suggest that the retained indicators adequately represent the three latent constructs (Hair et al. 2022).

Table 1: Outer loadings of the measurement model

Construct	Indicator	Outer loading
Clinical Trial Evidence	CTE1	0.903
Clinical Trial Evidence	CTE2	0.886
Design Thinking Processes	DTP1_Define	0.815
Design Thinking Processes	DTP2_Ideate	0.879
Design Thinking Processes	DTP3_Prototype	0.857
Design Thinking Processes	DTP4_Test	0.709
Healthcare Product Development	HPD1	0.816
Healthcare Product Development	HPD2	0.818
Healthcare Product Development	HPD3	0.937

Source: Author's work

The reliability and convergent-validity results in Table 2 also support the adequacy of the measurement model. Cronbach's alpha values range from 0.751 to 0.833. Composite reliability values exceed recommended cut-offs, and all AVE values are above 0.50. Together, these statistics confirm satisfactory internal consistency and convergent validity for CTE, DTP and HPD (Hair et al. 2022).

Table 2: Reliability and convergent validity

Construct	Cronbach alpha	rho_a	rho_c	AVE
CTE	0.751	0.754	0.889	0.801
DTP	0.833	0.851	0.889	0.668
HPD	0.820	0.829	0.894	0.738

Source: Author's work

Discriminant validity was assessed primarily by the Fornell-Larcker criterion shown in Table 3. The square roots of AVE on the diagonal are greater than the inter-construct correlations, which indicates acceptable construct separation. However, HTMT diagnostics from the full analysis showed a high overlap between DTP and HPD. This implies that the two constructs are theoretically and empirically close in the present dataset. Accordingly, the structural findings are interpreted cautiously as evidence of a strong relationship rather than complete conceptual independence (Hair et al. 2022).

Table 3: Fornell-Larcker criterion

Construct	CTE	DTP	HPD
CTE	0.895		
DTP	0.731	0.817	
HPD	0.762	0.894	0.859

Source: Author's work

4.2 Structural-Model Assessment

Table 4 reports the path coefficients. All three direct hypotheses are supported. The strongest direct path is from CTE to DTP (β=0.731), indicating that structured clinical-trial evidence substantially strengthens design thinking processes. The path from DTP to HPD is also strong (β=0.724), which confirms that design-oriented innovation activity contributes positively to healthcare product-development outcomes. The direct effect of CTE on HPD remains positive and significant, but is notably smaller (β=0.232), suggesting that evidence alone has a more limited effect unless it is translated through a design process.

Table 4: Structural-path and mediation results

Path	Beta	Mean	STDEV	t-value	p-value
CTE → DTP	0.731	0.732	0.013	54.439	0.000
DTP → HPD	0.724	0.724	0.017	41.908	0.000
CTE → HPD	0.232	0.232	0.020	11.436	0.000
CTE → DTP → HPD	0.529	0.530	0.014	36.634	0.000

Source: Author's work

The model-quality results are presented in Table 5. CTE explains 53.5% of the variance in DTP, which indicates moderate explanatory power. CTE and DTP together explain 82.4% of the variance in HPD, which indicates strong explanatory power for healthcare product development. Effect-size results show that CTE has a very large effect on DTP, while DTP has a very large effect on HPD. The direct effect of CTE on HPD is meaningful but comparatively small. Positive Q^2 values for DTP and HPD confirm predictive relevance (Hair et al. 2022).

Table 5: Explanatory power, effect size and predictive relevance

Assessment	DTP	HPD	Interpretation
R^2	0.535	0.824	Moderate for DTP; strong for HPD
Adjusted R^2	0.534	0.823	Stable explanatory power
f^2 (CTE effect)	1.149	0.143	Large effect on DTP; small direct effect on HPD
f^2 (DTP effect)	–	1.382	Large effect on HPD
Q^2 predict	0.534	0.580	Predictive relevance confirmed

Source: Author's work

At the indicator level, the prediction-oriented assessment also remained positive. Q^2_predict values ranged from 0.274 to 0.503 for the retained DTP indicators and from 0.395 to 0.447 for the retained HPD indicators, which provides additional support for predictive relevance. Finally, the mediation result confirms that DTP plays a central translating role between structured evidence and product-development outcomes.

Table 6: Hypothesis-testing summary

Hypothesis	Relationship	Result
H1	CTE positively influences DTP	Supported
H2	DTP positively influences HPD	Supported
H3	CTE positively influences HPD	Supported
H4	DTP mediates the relationship between CTE and HPD	Supported

Source: Author's work

4.3 Predictive Assessment and Robustness

The prediction-oriented results provide an additional check on model usefulness. Table 7 summarises indicator-level predictive assessment for retained DTP and HPD indicators. All Q^2_predict values are positive, indicating that the model has predictive relevance at the indicator level. Some PLS-SEM prediction errors are close to the linear-model benchmark, which suggests that the model is useful but should not be overstated as uniformly superior for every indicator. This interpretation is consistent with the exploratory nature of the study (Hair et al. 2022).

Table 7: Summary of indicator-level predictive assessment

Indicator Group	Q^2 Predict Range	PLS-SEM RMSE Range	PLS-SEM MAE Range	Interpretation
DTP indicators	0.274-0.503	0.677-0.832	0.560-0.706	Positive predictive relevance
HPD indicators	0.395-0.447	0.590-0.833	0.473-0.678	Positive predictive relevance

Source: Author's work

Taken together, the structural and predictive results indicate that the model has both explanatory and practical relevance. The strongest empirical pattern is not simply that clinical-trial evidence is related to healthcare product development, but that the relationship becomes much stronger when design thinking processes are included as a translating mechanism. This finding supports the central argument of the paper and gives the model a clear managerial interpretation.

5. Discussion

5.1 Theoretical Implications

The results make three main theoretical contributions. First, they show that clinical-trial evidence can be treated as an innovation input rather than only as a clinical or regulatory resource. This extends the evidence-based healthcare perspective by suggesting that structured trial information has value in the earliest stages of

innovation, particularly for problem definition and opportunity identification (Zarin et al. 2011; Varvara et al. 2025).

Second, the findings strengthen the argument that design thinking can serve as a mechanism for evidence translation. The large and significant indirect effect of CTE on HPD through DTP indicates that structured evidence becomes more useful for innovation when it is processed through define, ideate, prototype and test activities. In this sense, design thinking does not replace evidence; it operationalises it.

Third, the high explanatory power for HPD indicates that the joint consideration of evidence and design activity offers a useful way to understand healthcare product development. The study therefore contributes to the innovation and entrepreneurship literature by connecting evidence-based reasoning with human-centred problem solving in a single empirical model (Brown and Katz 2011; Ulrich and Eppinger 2016).

5.2 Practical Implications

For practitioners, the findings suggest that healthcare organisations and pharmaceutical or med-tech innovation teams should not treat clinical-trial databases as resources relevant only to researchers or regulatory specialists. Trial data can be used earlier in the innovation process to reveal unmet needs, user barriers and clinically meaningful priorities. This can improve the quality of innovation briefs and guide more targeted concept development (Zarin et al. 2011; Varvara et al. 2025).

The results also imply that innovation teams benefit from combining evidence with structured design activity. Evidence alone produced only a modest direct contribution to healthcare product development, whereas the mediated effect through DTP was substantially stronger. Practically, this means that teams should create routines for translating evidence into design workshops, concept generation, prototype evaluation and user testing rather than keeping evidence separate from innovation practice.

This implication is especially important in chronic disease contexts. In areas such as Type 2 Diabetes, solutions must fit both clinical requirements and long-term patient behaviour. Evidence-informed design thinking can therefore help organisations develop products and services that are not only novel, but also clinically grounded and more likely to be accepted in real use environments (World Health Organization 2024; Roberts et al. 2021).

5.3 Limitations and Future Research

This study focuses on one disease context, Type 2 Diabetes, which may limit the generalizability of the findings to other therapeutic areas. Second, the analysis is based on a structured dataset derived from clinical-trial information; future research could complement this approach with organizational data, interviews with healthcare innovators, or case studies of product-development teams. Third, the constructs examined in this study are conceptually related, particularly design thinking processes and healthcare product development, so future studies could further refine the measurement items and test the framework in different healthcare settings (Hair et al. 2022).

Future research could extend the framework to other chronic disease areas, compare different forms of healthcare evidence, and examine how evidence-informed design thinking influences product-development outcomes over time. Longitudinal studies would be especially useful for understanding whether early design decisions based on clinical evidence led to stronger implementation, adoption, and patient-centered innovation outcomes (Roberts et al. 2021; Varvara et al. 2025).

6. Conclusion

This paper set out to examine whether clinical-trial evidence can support healthcare product development through design thinking. Using Type 2 Diabetes clinical-trial data and PLS-SEM, the study found that structured evidence strongly supports design thinking processes, that design thinking strongly supports healthcare product development, and that design thinking mediates the relationship between evidence and product-development outcomes.

Overall, the findings indicate that evidence-informed design thinking provides a promising pathway for more effective healthcare innovation. The framework offers a practical and theoretical basis for integrating structured clinical knowledge with human-centred innovation activity, while remaining sufficiently concise for conference discussion and further development.

The expanded version of the paper therefore presents the research as a complete conference contribution: it defines the problem, positions the theoretical gap, presents the conceptual framework, tests the model empirically and acknowledges the methodological limits of the data. This balance is intended to meet the conference requirements while still preserving the strongest elements of the full doctoral research paper.

Acknowledgements

The author thanks colleagues and advisors for their valuable feedback. This research used publicly available structured clinical-trial information and complied with relevant ethical guidelines.

Ethics Declaration

Ethical clearance was not required for this study because the analysis used secondary structured clinical-trial data and did not involve direct contact with human participants or the collection of new personal data.

AI Declaration

AI-based language assistance tools were used in a limited way to support drafting and language refinement. The research design, conceptual development, data analysis, interpretation of findings and final verification of the manuscript were undertaken by the author.

Measuring Entrepreneurship Competence Progression: Evidence from Muslim Youth in Australia

Rinto Azhar and Zuleyha Keskin
Centre for Islamic Studies and Civilisation, Charles Sturt University, Melbourne, Australia

razhar@csu.edu.au
zkeskin@csu.edu.au

Abstract: Entrepreneurship competence is increasingly recognised as a critical driver of entrepreneurial behaviour and venture creation among young people. The European Entrepreneurship Competence Framework (EntreComp) has become one of the most widely adopted frameworks for conceptualising and assessing entrepreneurship competence; however, most empirical applications rely on self-assessment instruments that capture perceptions of capability rather than behaviourally anchored evidence of progression, and therefore offer limited insight into competence progression. This study addresses that gap by examining entrepreneurship competence progression among Muslim youth in Australia through the Entrepreneurship Competence Progression Index (ECPI), a progression-based measurement approach aligned with the eight-level EntreComp progression model. Drawing on survey data from 109 Muslim youth aged 18 to 25 across Australia, the study evaluates competence across the three EntreComp areas of Ideas and Opportunities, Resources, and Into Action. The ECPI operationalises progression by classifying each respondent at a behaviourally anchored stage of entrepreneurial capability for ten non-cognitive competences, rather than recording a self-rated score. Descriptive, classification, and inferential analyses were used to identify progression patterns and to compare progression-based measurement with parallel self-assessment of the same competences. Respondents were generally positioned at an intermediate level of progression (mean 3.58 on the eight-point scale), with most classified at the Intermediate stage and a substantial minority at the Advanced stage. Progression varied meaningfully across competence areas, with Ideas and Opportunities highest and Resources lowest. Self-assessment scores significantly and systematically exceeded behaviourally anchored progression (mean difference 0.99, large effect), while remaining only moderately correlated with it, indicating that the two approaches capture related but distinct information. Prior entrepreneurial experience, rather than gender or schooling pathway, was the strongest correlate of progression, and religiosity was associated with self-assessed competence but not with behaviourally anchored progression, underscoring the distinction between the two. The findings provide evidence that progression-based assessment offers a more conservative and more diagnostic account of capability development than conventional self-assessment, and they extend EntreComp into an underrepresented, predominantly diaspora population. As a large and young population, Muslim youth in Australia are a significant yet under-examined community for entrepreneurship and innovation. The study has implications for entrepreneurship educators, policymakers, and youth-development organisations seeking to design targeted competence-development interventions and to evaluate entrepreneurial learning outcomes more rigorously.

Keywords: Entrepreneurship Competence Progression Index, EntreComp, Entrepreneurship Education, Youth Entrepreneurship, Competence Development, Progression-Based Assessment

1. Introduction

Entrepreneurship is now widely understood as a competence that can be learned, developed and assessed rather than being an innate trait that one is born with (Bacigalupo et al. 2016). This reframing has shifted the agenda from teaching about business and business management, towards developing the knowledge, skills and attitudes that enable young people to create value. For young people in particular, it is linked to employability and initiative taking, and has become a focus of entrepreneurship education across schools, universities and community programmes (Nabi et al. 2017).

The European Entrepreneurship Competence Framework, known as EntreComp, has become the most influential reference model for this agenda. It defines entrepreneurship as a transversal competence organised into three competence areas, fifteen competences and an eight-level progression model spanning 442 learning outcomes (Bacigalupo et al. 2016; Bernadó and Bratzke 2024). Despite the prominence of its progression model, most empirical applications of EntreComp operationalise competence through self-assessment questionnaires, in which respondents rate their perceived capability on a numerical scale (López-Núñez et al. 2022). Self-assessment is efficient and scalable, but it measures perceptions of competence rather than behaviourally anchored progression, and a substantial body of evidence indicates that self-assessments of knowledge and skill correlate only modestly with objective indicators and are coloured by motivational and affective factors (Sitzmann et al. 2010). When the construct of interest is *progression*, movement along a developmental trajectory, a self-rated score on an undefined scale offers little diagnostic information about the stage a learner has actually reached.

This study responds by applying the Entrepreneurship Competence Progression Index (ECPI), which positions respondents at an EntreComp progression stage for each competence using behaviourally anchored descriptors, rather than a self-rated magnitude. This paper focuses on examining an underrepresented population: Muslim youth in Australia, a predominantly migrant-heritage, diaspora community. Muslim minorities in Western diaspora settings remain substantially under-represented in the entrepreneurship competence literature, which is dominated by Western university samples. When the literature does engage diaspora communities, it concentrates on established adult immigrant founders rather than the developing capability of diaspora youth (Fallahi et al. 2024). Applying a progression-based operationalisation of EntreComp to diaspora youth is therefore novel on two counts: it extends the framework to an untested population, and it shifts attention from immigrant entrepreneurial outcomes to the next generation's competence development, a population central to entrepreneurship and innovation yet largely outside the measurement literature.

This focus is not incidental. The paper forms part of a broader research programme examining how religiosity relates to entrepreneurship competence among Muslim youth in Australia. Religion has been linked to entrepreneurial values and intention (Giacomin et al. 2023), but its bearing on competence is theorised to operate less through the technical or cognitive aspects of enterprise than through the non-cognitive dispositions that underpin entrepreneurial action, namely, motivation and perseverance, self-efficacy, ethical orientation, and the readiness to act under uncertainty. For young people forming an entrepreneurial identity within a faith tradition, these dispositions are especially salient, so the study concentrates its progression measurement on the non-cognitive competences within EntreComp (Section 2.3).

The broader research programme examines entrepreneurship competence progression among Muslim youth in Australia, including the influence of religiosity and socio-demographic factors. The analysis reported here focuses on establishing the level and pattern of competence progression and evaluating the extent to which a progression-based measure captures development more effectively than conventional self-assessment approaches. While the relationship between religiosity and entrepreneurship competence is briefly considered, a more detailed examination of this pathway, situated within the Muslimpreneurship Competence Development Framework (MCDF) (Azhar 2024), is beyond the scope of the present paper. The remainder of the paper situates these questions within the EntreComp and competence-measurement literature, describes the ECPI and study design, reports the findings, and discusses their implications for entrepreneurship education and youth development.

2. Conceptual Background

2.1 EntreComp and the Three Competence Areas

EntreComp models entrepreneurship as a competence to act upon opportunities and ideas in order to create value for others (Bacigalupo et al. 2016). Its fifteen competences are grouped into three interconnected areas. *Ideas and Opportunities* concerns spotting opportunities, creativity, vision, valuing ideas, and ethical and sustainable thinking. *Resources* concerns self-awareness and self-efficacy, motivation and perseverance, mobilising resources, financial and economic literacy, and mobilising others. *Into Action* concerns taking the initiative, planning and management, coping with uncertainty, ambiguity and risk, working with others, and learning through experience. The three areas are intended to be read together: an entrepreneurial actor moves from recognising opportunity, through marshalling resources, to acting under uncertainty (Bernadó and Bratzke 2024).

A defining feature of EntreComp is its progression model, which describes development across eight levels in four phases; Foundation, Intermediate, Advanced and Expert. The progression moves from acting with support to driving transformation and creating value for others. Even though the progression model is conceptually central to EntreComp's claim to support lifelong development, it is nonetheless the element least often used in measurement, which tends to reduce competence to a single self-rated magnitude (López-Núñez et al. 2022; Bernadó and Bratzke 2024).

2.2 The Dominance and Limits of Self-Assessment

Self-assessment dominates competence measurement in entrepreneurship because it is inexpensive, scalable and well suited to large student samples. Validated instruments such as the EntreComp self-assessment questionnaire demonstrate good internal reliability and broadly sensible factor structures (López-Núñez et al. 2022). The limitation is not reliability but construct validity for the developmental question. A meta-analytic

review found that self-assessments of knowledge share only a limited proportion of variance with objective measures of the same knowledge, and behave partly as affective or motivational indicators rather than as cognitive ones (Sitzmann et al. 2010). In entrepreneurship education, a high self-rated score may reflect confidence, optimism or social desirability as much as actual capability.

Two consequences follow. First, self-assessment tends to overstate capability, especially among less experienced learners who lack the reference points to calibrate their judgements. Second, because a self-rated score is anchored to the respondent's own subjective scale, it cannot readily be mapped onto a shared developmental benchmark: two respondents who both rate themselves four out of seven may be at very different developmental stages. When the aim is to understand how competence develops and whether an intervention has facilitated progression within the EntreComp framework, measurement should be anchored to behaviourally defined stages rather than learners' perceptions of their competence. (Mitchelmore and Rowley 2010).

2.3 Religiosity, Values and the Selection of Non-Cognitive Competences

The choice of competences is theoretically motivated rather than arbitrary. Although religion has been associated with entrepreneurial intention and values (Giacomin et al. 2023), its influence on competence is understood to work principally through non-cognitive channels. That is, religion may shape the attitudes and self-regulatory dispositions that determine whether knowledge is translated into entrepreneurial action. Dispositions such as perseverance, ethical motivation, self-efficacy and the readiness to act under uncertainty are those most plausibly shaped by a young person's values and faith commitments.

Accordingly, the ECPI concentrates on the ten EntreComp competences identified in the wider study as predominantly non-cognitive in character. From Ideas and Opportunities it includes Creativity, Vision, and Ethical and Sustainable Thinking; from Resources it includes Self-Awareness and Self-Efficacy, Motivation and Perseverance, Mobilising Resources, and Mobilising Others; and from Into Action it includes Taking the Initiative, Coping with Uncertainty, Ambiguity and Risk, and Working with Others. The five competences that are more cognitive or technical in nature are Spotting Opportunities, Valuing Ideas, Financial and Economic Literacy, Planning and Management, and Learning through Experience. These fall outside this non-cognitive focus and are not part of the index. Concentrating on the non-cognitive competences keeps the measure theoretically aligned with the wider study and sharpens its diagnostic value for the dispositional capabilities most relevant to youth entrepreneurial development. These choices are organised by the MCDF. Developed by applying an Islamisation-of-knowledge methodology to EntreComp, it reframes the framework's competence architecture in light of Islamic ethical and value commitments and identifies the non-cognitive, dispositional competences as those most directly informed by a Muslim entrepreneur's faith. This provides the rationale for the competence subset measured here. This emphasis aligns with evidence that non-cognitive, attitudinal capabilities are central antecedents of entrepreneurial action and learning (Newman et al. 2019). The ten competences and their EntreComp areas are listed in Table 3.

2.4 The Entrepreneurship Competence Progression Index

The Entrepreneurship Competence Progression Index (ECPI) is a progression-based measure developed for this research programme. Rather than asking respondents to provide an abstract rating of how competent they feel, the ECPI asks them to locate their capability against behaviourally anchored progression statements for each competence and records the EntreComp level that a respondent's reported pattern of activity corresponds to. The ECPI is therefore a behaviourally anchored self-assessment: it ties self-judgement to concrete descriptions of activity rather than an abstract magnitude, but remains self-reported. It is not an independently observed measure of capability. As described in Section 2.3, the ten competences are each operationalised through a set of underlying behavioural indicators, or threads. Each thread is coded to an EntreComp level, the competence score is the mean of its threads, and the ECPI is the aggregate across competences, expressed on the eight-point EntreComp scale.

To illustrate the scoring architecture, Table 1 shows how a single competence, Taking the Initiative, is anchored across the four progression stages. Each behavioural thread is matched to the stage whose anchor it best fits, and the competence score is the mean of its threads.

Table 1: Illustrative ECPI scoring anchors for one competence

Progression Stage	Level	Illustrative Behavioural Anchor — Taking the Initiative
Foundation	1	Acts on tasks mainly when prompted or directed by others
Intermediate	3	Initiates and carries out own tasks independently
Advanced	5	Initiates and drives activities that mobilise and direct others
Expert	7	Leads ventures that create lasting value for others

To support interpretation, ECPI scores are classified into four progression stages aligned with the EntreComp phases, representing the EntreComp eight-level model through four anchor levels: 1 (Foundation), 3 (Intermediate), 5 (Advanced) and 7 (Expert, or Transformative). The intermediate scores fall on the continuum between these anchors. The index is treated as a formative composite. This means that the competences are understood as conceptually distinct elements that each contribute to an overall progression profile. They are not treated as interchangeable indicators of a single underlying trait. For this reason, internal-consistency reliability is reported at the thread level for transparency only. It is not treated as a requirement for validity. Coefficient alpha therefore indicates how consistently the thread-level indicators have been coded rather than whether the composite itself is valid. The validity of the composite depends instead on whether its components adequately cover the competence domain (Nunnally and Bernstein 1994). The ECPI is designed to be used alongside, not instead of, conventional self-rating, so that the relationship between progression-based and self-rated competence can itself be examined. Because the design is cross-sectional, the ECPI captures a respondent's current progression level, their position on the EntreComp continuum, rather than change over time; the term progression is used throughout in this positional sense.

3. Research Method

3.1 Design and Research Philosophy

The study is underpinned by a pragmatist research philosophy and a mixed methods design with a quantitative-dominant orientation (Johnson and Onwuegbuzie 2004; Creswell and Creswell 2023). Pragmatism treats the research question, rather than a fixed epistemological commitment, as the arbiter of method, and licenses the integration of objective measurement with contextual interpretation. The quantitative component is a cross-sectional survey. It forms the core of the analysis, enabling systematic measurement and comparison of competence progression; the wider study also draws on limited qualitative material, but the present paper reports its quantitative strand. The design operationalised the ECPI as the primary developmental measure alongside a parallel self-assessment instrument, enabling both description and direct comparison of the two measurement approaches.

3.2 Sample

The target population was Muslim youth aged 18 to 25 residing in Australia. Respondents were recruited through Muslim community organisations and networks and completed an online survey distributed across Australia. A total of 122 responses was obtained; after excluding thirteen age-ineligible cases, the final analytic sample comprised 109 valid respondents. The sample was balanced by gender (55 male, 54 female) with a mean age of 20.8 years (SD = 2.4). Respondents were distributed across schooling pathways, most having completed all schooling in Australia.

3.3 Measures

Competence progression (ECPI). Progression was captured using behaviourally anchored progression statements for the ten non-cognitive competences described in Section 2.3, coded at thread level to the EntreComp eight-level scale and aggregated to a weighted competence-progression index. While the ECPI is treated as a formative composite, thread-level coding demonstrated good internal consistency ($\alpha = 0.90$), supporting the consistency of the coding scheme. Coding was conducted by a single trained researcher; inter-rater reliability was therefore not assessed and is identified as a priority for future validation.

Self-assessed competence (SAT). In parallel, respondents rated their perceived competence on a validated multi-item seven-point instrument aligned to the same competences; the non-cognitive subscale (SAT-NC) used for comparison was highly reliable (α = 0.92). This provides the benchmark against which progression-based measurement is compared.

Covariates. Prior entrepreneurial experience was a formative index summing binary indicators of prior activity, such as business ownership, entrepreneurship programmes, and family business background. Religiosity was measured with the ten-item IIUM Religiosity Scale (Mahudin et al. 2016) (α = 0.92). Gender and schooling pathway were recorded as background variables. These covariates were used to examine correlates of progression rather than to test a causal model.

3.4 Analysis

Analysis proceeded in four steps. Descriptive statistics summarised overall ECPI and its distribution across progression stages. Competence-area scores described the profile across the three areas. Progression and self-assessment were compared using Pearson correlation and a paired comparison of mean scores, with Cohen's d for effect size. Finally, correlations and group comparisons examined whether progression varied by prior experience, gender and schooling pathway. Reliability, correlation and regression procedures, following established conventions for multivariate analysis (Hair et al. 2019), were conducted in the Jamovi statistical package.

4. Findings

4.1 Overall Progression and Stage Distribution

Across the full sample, the mean ECPI was 3.58 (SD = 0.84) on the eight-point EntreComp scale, with scores ranging from 1.44 to 5.49 and an approximately symmetric distribution. This places the typical respondent at the Intermediate phase. That is, the respondents were acting with growing independence and beginning to act on their own ideas. As Table 2 shows, two-thirds of respondents were classified at the Intermediate stage and a substantial minority at the Advanced stage, while only a small group remained at Foundation and none reached the Expert (Transformative) stage.

Table 2: Distribution of respondents across ECPI progression stages (N = 109)

Progression Stage	EntreComp Phase	Score Range	n	%
Foundation	Level 1	< 2.0	5	4.6
Intermediate	Level 3	2.0–3.99	73	67.0
Advanced	Level 5	4.0–5.99	31	28.4
Expert (Transformative)	Level 7	≥ 6.0	0	0.0

The concentration of respondents at the Intermediate stage, with a meaningful Advanced minority and an empty Expert stage, is consistent with a youth population that has acquired foundational entrepreneurial capability through education and early experience but has not yet undertaken the transformative, value-creating activity that characterises the highest EntreComp levels. The progression-based picture is thus more developmentally informative than a single mean self-rating would be.

4.2 Progression Across Competence Areas

Progression varied across the three EntreComp areas. As Table 3 shows, Ideas and Opportunities recorded the highest mean progression (3.96), followed by Into Action (3.70), with Resources lowest (3.34). At competence level, Vision (4.69) and Ethical and Sustainable Thinking (3.96) were the strongest, while Mobilising Resources (3.19), Creativity (3.23) and Self-Efficacy and Self-Awareness (3.29) were the weakest. The pattern indicates that respondents were comparatively stronger at recognising and valuing opportunities than at mobilising the resources required to pursue them. The prominence of Vision is consistent with aspirational, future-oriented thinking developing earlier in young people than the resources and skills required to enact it.

Table 3: ECPI progression by competence area and competence (N = 109)

EntreComp Area / Competence	Mean	SD
Ideas and Opportunities (Area)	**3.96**	**0.90**
Creativity	3.23	1.13
Vision	4.69	1.26
Ethical and Sustainable Thinking	3.96	1.21
Resources (Area)	**3.34**	**0.90**
Self-Efficacy and Self-Awareness	3.29	1.13
Motivation and Perseverance	3.43	1.05
Mobilising Resources	3.19	1.31
Mobilising Others	3.46	1.40
Into Action (Area)	**3.70**	**1.14**
Taking the Initiative	3.58	1.63
Coping with Uncertainty, Ambiguity and Risk	3.88	1.24
Working with Others	3.65	1.44

This area-level asymmetry is diagnostically useful. It suggests that, for this population, the binding constraint on entrepreneurial progression lies less in ideation and more in the resource domain, which includes self-efficacy and the capability to mobilise financial, material and human resources. This is precisely where targeted competence-development support could be concentrated.

4.3 Progression Versus Self-Assessment

The comparison of the two approaches is the study's central methodological finding. Self-assessment and progression scores were moderately and significantly correlated ($r = 0.55$, $p < 0.001$), indicating that they capture related information, yet they shared less than a third of their variance ($r^2 = 0.30$). This is far from interchangeable. At the same time, the magnitude self-rating systematically exceeded the behaviour-anchored progression score: the mean self-assessed score stood 0.99 scale points above the mean ECPI score, a large and significant difference ($t(108) = 10.6$, $p < 0.001$; Cohen's $d = 1.01$).

In other words, respondents consistently rated their perceived competence above the progression stage indicated by their behaviourally anchored measure. The size of this gap was not trivial. This pattern is consistent with the broader evidence that self-assessment behaves partly as a confidence or affective measure rather than a direct index of behaviourally anchored capability (Sitzmann et al. 2010). For the developmental question at the heart of EntreComp, the implication is clear: relying on self-assessment alone would have substantially overstated how far this youth population has progressed and would have obscured the area-level pattern reported above. Progression-based measurement provides a more conservative and more diagnostic account.

4.4 Correlates of Progression

Examining covariates clarified what is, and is not, associated with progression. Prior entrepreneurial experience was the strongest correlate: respondents with entrepreneurial experience scored markedly higher on the ECPI than those without (3.93 versus 3.40), and experience correlated significantly with progression ($r = 0.35$, $p < 0.001$). By contrast, there was no meaningful difference by gender (Cohen's $d = 0.01$, $p = 0.96$). Furthermore, schooling pathway was not associated with significant differences in progression. These results indicate that competence progression in this sample is driven by entrepreneurial exposure and practice rather than by demographic category or schooling context, reinforcing the case for experiential, practice-based competence development.

4.5 Religiosity and Progression

Religiosity was not associated with progression-based competence: its correlation with the ECPI was negligible ($r = 0.08$, $p = 0.38$), and it did not predict progression once gender, Islamic educational background and prior experience were controlled ($\beta = 0.03$, $p = 0.71$). Religiosity was, however, a robust predictor of self-assessed non-cognitive competence ($r = 0.37$, $p < 0.001$; $\beta = 0.33$, $p < 0.001$) and was positively associated with the size of the self-assessment–progression gap ($r = 0.35$, $p < 0.001$). In other words, more religious respondents rated their competence more highly than their behaviourally anchored progression indicated, though their progression-based score was no higher. The findings indicate that religiosity is more strongly associated with perceived entrepreneurial capability than with behaviourally anchored competence progression. This suggests caution in assuming a direct religiosity-to-competence effect and highlights the distinction between perceived and progression-based measures of competence.

5. Discussion

The findings make three contributions. The first is methodological. Applying a progression-based index alongside conventional self-assessment showed that the two approaches, while correlated, diverge sharply in level: the magnitude self-rating exceeded the behaviour-anchored progression score by a large and significant margin. This provides empirical support for a concern raised in principle but rarely shown within EntreComp research, that self-assessment overstates capability and is ill-suited to the developmental questions the framework addresses (Sitzmann et al. 2010; Bernadó and Bratzke 2024). By anchoring measurement to behaviourally defined EntreComp stages, the ECPI recovers the progression information that a single magnitude self-rating discards. Understood as a matter of calibration, the gap suggests that magnitude-based self-assessment may inflate estimates of competence progression (Sitzmann et al. 2010).

The second contribution is substantive. The progression profile of Muslim youth in Australia was concentrated at the Intermediate stage, strongest in Ideas and Opportunities and weakest in Resources, with prior experience the dominant correlate. This profile is coherent: young people may develop entrepreneurial ideas and aspirations before acquiring the resources and practical experience needed to enact them. The absence of any respondent at the Expert stage is consistent with the developmental position of a youth cohort and underlines that the highest EntreComp levels describe sustained value-creating activity that few young people will yet have undertaken.

The third contribution is to the reach of the evidence base. Entrepreneurship competence research has been built largely on Western university samples; extending a progression-based application of EntreComp to Muslim youth in Australia both demonstrates the framework's portability and begins to redress the underrepresentation of culturally and religiously diverse youth in this literature (Giacomin et al. 2023). It also contributes to the diaspora-entrepreneurship literature. Much of this literature has focused on established immigrant founders (Fallahi et al. 2024). By contrast, a progression lens shows how competence develops among diaspora youth before venture creation. This is directly relevant to developing the next generation of entrepreneurs. The competences and progression stages translated meaningfully to this population, while the area-level profile points to context-specific development needs. By concentrating on the non-cognitive competences, the study also lays the groundwork for a broader research agenda examining how religiosity and values relate to entrepreneurial capability among Muslim youth, particularly within the dispositional domain where that relationship is theorised to be strongest.

The findings regarding religiosity further reinforce the study's methodological contribution. Religiosity was associated with self-assessed competence but not with progression-based competence. This suggests that religiosity may influence confidence, motivation, identity, or perceptions of capability more strongly than it influences behaviourally anchored competence progression itself. More broadly, the finding highlights that self-assessment and progression-based measures capture different dimensions of entrepreneurship competence and may therefore lead to different substantive conclusions.

These contributions also carry practical implications. For educators, the results argue for assessment that locates learners on a developmental trajectory rather than a self-rated snapshot, and for curricula that concentrate support where progression is weakest; self-efficacy and resource mobilisation. For policymakers and youth-development organisations, the dominance of prior experience over demographic factors supports investment in experiential, practice-based opportunities. More broadly, the observed gap between self-rated and

behaviour-anchored competence cautions against evaluating programmes on magnitude self-ratings alone, which may flatter outcomes and misdirect resources.

6. Limitations and Future Research

Several limitations should be noted. The study is cross-sectional, so progression is inferred at one point in time rather than tracked longitudinally. Future research should apply the ECPI over time to examine genuine developmental movement and evaluate the impact of entrepreneurship education interventions.

The sample is not a probability sample, so findings should be generalised with caution. Two targeted competences also lacked directly matching self-assessment items, limiting the comparison between ECPI and conventional self-rating for those areas. Finally, because the ECPI relies on coded accounts, future work should examine inter-rater reliability and external criterion validity more directly.

7. Conclusion

This study applied the ECPI as a progression-based measure of entrepreneurship competence among Muslim youth in Australia. The findings show that respondents were positioned at an intermediate level of progression overall, with variation across the three EntreComp areas. They also show that progression-based measurement produces a different picture from conventional self-rating, with self-assessment yielding systematically higher scores.

The study makes two main contributions. Methodologically, it extends the use of EntreComp by operationalising its progression model rather than reducing competence to a single self-rated score. Empirically, it provides evidence from Muslim youth in Australia, a population largely absent from entrepreneurship competence research.

Beyond its academic contribution, the study responds to a practical need. Muslim youth in Australia represent an important but under-supported source of entrepreneurial potential. More broadly, the findings suggest that entrepreneurship competence should be assessed as a developmental construct, not only as a self-perception. If entrepreneurship education aims to foster progression, then progression itself must become a central focus of assessment.

Conceptual Maturity Framework for Digital Twin Technology Adoption and Scaling

Abstract: A Digital Twin is a dynamic virtual representation of a physical entity that mirrors its real-world counterpart through continuous, bi-directional data exchange. It promises to transform how organisations design, monitor, and improve complex systems, yet adoption remains uneven. Although use-cases have spread across smart cities, manufacturing, healthcare, energy, transportation, and supply chains, most implementations stay confined to a single site or use-case, and many never move beyond the pilot stage. Existing digital maturity models describe progress as a single linear staircase. This approach does not fit Digital Twin technology, which behaves as both an intelligent environment and a complex adaptive system. The literature therefore lacks a maturity model that connects early adoption to enterprise-wide and cross-organisational scaling, and it rarely treats the two as separate problems. This paper proposes the Digital Twin Adoption-and-Scaling Maturity (DT-ASM) Framework, which conceptualises implementation as two interrelated but fundamentally different capability-building journeys. The Adoption Maturity ladder describes progression at the use-case level, from awareness through pilot selection, deployment and operational integration to routinised use. The Scaling Maturity ladder describes how the same organisation, with its ecosystem, moves from a single use-case through multi-asset replication, cross-domain federation, and ecosystem orchestration to a self-evolving industrial ecosystem. Four cross-cutting determinants shape both journeys: risk exposure, resource allocation cycles, ecosystem maturity, and organisational alignment. The framework is expressed as seven testable propositions with an operationalisation strategy providing a foundation for empirical validation and actionable guidance for industry leaders seeking a roadmap from experimentation to scalable deployment.

Keywords: Digital Twin, Technology Adoption, Technology Scaling, Maturity Model, Innovation

1. Introduction

A Digital Twin comprises a physical entity, its virtual counterpart, and the bidirectional data connections that synchronise the two, so that the digital model reflects the real-world state in near real time (Grieves and Vickers, 2017; Jones et al., 2020; Sharma et al., 2022). The concept was articulated by Michael Grieves in the early 2000s within the context of product life-cycle management and popularised through NASA's high-fidelity virtual models to mirror spacecraft conditions and rehearse missions before flight (Grieves, 2025; Jones et al., 2020). This continuous loop, or twinning, is what distinguishes a Digital Twin from conventional simulation with fixed inputs (Jones et al., 2020). Its value lies in allowing engineers and decision-makers to test ideas, predict failures, and optimise performance virtually before acting physically, cutting cost, shortening development cycles, and averting harm from unforeseen failures (Sharma et al., 2022). These capabilities have driven uptake across aerospace, manufacturing, healthcare, smart cities, and supply chains (Grieves, 2025; Richter, Campbell and Riedl, 2025).

Despite this momentum, full enterprise-wide deployment has not been achieved. Unlike mass technologies adopted on perceived usefulness and ease of use (Davis, 1989; Venkatesh et al., 2003), Digital Twin adoption stalls at the pilot stage for structural reasons: there is no agreed reference architecture and standards remain scarce (Sharma et al., 2022); every twin is domain-dependent and requires bespoke modelling, dedicated sensors, and continuous integration; and most applications sit at low readiness levels, constrained by limited organisational readiness, unclear benefit-cost cases, and regulatory ambiguity (Jones et al., 2020; Richter, Campbell and Riedl, 2025).

A Digital Twin is best understood as both an intelligent environment and a complex adaptive system. As an intelligent environment it relies on sensors, the Internet of Things (IoT), edge and cloud processing, and machine learning to sense, interpret, and support decisions in real time (Augusto et al., 2013). As a complex adaptive system it is a network of interconnected sub-systems that continuously exchange data and adjust to one another, each acting autonomously while sharing information with the rest (Hasgall, Ahituv and Naveh, 2019). This dual nature is what makes Digital Twins both promising and challenging to scale.

This paper synthesises a maturity framework that organisations can use to map their current state and to chart a path toward scaling, reframing the strategic question from how sophisticated a twin is to how an organisation

converts adoption into scaling and captures value across its ecosystem. Maturity models translate abstract transformation goals into sequential stages, helping decision-makers assess capability and set targets (Haryanti, Rakhmawati and Subriadi, 2023; Senna et al., 2023), and they address the need for clearer pathways from pilots to institutional uptake (Richter, Campbell and Riedl, 2025). The central argument is that a single maturity axis conflates two capability journeys, adoption and scaling, whose risk profiles, time horizons, and ecosystem dependencies differ sharply. The Digital Twin Adoption-and-Scaling Maturity (DT-ASM) framework is developed to be empirically testable, positioned within three integrated theoretical lenses and against existing models, along with its matrix, determinants, and propositions.

2. Research Methodology

This research combines literature review with thematic synthesis and framework construction. This approach is suitable because Digital Twin empirical work is fragmented across disciplines, multiple theoretical lenses already exist, and many organisations succeed at pilots but stall at scale (Plekhanov, Franke and Netland, 2023; Senna et al., 2023). The paper is deliberately conceptual as it builds and positions a framework and derives testable propositions as a basis for empirical validation.

The search proceeded in two steps. First, scoping queries were run in Scopus (2010-2025) to map how the adoption and scaling literatures relate. They returned 56,540 records addressing technology adoption without any scaling terminology and 82,062 addressing scaling without any adoption terminology, but only 249 indexing both; restricted to the Digital Twin, 234 records paired the twin with adoption terms only, 150 with scaling terms only, a single record indexed both, and only 13 connected either to maturity. These counts confirmed that the two literatures run largely in parallel and shaped the master search string, which paired a Digital Twin block with a block of adoption-related and scaling-related terms, for example “technology adoption”, “technology acceptance”, “innovation adoption”, “scaling up”, “technology rollout”, “enterprise-wide implementation”, and “pilot to production”. The search string was also run in IEEE Xplore and the ACM Digital Library, chosen because the topic sits between management and digitalisation technology, and supplemented with backward and forward snowballing, which also retained foundational earlier works on the Digital Twin concept and the classical adoption and assimilation theories together with authoritative grey literature.

The searches identified 559 records: 385 from Scopus, 135 from IEEE Xplore, 12 from the ACM Digital Library, and 27 through snowballing. After removal of duplicates, titles and abstracts were screened and the remaining full texts were assessed against predefined inclusion and exclusion criteria. Studies were included when they defined or characterised the Digital Twin or examined the adoption, acceptance, scaling or maturity of the technology in an organisational setting. Reports were excluded when they addressed a non-industrial Digital Twin domain without theory-building intent, when they fell below the quality and relevance appraisal, or when the full text could not be retrieved. This yielded a focused corpus of 165 substantive records, each coded for theoretical lens, sector, unit of analysis, maturity stages, enablers and barriers, and the treatment of adoption versus scaling.

Coded extracts were grouped into five themes: the conceptual evolution of the Digital Twin; capability-based maturity models; classical adoption and acceptance theory; organisational assimilation; and industry deployment evidence. The synthesis showed that a single maturity axis conflates two capability journeys, a finding translated into the conceptual framework architecture of the Digital Twin Adoption-and-Scaling Maturity (DT-ASM), consisting of two five-stage ladders coupled by four cross-cutting determinants.

3. Literature Review

Across the focused corpus, the evidence indicates that the Digital Twin has now entered a phase of development in which adoption is expanding across smart cities, smart manufacturing, individually tailored healthcare, transportation, energy, and supply chains, supported by cloud-based Digital Twin platforms and increasingly sophisticated digital models (Sharma et al., 2022; Grieves, 2025). Industry leaders are using Digital Twins for production monitoring, medical-equipment diagnostics, port operations, and power-grid management (Sharma et al., 2022). A systematic review of Digital Twin publications found that the most frequently cited benefits include what-if scenario simulations, physical-twin performance optimisation, real-time monitoring, and improved decision-making (Richter, Campbell and Riedl, 2025). Despite this momentum, full enterprise-wide deployment has not yet been achieved: most implementations remain limited in scope, are confined to a single use-case or a single site, and many initiatives stay at the pilot or proof-of-concept stage.

3.1 Adoption, Assimilation, and Scaling

The innovation literature separates three related but distinct concepts. Technology adoption is the decision and first act of taking up a technology, shaped by perceived usefulness, ease of use, social influence, and facilitating conditions (Davis, 1989; Venkatesh et al., 2003; Dwivedi et al., 2019); in firms it typically takes the form of pilots driven by champions and gatekeepers (Roberts et al., 2021). Technology assimilation is the deeper process that follows adoption: the embedding of the technology into everyday routines, structures, skills, and culture. Zhu, Kraemer and Xu (2006) describe assimilation as three stages: initiation, adoption, and routinisation, and show that different factors matter at different stages, so the conditions that help a firm begin using a technology are not those that help it spread. Liang et al. (2007) find that institutional pressures drive assimilation mainly through the mediating role of top management, and Hasgall, Ahituv and Naveh (2019) show that organisations behaving as complex adaptive systems assimilate innovation more readily when structure is decentralised. Technology scaling is the broader expansion of an assimilated technology from local to widespread, cross-functional, and often cross-organisational use, which for Digital Twins depends on shared standards and regulation rather than isolated pilots (Sharma et al., 2022).

These concepts are frequently collapsed in practice. Much of the Digital Twin literature treats adoption as a single event and presents scaling as more of the same, obscuring that the two are governed by different logics: adoption is a decision at the use-case level under bounded risk, whereas scaling is an ecosystem-level achievement contingent on conditions the organisation does not fully control. The assimilation literature is the key to separating them, yet its stage logic has rarely been built into a Digital Twin maturity model.

3.2 An Integrative Theoretical Foundation

Because Digital Twin deployment spans organisational decision-making, individual acceptance, and ecosystem dynamics, no single theory explains it. The framework therefore integrates three complementary lenses. The technology-organisation-environment (TOE) framework (Tornatzky and Fleischer, 1990) organises the firm-level and contextual conditions of adoption into technology, organisation, and environment; it grounds the four cross-cutting determinants and suits a setting where progress depends on data governance, infrastructure investment, operating-model change, and risk governance rather than individual preference (Senna et al., 2023). The unified theory of acceptance and use of technology (UTAUT) supplies the individual-level micro-foundations that become decisive once end-users encounter a working twin, through performance expectancy, effort expectancy, social influence, and facilitating conditions (Venkatesh et al., 2003; Dwivedi et al., 2019); UTAUT is preferred over the technology acceptance model because its constructs subsume perceived usefulness and ease of use while better reflecting enterprise realities (Davis, 1989). The organisational assimilation perspective supplies the temporal logic of initiation, adoption, and routinisation, and the complex adaptive systems view that connects adoption to scaling (Zhu, Kraemer and Xu, 2006; Liang et al., 2007; Hasgall, Ahituv and Naveh, 2019). Combining the three yields an account that is organisational without ignoring users, and dynamic rather than static: TOE frames the conditions, UTAUT the acceptance, and assimilation the progression.

3.3 Existing Maturity Models and Their Limits

Across the focused corpus of previous research, three limitations recur in the maturity models most often used to describe technology progress. First, adoption models such as UTAUT measure individual perceptions well but stop at the point of decision, with limited elaboration on how readiness emerges across interacting sub-systems and organisational boundaries (Hasgall, Ahituv and Naveh, 2019). Second, stage-based maturity models: the acatech Industrie 4.0 Maturity Index (Schuh et al., 2017), the TOE-based Industry 4.0 model (Senna et al., 2023), the Extended Digital Maturity Model (Haryanti, Rakhmawati and Subriadi, 2023), the CITYSTEPS city-twin model (Haraguchi, Funahashi and Biljecki, 2024), and the capability-based model of Liu et al. (2024) describe progress as a single linear staircase. Linearity suits a standardised infrastructure such as a 5G mobile network, whose diffusion follows a log-normal saturation curve (Hutajulu, Dhewanto and Prasetio, 2021), but fits a Digital Twin poorly, since the twin behaves as a complex adaptive system whose deployment is non-linear and emergent (Jones et al., 2020; Grieves, 2025). Third, the assimilation literature separates the determinants of early use from those of routinised, cross-firm use (Zhu, Kraemer and Xu, 2006), but this insight has not been built into a Digital Twin maturity model. None of the existing models separates the use-case level decision to adopt from the enterprise level or ecosystem level achievement of scaling, or makes explicit the determinants that couple the two.

3.4 Research Gaps

Three gaps follow, each grounded in a trend observed across the focused corpus. First, the Digital Twin delivers clear benefits, but its uptake in capital-intensive industries remains confined to isolated pilots, and the causes are not well explained (Hamidishad et al., 2025; Richter, Campbell and Riedl, 2025). Second, maturity models describe growth as a single linear staircase and do not separate adoption from scaling, even though assimilation research shows the two are driven by different factors (Zhu, Kraemer and Xu, 2006; Liang et al., 2007). Third, the organisational (TOE) and individual (UTAUT) lenses are typically used separately and for adoption only; few studies combine them, and fewer still apply them to both the adoption and the scaling of a Digital Twin (Atencio and Alzamora, 2025). Closing these gaps requires a framework that defines adoption maturity and scaling maturity as distinct but coupled constructs and integrates the organisational, individual, and assimilation lenses.

4. Proposed Conceptual Maturity Framework

The proposed Digital Twin Adoption-and-Scaling Maturity (DT-ASM) Framework addresses the limitations of linear models by separating the maturity question into two interrelated but distinct journeys: an adoption maturity journey at the use-case level, and a scaling maturity journey at the firm or ecosystem level. The two journeys are coupled through four cross-cutting determinants that have emerged from the synthesis: risk exposure, resource allocation cycles, ecosystem maturity, and organisational alignment (Schuh et al., 2017; Plekhanov, Franke and Netland, 2023; Atencio and Alzamora, 2025; Hamidishad et al., 2025).

4.1 Architecture of the Maturity Framework

The framework is structured around two five-stage maturity ladders. The Adoption Maturity ladder (Table 1) describes how an organisation moves from awareness to routinised use within a defined scope; the Scaling Maturity ladder (Table 2) describes how the firm, with its ecosystem, moves from a single routinised twin to federated, ecosystem-level capability.

Table 1: Adoption maturity ladder

Maturity Stage	Description
A1. Awareness and strategic framing	Recognises the twin as a strategic option and links a vision to corporate strategy; corresponds to the initiation stage of assimilation, in which the firm evaluates potential benefits and scans for fitting innovations (Zhu, Kraemer and Xu, 2006; Schuh et al., 2017).
A2. Pilot selection and sociotechnical readiness	Selects a bounded use-case where data, instrumentation, and sponsorship align - the assimilation adoption decision - where success turns on sociotechnical alignment rather than technical skill alone (Atencio and Alzamora, 2025).
A3. Pilot deployment and validation	Implements a model or shadow on near-real-time data, validated against ground truth; as end-users engage, UTAUT acceptance drivers begin to dominate (Venkatesh et al., 2003; Dwivedi et al., 2019).
A4. Operational deployment	Evolves into a full twin with bidirectional feedback embedded in operational control; top-management support and absorptive capacity become decisive (Liang et al., 2007; Shao, Feng and Hu, 2012).
A5. Routinised use within scope	Monitored, maintained, retrained, and audited as business-as-usual, the routinisation stage, where an assimilation gap often leaves widespread use lagging initial adoption (Zhu, Kraemer and Xu, 2006; Hasgall, Ahituv and Naveh, 2019).

Table 2: Scaling maturity ladder

Maturity Stage	Description
S1. Single use-case	Builds the twin as a replicable pattern, for example data contracts, model artefacts, validation protocols, governance roles, economic baselines, so the next deployment is cheaper and faster (Schuh et al., 2017; Hamidishad et al., 2025).
S2. Multi-asset replication	Replicates the pattern across similar assets; CAPEX and OPEX logics merge into a TOTEX view with staged, real-option financing (Hamidishad et al., 2025).
S3. Cross-domain federation	Federates twins into a system of systems; because twin interpretations are heterogeneous, federation needs semantic alignment and shared standards, not data exchange alone (Cimino, Ferretti and Leva, 2021; Liu et al., 2024).

Maturity Stage	Description
S4. Ecosystem twin and platform orchestration	Connects the federated twin with suppliers, customers, and regulators; value shifts from inside firm boundaries to across the ecosystem, bringing platform economics and multi-tenant governance to the fore (Su et al., 2022; Plekhanov, Franke and Netland, 2023).
S5. Self-evolving industrial ecosystem	Processes self-organise through agentic, AI-augmented decision logic under industry-wide standards; advantage is no longer the individual twin but the firm's position in the ecosystem it orchestrates (Grieves, 2025).

The two ladders can be read together as a single diagnostic space. Plotting adoption maturity against scaling maturity produces the DT-ASM matrix (Figure), in which any organisation occupies a cell defined by its position on each ladder. The matrix turns the framework into a map: it shows not only where a firm stands but also the direction and balance of its progress, and it distinguishes three qualitatively different trajectories.

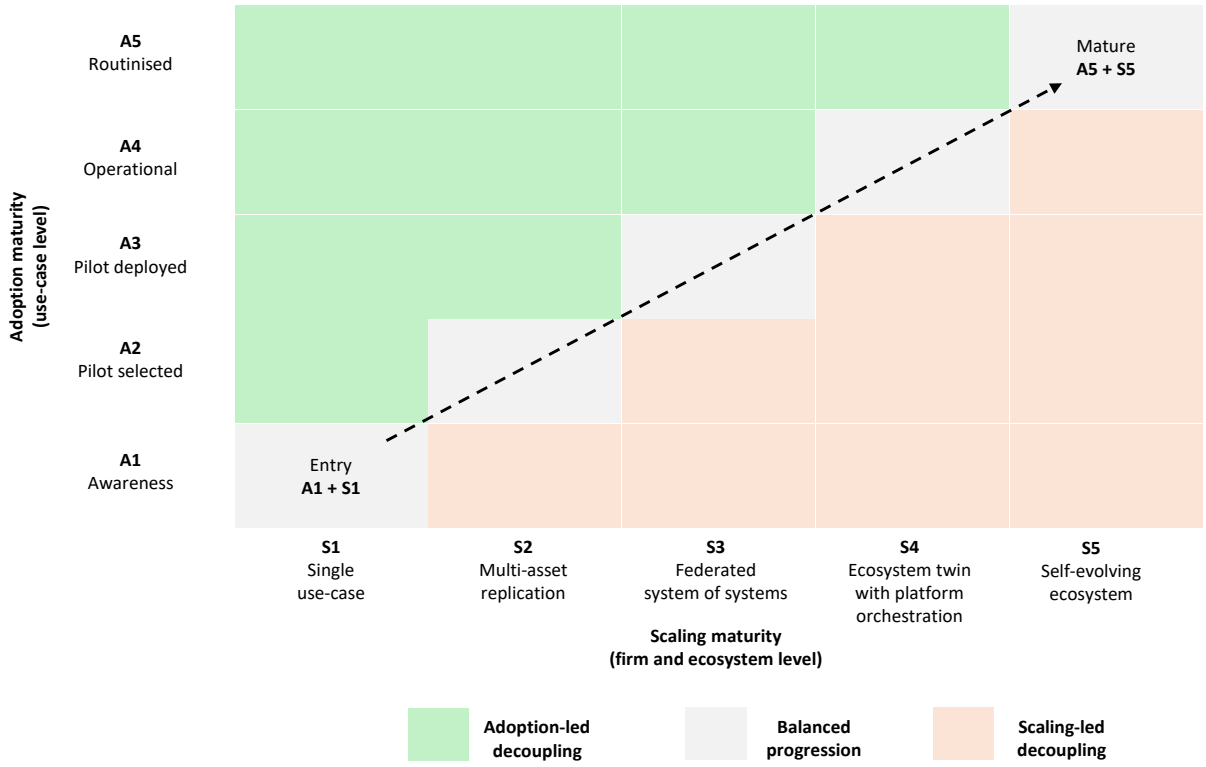

Figure 1: The Digital Twin Adoption-and-Scaling Maturity (DT-ASM) Matrix

Cells on the diagonal represent balanced progression, where use-case level capability and ecosystem-level scaling advance in step. Cells above the diagonal represent adoption-led decoupling, where an organisation builds sophisticated twins internally but has yet to replicate or federate. Cells below the diagonal represent scaling-led decoupling, where ecosystem platforms enable rapid scaling without deep use-case level adoption. Movement is expected to be non-linear where an organisation may advance on one axis, stall, or regress. Therefore, adoption and scaling maturity are interrelated but strategically separable.

4.2 Cross-cutting Determinants

Four cross-cutting determinants moderate progress on each ladder and govern the coupling between them:

- *Risk exposure*: the changing portfolio of technical, financial, organisational, regulatory, and systemic risks faced at each stage. Adoption stages emphasise use-case and vendor risk; scaling stages emphasise integration, model-drift, cybersecurity, partner, and systemic risks (Roberts et al., 2021; Hamidishad et al., 2025).
- *Resource allocation cycles*: the governance logic and time horizon of investment. Adoption is dominated by project CAPEX and short cycles; scaling is dominated by total expenditure, real options, and long cycles, with explicit budget for model maintenance, retraining, and ecosystem participation (Schuh et al., 2017; Hamidishad et al., 2025).

- *Ecosystem maturity*: the readiness of standards, platforms, supplier networks, talent markets, regulatory frameworks, and industrial commons that surround the firm. A firm cannot scale faster than its ecosystem allows (Cimino, Ferretti and Leva, 2021; Plekhanov, Franke and Netland, 2023; Watts et al., 2025).
- *Organisational alignment*: the alignment of strategy, structure, leadership style, culture, and end-user behaviour. Adoption requires vertical alignment; scaling requires networked alignment, including with external partners and standards bodies (Shao, Feng and Hu, 2012; Haryanti, Rakhmawati and Subriadi, 2023).

Each determinant pulls differently at the two stages, as summarised in Table 3. This role differentiation is what allows a firm to be constrained by one determinant during adoption and by another during scaling.

Table 3: Differentiated role of each determinant across the adoption and scaling ladders

Determinant	Role in Adoption	Role in Scaling
Risk exposure	Use-case and vendor risk dominate; low tolerance keeps pilots small.	Integration, model-drift, cybersecurity, and systemic risk dominate.
Resource allocation cycles	Short project CAPEX cycles fund pilots.	Long TOTEX and real-option logic fund replication and federation.
Ecosystem maturity	Limited effect; firms can pilot in isolation.	Strong effect; standards and platforms set the speed limit for scaling.
Organisational alignment	Vertical alignment and leadership support are decisive.	Networked alignment with external partners becomes decisive.

The ladders are coupled in three ways: adoption successes create the patterns and credibility scaling requires; scaling expectations shape adoption-stage choices about vendors and architectures; and the four determinants act on both. They are also strategically decoupled as the matrix shows.

4.3 Propositions and Operationalisation

The framework yields seven propositions that constitute a directly testable agenda; each is formalised as a hypothesis in ongoing empirical work:

P1. Adoption maturity and scaling maturity are two empirically distinct constructs, not a single dimension.

P2. The five adoption stages (A1–A5) form a cumulative, correctly ordered progression.

P3. The five scaling stages (S1–S5) form a cumulative, correctly ordered progression.

P4. An organisation can reach high adoption maturity while remaining low on scaling maturity, and vice versa (decoupling).

P5. Each of the four determinants significantly predicts progression along the adoption ladder.

P6. Each of the four determinants significantly predicts progression along the scaling ladder.

P7. The relative weight of the four determinants differs between the adoption and the scaling ladder.

The framework is designed to be operationalised through maturity ladder validation (P1, P2, P3), where each ladder is measured both by a single ordered self-classification and by a cumulative battery of stage capability items using ordinal structure testing. The determinant paths (P5, P6, P7) are estimated as two structural models with adoption and scaling as endogenous constructs; and decoupling (P4) is examined by locating firms on the adoption-by-scaling matrix. The intended validation context is capital-intensive, safety-critical, and data-rich industrial settings.

5. Theoretical Implications

The DT-ASM framework contributes to theoretical development by disaggregating Digital Twin maturity into two distinct constructs: Adoption Maturity and Scaling Maturity. This paper introduced four explicit cross-cutting determinants taken from classical technology adoption theories (Davis, 1989; Tornatzky and Fleischer, 1990; Venkatesh et al., 2003; Dwivedi et al., 2019), technology assimilation research (Zhu, Kraemer and Xu, 2006; Hasgall, Ahituv and Naveh, 2019), leadership and psychological frameworks (Shao, Feng and Hu, 2012; Roberts

et al., 2021), and digital transformation literatures (Schuh et al., 2017; Plekhanov, Franke and Netland, 2023). From a parsimony perspective, two coupled ladders and four determinants are harder to operationalise than a single staircase, therefore the propositions and measurement strategy are designed to justify this added complexity.

6. Practical Implications

For industry leaders, the framework reframes the central strategic question. Rather than asking how mature is our Digital Twin, leaders are invited to ask: how mature is our adoption capability for the use-cases we are pursuing; how mature is our scaling capability for the asset portfolio, value chain, and ecosystem we operate in; and where is the binding constraint, in our risk posture, in our resource cycles, in our ecosystem, or in our organisational alignment.

The DT-ASM framework prescribes balanced, capability-aware progress along both ladders, with deliberate attention to which determinant is currently binding. Doubling down on technology investment without addressing organisational alignment leaves adoption maturity stalled at level A3 or A4 (Shao, Feng and Hu, 2012; Roberts et al., 2021). Pursuing aggressive scaling targets without first achieving routinised use at level A5 produces fragile deployments that collapse under operational stress (Hamidishad et al., 2025). Assuming that ecosystem standards will arrive on demand leaves firms exposed when they do not (Cimino, Ferretti and Leva, 2021; Watts et al., 2025).

7. Limitations and Future Research

The framework is conceptual and synthetic, and it inherits the limitations of the literatures from which it draws. The five-stage articulation of each ladder is a heuristic rather than an empirical partition. Real organisations are unlikely to occupy a single stage cleanly, and both ladders are likely to exhibit local cycles of regression and recovery, especially when leadership turnover, technology shocks, or regulatory changes occur. Further research follows directly. Empirical validation of the dual ladders is a priority: cross-sectoral mixed-methods studies are needed to test the seven propositions set out in Section 4.3.

8. Conclusion

The synthesis presented in this paper addresses the limitation of single-axis maturity models by separating adoption maturity from scaling maturity, articulating each as a five-stage ladder, and identifying four cross-cutting determinants that govern progress along and between the ladders: risk exposure, resource allocation cycles, ecosystem maturity, and organisational alignment. None of the existing maturity models, from the acatech Index (Schuh et al., 2017) and the Extended Digital Maturity Model (Haryanti, Rakhmawati and Subriadi, 2023) to CITYSTEPS (Haraguchi, Funahashi and Biljecki, 2024) and the capability-based model (Liu et al., 2024), separates the decision to adopt from the capability to scale. The DT-ASM framework makes that separation, and the determinants that couple the two ladders, explicit and testable.

Empirical applicability rests on three conditions: measurement instruments that operationalise each stage through observable criteria; access to organisations at different positions on the DT-ASM matrix representing coupled and decoupled progression; and longitudinal or retrospective data to evaluate movement between stages rather than static positions. Within these conditions, the framework supports three classes of action: a foundation for empirical validation by researchers, a diagnostic instrument for industry leaders to identify binding constraints, and a clearer view for policymakers of the ecosystem investments covering standards, platforms, talent, and regulation needed for scalable Digital Twin deployment.

Abstract: *Purpose:* Entrepreneurial coaching (EC) has emerged as a recognised support mechanism for venture creation. Yet its intellectual structure, thematic organisation, and conceptual positioning within the broader entrepreneurial support ecosystem remain insufficiently mapped. *Design/Methodology/Approach:* This study adopts a two-layer scientometric design. Layer 1 examines the internal intellectual structure of EC through 31 peer-reviewed articles retrieved from Web of Science and Scopus (2009–2026). Layer 2 extends the analysis to 74 articles from broader entrepreneurial support literature. Performance analysis and science mapping, including co-citation analysis, keyword co-occurrence, thematic mapping, and Multiple Correspondence Analysis, were conducted using VOSviewer and Biblioshiny within the Bibliometrix R package. *Findings:* Layer 1 reveals that EC is an emerging but progressively consolidating research domain with interdisciplinary foundations across social cognitive theory, entrepreneurship, and relational support traditions. Coaching and entrepreneurial support constitute the field's motor theme, while entrepreneurial coaching and entrepreneurial self-efficacy form a developing niche. A structural shift is identified from EC as a programmatic incubation tool to EC as a mechanism of entrepreneurial identity and capability development. Layer 2 reveals that EC occupies a conceptually distinct but structurally peripheral position within the ecosystem, forming its own cluster defined by self-efficacy, mentoring, and behaviour though absent from the ecosystem's motor themes. Multiple Correspondence Analysis confirms a fundamental conceptual separation between EC research discourse and the structural ecosystem vocabulary. *Originality/Value***:** This study contributes a two-layer scientometric mapping of EC, an analytical architecture that simultaneously maps the field's internal intellectual structure and its positioning within the broader entrepreneurial support ecosystem, an approach not previously applied to entrepreneurial coaching research. *Theoretical implications.* EC's interdisciplinary embeddedness explains its persistent terminological fragmentation, while the progressive dominance of social cognitive theory signals an emerging phase of conceptual consolidation. *Practical implications:* EC should be understood as a psychologically grounded complement to structural support mechanisms. Its value lying in the relational and behavioural dimensions that incubation and acceleration programmes do not address.

Keywords: Entrepreneurial Coaching; Scientometric Analysis; Bibliometric Mapping; Entrepreneurship Support; Thematic Evolution; Knowledge Development.

1. Introduction

Entrepreneurial coaching (EC) has emerged as a critical support mechanism for venture creation and development, equipping entrepreneurs with the skills, resilience, and decision-making capabilities necessary to navigate the complexities of the entrepreneurial process (Azizi et al., 2023; Kotte et al., 2021). Defined as a customised, reflective, and results-oriented developmental intervention directed toward entrepreneurs across different stages and experience levels (Kotte et al., 2021), EC has attracted growing scholarly attention, particularly since 2018. As entrepreneurial ecosystems became increasingly complex and competitive, demand for structured, individualised support mechanisms has intensified, positioning EC as a strategically relevant yet an insufficiently understood component of the entrepreneurial support landscape (Marras et al., 2024).

Despite this growing interest, significant gaps persist in the literature. EC lacks a unified conceptual definition and is frequently conflated with adjacent support forms including mentoring, business coaching, and consulting, generating terminological fragmentation that hinders cumulative knowledge development (Audet & Couteret, 2012; Kotte et al., 2021). Existing studies tend to address specific aspects of EC, outcomes, populations, or interventions in isolation without providing a comprehensive view of the field's intellectual evolution, thematic organisation, or conceptual positioning relative to other entrepreneurial support mechanisms. To date, no study has systematically applied a scientometric approach to map the knowledge structure of entrepreneurial coaching (EC) across both its internal scholarly literature and the broader entrepreneurial support ecosystem in which it is embedded.

To address this gap, this study pursues three research questions:

> RQ1: How has the intellectual and thematic structure of entrepreneurial coaching research evolved over time?

RQ2: What are the dominant, emerging, and declining themes in EC literature?

RQ3: What distinguishes EC from other forms of entrepreneurial support, and how does EC establish its conceptual boundaries within the broader entrepreneurial support ecosystem?

Answering these questions, this study makes three contributions. It provides a comprehensive systematic two-layer scientometric mapping of EC, clarifies the field's thematic trajectories and intellectual foundations, and establishes EC's conceptual boundaries relative to adjacent support mechanisms, thereby supporting both cumulative theory building and evidence-informed practice.

2. Literature Review

This review applies the Theory-Context-Characteristics-Methodology (TCCM) framework (Paul & Menzies, 2023) to structure existing EC scholarship, enabling systematic identification of what is established and where critical gaps persist.

Theory: The theoretical foundations of EC are inherently interdisciplinary, reflecting its roots across psychology, education, and management rather than constituting a standalone discipline (Kotte et al., 2021). Within psychology, self-efficacy theory (Bandura, 1977) and social cognitive theory constitute the most consistently deployed frameworks, with empirical studies demonstrating that coaching interventions strengthen entrepreneurial self-belief through mastery experiences, vicarious learning, and social persuasion (L. M. Molema & Ndlovu-Hlatshwayo, 2024a; Ndlovu et al., 2025). Human capital theory and experiential learning approaches conceptualise coaching as a mechanism for developing entrepreneurial competencies and knowledge transfer (Marvel et al., 2025; Mohamed & Zouaoui, 2022). Relationship-based perspectives further emphasise that effective EC extends beyond skill development to encompass emotional support, identity navigation, and deeper relational dynamics (Marras et al., 2024). Despite this theoretical richness, integration across traditions remains limited with most studies adopting single-theory frameworks rather than integrative models capable of capturing EC's multidimensional nature.

Context: EC research addresses diverse entrepreneurial populations and organisational settings. Novice and nascent entrepreneurs constitute the most studied population, with coaching shown to facilitate skill acquisition and learning during the critical early stages of venture creation (Audet & Couteret, 2012; Fitouri & Zouaoui, 2021). Women entrepreneurs represent a growing focus, with studies demonstrating coaching's effectiveness in addressing gender-specific confidence barriers and self-efficacy deficits (L. M. Molema & Ndlovu-Hlatshwayo, 2024a). Post-failure entrepreneurs constitute a particularly vulnerable context where coaching supports psychological recovery and renewed entrepreneurial action (Anis et al., 2018). Organisationally, business incubators and SMEs are the most prevalent settings, with coaching increasingly positioned as a structured component of incubation and acceleration programmes (Azizi et al., 2023; Ndlovu-Hlatshwayo & Msimango-Galawe, 2023). Geographically, research remains concentrated in Western and North African contexts, with comparative cross-cultural studies notably absent.

Characteristics: EC is distinguished by its multifunctional role, simultaneously serving developmental, instrumental, and psychosocial functions (Marras et al., 2024). Kotte et al. (2021) propose a two-dimensional framework differentiating the process dimension, encompassing goal setting, reflective questioning, and feedback provision, from the content dimension addressing specific entrepreneurial challenges. Critical success factors identified across studies include coach entrepreneurial experience, entrepreneur openness to change, effective coach-coachee matching, and integration with complementary support services.

Methodology: EC scholarship employs diverse approaches including quantitative surveys with structural equation modelling, qualitative case studies, systematic literature reviews, and psychometric scale development (Marras et al., 2024; Azizi et al., 2023). Scientometric and bibliometric methods have emerged as valuable tools for mapping a field's intellectual structure (Donthu et al., 2021; Zupic and Čater, 2015), though their systematic application to EC specifically remains nascent, a gap this study directly addresses.

Collectively, the TCCM analysis reveals a field characterised by theoretical diversity and contextual breadth, yet lacking a comprehensive structural mapping of its knowledge architecture and conceptual boundaries within the broader entrepreneurial support ecosystem, whinch the dual gap this study is designed to fill.

3. Methodology

Following established bibliometric research guidelines (Donthu et al., 2021), this study adopts a two-layer scientometric approach combining performance analysis and science mapping techniques. Performance analysis evaluates the productivity and scholarly influence of the field through publication trends and citation patterns, while science mapping explores the intellectual and conceptual structure of EC research through co-occurrence and thematic mapping analyses (Zupic & Čater, 2015). Layer 1 examines the internal intellectual structure of EC to answer RQ1 and RQ2, while Layer 2 positions EC within the broader entrepreneurial support ecosystem to address RQ3. To avoid conceptual dilution while still examining the broader entrepreneurial support ecosystem, the extended retrieval strategy associated with RQ3 was not integrated into the main scientometric corpus. Instead, it was used as a comparative conceptual layer to identify adjacent support mechanisms and evaluate the positioning of entrepreneurial coaching relative to mentoring, incubation, acceleration, and entrepreneurial support systems.

3.1 Search Protocol

Both layers were retrieved from Web of Science (TS field) and Scopus (title, abstract, and keywords) in May 2026 with no date restriction, allowing full longitudinal coverage of the field. Only peer-reviewed journal articles in English were retained, with subject categories restricted to business, management, entrepreneurship, psychology, and social sciences. The full screening procedure followed PRISMA guidelines (Page et al., 2021) and is summarised in Table 1 (complete search strings are provided in Appendix N°1).

For Layer 1, the search targeted explicit EC terminology intersected with an entrepreneurial population anchor, yielding 76 records (WoS = 36; Scopus = 40). After removing 21 duplicates and applying document type, language, and subject category filters, the final corpus comprised 31 articles. For Layer 2, the search string extended to adjacent support mechanisms, including entrepreneurial mentoring, business incubation, startup acceleration, and venture support — intersected with a coaching anchor, yielding 163 records (WoS = 72; Scopus = 91). After removing 36 duplicates and applying equivalent criteria, the layer 2 corpus comprised 74 articles.

Table 1: PRISMA based Two-Layer Search Strategy and Corpus Construction

Section	Layer 1 (RQ1–RQ2)	Outcome	Layer 2 (RQ3)	Outcome
Identification	WoS (TS field) + Scopus (Title/Abstract/Keywords). EC-specific terminology (Appendix N°1: Detailed Search string). Date of search: May 2026 Time span: Not restricted	76 records (WoS=36; Scopus=40)	WoS (TS field) + Scopus (Title/Abstract/Keywords). Extended entrepreneurial support terminology intersected with coaching anchor (Appendix N°1: Detailed Search string). Date of search: May 2026 Time span: Not restricted	163 records (WoS=72; Scopus=91)
Screening	Peer-reviewed articles, English only, relevant subject categories, duplicates removed (n=21)	31 articles	Peer-reviewed articles, English only, relevant subject categories, duplicates removed (n=36)	74 articles
Included	Articles explicitly addressing EC within entrepreneurial contexts	31 articles	Articles positioning EC within the broader entrepreneurial support ecosystem	74 articles

3.2 Analytical Methods

All analyses were conducted using Biblioshiny within the Bibliometrix R package (Aria & Cuccurullo, 2017) and VOSviewer (van Eck & Waltman, 2010). For Layer 1, performance analysis addresses RQ1 through descriptive bibliometrics tracking publication trends and citation patterns. Co-citation analysis of authors, conducted in VOSviewer, reveals the theoretical traditions underpinning EC by identifying clusters of systematically co-cited scholars. Keyword co-occurrence analysis and thematic mapping, conducted in Biblioshiny, address RQ2 by

classifying conceptual clusters according to centrality, reflecting external connectivity, and density, reflecting internal cohesion, producing a four-quadrant strategic map distinguishing motor, niche, basic, and emerging or declining themes (Callon et al., 1983). Thematic evolution is applied across two-time windows (2009–2020 and 2021–2026) to capture structural shifts in EC scholarship. For Layer 2, keyword co-occurrence analysis is applied in VOSviewer using author keywords and in Biblioshiny for broader ecosystem coverage. Thematic mapping following the same framework determines EC's strategic position relative to adjacent support mechanisms. Multiple Correspondence Analysis (MCA) additionally provides multivariate confirmation of EC's conceptual distance from ecosystem structures (Aria & Cuccurullo, 2017).

Two limitations are acknowledged: a linguistic bias toward English-language publications, and the unavailability of complete cited-reference metadata in the merged dataset, which precluded document-level co-citation analysis (a dataset overview is provided in Appendix N°2).

4. Findings and Results

4.1 Layer 1: Intellectual and Thematic Structure of EC Research

4.1.1 Descriptive Overview and Production Trajectory

The Layer 1 corpus comprises 31 peer-reviewed articles published across 27 distinct sources between 2009 and 2026 (Figure 1). The near parity between document count and source count indicates a highly dispersed publication landscape with no dominant outlet, a structural feature characteristic of fields not yet coalesced around a core disciplinary venue. The 75 contributing authors, with a mean co-authorship rate of 2.65 per document and an international co-authorship rate of 29.03%, reflect a predominantly collaborative field producing nearly a third of its output through cross-national partnerships. The 151 unique author keywords across 31 articles signals strong terminological heterogeneity and the absence of a stabilised conceptual vocabulary, a structural feature that (Kotte et al., 2021) identify as one of EC's defining developmental characteristics. An average citation rate of 14.48 per document over a mean document age of 4.87 years confirms that EC scholarship is attaining meaningful scholarly visibility relative to its field size.

Figure 1: Descriptive Bibliometric Indicators of the Layer 1 Corpus (Source: Biblioshiny)

The annual scientific production (Figure 2) reveals a trajectory of prolonged latency followed by progressive acceleration, a pattern consistent with the pre-paradigmatic growth phase identified in scientometric lifecycle models (Donthu et al., 2021).

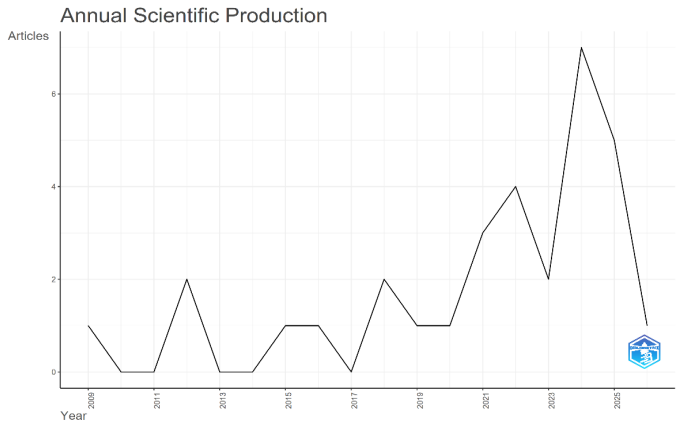

Figure 2: The Annual Scientific Production (Source: Biblioshiny)

Output remained sporadic between 2009 and 2017, a period in which EC lacked both definitional consensus and a critical mass of scholars, constraining cumulative development. The inflection point after 2018, culminating in a peak of seven articles in 2024, signals that the field has crossed the threshold from emergence into structured growth, driven by increasing theoretical specialisation around self-efficacy and a growing recognition of coaching as distinct from mentoring and consulting. This acceleration confirms that EC

is not a peripheral sub-topic absorbed within broader entrepreneurship research, but an increasingly autonomous scholarly domain building its own intellectual corpus.

4.1.2 Intellectual Foundations

The most globally cited documents (Appendix N°3) reveal the foundational architecture of EC scholarship. Kutzhanova et al. (2009, 95 citations) grounded EC in competency-based development theory, establishing individual skill acquisition as a primary mechanism of coaching impact. Mansoori (2019, 74 citations) extended EC's conceptual scope toward technology-intensive venture contexts, while Audet and Couteret (2012, 67 citations) provided the field's most widely cited empirical framework of EC features and success factors. Kotte et al. (2021, 27 citations) proposed the most structurally influential theoretical contribution, a two-dimensional process-content framework that currently anchors definitional debates. The temporal distribution of these papers, spanning 2009 to 2024, confirms that EC's intellectual architecture remains actively under construction.

Co-citation analysis (Appendix N°4) identifies three distinct intellectual clusters through which EC derives its theoretical resources. The first, anchored by Bandura (1977), reflects EC's deep roots in social cognitive theory and self-efficacy, the most consistently deployed theoretical framework across EC empirical studies (L. M. Molema & Ndlovu-Hlatshwayo, 2024a; Ndlovu et al., 2025). The second groups entrepreneurship scholars including Kuratko, Marvel, Audretsch, and Mansoori, confirm EC's substantial grounding in entrepreneurship theory around venture learning and performance (Marvel et al., 2025). The third, centred on St-Jean, captures mentoring and relational support traditions, underscoring the theoretical proximity of EC to adjacent mechanisms that has historically complicated boundary-drawing efforts (Audet & Couteret, 2012; Marras et al., 2024). This tripartite intellectual structure confirms EC as an inherently interdisciplinary construct embedded simultaneously in psychological, entrepreneurial, and relational traditions. This interdisciplinarity explains both EC's richness and its persistent fragmentation: a field drawing simultaneously on three distinct theoretical traditions will naturally resist terminological unification until one tradition achieves sufficient dominance to anchor the others, a process that the trend topic analysis suggests is now underway through the progressive ascendancy of social cognitive theory.

4.1.3 Thematic Structure and Evolution

The overall thematic map (Figure 3) reveals four thematically distinct positions. The motor theme cluster, grouping *coaching* and *entrepreneurial support*, exhibits high internal coherence and strong external connectivity, confirming that EC scholarship is principally organised around coaching as a functional support mechanism (Ben Salem & Lakhal, 2018; Marras et al., 2024). The niche theme cluster positions *entrepreneurial coaching* and *entrepreneurial self-efficacy* above average density but below average centrality, revealing the progressive convergence of EC scholarship on Bandura's (1977) social cognitive theory as its primary explanatory mechanism, particularly in accounting for how coaching translates into enhanced entrepreneurial confidence and action (Crompton et al. 2012; Molema et al., 2024). *Entrepreneurship* occupies the basic themes quadrant, high centrality, low density, functioning as a foundational contextual backdrop without constituting a theoretically integrated partner construct. *Entrepreneurial learning* remains in the emerging or declining themes quadrant, identifying a persistent conceptual gap that Marvel et al. (2025) and Fitouri and Zouaoui (2021) have begun to address but which has not yet achieved sufficient critical mass.

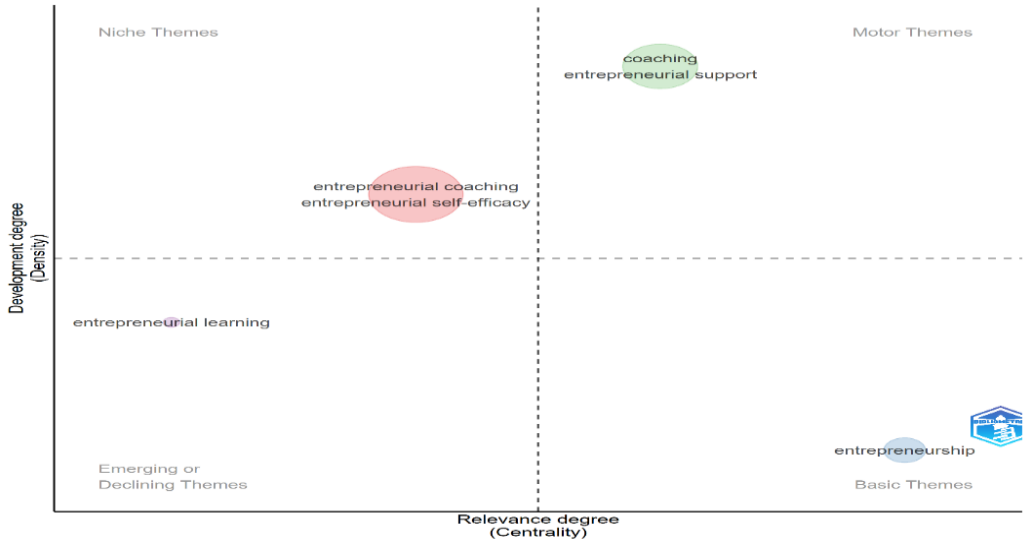

Figure 3: EC Thematic Map (Source: Biblioshiny)

The comparative thematic maps (Figure 4) reveal a meaningful structural reconfiguration. During 2009–2020, *coaching* paired with *incubator* constituted the motor theme, reflecting a dominant preoccupation with EC as a programmatic tool within structured organisational environments. By 2021–2026, *coaching* pairs with *entrepreneurship* as the motor theme, signalling a conceptual transition from EC as an institutional instrument to EC as an intrinsic component of entrepreneurial identity and capability development. Simultaneously, *entrepreneurial coaching*, *entrepreneurial self-efficacy*, and *women entrepreneurs* consolidate into a clearly defined developing theme, reflecting the field's growing attention to psychological depth and demographic specificity in coaching interventions (Cronje et al., 2025;L.Molema et al.,2024) .Trend topic analysis further confirms that *entrepreneurial self-efficacy* and *innovation* are the most recently activated and still-growing terms in the corpus, identifying the field's current research frontier.

Figure 4: The comparative thematic maps (2009-2020 & 2021-2026) (Source: Biblioshiny)

4.2 Layer 2: EC's Conceptual Position within the Entrepreneurial Support Ecosystem

4.2.1 Conceptual Structure and Cluster Differentiation

The keyword co-occurrence network for Layer 2 (Appendix N°5) resolves into four structurally distinct clusters across 74 articles. The first, anchored by *entrepreneurship*, *start-up*, and *university*, represents the institutional dimension of the ecosystem. The second, grouping *accelerator*, *entrepreneurial ecosystems*, and *impact*, captures innovation-oriented infrastructure. The third, comprising *entrepreneurial support*, *entrepreneurial learning*, *women entrepreneurs*, and *novice entrepreneurs*, reflects the relational and developmental support tradition. *Entrepreneurial coaching* constitutes a distinct fourth cluster, co-occurring primarily with *self-efficacy*, *mentoring*, *behaviour*, and *SMEs*, a psychologically grounded configuration that clearly differentiates EC from

the institutional vocabulary dominating the remaining clusters (Kotte et al., 2021; Marras et al., 2024). The presence of *mentoring* within EC's cluster reveals the definitional proximity that has historically complicated boundary-drawing within the ecosystem (Audet & Couteret, 2012). Inter-cluster connections confirm EC's engagement with adjacent research traditions without dissolving its structural separateness, indicating that EC has established a recognisable conceptual identity while remaining insufficiently integrated with the structural mainstream of entrepreneurial support research.

4.2.2 Strategic Positioning within the Ecosystem

The Layer 2 thematic map (Figure 5) positions *innovation*, *business incubation*, *performance*, *networks*, *coaching*, and *self-efficacy* in the motor themes quadrant, establishing these as the most developed and centrally connected themes in the ecosystem literature and confirming that structured support mechanisms, particularly incubation, constitute the theoretical mainstream of entrepreneurial support scholarship (Bruneel et al., 2012). In direct contrast, *entrepreneurial coaching*, *entrepreneurial self-efficacy*, *startup accelerator*, and *entrepreneurial competencies* appear collectively in the emerging or declining themes quadrant, characterised by both low centrality and low density.

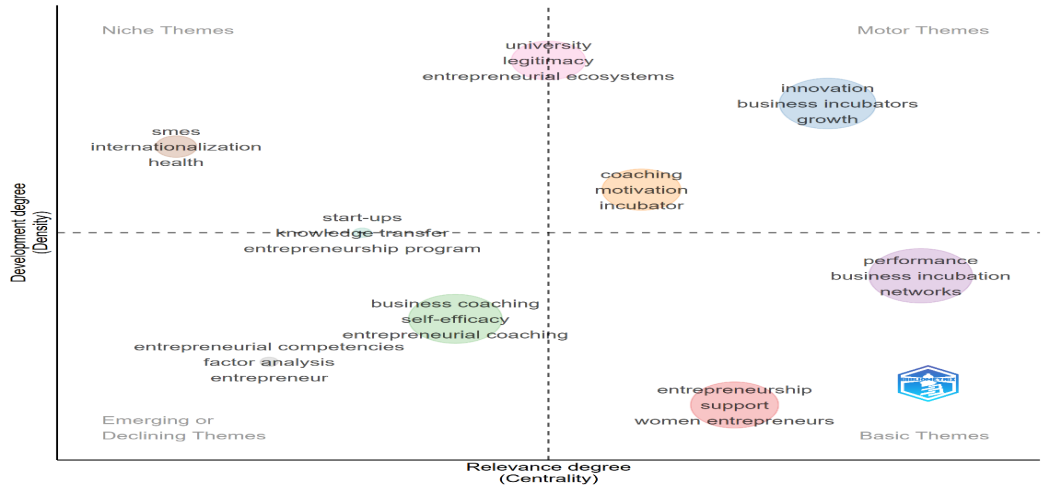

Figure 5: Thematic Evolution Layer 2 (Source: Biblioshiny)

This positioning indicates that EC has not yet achieved the conceptual development or network integration required to function as a core mechanism in ecosystem-level discourse. The divergence between EC's niche status within its own internal corpus, where it demonstrates above-average internal coherence, and its marginal ecosystem position constitutes the central empirical answer to RQ3: EC is conceptually self-contained but structurally peripheral within the broader entrepreneurial support ecosystem.

4.2.3 Temporal and Intellectual Evidence

Words' frequency over time analysis (Appendix N°6) reveals a lexical asymmetry that has direct theoretical implications. *Entrepreneurship* (17 occurrences by 2026), *innovation* (14), and *business coaching* (11) have accumulated sustained referential presence since the early 2010s, establishing their status as the ecosystem's primary conceptual currency. *Entrepreneurial coaching*, by contrast, records only 5 occurrences, the lowest of all tracked terms, with first appearances emerging only from 2018. This is not merely a difference in frequency: it indicates that EC has not yet been absorbed into the shared vocabulary through which the entrepreneurial support ecosystem defines itself and its boundaries. A construct must be named before it can be theorised, and EC's late and limited lexical presence confirms that the process of boundary recognition, the first step toward institutional legitimacy, remains incomplete (Azizi et al., 2023; Ben Salem & Lakhal, 2018).

4.2.4 Multivariate Confirmation of Conceptual Boundaries

The Multiple Correspondence Analysis (Figure 6) provides the most analytically precise answer to RQ3. The first factorial dimension accounts for 50.36% of total variance, achieving a statistically robust separation between two conceptual spaces. The red cluster encompasses the entire EC and coaching research discourse, grouping *entrepreneurial coaching*, *business coaching*, *self-efficacy*, *motivation*, *performance*, *entrepreneurship*, and *business incubation*. The blue cluster, positioned distinctly to the right, groups the structural ecosystem

vocabulary exclusively: *business incubators*, *networks*, *firms*, *support*, and *impact*. This separation, more than half the total explained variance on a single axis, reveals a fundamental conceptual divide: EC belongs to the discourse of coaching outcomes, psychological mechanisms, and individual-level capability development, while ecosystem structures belong to the discourse of networks, institutional performance, and impact assessment. EC has established a recognisable conceptual identity, but one defined by its distinctiveness from rather than its integration with the structural mainstream of entrepreneurial support research (Kotte et al., 2021; Marras et al., 2024).

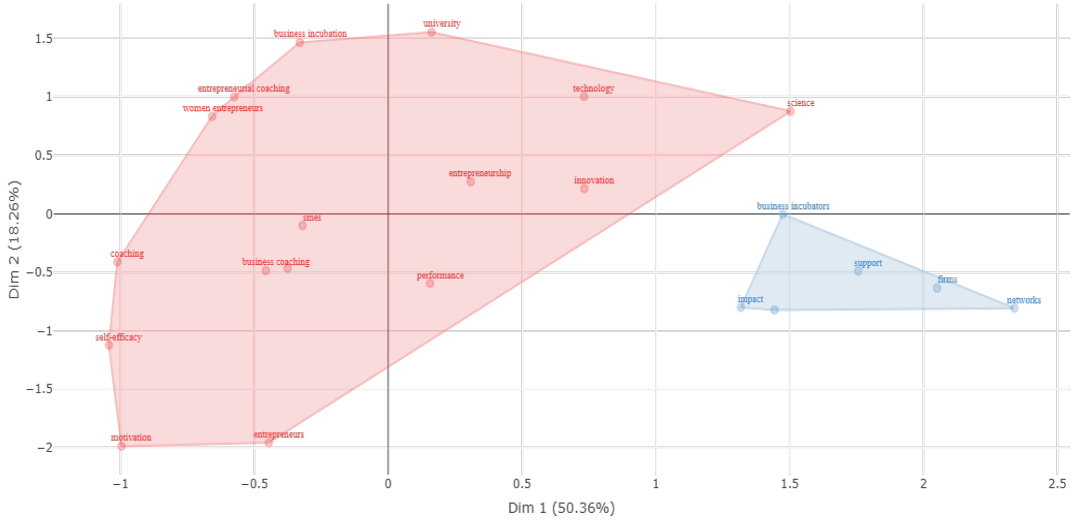

Figure 6: Multiple Correspondence Analysis (Source : Biblioshiny)

5. Discussion

The findings collectively position entrepreneurial coaching as a field in productive tension: internally consolidated yet externally marginalised, conceptually distinct but terminologically unstable. This tension constitutes both the field's defining characteristic and its most pressing scholarly challenge.

With respect to RQ1, the bibliometric evidence confirms that EC has transitioned from an implicit peripheral concept toward an increasingly explicit and autonomous research domain. The post-2018 acceleration in annual production, combined with an interdisciplinary intellectual heritage spanning social cognitive theory, entrepreneurship, and relational support traditions, is consistent with the expansion phase of emerging interdisciplinary fields. This trajectory aligns with Marras et al.'s (2024) characterisation of EC as a maturing but definitionally contested field. Yet, the persistence of 151 unique author keywords across only 31 articles demonstrates that fragmentation is not merely conceptual but structurally embedded in the field's citation and keyword architecture, extending Kotte et al.'s (2021) observation that definitional ambiguity constitutes a structural barrier to cumulative knowledge building. Until the field consolidates shared conceptual vocabulary, cross-study comparison and theory accumulation will remain fundamentally constrained.

With respect to RQ2, the progressive convergence of EC scholarship on self-efficacy reflects a broader pattern in coaching research, where social cognitive theory consistently provides the most tractable framework for measuring coaching outcomes (Bozer & Jones, 2018). Our findings confirm that Bandura's (1977) framework has migrated from executive coaching into entrepreneurial coaching contexts with growing dominance, providing theoretical coherence but also risking a narrowing of explanatory ambition toward psychological outcomes at the expense of systemic and relational dimensions. The persistent marginalisation of entrepreneurial learning within the emerging or declining themes quadrant is particularly notable: coaching is fundamentally a developmental intervention, yet its learning theory foundations within EC remain underdeveloped, a gap that Marvel et al. (2025) and Fitouri and Zouaoui (2021) have begun to address but which represents the field's most urgent theoretical deficit.

With respect to RQ3, the cross-layer comparison yields the study's central theoretical contribution. EC demonstrates above-average internal coherence within its own literature yet occupies the emerging or declining themes quadrant within the ecosystem map, a structural decoupling between scholarly self-definition and institutional recognition. EC knows what it is; the ecosystem does not yet know what to do with it. This finding

suggests that EC has not yet achieved the institutional legitimacy required to drive its adoption as a mainstream support mechanism alongside incubation and acceleration. For researchers, boundary-spanning work connecting EC frameworks to ecosystem-level support structures represents the most urgent theoretical frontier. For practitioners and policymakers, EC should be understood as a psychologically grounded complement to structural mechanisms. Its value lying precisely in the relational and behavioural dimensions that incubation and acceleration programmes do not address (Audet and Couteret, 2012; Crompton et al., 2012). Deliberately integrating EC into incubation programmes, rather than positioning it as an alternative, represents the most productive path toward closing the gap the MCA identifies.

6. Conclusion

This study provides a systematic two-layer scientometric mapping of entrepreneurial coaching, addressing its intellectual evolution, thematic organisation, and ecosystem positioning. Three principal contributions emerge. First, EC is confirmed as an emerging but accelerating research domain, grounded in interdisciplinary foundations across social cognitive theory, entrepreneurship, and relational support traditions, with momentum concentrated post-2018. Second, thematic analysis reveals a structurally evolving field in which coaching and entrepreneurial support constitute the motor theme, while entrepreneurial coaching and entrepreneurial self-efficacy form a developing niche of growing internal coherence, signalling progressive conceptual specialisation. Third, cross-layer analysis establishes that EC occupies a distinct yet peripheral position within the entrepreneurial support ecosystem, characterised by psychological and relational constructs that differentiate it from the structural mainstream of incubation and acceleration research.

Several limitations warrant acknowledgement. Restriction to English-language publications introduces a linguistic bias, potentially under-representing non-Anglophone EC scholarship. The unavailability of complete cited-reference metadata in the merged dataset precluded document-level co-citation analysis. The Layer 1 corpus of 31 articles also constrains the statistical robustness of certain bibliometric indicators.

Three future research directions emerge: longitudinal studies examining whether coaching effects persist across the entrepreneurial lifecycle, cross-cultural investigations assessing the transferability of entrepreneurial coaching models beyond predominantly Western contexts, and process-oriented research exploring the micro-level mechanisms through which coaching interactions generate entrepreneurial self-efficacy, learning, and capability development. More broadly, this study positions entrepreneurial coaching at a scholarly inflection point, where its conceptual identity is increasingly established but its institutional consolidation within the entrepreneurial support ecosystem remains incomplete. The navigational map provided by this study offers a foundation for future scholarship to strengthen theoretical linkages, broaden geographical and contextual coverage, and deepen understanding of developmental processes that may ultimately establish entrepreneurial coaching as a theoretically mature and institutionally recognised domain within entrepreneurship research.

Abstract: Small and Medium Enterprises (SMEs) are the center of the economy for every country, but they are lagging behind the large enterprises in the digitalization, AI implementation and ML optimization due to different facts like the absence of skills, limited digital maturity and cautious investment cultures. This study is focused on exploring how organizational cultural typologies shapes artificial intelligence (AI) and machine learning (ML) adoption and digital transformation capabilities by SMEs in Italy and Germany. Focusing on Competing Values Framework (CVF), in this study the goal is to find out how these cultural typologies (e.g. Clan, adhocracy, hierarchy and market) constrain or enable AI/ML and digital transformation in processes and products innovation. A comparative qualitative research design is considered which is based on twenty semi structured interviews where ten interviews will be from German SMEs and ten interviews will be from Italian SMEs. These semi structured interviews are covering the CVF dimensions, digital transformation capabilities, AI/ML use cases and their impact on process and products innovation. Interview transcripts will be analyzed thematically through NVivo, and a four-stage coding framework is considered to capture General, Cultural, AI/ML and performance related themes like resistance, perceived risk and challenges including dark side of digital transformation. The results of this study will be showing the mixture of how cultural aspects are either driving or resisting the usage of AI/ML and digital transformation in process and products of SMEs. The aim of this study is to contribute to digital transformation and AI-adoption research through organizational culture, not just the resources and technology as a key mechanism. Further the cross-country analysis will highlight the key differences in how SMEs realize the value from AI-based digital transformation. The results may provide new insights for industry professionals and policymakers on how to diagnose cultural typologies and align policy support, capability building and cultural change to foster effective and responsible AI adoption in European SMEs.

Keywords: Organizational Culture, Digital Transformation, SMEs, Artificial Intelligence, Machine Learning, Competing Values Framework, Innovation, Digital Maturity, Artificial Stupidity

1. Introduction

We have seen Nokia, Walmart, Pay-tv Providers, and top hotels (Hilton, Marriott) are left behind and Apple, Google, Alibaba, Amazon, Netflix, Airbnb and Booking.com are successful (Lang, 2021). Rapid technological advancements make the adoption of digital transformation (DT) challenging for many firms. There are several reasons where many countries, companies, and industries have faced challenges in why organizations struggle with adaptation of digital transformation (DT) internally (Kraus et al., 2022). Small and medium enterprises (SMEs) are considered the backbone of economy globally as more than 400 million enterprises where 90% are SMEs and contribute around 70% of GDP and employment (World Economic Forum, 2024).

In Europe, 99.8% enterprises are SMEs which are the backbone of the EU economy and employment (SCHULZE et al., 2024) but still they are behind large enterprises in adoption of digital technologies (Judijanto et al., 2024). The biggest challenges faced by small and medium enterprises (SMEs), are the resistance to change (Alojail et al., 2023 ; Kallmuenzer et al., 2024), lack of resources (Mahboub & Sadok, 2024), complexity of advanced technologies like artificial intelligence and machine learning (Voronkova et al., 2024; Bradač Hojnik & Huđek, 2023), regulatory barriers (Zeya et al., 2023), cyber security risks (Möller, 2023), lack of innovation initiatives by the management (Ju & Weiwei, 2024), and lack of trained staff with digital skills (Rupeika-Apoga & Petrovska, 2022; Zhang et al., 2023).

SMEs also struggle for alignment of their overall business goals with the digital strategies which led to inefficiencies and failures (Oliveira Pereira et al., 2020; Ajibade & Mutula, 2020; Pelletier & Raymond, 2024). Another aspect is the absence of DT-oriented culture which is a barrier in adoption of DT in SMEs (Restrepo-Morales et al., 2024), because organizational structure, culture and leadership influence DT in SMEs (Leso et al., 2023). If an organization is having good leadership as role model, and support innovation, then either it is a family business, non-family business or a sole proprietorship, it will have innovation culture (Villaluz & Hechanova, 2019). This innovative culture can improve the innovative performance regardless of their job type while, if the organization is having a conservative culture, there will be reduced benefits (Al-Khatib et al., 2022).

Another important thing which helps in adaption of innovation is the creativity of employees which can be used as a strategy to foster the innovation but organizational culture (OC) and less trust of employees in management create hurdles for innovation.

Further, SMEs can enhance their market flexibility through OC and the leadership, which allows them to adapt market changes and environmental dynamics to be competitive in the market (Anning-Dorson, 2021). It may result in likeness of flexibility and agility inside the organizational structures but with the support of the management who can guide organizational flexibility and promote a culture to tolerate the risk (Mladenova, 2024). Therefore, we can say that OC, leadership and organizational structure in SMEs influence the adaption of digital transformation (Leso et al., 2023).

SMEs need a clear roadmap driven by a digital strategy (Gobble, 2018) because it can enhance the efficiency, productivity, competitive advantage, resilience (Unegbu et al., 2024;Teixeira et al., 2025) and ESG performance (Chen & Wang, 2024). DT can be through new digital technologies like artificial intelligence (AI), Mobile phones, Internet of things (IoT), Blockchain (BC), and cloud services (Warner & Wäger, 2019). SMEs in general are having less funds to invest in adoption of digital technologies like AI and ML (Sargut, 2019; Kassem et al., 2024), but in most cases there is no clear vision and strategic direction in SMEs (Pujari & Saha, 2024).

This study is focused on European context where EU initiatives and policies shape the DT and AI adoption but national differences in terms of cultures, and structures of SMEs remain pronounced. Italian business landscape is dominated by SMEs with 94.5% share and contribute to 40% GDP and account two third of employment in private sector (Habibi et al., 2024). However, Italian SMEs face resistance in adoption of digital technologies (AI/ML) because of several factors. Major issue which hinders this adoption is the presence of managerial conservatism, since these are family-owned SMEs where conservatism impacts the organizational culture and decisions (Costa et al., 2023; Farace & Tarabella, 2024). Lack of skilled staff and resistance to change are also some reasons where employees are not aware of digital know-how and keep relying on their legacy systems (Seppänen et al., 2025).

In Italy, the governance of AI is also aligned with EU directives for transparency and human centred AI usage (Bertolini et al., 2024). For example, an initiative for AI research and development for industries (SMEs/LEs) is established which is called, High performance computing for Artificial Intelligence (HPC4AI) in Turin (Aldinucci et al., 2018). Digital literacy can be enhanced in Italian SMEs by proper training, through networking and co-created initiatives which can promote to adopt the new technologies (Coco et al., 2024). Adoption of AI/ML in Italy is not widespread and there are many regional disparities for DT readiness (Marino & Tebala, 2020). However, participation of Italy in GPAI is a broader strategy to integrate AI in national frameworks, ethical concerns and for promoting innovation (Colcelli & Burzagli, 2021).

SMEs in Germany are the main driver of economy where around 99% of industries are SMEs and generate 33% of revenue and 57% of workforce (Hopf, 2021). Implementation of AI and ML in German SMEs is considered as the main success factor which can improve efficiency, productivity and improved decision making (Schönberger, 2023), but it is sluggish (Ulrich et al., 2021; Böhme et al., 2024) as compared to larger German companies (Licht & Wohlrabe, 2024). Same resistance reasons are evident in German SMEs like lack of knowledge, funds, skilled workforce (Sargut, 2019;Oldemeyer et al., 2025) and cultural factors (Ångström et al., 2023). However, the focus on ethical AI and governance are the main focus in Germany where “AI made in Germany” is a strategy to promote human centric approach to balance innovation and legal principles (Hälterlein, 2025).

Overall, digital transformation through AI/ML usage in work, for productivity, for innovation and for skills programs have no borders. But its usage need more rules and laws and governance system like GPAI, to monitor the changes and the progress to ensure that AI technologies are providing benefits for humanity and minimizing the risks (Keith, 2024;Ala-Pietilä & Smuha, 2021;Mike, 2024). In this study, we compared the role of organizational culture in German and Italian SMEs to see if it shapes their DT capabilities particularly AI/ML adoption, skills and digital strategies. Further how these cultural typologies can influence the impacts of DT on processes, performance and products.

1.1 Problem Statement

Digital transformation drives the adoption of key technologies (Artificial Intelligence/Machine learning, Internet of Things and data analytics for enhancing efficiency, products innovation and sustainability in SMEs. However, DT brings challenges which includes resistance in workforce, over-reliance on algorithms, and cyber security risks. Among DT enabling factors, organizational culture plays a vital role (Vial, 2019; Meena et al., 2024; Grover

et al., 2022; Ghafoori et al. 2024; Pedersen, 2022). But it is a complex set of values, assumptions, beliefs and symbols which defines how the firm conducts its business (Barney, 1986, p. 657). Recent studies expand the concept of DT by examining digital transformation capabilities, while assuming that they are influenced by four cultural types; clan, adhocracy, market, and hierarchy (Cameron and Quinn, 2011). In particular, adhocracy, more than others, is positively related to DT, while hierarchy is the weakest driver. Adhocracy emphasizes a high level of individual flexibility while hierarchy promotes control and efficiency. These typologies have been applied in prior research on DT (Grover et al., 2022; Sánchez-Báez, 2020) and align with processes observed in SMEs. The concept of digital transformation capability encompasses a wide set of organizational capabilities, such as digital skills, strategic orientation, the company values, and other resources which interact with technologies into the processes. Thus, according to Cao et al (2025), this conceptualization opens to a comprehensive observation of drivers and impacts of DT. This study explores how organizational cultural typologies shape digital transformation capabilities including AL/ML adoption, skills and digital strategies in German and Italian SMEs and their competitive impact on services, products and performance. We focus on the SMEs setting for the following reasons but still gap persist in understanding the role of culture in SMEs. Particularly the comparative dynamics of Italy and Germany and the underexplored ”dark side” of DT like risks and resistance which could be addressed through qualitative interviews.

1.2 Research Gap

Leadership in SMEs have to be empowered strategically so that they can foster a culture of innovation and Digital transformation adaptability (Colombo, 2024). According to a study by Matarazzo, there is strong cultural difference between southern and northern regions of Italy which is also seen in SMEs, and they recommend expanding analysis to different drivers and applications of DT (Matarazzo et al., 2021). Literature is less focused on role of AI/ML as most of the scholars have focused on either AI as a Blackbox or they have just described it descriptively (Richard, et al., 2023). We also found in literature that in the context of small and medium enterprises (SMEs), AI/ML tools and the application of these tools is not similar as in LEs (Ayinaddis, S. G., 2025). Despite the usage of these, several significant issues are there due to interaction of AI and humans including, interplay between existing human capital and AL/ML technologies, the relationship of AI to human judgment and the variability of this relationship across different contexts (Natarajan, et al., 2018). Germany is the largest economy in EU and having a well-established innovative ecosystem where government supports DT in SMEs, still there is a need to check how organizational culture conditions for DT benefits in German SMEs (Bella, et al., 2024). Overall, productivity of Italian SMEs is lower than peer countries Germany and France where Germany is 21% more productive than Italy which is because of lower level of DT in Italian SMEs and most of productivity difference between these countries is unexplained (Eib. (2021). In another study on German SMEs, authors found that DT in SMEs can increase revenue, higher productivity, enhanced customer and employee satisfaction and they recommend to test it on SMEs of different countries (Pfister, et al., 2023). However, another study has found that small enterprises lack of IT support and knowledge in Italy and future research should study international markets to understand digitalization and e-commerce (Dallocchio, et al., 2024). Literature from other European countries such as from Netherlands, shows that in Dutch SMEs, they concluded that DT helped in improving the performance which depends on the characteristics of SMEs and further they suggested to explore other countries where DT have different strategic importance and have different performance outcomes (Etienne, et al., 2024).

Keeping these gaps in view, there is little comparative research available which is focused on how the cultural typologies of a firm can shape DT capabilities and AI/ML adoption in SMEs across countries. Especially between Germany and Italy and how this contributes to difference in performance and innovation. Therefore, this study will be playing its part to enhance the existing literature from a cultural and comparative aspect.

1.3 Research Objectives

- To identify and compare dominant cultural typologies in SMEs of Italy and Germany
- To find how cultural typologies influence adoption and utilization of AI/ML in SMEs?
- To evaluate impact of DT on products and services

1.4 Hypotheses

- OC typologies significantly differ between SMEs in Italy and Germany

- Certain cultural typologies (Adhocracy, clan, market, hierarchy) positively influence AI/ML usage in SMEs
- More level of AL/ML in SMEs improve the products and process innovation.

1.5 Theoretical Explanation

This study is focused on the CVF theory which categorize organizational culture into four categories (Adhocracy, Hierarchy, Clan, Market) which impacts the organizational performance differently (Ortega & Acero, 2025). CVF can be used as a blueprint for culture change and to map the organizational culture (L. Gong et al., 2022), which can promote innovation and enhance performance (Zeb et al., 2021). OC has a critical role in adoption of digital technologies as the culture support resilience, agility and adaptability which foster the success of digital technologies implementation in SMEs (Nugraha et al., 2024). DT, sustainability and OC are interconnected which can affect the business management and need successful approaches of management (Isensee et al., 2020). Because good leadership and OC can allow SMEs to adapt the environmental dynamics, market flexibility and DT for a competitive advantage (Anning-Dorson, 2021). OC is divided into two dimensions (Internal vs External, and Flexibility Vs Stability) as per the objectives of the current study. CVF support cross cultural analysis because of its framework to understand different cultures based on the cultural values and management styles. Further it helps in predicting which cultural settings are less conducive or more towards AI/ML adoption, therefore this makes CVF a valuable theory to explain behaviour of SMEs regarding digital transformation. Since this study is also aimed at understanding how culture shapes DT capabilities and their effects of process and product innovation, CVF offers cultural profiles to link with these outcomes. Overall CVF can help in understanding the dominant cultural profiles in Germany and Italy and facilitate the exploration of how different cultural typologies can influence the technology adoption (AI/ML). CVF can help in diagnosing and changing the organizational culture where individual change and personal management skills are crucial (Cameron Kim & Quinn Robert, 1999) and it boost innovation, financial performance, organizational effectiveness and value creation (Cameron et al., 2006).

2. Literature Review

2.1 Digital Transformation

We often get confused in terms digitation, *digitalization* and *digital transformation* as interchangeable terms or similar. But it is very important to understand that these three concepts, as the incorrect use of these will lead to distortion and may affect the organization negatively (Polyvana et al., 2022). Therefore, we have to go into the concept of data, processes and strategy where the *digitization* is about transforming the data from analog to digital numbers (0s & 1s), and then this data is processed for meaningful values (Hippmann et al., 2019; (Vrana & Singh, 2021). Processing this data into physical space after transforming the information into a digital format is *digitalization* (Востряков & Сибірцева, 2024) which is technical driver for *digital transformation* (Турковский, 2023) and used to improve the way of working of an organization (Große Kamphake, 2020). While *digital transformation* is about using these processes to make business strategies, and it is an ongoing process to improve business processes. But still a unified definition of DT is needed to understand by the researchers and the practitioners to advance the theory, and the practice of the discipline (C. Gong & Ribiere, 2021). The term “Digital transformation” refers to a process where organizations improve their performance, profit, competitive position and market penetration by using digital technology (Froehlich et al., 2024). It plays an umbrella role where it encompasses digitization and digitalization and their constituting components even, they are small components because DT has major impact on the activities carried by the organization(Savić, 2020). The emergent digital technologies explored in the literature encompass a wide range of ICT tools, such as artificial intelligence, digital platforms, cloud computing, robotics, big data, blockchain and other cyber technologies (Wang, 2021;Pchelintsev, 2024;Joel et al., 2024)

2.2 Organizational Culture

Culture is used as a word which indicate sophistication when we say this person is very cultured whereas anthropologists used it as some customs which develops with time (PEAKE, 1922). In management perspective, culture is considered as certain values which managers want to indicate in their organization by speaking that they need a culture of quality or right kind of culture. We cannot analyse organizational culture (OC) as a universal concept, but it can be better understood through myth, ideational systems, symbols and ritual (Meek, 1988). It is also a prominent barrier where resistance to change within the corporate and structural culture

mismatched (Packmohr et al., 2023). Because it significantly impacts employee's behavior, organizational efficiency (Fernandes et al., 2023), performance by influencing the strategies (Marcoulides & Heck, 1993), and organizational learning through leadership style (Hosseini et al., 2020).

However, SMEs with hierarchy culture value efficiency, consistency and internally focused with control on stability. This cultural type effect on business performance in negative way which shows that such SMEs will face low performance comparing to other cultural SMEs (Eisend, et al., 2016; Greer, et al., 2018; Hawa, et al., 2023). SMEs use this culture to emphasize compliance and order but for higher performance and competitive advantage they must create a family type environment with internal cohesion (Oborilová, et al., 2020).

2.3 Artificial Intelligence/Machine Learning

Artificial intelligence is a set of algorithms which are used for information research (Bendig, et al., 2024), and it is an expansive domain dedicated to developing intelligent systems. It is a technology which uses machines for simulation of human cognitive processes like how they learn, process, generate reasons, solve problems and make decisions (Haenlein, et al., 2019). However, speculative fiction's AI storylines profoundly influence and mirror society aspirations and anxieties offering essential insights for developers, policy makers, and media professionals to promote responsible AI innovation consistent with ethical and social principles (Appio, et al., 2025). AI is intended to enhance human capabilities, but it may paradoxically dehumanize, demobilize individuals, oppress, leads to failures, or maybe towards potential calamities which means it exhibit manifestations of artificial stupidity (Su, M., & Ma, H. 2024). These risks arise from limitations and errors which are made by AI, including the biased algorithms, incomplete data or the inherent restrictions can be placed by the AI to stimulate more human like decision making (Dayal, A. (2024). Further a system which is using artificial stupidity and provide wrong tasks, can lead to absurd solutions (Lieber, et al., 2024) and it could be because of any AI failure or by an accident or due to design as seen in robotics (Roldán-Gómez, et al., 2024).

Machine learning is often quoted as "A discipline which enables computers to acquire knowledge autonomously without explicit programming". It is also a kind of AI, and it use algorithms to train itself from previous data, experiences, patterns and relationships. The concept was given by Arthur Samuel in 1959 who defined it as a subset of Artificial Intelligence (AI) which is based on supervised learning, unsupervised learning and in case of errors, reinforcement learning (Shapiro, A. F. 2021). It is a branch of AI which employs computational techniques to enhance system performance from experimental learning, statistics, mathematics and. Computer science (Zhou, Z. H. (2021). It can help in lowering the costs, to boost the business processes or to improve customer service (Lee, I., & Shin, Y. J., 2020)) but SMEs face several issues and struggle to use the ML due to knowledge (Aruna, et al., 2023). AI and ML are general purpose technologies which are swiftly disseminating across enterprises and these technologies possess the capacity to revolutionize the industry and influence the efficacy of enterprises (Natarajan, et al., 2021). They are advancing different fields rapidly like the field of oncology to improve diagnostic approaches and therapeutic strategies for cancer patients (Fountzilas, et al., 2025), in finding solutions to complex science and engineering problems (Willard, et al., 2022).

2.4 DT in Italian SMEs Vs German SMEs

SMEs play a very important role in job creation, economic growth and poverty alleviation with innovation and investments (Gherghina, et al., 2020). SMEs are providing 50% of global employment and 90% of global organizations are SMEs (Raihan, A. (2024). In Europe, SMEs contribute 50% plus gross value in the economy but still these SMEs are lacking in implementing industry 4.0 and business innovation models (Satı, Z. E., 2024). In the EU, DT in SMEs serves different purposes like 40% SMEs use it for digital commerce, 30% are using it for digital presence, 10% are using for technological infrastructure, 10% for Research and innovation and 10% are using it for digital skills whereas only 7% SMEs in EU are using AI (Webidoo., 2025). DT leads to increased SMEs' revenue with an average of 13.44%, high efficiency and productivity, improved employee satisfaction and customer satisfaction (Pfister, et al., 2023), competitiveness, more value creation and distribution channels (Garzoni, et al., 2020). Nevertheless, both government and scholars assume that despite these potential benefits, SMEs lag in the digital transformation (OECD, 2021; Sati, 2024).

In Italy, 99% of businesses are SMEs (Amiri, et al., 2023) which are the basis of Italian economy and generate 70% of turnover and 81% employment (PMI.IT, 2021). Italian SMEs require awareness, inquiry, collaboration and transformation to fully exploit DT (Matarazzo, et al., 2021). Italy is at 24th position in EU ranking for adoption of DT in SMEs and Germany is at 13th, whereas Italy is at 10th number in adoption of AI and Germany at 12th position (Marino, et al., 2023). According to ISTAT, around 60.3% SMEs in Italy have basic digitalization which is

more than average EU index of 56% and government have a vision that 90% of SMEs in Italy will be having DT by 2030 (Martinelli, et al., 2024). AI adoption in Italian SMEs can be successful if SMEs are considering processes, people, customers and products (Del Sarto, et al., 2021).

In German SMEs, digital transformation increases revenue with 33.77% average return on investment (ROI) and cuts operational expenditure (Pfister, et al., 2024). DT in these SMEs of Germany, not just increase the revenue, it also help in improving customer satisfaction, efficiency, employees productivity and satisfaction with a weighted average ROI of 13.44 (Pfister, et al., 2023). SMEs in Germany have a vital role in sustainability and digitalization where the focus is on risk management, innovation, and digitalization with a future perspective of market diffusion, sustainability and governmental programs (Bella, et al., 2024). SMEs in Germany have shown sluggish adoption of AI where some of them focused on enhancing customer service and reduction of costs (Ulrich, et al., 2021) while there are lack of skills concerns by some SMEs in adoption of AI (Schönberger, M. (2023) however, family-owned SMEs intend to adopt AI (Saleem, et al., 2023).

3. Methodology

For a better understanding of the research questions of this study a qualitative research design is considered because it allows an in-depth exploration of how organizational culture can shape DT capabilities and adoption of AI/ML in SMEs. The sample is divided between Italian SMEs and German SMEs where 20 semi-structured interviews were conducted with 10 interviews from each country. Only those SMEs which have initiated or completed the implementation of some emergent technologies, such as AI and ML, were selected using purposive sampling to made sure the information is enriched. We developed literature informed semi-structured interview guide from the actual measurements for the study variables. For measuring organizational culture, we have used competing values framework (CVF) which is a useful scale to explore impact of organizational culture (Ojogiwa, et al., 2023; Mardalis, et al., 2023; Asri, et al., 2024). It is developed by Quinn, et al., (1991) where it consists of 16 scale items which are divided equally into four subscales and each subscale have four items and a seven points Likert scale. CVF help managers in developing their behavior repertoire which will enrich their skills to manage complexity (Tong, et al., 2015). For measuring digital transformation capabilities especially adoption of Artificial Intelligence (AI) by SMEs, we used Digital maturity model which can measure the level of digital maturity in SMEs from basic to advance technologies and it provides a roadmap to improve digital maturity after identification of maturity levels and it recommends future growth (Haryanti, et al., 2023). For measuring organizational performance which is measured here by checking if the organization has innovation (Product or Process) and for that related scale of Wang et al., (2004). This study is designed to identify a comparison of SMEs in Italy and Germany and therefore a cross-country data, considering different national cultural aspects and institutional setting as control variables and policy documents will help in understanding the role of digital technologies in SMEs of both countries. Further if a quantitative study survey is required in future, same CVF and digital maturity model scales can be used to complement the qualitative findings and test relationships statistically.

4. Results and Implications

The data from some German SMEs is collected and being tested for pilot results however for Italian SMEs the data is scheduled to be collected in coming months (e.g. May, June, July). The basic idea of this research is to contribute to the existing literature on DT in SMEs by shifting the focus from technology alone to cultural drivers which enable or constrain DT capabilities. It is focused on digital transformation as a process or outcome, expanding the vision beyond the dynamic system of drivers that enables this transition within SMEs. Also focusing on the role of organizational culture that in small context refers directly to entrepreneur's imprinting. Different typologies of organizational culture in SMEs will provide novel insights about the DT in SMEs. Further this study will help policy makers, governments and management on implementing the DT in SMEs and the learning processes, with some recommendations for entrepreneurship on fostering a culture of innovation and technological readiness.

Acknowledgments

A big role which must be appreciated here is of Prof. Daniela Di Berardino (Italy) for her mentorship and special thanks to Prof. Dr. Daniel Schallmo (Germany) for his support.

Ethics Declaration

The participants of this study are from the SMEs of Italy and Germany, and their inputs are included after their full consent. All the ethical protocols will be followed, and individual identities will not be disclosed, perhaps the study results will be shared with them.

AI Declaration

For the formation of semi structured interviews, some AI-tools (e.g. Perplexity, Scholar AI Labs, ScopusAI) have been used which helped in linking the context of the semi structured interviews with the scales selected for the study variables. Further these semi-structured interviews were translated through AI-tools (e.g. Gemini, GPT, Claude) and then refined with human input.

Abstract: Cross-sector partnerships (CSPs) are increasingly mobilized to address wicked problems such as climate change, health inequalities, and energy transitions. While innovation intermediaries are widely recognized as critical actors in facilitating collaboration within such partnerships, existing research offers fragmented insights into how intermediary roles evolve over time and why particular forms of intermediation become salient at different moments in wicked problem innovation processes. Prior studies typically conceptualize intermediary roles as static or sector-specific, providing limited guidance for understanding their dynamic contribution across partnership phases. This paper addresses this gap by developing a role–phase framework that explains how innovation intermediary roles emerge, shift, and recombine throughout the lifecycle of cross-sector partnerships addressing wicked problems. Drawing on an integrative literature review, we synthesize insights from 20 empirical and conceptual studies examining innovation intermediaries operating within collaborations characterized by high knowledge uncertainty, value conflict, and dynamic complexity. These three dimensions of wickedness are used as analytical lenses to interpret how intermediary activities function as responses to changing collaboration challenges over time. Our analysis identifies seven recurring intermediary roles—convenor, mediator, learning catalyst, integrator, scoping leader, orchestrator, and policy advocate—and maps their associated mechanisms (e.g. trust building, sensemaking, alignment, coordination, and institutional influence) to distinct phases of the CSP lifecycle and the wicked problem innovation process. The framework shows that intermediary roles are not stable attributes but are enacted dynamically, with specific role configurations becoming more salient as partnerships move from problem-setting and direction-setting to implementation and review. By explicitly linking intermediary roles to phases of collaboration and dimensions of wickedness, this paper makes three contributions. First, it advances innovation intermediation research by introducing a processual, phase-sensitive perspective on intermediary roles. Second, it shifts analytical attention from intermediary activities to the underlying mechanisms through which intermediation enables collaboration under conditions of wickedness. Third, it provides a conceptual bridge between CSP lifecycle research and wicked problem innovation studies. The framework offers actionable insights for both scholars and practitioners seeking to design and govern intermediary support in collaborations addressing complex societal challenges.

Keywords: Innovation Intermediaries; Cross-Sector Partnerships; Wicked Problems; Literature Review

1. Introduction

Many of today's most pressing societal challenges such as climate change, biodiversity loss, and public health crises are widely characterized as wicked problems (Rittel and Webber, 1973; Danken, Dribbisch and Lange, 2016). These problems are persistent, interconnected, and resistant to definitive solutions, and are marked by high levels of knowledge uncertainty, value conflict, and dynamic complexity (Dentoni, Bitzer and Schouten, 2018; Van Tulder and Keen, 2018). As no single actor possesses the authority, knowledge, or resources to address such challenges alone, innovation increasingly depends on collective, cross-sector collaboration.

Cross-sector partnerships (CSPs) have emerged as a prominent organizational form for coordinating such collective innovation efforts (Selsky and Parker, 2005; Clarke and MacDonald, 2019). By bringing together actors from business, government, civil society, and academia, CSPs aim to integrate diverse resources and perspectives across multiple phases of problem exploration, solution development, and scaling (Gray and Purdy, 2018; Mair and Gegenhuber, 2021). However, despite their promise, many CSPs struggle to deliver timely or scalable innovation. Conflicting values, divergent incentives, ambiguous goals, and coordination challenges frequently undermine collaboration, particularly in early phases (Doh, Tashman and Benischke, 2019; Gray, Purdy and Ansari, 2022).

A growing body of literature suggests that innovation intermediaries can help CSPs overcome these challenges (Howells, 2006; Kivimaa *et al.*, 2019; van Hille *et al.*, 2021). Innovation intermediaries which are actors or organizations that connect, coordinate, and support collaboration among multiple parties, are argued to play a crucial role in facilitating learning, alignment, and orchestration across organizational boundaries. Yet, research on intermediaries in CSPs addressing wicked problems remains fragmented, sector-specific, and largely static

(Zhang and Liu, 2024). While individual studies identify intermediary functions such as convening, brokering, or orchestrating, they rarely examine how these roles evolve over time or how they relate to different phases of collaboration and problem-solving.

This paper addresses this gap by asking: What roles do innovation intermediaries play in facilitating cross-sector partnerships that address wicked problems, and through which mechanisms do these roles support collaboration across phases? To answer this question, we conduct an integrative literature review that synthesizes dispersed insights across innovation management, sustainability, and collaboration research. By linking intermediary roles to both CSP lifecycle phases (Stadtler and Probst, 2012) and the wicked problem innovation process (Elia and Margherita, 2018), we develop a role–phase framework that captures the dynamic nature of innovation intermediation.

2. Conceptual Background

2.1 Innovation Intermediaries

Innovation intermediaries are commonly defined as actors or organizations that support collaboration between multiple parties during different stages of the innovation process (Howells, 2006). They may take diverse organizational forms, including public agencies, non-profit organizations, research institutes, consultancies, networks, or temporary platforms (Winch and Courtney, 2007; Lee *et al.*, 2010). Prior research identifies a wide range of intermediary activities, such as knowledge brokering, network orchestration, facilitation, mediation, and support for experimentation (Howells, 2006; Caloffi *et al.*, 2023).

While recent reviews provide valuable overviews of intermediary types and functions, they tend to treat intermediary roles as relatively stable and context-independent (Kivimaa *et al.*, 2019; Noviaristanti, Acur and Mendibil, 2023). Moreover, much of this work focuses on sectoral innovation systems or sustainability transitions, paying limited attention to how intermediaries operate within CSPs explicitly aimed at addressing wicked problems. As a result, we still lack an integrative understanding of how intermediary roles vary over time and across different collaboration challenges.

2.2 Wicked Problems and Collective Innovation

Wicked problems are defined by ambiguous problem formulations, contested values, and evolving system dynamics (Rittel and Webber, 1973). Rather than treating wickedness as a general label for complexity, recent scholarship conceptualizes wickedness along three dimensions: knowledge uncertainty, value conflict, and dynamic complexity (Dentoni, Bitzer and Schouten, 2018). Knowledge uncertainty refers to fragmented and evolving understandings of both problems and solutions; value conflict captures divergent interests, priorities, and normative commitments among stakeholders; and dynamic complexity reflects feedback effects, interdependencies, and unintended consequences over time. This dimensional perspective clarifies why conventional innovation management approaches, often premised on stable problem definitions, clear objectives, and controllable solution pathways, frequently fail in wicked contexts. It also highlights why collaboration across organizational and sectoral boundaries is both necessary and inherently challenging, underscoring the critical role of innovation intermediation in enabling sensemaking, alignment, and adaptive coordination.

2.3 Cross-Sector Partnerships and Lifecycle Phases

CSPs typically unfold through recurring phases of problem setting, direction setting, implementation, and review (Gray, 1989; Stadtler and Probst, 2012). These phases align closely with the stages of the wicked problem innovation process, which include problem conceptualization, solution development, experimentation, implementation, and maintenance (Elia and Margherita, 2018). Understanding how intermediary roles relate to these phases is essential for explaining their contribution to collective innovation (Figure 1).

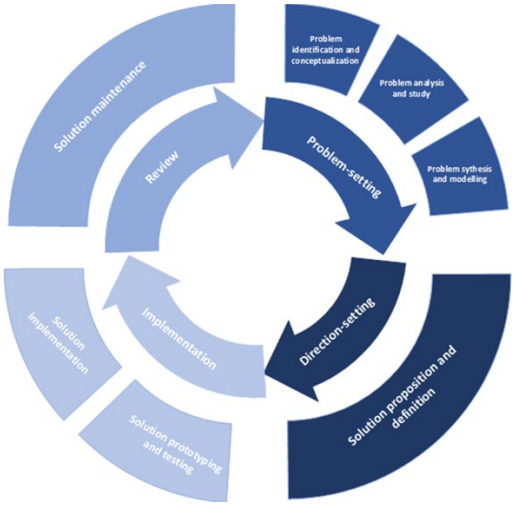

Figure 1: Integration of CSP life cycle (Stadtler and Probst, 2012) and wicked problem innovation process (Elia and Margherita, 2018)

3. Methodology

We adopted an integrative literature review methodology (Torraco, 2005) to synthesize existing research on innovation intermediaries in CSPs addressing wicked problems. A systematic database search (Web of Science, Scopus, ProQuest One Business) combined intermediary-related terms (e.g. intermediary, broker, boundary spanner, orchestrator) with keywords related to cross-sector collaboration and societal challenges. Following title, abstract, and full-text screening, 20 peer-reviewed studies were retained for in-depth analysis.

Data were coded iteratively, distinguishing between intermediary roles, activities, and underlying mechanisms. We mapped roles to CSP lifecycle phases and analysed how intermediary mechanisms respond to dominant dimensions of wickedness. An interpretive synthesis (Suddaby, Bitektine and Haack, 2017) was used to integrate findings into a coherent role–phase framework.

4. Findings: a Role-Phase Framework

The analysis identifies seven intermediary roles: convenor, mediator, learning catalyst, integrator, scoping leader, orchestrator, and policy advocate (Table 1).

Table 1: Roles of innovation intermediaries in cross-sector partnerships

Role	Definition	Category emerged In
Convenor	Brings together diverse stakeholders, facilitating discussions and establishing collaboration platforms	Assan and Gupta (2019); Calzada (2020); Hamann and April (2013); Jha, Gold and Dubé (2021); Kilelu, Klerkx and Leeuwis (2013); Kolovou et al. (2024); Loosemore, Higgon and Osborne (2020); Manning and Roessler (2014); Mariani et al. (2022); Masuda et al. (2022); Mitra (2018); Moreno-Serna et al. (2020); Reypens, Lievens and Blazevic (2021); Sonday and Wilson-Prangley (2018); Stadtler and Probst (2012); Van Hille et al. (2021); Yan, Lin and Clarke (2018)
Mediator	Helps resolve conflicts, align interests, and maintain communication	Assan and Gupta (2019); Calzada (2020); Eitan and Fischhendler (2023); Harris and Lyon (2013); Jha, Gold and Dubé (2021); Kilelu, Klerkx and Leeuwis (2013); Loosemore, Higgon and Osborne (2020); Manning and Roessler (2014); Mariani et al. (2022); Moreno-Serna et al. (2020); Sonday and Wilson-Prangley (2018); Stadtler and Karakulak (2020); Stadtler and Probst (2012); Van Hille et al. (2020)
Learning Catalyst	Enables collective learning by translating knowledge, building capability, and supporting joint sensemaking	Assan and Gupta (2019); Calzada (2020); Hamann and April (2013); Jha, Gold and Dubé (2021); Kilelu, Klerkx and Leeuwis (2013); Loosemore, Higgon and Osborne (2020); Manning and Roessler (2014); Mariani et al. (2022); Masuda et al. (2022); Mitra (2018); Moreno-Serna et al. (2020); Reypens, Lievens and Blazevic (2021); Sonday and Wilson-Prangley (2018);

Role	Definition	Category emerged In
		Stadtler and Karakulak (2020); Stadtler and Probst (2012); Van Hille et al. (2020); Yan, Lin and Clarke (2018)
Integrator	Synthesizes information, coordinates activities, and aligns all aspects of the partnership	Assan and Gupta (2019); Kilelu, Klerkx and Leeuwis (2013); Stadtler and Probst (2012); Van Hille et al. (2020); Yan, Lin and Clarke (2018)
Scoping Leader	Leads in identifying and prioritizing key issues for the partnership to address	Mitra (2018); Van Hille et al. (2020)
Orchestrator	Manages the implementation of initiatives, coordinates resources, and oversees project execution	Assan and Gupta (2019); Kilelu, Klerkx and Leeuwis (2013); Masuda et al. (2022); Moreno-Serna et al. (2020); Reypens, Lievens and Blazevic (2021); Stadtler and Karakulak (2020)
Policy Advocate	Works to influence policy changes that support the partnership's objectives	Masuda et al. (2022); Van Hille et al. (2020)

These roles are distributed unevenly across CSP lifecycle phases and respond to shifting collaboration challenges. Instead, the findings show that intermediary roles shift in prominence over time and are enacted in response to phase-specific collaboration challenges associated with changing dimensions of wickedness.

In the problem-setting phase, intermediaries primarily enact convenor, mediator, learning catalyst, and scoping leader roles. At this stage, collaboration is characterized by high levels of knowledge uncertainty and the early emergence of value conflict, as actors enter with divergent problem framings, expectations, and sector-specific logics. Convenors play a central role by bringing together heterogeneous stakeholders and creating protected spaces for interaction. Mediators and learning catalysts complement this role by facilitating joint sensemaking, translating across knowledge domains, and supporting the development of shared language and understanding. Scoping leaders further contribute by narrowing the problem space, prioritizing issues, and helping partners distinguish between broadly shared concerns and tractable focal points for collective action. Together, these roles enable CSPs to move from loosely connected participation toward a minimally coherent problem definition.

During the direction-setting phase, intermediary emphasis shifts toward mediator, orchestrator, and learning catalyst roles. As partners move from exploration to commitment, value conflict becomes more explicit, requiring active alignment and negotiation. Mediators are especially salient in managing tensions around priorities, resource allocation, and governance arrangements. Orchestrators gain prominence by translating emerging agreements into concrete structures, such as work programs, governance mechanisms, and coordination routines. Learning catalysts remain important, but their focus shifts from exploratory sensemaking to feasibility assessment, capacity building, and the integration of lessons from prior initiatives. This phase marks a transition from open-ended problem exploration to the stabilization of a shared innovation direction.

The implementation phase is dominated by orchestrator, mediator, and learning catalyst roles, reflecting heightened dynamic complexity as proposed solutions interact with existing systems, institutional constraints, and evolving stakeholder configurations. Orchestrators coordinate resources, manage interdependencies between activities, and adapt structures as conditions change. Mediators address emerging conflicts, partner turnover, and misalignments that arise during execution. Learning catalysts support experimentation, facilitate feedback loops, and enable partners to adjust practices in response to unanticipated effects, underscoring the non-linear nature of innovation in wicked problem contexts.

Finally, in the review phase, intermediaries primarily act as convenors, learning catalysts, and policy advocates. In the absence of clear end states or definitive success criteria, intermediaries support evaluation, collective reflection, and decisions about continuation, adaptation, or scaling. Convenors reconnect partners and external stakeholders, learning catalysts facilitate performance assessment and knowledge transfer, and policy advocates work to embed collaboration outcomes in broader institutional or regulatory contexts. This phase highlights how intermediary roles extend beyond project completion toward longer-term system alignment and institutional change.

5. Discussion

This study advances research on innovation intermediaries and cross-sector partnerships in three interrelated ways by explicitly positioning intermediary roles as dynamic, mechanism-based, and responsive to wickedness across collaboration phases.

First, the study contributes a processual understanding of innovation intermediation. Foundational work on innovation intermediaries has established their importance and identified a wide range of roles such as brokering, convening, and orchestration (Van Lente *et al.*, 2003; Howells, 2006). More recent reviews have further systematized intermediary types, activities, and value creation mechanisms across sectors and innovation systems (Kivimaa *et al.*, 2019; Caloffi *et al.*, 2023; Noviaristanti, Acur and Mendibil, 2023). While this work provides important descriptive clarity, it largely treats intermediary roles as stable attributes or generalized functions. In contrast, our findings show that intermediary roles are phase-contingent and dynamically reconfigured as CSPs move through problem setting, direction setting, implementation, and review. By explicitly linking roles to CSP lifecycle phases (Stadtler and Probst, 2012), this study extends existing typologies with a temporal and processual perspective that helps explain when and why particular forms of intermediation become salient.

Second, this study shifts analytical attention from activities to mechanisms. Prior research has richly documented intermediary activities such as organizing meetings, facilitating learning, or coordinating experimentation (Howells, 2006; Kivimaa *et al.*, 2019). However, the mechanisms through which these activities support collaboration such as sensemaking, trust building, alignment, and adaptive learning, have often remained implicit. By distinguishing activities from mechanisms, our framework provides greater explanatory depth and responds to calls for theory development that moves beyond role catalogues toward understanding how intermediaries enable coordination under conditions of complexity (Caloffi *et al.*, 2023; Zhang and Liu, 2024).

Third, the study makes wickedness analytically consequential for innovation intermediation research. While innovation intermediaries are increasingly studied in the context of societal challenges and sustainability transitions (Kivimaa, 2014; Kivimaa *et al.*, 2019), much of this work implicitly assumes problem complexity without theorizing how different dimensions of wickedness shape intermediary roles. Building on Dentoni et al.'s (2018) conceptualization of wickedness as knowledge uncertainty, value conflict, and dynamic complexity, we show that intermediary roles can be understood as context-sensitive responses to dominant wickedness challenges at different points in the collaboration process. This perspective complements and extends CSP research that emphasizes lifecycle dynamics (Stadtler and Probst, 2012; Van Tulder and Keen, 2018) by clarifying why certain intermediary mechanisms are particularly critical in specific phases.

Together, these contributions reposition innovation intermediaries not as static brokers or neutral facilitators, but as dynamic enablers of coordination, learning, and adaptation whose relevance unfolds over time. The role–phase framework developed here provides a foundation for future longitudinal and comparative studies examining how intermediary role configurations influence collaboration durability, innovation outcomes, and scaling trajectories in wicked problem contexts.

6. Conclusion

This paper develops a role–phase framework that clarifies how innovation intermediaries dynamically support cross-sector partnerships addressing wicked problems. By integrating insights across fragmented literatures on innovation intermediation, cross-sector collaboration, and wicked problem innovation, the framework highlights why intermediary roles shift over time and how these shifts are shaped by changing collaboration challenges. Rather than treating intermediary roles as static or universally applicable, the framework shows that effective intermediation depends on the alignment between roles, underlying mechanisms, and the dominant dimensions of wickedness (knowledge uncertainty, value conflict, and dynamic complexity) across different phases of the CSP lifecycle.

The central contribution of this study lies in making the temporal and contextual nature of innovation intermediation explicit. By linking roles to phases of problem setting, direction setting, implementation, and review, the framework provides a structured yet flexible lens for understanding how intermediaries sustain collaboration when problems resist definitive formulation and linear solutions. This perspective helps explain why CSPs often struggle when intermediary support is misaligned with phase-specific needs, such as emphasizing orchestration too early or underinvesting in learning and mediation during implementation.

Beyond its theoretical contributions, the framework offers practical guidance for policymakers, funders, and intermediary organizations involved in societal transition initiatives. It suggests that intermediary capacity should be designed as a portfolio of roles that can be activated and reconfigured over time, rather than as a fixed mandate or organizational function. For practitioners, this implies paying closer attention to when particular forms of intermediation are most valuable and investing in adaptive capabilities that support reflection, learning, and realignment.

Overall, this study positions innovation intermediaries as dynamic enablers of collective action whose value lies not only in what they do, but in when and how they do it throughout the lifecycle of wicked problem innovation.

Ethics Declaration

This study is based solely on a review and analysis of existing literature. As it did not involve the collection of primary data, human participants, animals, or personal data, ethical clearance was not required.

AI Declaration

An AI-based language tool was used to support the improvement of writing style, clarity, and readability of the manuscript. The tool was employed to rephrase sentences, enhance flow, and correct language issues. From Accelerator Programs to Business Model Innovation in Startups: The Roles of Program Quality, Knowledge Spillovers and Founder Absorptive Capacity

Safae Khloufi Belhachmi and Luis Miguel Molina Fernández
University of Granada, Granada, Spain

safaekhloufi@correo.ugr.es
l.molina@ugr.es

Abstract: Business model innovation (BMI) is an important mechanism through which startups refine their value proposition, adapt to market needs and strengthen their growth potential. Although accelerator programs are widely used to support early-stage ventures, the knowledge-based mechanisms through which they are associated with BMI remain insufficiently understood. This study examines how accelerator program quality is associated with business model innovation in accelerated startups, focusing on the mediating roles of knowledge spillover exposure and founders' absorptive capacity. Drawing on knowledge spillover theory and the absorptive capacity perspective, we conceptualise accelerator programs as structured knowledge environments where startups access external knowledge through mentoring, training, peer interaction, expert feedback, market validation, investor exposure and ecosystem connections. We argue that perceived program quality is associated with BMI because higher-quality accelerator experiences provide founders with more relevant opportunities to access, interpret and apply external knowledge. However, this process also depends on founders' absorptive capacity, understood as their ability to recognize, assimilate, transform and exploit such knowledge. Using cross-sectional survey data from 226 founders of startups that participated in accelerator programs in Spain, the study tests a Partial Least Squares Structural Equation Modelling (PLS-SEM) model linking perceived program quality, knowledge spillover exposure, founders' absorptive capacity and BMI. The findings indicate that perceived accelerator program quality is positively associated with knowledge spillover exposure, founders' absorptive capacity and business model innovation. Knowledge spillover exposure partially mediates the relationship between program quality and BMI. Although founders' absorptive capacity does not show a significant direct effect on BMI, its total effect becomes significant when the indirect path through knowledge spillover exposure is considered. The study contributes to accelerator research by shifting attention from accelerator participation to perceived program quality and by explaining BMI as a knowledge-driven outcome of acceleration. It also contributes to knowledge spillover and absorptive capacity perspectives by showing how accelerated startups transform external knowledge exposure into business model reconfiguration.

Keywords: Accelerator Program Quality; Business Model Innovation; Knowledge Spillovers; Founders' Absorptive Capacity; Accelerated Startups.

1. Introduction

Startup accelerators have emerged as influential entrepreneurial intermediaries that connect early-stage ventures with mentoring, specialised education, financial resources, feedback, and network access (Kohler, 2016; Cohen *et al.*, 2019; Ulmer and Pape, 2022). They are typically defined as fixed-term, cohort-based programs that provide intensive and structured support to help startups reach key development milestones (Cohen *et al.*, 2019; Del Sarto *et al.*, 2023). Prior research suggests that participation in accelerator programs is associated with improved venture development trajectories, including faster access to capital, revenue scaling, employment growth, and broader ecosystem development through network building and resource mobilization (Fehder, 2023; Assenova and Amit, 2024).

Despite these contributions, the internal processes through which accelerator programs support startup innovation remain insufficiently understood (Cohen *et al.*, 2019; García-Ochoa, De-Pablos-Heredero and Jiménez, 2020). This ambiguity is partly explained by program heterogeneity, as accelerators differ in curriculum structure, duration, mentor expertise, cohort composition, and the nature of the support provided (Cohen *et al.*, 2019; Seitz, Lehmann and Haslanger, 2024; Doçaj, 2025). Recent scholarship conceptualise accelerators as open, knowledge-rich environments where ventures access external information through networks of mentors, peers, investors, and other ecosystem actors (Hallen, Cohen and Bingham, 2020; del Sarto, Cruz-Cázares and Di Minin, 2022). Within these settings, knowledge spillover exposure offers a promising mechanism for explaining how perceived program quality may be associated with innovation-related change, although the ways in which program quality dimensions shape such exposure remain underexplored (Cohen, Bingham and Hallen, 2018; Cuvero *et al.*, 2023).

Prior accelerator research has generated important insights into startup survival, funding, growth, and performance (Hallen, Cohen and Bingham, 2020; Assenova and Amit, 2024). However, less is known about

whether and how accelerator programs contribute to deeper changes in startups' business model logic (Doçaj, 2025). Business model innovation (BMI), understood as changes in a firm's value offering, value creation architecture, and revenue logic, remains less directly examined as an outcome of accelerator program quality (Miroshnychenko *et al.*, 2021; Urbaniec and Żur, 2021). This gap is important because BMI can be treated as a proximal transformation outcome of acceleration, reflecting how startups refine the way they create, deliver, and capture value before such changes appear in distal performance indicators (Sorescu, 2017; Rechter and Avnimelech, 2025).

Absorptive capacity (ACAP) is also central to this knowledge-based explanation, as it helps explain why some founders are better able than others to recognize, assimilate, transform, and exploit external knowledge (Alejandra Flechas Chaparro and Salles Camargo Júnior, 2021) In particular, it remains unclear how founder-level ACAP contributes to the transformation of accelerator-based knowledge spillovers into business model reconfiguration (Chang and Assenova, 2025). Therefore, this paper examines perceived accelerator program quality as a knowledge-enabling condition and investigates how knowledge spillover exposure and founders' absorptive capacity are associated with business model innovation in accelerated startups. Specifically, this study addresses the following research questions:

> RQ1. How is accelerator program quality associated with business model innovation in accelerated startups?
>
> RQ2. What role do knowledge spillovers play in the relationship between accelerator program quality and business model innovation?
>
> RQ3. How does founders' absorptive capacity contribute to the transformation of accelerator-based knowledge into business model innovation?

The proposed model is tested using cross-sectional post-program survey data from 226 founders of startups that participated in accelerator programs in Spain. The study focuses on founders' assessments of accelerator program quality, knowledge spillover exposure, absorptive capacity, and business model innovation linked to the acceleration experience. The proposed relationships are analysed using Partial Least Squares Structural Equation Modelling (PLS-SEM), which is suitable for examining latent constructs, mediation relationships, and complex models based on multiple indicators (F. Hair Jr *et al.*, 2014).

This study contributes to accelerator research by shifting attention from accelerator participation and distal performance outcomes toward perceived program quality, knowledge-based mechanisms, and business model innovation as a proximal transformation outcome. The remainder of the paper reviews the relevant literature and hypotheses, describes the methodology, presents the results, and discusses the main implications, limitations, and avenues for future research.

2. Theoretical Background and Hypotheses

2.1 Startup Accelerators as Knowledge-Intensive Entrepreneurial Support Programs

Startup accelerators function as knowledge-intensive entrepreneurial support programs that go beyond simple resource provision (Hallen, Cohen and Bingham, 2020; De Andrade and Pinheiro, 2023). Although their fixed-term, cohort-based structure facilitates access to seed capital and workspace, their distinctive value lies in concentrating and structuring external knowledge flows in an intensive, time-compressed environment (Cohen *et al.*, 2019; García-Ochoa, De-Pablos-Heredero and Jiménez, 2020; Assenova and Amit, 2024). In doing so, accelerators act as innovation intermediaries that connect early-stage ventures with mentors, peers, investors, experts, and business networks that support venture development (Goswami and Ivey, 2018; Rechter and Avnimelech, 2025).

Within these environments, startups access both tacit and explicit knowledge. Tacit knowledge is acquired through informal interactions, mentoring, peer learning, investor feedback, and physical proximity, while explicit knowledge is delivered through curricula, workshops, technical seminars, and digital knowledge platforms (Goswami and Ivey, 2018; Cuvero *et al.*, 2023; Del Sarto *et al.*, 2023). These mechanisms help startups compensate for resource and capability limitations associated with early-stage ventures and support founders in interpreting feedback, reducing uncertainty, and refining their venture assumptions (Battistella, De Toni and Pessot, 2017; Cohen, Bingham and Hallen, 2018; Seitz, Lehmann and Haslanger, 2024). This knowledge-intensive view provides the basis for examining how program quality shapes startups' knowledge spillover exposure.

2.2 Accelerator Program Quality and Knowledge Spillover Exposure

Start-up accelerators should not be viewed as uniform interventions, as they differ in their organizational designs, practices, and support structures (Cohen *et al.*, 2019). Program quality can therefore be understood as a multidimensional construct reflecting the relevance of the curriculum, mentor expertise, and the effectiveness of investor and ecosystem network access (Assenova and Amit, 2024; Seitz, Lehmann and Haslanger, 2024). High-quality programs are more likely to provide broad, intensive, and paced consultation routines that facilitate rapid learning and help founders navigate market uncertainty (Hallen, Cohen and Bingham, 2020).

These design choices are expected to shape the intensity, diversity, and usefulness of startups' knowledge spillover exposure. Accelerators are increasingly conceptualised as open environments or information-rich coworking spaces that facilitate interactions among mentors, peers, investors, corporate partners, and other ecosystem actors (del Sarto, Cruz-Cázares and Di Minin, 2022; Del Sarto *et al.*, 2023). Within these settings, knowledge spillovers emerge through formal and informal interactions that expose startups to external technical, market, entrepreneurial, and strategic knowledge (Cuvero *et al.*, 2023; Del Sarto *et al.*, 2023). By structuring mentoring, cohort interaction, investor access, and feedback opportunities, higher-quality programs may help founders access and interpret external knowledge that is relevant for strategic change (Hallen, Cohen and Bingham, 2020; Rechter and Avnimelech, 2025). Based on this logic, we propose:

H1: Accelerator program quality is positively associated with startups' knowledge spillover exposure.

2.3 Business Model Innovation in Accelerated Startups

Business model innovation (BMI) refers to a new-to-the-firm change in at least one of three core dimensions: the value offering, the value creation architecture, or the revenue model logic (Sorescu, 2017; Miroshnychenko *et al.*, 2021). Unlike incremental product innovation, BMI involves a broader reconfiguration of how a venture creates, delivers, and captures value (Miroshnychenko *et al.*, 2021; Ramadan *et al.*, 2023). This outcome is particularly relevant for startups, which are often engaged in the search for a repeatable and scalable business model (Battistella, De Toni and Pessot, 2017). In this sense, BMI can be understood as a proximal transformation outcome of acceleration, whereas funding and revenue growth represent more distal indicators of venture development (Del Sarto *et al.*, 2023; Rechter and Avnimelech, 2025).

High-quality accelerator programs may contribute to BMI by providing structured support that helps founders question, validate, and refine key business model assumptions. Through mentoring, investor feedback, peer learning, and exposure to external expertise, founders can identify weaknesses in their value propositions, validate market needs, adjust customer relationships, and reconsider revenue or cost structures before costly implementation (Cohen, Bingham and Hallen, 2018; Del Sarto *et al.*, 2023). Therefore, when accelerator support is well structured, relevant, and connected to high-quality expertise and networks, founders are better positioned to refine how their ventures create, deliver, and capture value. Based on this logic, we propose:

H2: Accelerator program quality is positively associated with business model innovation in accelerated startups.

2.4 Founders' Absorptive Capacity as a Knowledge Transformation Capability

Absorptive capacity (ACAP) refers to a firm's ability to recognize, assimilate, transform, and exploit external knowledge for commercial purposes (Cohen, Bingham and Hallen, 2018; Del Sarto *et al.*, 2023). In new ventures, this capability is closely tied to founders' prior knowledge and cognitive frameworks, as startups often lack formalized routines for acquiring, interpreting, and applying external knowledge (Cohen, Bingham and Hallen, 2018). Founders' ability to process external information therefore becomes central to early-stage learning, particularly in resource-constrained startups that must rapidly transform external knowledge into innovation.
High-quality accelerator programs may strengthen founders' ACAP by exposing them to structured and intensive learning mechanisms. Expert mentoring, iterative feedback, peer interaction, curricula, and access to industry-specific expertise can help founders interpret market information, identify opportunities, and process knowledge in a time-compressed context (Cohen, Bingham and Hallen, 2018; Del Sarto *et al.*, 2023). Through these mechanisms, accelerator program quality may support founders' internal learning capabilities and their ability to reconfigure business model elements. Therefore, we propose:

H3: Accelerator program quality is positively associated with founders' absorptive capacity.

Founders with stronger ACAP are better able to recognize, interpret, and engage with knowledge flows within the accelerator's open environment (Alejandra Flechas Chaparro and Salles Camargo Júnior, 2021; del Sarto, Cruz-Cázares and Di Minin, 2022). This founder-level capability helps them identify valuable informal knowledge spillovers that might otherwise be overlooked or misinterpreted (Cuvero *et al.*, 2022, 2023). By interpreting external information from mentors, peers, and investors more effectively, founders with higher ACAP may increase their effective exposure to relevant external knowledge (del Sarto, Cruz-Cázares and Di Minin, 2022; Fehder, 2023; Chang and Assenova, 2025). Thus:

H4: Founders' absorptive capacity is positively associated with startups' knowledge spillover exposure.

Furthermore, ACAP should contribute to business model innovation (BMI) because founders need to transform external insights into changes in the venture's business model logic (Urbaniec and Żur, 2021; Guckenbiehl, de Zubielqui and Lindsay, 2024). BMI entails a comprehensive reconfiguration of the firm's value offering, creation architecture, and revenue logic (Bouncken, Kraus and Roig-Tierno, 2021; Miroshnychenko *et al.*, 2021; Li *et al.*, 2022). This requires founders to move beyond simple acquisition to a transformation stage, where external knowledge is combined with the venture's internal knowledge base to facilitate strategic renewal (Von Delft *et al.*, 2019; Miroshnychenko *et al.*, 2021). In this sense, ACAP serves as the transformative capability that enables founders to use external knowledge for business model reconfiguration rather than just incremental improvements (Li *et al.*, 2022; Del Sarto *et al.*, 2023). Based on this logic:

H5: Founders' absorptive capacity is positively associated with business model innovation.

Finally, while prior studies show that ACAP can act as a mediator or a moderator, for this study, we test it as part of an integrated partial mediation model (Guckenbiehl, Corral De Zubielqui and Lindsay, 2021; Vincent and K.A., 2021; Pigola and Fischer, no date). Knowledge exposure alone is not enough to produce strategic change; founders must be able to interpret and exploit that knowledge (Cohen, Bingham and Hallen, 2018; Arif *et al.*, 2026). Accelerator program quality may influence BMI directly through its design, but it is also likely to influence it indirectly through the mechanisms of knowledge spillover exposure and founders' ACAP (Cohen, Bingham and Hallen, 2018; Fehder, 2023). Therefore, these factors are expected to partially mediate the relationship between program quality and business model innovation.

H6: Knowledge spillover exposure and founders' absorptive capacity partially mediate the relationship between accelerator program quality and business model innovation.

Overall, this study examines BMI at the accelerated-startup level, using founders' perceptions of accelerator program quality. The model proposes that perceived program quality is associated with BMI directly and indirectly through knowledge spillover exposure and founders' absorptive capacity. Figure 1 summarizes the proposed model and hypotheses.

3. Methodology

3.1 Research Design

This study adopts a quantitative, cross-sectional survey design to examine the associations between perceived accelerator program quality, knowledge spillover exposure, founders' absorptive capacity, and business model innovation. The unit of analysis is the accelerated startup, captured through founder-level or key respondent survey responses. Accordingly, the study does not evaluate accelerator organizations as independent units, nor does it use objective accelerator-level indicators. Instead, accelerator program quality is operationalized as perceived program quality, reflecting respondents' assessment of the structure, relevance, and usefulness of the support received during the acceleration process.

Given the cross-sectional nature of the data, the analysis does not claim causal inference. Rather, it examines whether the observed associations are consistent with the proposed knowledge-based mechanism linking perceived program quality, knowledge spillover exposure, founders' absorptive capacity, and business model innovation. Figure 1 presents the research model tested in this study.

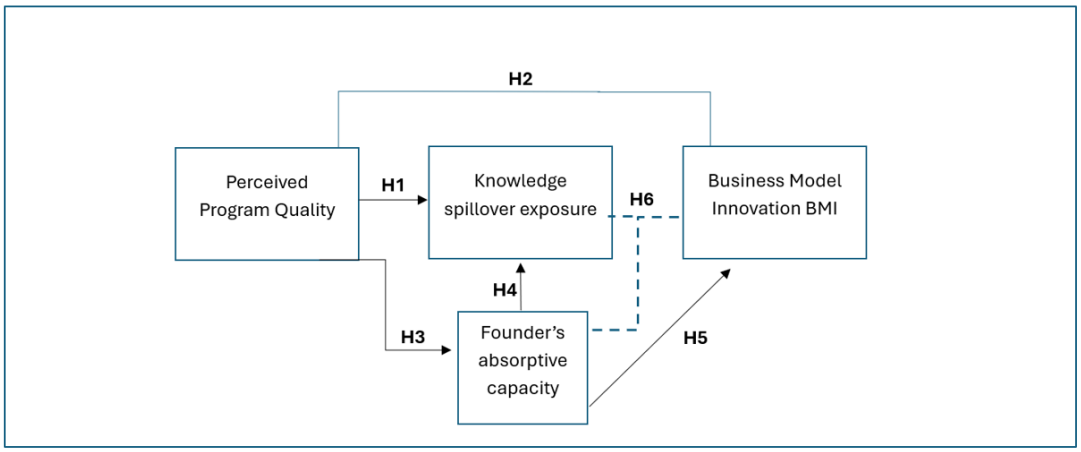

Figure 1: Research model

3.2 Sample and Data Collection

The empirical context consists of startups that participated in accelerator programs in Spain. Data were collected through a structured survey addressed to founders or key representatives with direct knowledge of their startup's accelerator experience. The questionnaire captured respondents' perceptions of accelerator program quality, their exposure to different sources of knowledge during the program, their absorptive capacity, and the extent to which their venture modified different elements of its business model.

The survey was distributed to a database of 1,745 founders of accelerated startups identified across 45 Spanish accelerator programs, resulting in a response rate of approximately 13%. Although the sampling frame covered founders identified through 45 Spanish accelerator programs, the response rate was approximately 13%, and the distribution of respondents across individual programs could not be fully assessed. Consequently, non-response bias cannot be ruled out, and the sample should not be interpreted as statistically representative of the entire population of accelerated startups in Spain. After screening the responses and removing incomplete or duplicate entries, the final sample consisted of 226 valid startup-level responses. To maintain consistency in the unit of analysis, each response was treated as representing one accelerated startup. The final dataset therefore reflects founder-level perceptions of program quality and knowledge mechanisms, together with self-reported business model innovation outcomes.

3.3 Measures

To analyse the different constructs, we developed scales based on the existing literature. We measured the independent variable, Business Model Innovation, using a Likert scale with nine sub-dimensions, each of which was measured using a three-item scale. The nine dimensions correspond to the classic Business Model framework: value proposition, customer segments, distribution channels, customer relationships, revenue streams, key resources, key activities, partnerships, and costs. This scale, therefore, has been considered a Formative Higher-Order Construct (HOC) composed of nine primary second-order dimensions.

To assess perceived program quality, we used an 8-item Likert scale, including program structure, curriculum relevance, curriculum uniqueness, exclusivity of information and materials, effectiveness of market interaction, innovation in program interactions, clarity regarding post-program startup, and quality of funding opportunities.

Knowledge Spillover exposure was measured using a five-item scale considering the extent of contribution from face to face, contribution of provided materials R&D activities, technological knowledge and entrepreneurial knowledge. Finally, founders' absorptive capacity was measured using a two-item reflective scale adapted from prior literature. The short scale was retained to reduce respondent burden in a survey covering multiple constructs and because both items capture the founders' ability to assimilate and apply external knowledge. Although the indicators showed unequal loadings, the construct met the recommended thresholds for composite reliability (ρc = 0.820) and average variance extracted (AVE = 0.709).

A PLS-SEM model was used to assess the scale and construct validity. To test the validity of the measurement model, the recommendations of (Benitez *et al.*, 2020) were followed. The results are shown in Table 1. For the latent variables, ρc was found to be higher than 0.77 and Average Variance Extracted (AVE) was found to be

higher than 0.5. Some of the weights are not significant, but since the loadings are significant and to maximize content validity, it is recommended to retain them in the measurement model. Discriminant analysis was checked using Heterotrait-monotrait ratio (HTMT).

Table 1: Scale and construct analysis

Construct	Type	Items / Dimensions	ρc	AVE	VIF range	Weight range	Loading range
Perceived program quality	Formative	8	—	—	1.814–3.068	0.044–0.305	0.739–0.869
Knowledge spillover exposure	Reflective	5	0.893	0.628	—	0.229–0.283	0.761–0.817
Founders' absorptive capacity	Reflective	2	0.820	0.709	—	0.204–0.864	0.669–0.976
Business model innovation	Formative	9	—	—	3.098–4.533	0.032–0.382	0.761–0.917

Note: For formative constructs, VIF values, weights and loadings are reported. For reflective constructs, composite reliability (ρc), AVE, weights and loadings are reported. Significance levels: ***p<0.001; **p<0.01; *p<0.05.

4. Results

To test the hypotheses, a PLS-SEM analysis was performed using the SMART-PLS application. Considering that there are both composite and reflective variables in the model, the use of PLS is especially indicated (Benitez et al., 2020). Table 2 shows the model that has been tested. Overall fit of the estimated model has been analysed using the SRMR, and dULS indicators. In all cases these indicators are within the values considered acceptable for the models to be a good representation of data (Benitez, et al., 2020).

Table 2: Structural model

Independent Variable	Knowledge Spillover	Absorptive Capacity	Business Model Innovation
Program quality	0.775*** (25.343)	0.275*** (4.049)	0.659*** (8.346)
Knowledge spillover	—	—	0.177* (2.359)
Absorptive capacity	0.126** (3.198)	—	0.098 (1.857)
R^2	0.668	0.075	0.712
Model fit	SRMR = 0.035 (HI95 = 0.042)	dULS = 0.376 (HI95 = 0.529)	

*Note: t-values in parentheses. Significance levels: ***p<0.001; **p<0.01; *p<0.05; †p<0.1.*

Hypotheses 1 and 3 state that program quality is positively associated with knowledge spillover exposure and founders' absorptive capacity. The results support both H1 ($\beta = 0.775$, $p < 0.001$) and H3 ($\beta = 0.275$, $p < 0.001$). H2 proposed that program quality is positively associated with business model innovation, and this relationship is also supported ($\beta = 0.659$, $p < 0.001$).

Regarding H4 and H5, the effect of founders' absorptive capacity on knowledge spillover exposure is positive and significant ($\beta = 0.126$, $p < 0.01$), supporting H4. However, the direct effect of absorptive capacity on business model innovation is positive but not statistically significant ($\beta = 0.098$, n.s.). Therefore, H5 is not supported for the direct relationship between absorptive capacity and business model innovation.

Table 3: Indirect effects

Path	Indirect Effect	Total Effect
AC–BMI	0.022 (1.862)	0.120* (2.323)
PQ–BMI	0.170** (2.657)	0.829*** (30.055)

*Note: t-values in parentheses. Significance levels: ***p<0.001; **p<0.01; *p<0.05; †p<0.1.*

Finally, hypothesis 6 holds that both Absorptive Capacity and Knowledge Spillover mediate the relationship between Program Quality and Business Model Innovation. In table 3 the indirect effects and total effects are

considered. As we can see, the total indirect effect of Program Quality on BMI is positive and significant (β=0.170, p<0.01). Following (Nitzl, Roldan and Cepeda, 2016), VAF was computed (VAF=20.5), indicating a partial complementary mediation. That partially supports H6.

Nevertheless, Table 3 shows that the total effect of absorptive capacity on business model innovation is positive and significant (β = 0.120, p < 0.05). This indicates that, although absorptive capacity does not directly explain business model innovation, it contributes indirectly through knowledge spillover exposure.

5. Discussion and Conclusion

The results support the relevance of perceived accelerator program quality for business model innovation. First, the findings contribute to accelerator research by showing that program quality is associated with business model innovation and by clarifying some of the mechanisms underlying this relationship. They also support Knowledge Spillover Theory as a relevant framework for explaining how acceleration programs contribute to startup transformation.

Second, the findings extend the knowledge-spillover perspective by showing that knowledge-spillover exposure and founders' absorptive capacity jointly contribute to the relationship between perceived program quality and business model innovation. However, this mediation is partial, suggesting that other mechanisms may also be involved, including mentor credibility, peer learning, strategic networks, investor feedback, and entrepreneurial self-efficacy. Future research should examine how these mechanisms contribute to business model reconfiguration.

Third, the findings contribute to the knowledge-management literature by clarifying the role of founders' absorptive capacity. Although its direct association with BMI was not statistically significant, absorptive capacity contributed indirectly through knowledge-spillover exposure, and its total effect was significant. This suggests that it helps founders interpret and apply the external knowledge accessed through accelerator programs.

The findings also have practical implications. Accelerator organizers should design programs that provide relevant knowledge, effective mentoring, and meaningful interaction with ecosystem actors. For founders, benefiting from acceleration may depend not only on the support offered but also on their ability to internalize and apply the knowledge accessed during the program.

The study has several limitations. Its cross-sectional design precludes causal conclusions, while the relatively low response rate creates a potential risk of non-response bias. Moreover, the self-reported measures reflect respondents' perceptions rather than objective accelerator-level characteristics, and the study does not distinguish between founder- and accelerator-level effects. Finally, absorptive capacity was measured using only two items with unequal loadings. Although the construct met reliability and convergent-validity thresholds, future research should use a more comprehensive multidimensional scale. Longitudinal studies using objective measures and multilevel designs could address these limitations.

Despite these limitations, the study provides evidence that perceived program quality, knowledge-spillover exposure, and founders' absorptive capacity are relevant to understanding business model innovation in accelerated startups.

Ethics Declaration

This study is based on survey data collected from founders or key representatives of startups that participated in accelerator programs. Participation was voluntary, and responses were treated confidentially and used only for academic research purposes. No personal identifying information is reported in the paper.

AI Declaration

AI-assisted tools were used to support language refinement, structure development, and citation organization during the preparation of this paper. All AI-assisted outputs were reviewed, edited, and validated by the author, who remains fully responsible for the final content of the manuscript.

Abstract: Sustainable entrepreneurship has received considerable attention as a means of addressing environmental and social challenges through economically viable ventures. Existing research has examined opportunity identification, yet the processes through which sustainability-oriented opportunities are exploited under conditions of uncertainty and resource scarcity remain comparatively underexplored. The lean startup approach with its emphasis on rapid experimentation, iterative learning, and customer feedback has emerged as an influential approach in entrepreneurial practice. Though empirical applications remain concentrated largely in technology and digital venture contexts. This study examines how lean startup approach support opportunity exploitation in sustainable entrepreneurship. Semi-structured interviews were conducted with 8 founders operating in the sustainability-oriented ventures, and the resulting data were analysed using gioia methodology. Four themes emerged under aggregate dimensions, experimentation for sustainability validation, strategic resource utilization, feedback-driven opportunity refinement, and Iterative learning for adaptive opportunity exploitation. Each consistent with the lean startup literature. The findings indicate that lean startup practices with bricolage approach provide sustainable entrepreneurs with a structured pathway for translating sustainability-oriented ideas into viable ventures while navigating the dual constraints of environmental uncertainty and resource scarcity.

Keywords: Sustainable Entrepreneurship, Lean Startup, Opportunity Exploitation, Sustainability-Oriented Venture

1. Introduction

Climate change, biodiversity loss, and expanding waste streams created conditions to generate solutions which integrate environmental and social value alongside commercial returns (Magistretti et al., 2023). Sustainable entrepreneurship has developed as an important research domain examining ventures pursue economic, social, and environmental value (Muñoz and Cohen, 2018). The entrepreneurship research defines the field around the discovery, evaluation, and exploitation of opportunities (Shane and Venkataraman, 2000; Eckhardt and Shane, 2003). Within this framework, exploitation is the phase in which a recognised and evaluated opportunity is acted upon and converted into a functioning venture; it is analytically distinct from, and sequential to, recognition and evaluation (Shane and Venkataraman, 2000; Kuckertz et al., 2017).

Recognition concerns perceiving a means–ends relationship and evaluation concerns judging its feasibility and desirability (Choi and Shepherd, 2004; McMullen and Shepherd, 2006). Whereas "Opportunity exploitation is characterized by developing a product or service based on a perceived entrepreneurial opportunity, acquiring appropriate human resources, gathering financial resources, and setting up the organization" (Kuckertz et al., 2017). Research in sustainable entrepreneurship has engaged extensively with identification and recognition with an early significant framework, but the exploitation phase has received comparatively little attention (Di Vaio et al., 2022).

"Sustainability-oriented ventures aim to create viable businesses based upon environmentally and/or socially sound products" (Choi and Gray, 2008). They operate under uncertainty alongside market and technological, they must contend with environmental and demand uncertainty that often do not yet exist and uncertainty about whether their intended social and environmental impact will actually be realised (Hall et al., 2010; Bocken et al., 2021). They need to validate commercial, social, and environmental feasibility simultaneously (Belz and Binder, 2017).

Ries (2011) introduced the lean startup approach as a methodology for managing uncertainty in early-stage ventures. Its build–measure–learn (BML) cycle encourages entrepreneurs to develop minimum viable products (MVPs), measure real customer responses, and learn iteratively. Shepherd and Gruber (2021) describe the framework as comprising customer development, validated learning, MVPs, experimentation, and strategic

pivoting. Moreover, hypothesis-testing improves entrepreneurial decision quality, and hypothesis-driven experimentation helps early ventures converge more effectively on viable opportunities (Camuffo et al., 2020; Leatherbee and Katila, 2020). Recent research suggests that lean startup strategies can enhance organizational learning and contribute to the sustainable development of new ventures by promoting iterative learning and continuous adaptation (Zhuge et al., 2023).

Despite the growing application of lean startup in entrepreneurship research, empirical work remains concentrated in technology and digital startup contexts, leaving its relevance to sustainability-oriented ventures underexplored (Ghezzi and Cavallo, 2020). Sustainability-oriented ventures operate under distinct conditions, including longer development cycles, institutional complexity, multi-stakeholder accountability, and the need to validate commercial, social, and environmental feasibility (Bocken and Snihur, 2020).

Whether and how lean startup practices function under these conditions remains a question to be addressed. This study addresses this gap by examining how the lean startup approach supports opportunity exploitation in sustainable entrepreneurship. A qualitative multiple case study draws on semi-structured interviews with 8 sustainability-oriented ventures. The study contributes to the literature by extending lean startup into the context of sustainable entrepreneurship, with particular attention to opportunity exploitation and to the enabling conditions that shape the transferability of lean startup practices to sustainability-oriented ventures.

2. Literature Review

2.1 Opportunity Exploitation in Sustainable Entrepreneurship

Sustainable entrepreneurship integrates the triple bottom line into venture creation (Muñoz and Cohen, 2018), as a convergent process in which social, environmental, and economic objectives are pursued concurrently (Belz and Binder, 2017). However, these operate under conditions of market uncertainty, institutional barriers, and resource scarcity, and the processes through which entrepreneurs exploit opportunities remain poorly understood (Belz and Binder, 2017).

Opportunity exploitation is the translation of a recognised opportunity into a functioning venture (Shane and Venkataraman, 2000). Johnson and Schaltegger (2020) propose a multilevel mechanism linking recognition, venture development, and societal outcomes. Sustainability-oriented ventures face distinctive legitimacy pressures in terms of products addressing environmental problems frequently require customer education and behavioural change, forcing entrepreneurs to continuously refine value propositions and business models (Belz and Binder, 2017; Hockerts and Wüstenhagen, 2010). The creation of a new sustainable venture largely depends on the ability to translate the sustainability goals into product features that are valued by customers (Choi and Gray, 2008; Keskin et al., 2013). A significant gap within the existing literature is that how opportunities are acted on is less explored in sustainability settings (Muñoz & Cohen, 2018).

While Sarma et al. (2024) identify resilience capability as an antecedent of sustainable opportunity recognition, they subsume adaptability within resilience and describe adaptive responses to disruption without explicating the mechanisms through which adaptation unfolds across venture development. Johnson and Schaltegger (2020), advance a multilevel causal-mechanism framework connecting entrepreneurial action to broader market and societal transformation; but the framework remains largely conceptual and offers limited empirical insight. The lean startups minimum viable product, validated learning and the build–measure–learn loop were originally articulated in, and for, technology-driven ventures (Ries, 2011; Bortolini et al., 2021). In the absence of empirical evidence from sustainability settings, it therefore remains uncertain whether these conventional tools can be effectively adapted to the context of achieving triple bottom line (Belz and Binder, 2017). Existing work has focused predominantly on opportunity recognition, with Patzelt and Shepherd (2011) attending to the cognitive antecedents of recognition. However, the exploitation phase remains less studied. Considering this in its nascent stage, and to understand the applicability of lean startup on opportunity exploitation, this study addresses the gaps by providing empirical evidence on how opportunity exploitation unfolds in practice.

2.2 Lean Startup Approach and Sustainable Entrepreneurship

Early-stage firms rarely fail because they cannot build a product; they fail because they build something the market does not want. The central task of a venture is to search for a viable business model, the search proceeds through trial, testing, and analysis of evidence (Bortolini et al., 2021). This reframing of entrepreneurship as a

disciplined search underpins the lean startup methodology and its core engine, the build, measure and learn loop (Ries, 2011).

The lean startup approach originated as a practitioner methodology for managing new ventures under conditions of extreme uncertainty, drawing together ideas from customer development and agile and lean manufacturing (Ries, 2011; Blank, 2013). Its central mechanism is the BML cycle. In the build stage, the entrepreneur translates a business hypothesis into a minimum viable product (MVP) the simplest version of an offering capable of generating learning with the least effort (Ries, 2011; Frederiksen and Brem, 2017). In the measure stage, the entrepreneur collects data on real customer and market behaviour rather than on stated intentions, so that progress is assessed through validated learning (Ries, 2011; Shepherd and Gruber, 2021). In the learn stage, this evidence is used to confirm or refute the underlying hypothesis and to decide whether to persevere with the current course or to pivot to a revised one (Ries, 2011; Blank, 2013). The cycle is then repeated, so that the venture converges on a viable opportunity through iterations rather than through a single, pre-committed plan (Contigiani and Levinthal, 2019; Bortolini et al., 2021). Camuffo et al. (2020) demonstrate that ventures adopting a hypothesis-testing approach reached better decisions and were less susceptible to escalation of commitment than those operating without structured experimentation. Leatherbee and Katila (2020) find that hypothesis-driven probing enabled early-stage teams to converge on viable opportunities more reliably.

The BML cycle offers a mechanism for exploitation under this compounded uncertainty. Building a minimum viable product turns unknowable questions into low-cost, testable hypotheses (Frederiksen and Brem, 2017; Andries et al., 2013); measuring real behaviour rather than stated intention addresses demand uncertainty, as the expressed sustainability values are weak predictors of purchase (Shepherd and Gruber, 2021). Iterative learning, in turn, builds legitimacy and adaptive capacity while its affordable-loss character keeps repeated experimentation feasible for resource-scarce ventures (Reypens et al., 2021; York, O'Neil and Sarasvathy, 2016). Moreover resource scarcity is dealt using entrepreneurial bricolage which is making do by applying combinations of the resources at hand to new problems and opportunities (Baker and Nelson, 2005). What remains missing is direct evidence on how the cycle operates when validation must span commercial, social, and environmental criteria at once.

The intersection of lean startup approach and sustainable entrepreneurship is sparse but growing. Lean startup approach can support sustainability-oriented business model development by reducing uncertainty and building stakeholder confidence (Bocken and Snihur, 2020). Aagaard et al. (2021) find that cleantech startups use experimentation for organisational learning and investor legitimation. Reypens et al. (2021) demonstrate that resource-scarce ventures depend on adaptive resource mobilisation, a pattern structurally consistent with the experiment-first logic of lean startup. The BML cycle gives concrete, observable form to the exploitation stage each turn of the loop is an act of exploiting the opportunity a little further while re-evaluating it.

3. Methodology

3.1 Research Design

A qualitative multiple case study design was adopted following Yin (2018), who argues that case study methodology is appropriate for 'how' questions about processes in real-life contexts. This design allows in-depth examination of entrepreneurial decisions and learning mechanisms that are difficult to capture through quantitative methods, also considering the complexity of the phenomenon and application in non-tech ventures. Eight founders of sustainability-oriented ventures were selected through purposive sampling (see table 1). Cases were included based on secondary and primary data evaluation of venture (a) addressed an environmental and (or) social sustainability problem at its core alongside commercial and (b) at an early or growth stage. The interviews lasted for 45 to 90 minutes.

3.2 Data Collection and Analysis

Primary data came from semi-structured interviews conducted online. Questions covered around opportunity exploitation, experimentation activities, customer and stakeholder interactions, resource mobilization, learning, measuring and adaptation. Although the lean startup is a practitioner methodology, it is used here as an analytical framework rather than as an intervention, its concepts were used to interpret the validation practices founders described. This is a recognised use of the lean startup, where its building blocks are treated as an organising structure for studying early-stage firms (Shepherd and Gruber, 2021).

The BML cycle was selected as the specific lens for three reasons. First, it maps cleanly onto the opportunity exploitation (Shane and Venkataraman, 2000; Ardichvili et al., 2003). Second, it is the most concrete and widely recognised element of the lean startup, and its three phases provide clear, mutually exclusive categories for coding what founders actually do (Ries, 2011; Bortolini et al., 2021). Third, because sustainability-oriented ventures must validate environmental and social claims as well as commercial ones, an iterative, evidence-based framework is well suited to surfacing how they approach. Further supported by Bortolini et al. 2021, confirming that the BML cycle is the analytical core through which the lean startup connects to earlier theory on business-model validation.

All interviews were recorded and transcribed and analysed following the Gioia methodology (Magnani and Gioia, 2023). Coding proceeded in three stages. First, we developed first-order concepts staying close to informant's account. Second, we grouped these into theory-centric second-order themes. Third, we distilled the themes into aggregate dimensions. The design was abductive while the concepts and themes were derived inductively from the data, the build–measure–learn cycle provided the theoretically-informed aggregate dimensions, allowing the analysis to connect grounded evidence to an established process framework. The resulting data structure is presented in Table 2. Four major themes emerged across the three phase of lean startup approach. Reliability was supported through data triangulation across interviews and secondary sources, cross-case comparison to identify consistent patterns.

Table 1: Description of the ventures

Sustainable Venture	Founded in	State	Value Proposition
SV1	2020	Maharashtra	Sustainable fashion and lifestyle products
SV2	2021	Tamil Nadu	Solid waste collection and down-cycling enterprise
SV3	2023	Karnataka	Eco-friendly textile
SV4	2019	Delhi NCR	Technology-enabled recycling startup
SV5	2020	Bihar	Sustainable footwear
SV6	2020	Karnataka	Sustainable straws
SV7	2018	Maharashtra	Sustainable Home & Personal Care
SV8	2020	Uttar Pradesh	Agricultural Waste Utilisation

4. Findings

The analysis produced four second-order themes nested within the three aggregate dimensions of the BML cycle. Firstly, in every case the originating opportunity was framed around an environmental or social problem rather than a purely commercial gap, aligns with Shepherd and Patzelt's, 2011 account of sustainable entrepreneurship. Second, sustainability was embedded in the value proposition rather than treated as a marketing addition. Founders described their environmental or social outcome as inseparable from the product.

Findings show that these ventures operated under resource scarcity, they advanced their opportunities through entrepreneurial bricolage "making do" by recombining the physical, social and institutional resources already at hand alongside lean startup approach for exploiting the opportunity (Baker and Nelson, 2005). Bricolage did not remain static, rather it evolved from "making do" into a more selective, evidence-based way of constructing resources. The full data structure is presented in Table 2, which shows how moving from first order concepts evolved into second order themes to final aggregate dimensions.

4.1 Build: Bricolage-Based MVP Development Under Sustainability Constraints

The build phase was characterised by minimalism. Rather than waiting for a fully developed offering, founders assembled the smallest functional version of their product or service capable of generating operational data, using entry points such as neighbourhood waste-collection trials or product samples placed with a few retail buyers to test logistics before any wider rollout. Founders repurposed domestic settings, discarded or under-

valued inputs, and existing relationships instead of acquiring new assets (Baker and Nelson, 2005). At this stage the bricolage was largely improvisational and driven by necessity.

SV6: “Experimenting with the leaf, I discovered that when soaked, it became leathery, and steaming it revealed a nice shine..my kitchen became an experimentation place where I did my all initial experiments later verified it from my university colleagues”

SV2: “we started this as a side hustle, whether we can do it… during the pilot phase, we could see that there was a good amount of interest in the normal customers.”

SV8: "we had no money to build the full system, so we made this product using simple resources and did the first pilot testing...when I reached out to one of the incubators for financial assistance they asked for amount of agri waste treated till now…yes specific work which you do related to social or environmental you need to show that metrics also if targeting some financial or mentor help”

Constraining expenditure to what founders could afford to lose made repeated experimentation financially viable across multiple cycles. This improvised, low-cost resource behaviour constitutes the second-order theme of strategic resource utilisation. The build phase also exposed a tension specific to sustainability-oriented ventures; commercial viability and environmental effectiveness could not be treated as a single dimension. Early prototypes often performed well on one while failing on the other. Founders therefore used each MVP to test commercial and sustainability assumptions, a practice captured in the second-order theme of experimentation for sustainability validation. This was reinforced by external gatekeepers, who required evidence of impact as a condition of support.

4.2 Measure: Dual-Axis Validation and Stakeholder Signals

In the measure phase founders tracked two categories of metrics in parallel commercial and environmental and these did not operate independently. In several cases strong performance on one axis produced weak or ambiguous results on the other, and founders had to decide which signal to prioritise. Direct customer interaction was the primary channel for commercial validation, with social media serving as a secondary channel.

SV6: “When we went on to distribute our products initially to hotels nearby and waited for them to give some feedback, some customers said it is environment friendly some also mentioned that it is soggy after few hours so we did more refinement on this”

SV3: “There was a complaint posted online which told us more than our three months of surveys.”

Environmental positioning did not reliably predict adoption. Although customers often voiced strong sustainability values, purchase decisions were driven more by cost, convenience and reliability, so behavioural signals proved more dependable than stated attitudes (Shepherd and Gruber, 2021); founders who relied mainly on satisfaction-based feedback tended to misread demand. Feedback also extended beyond the customer relationship; interactions with stakeholders such as, waste collectors, municipal actors, community organisations and supply-chain partners generated insight into operational feasibility, regulatory compliance and service design, and introduced additional evaluative requirements that shaped what founders had to measure and report. This multi-stakeholder dynamic constitutes the second-order theme of feedback-driven opportunity refinement, exploitation proceeded not as the execution of a fixed plan but as an iterative revision of the opportunity through engagement with several stakeholder groups (Shane and Venkataraman, 2000; Ardichvili et al., 2003).

4.3 Learn: Evolving Bricolage and Adaptive Opportunity Exploitation

The learn phase produced continuous revision of foundational assumptions. Across repeated BML cycles, founders sharpened their understanding of customer identity, willingness to pay, service-delivery requirements and whether the claimed environmental or social impact was being realised, so that each cycle yielded a more calibrated account of the opportunity than the last (Ries, 2011).

It is here that bricolage is seen to evolve rather than simply recur. Early on, resource construction resembled what Baker and Nelson (2005) term parallel bricolage improvising across many domains at once, out of necessity. As validated learning accumulated, founders became more deliberate, retaining and upgrading the improvised combinations that had passed the dual-viability test and abandoning those that had not, moving toward a selective bricolage targeted at resource combinations shown to create both commercial and environmental value. This strengthened founders' adaptive capacity: those who completed several BML cycles adjusted more

readily to market shifts, regulatory change and stakeholder feedback than those who had committed early to fixed plans.

SV7: "Without research and without data, it's very difficult for us to analyze how the entire journey would be".

SV4: "We didn't get it right at the start, we got it right by going around enough times it took a lot of changes and every change showed us a new direction…it was a learning for us each failed step left a new idea behind to track and experiment with"

SV6: "We built a proper machinery for the straws as the earlier was handmade…after understanding the demand for it we switched to mechanize this process."

These accounts support the second-order theme of iterative learning for adaptive opportunity exploitation. Exploitation proceeded as a recursive process in which the attempt to act on an opportunity generated the learning needed to determine what that opportunity was and how it could be viably pursued. These emerged from completing enough BML cycles to convert initial uncertainty into actionable knowledge, and from allowing bricolage to mature under that learning.

Table 2: First order concepts to aggregate dimensions

1st-order concepts	2nd-order themes	Aggregate dimension
Piloting in a few local markets; building a cheap, simple first version; spending only what we could afford to lose; testing commercial and impact assumptions together; prototyping with what was available; home experiments	Experimentation for sustainability validation	**BUILD**
Turning waste into a usable input; using existing/left-over materials; drawing on local artisans and community networks; using whatever materials were on hand	Strategic resource utilisation	
Collecting customer feedback; watching what customers did, not what they said; learning from social-media comments and complaints; working with municipalities and suppliers; refining the product from user responses; tracking sales and commercial signals; measuring environmental impact; checking what customers would pay; validating both impact and revenue	Feedback-driven opportunity refinement	**MEASURE**
Trial-and-error learning; continuously revising our assumptions; learning from failed attempts; adapting based on data; changing across repeated cycles; revising who the customer is; adjusting to market and regulatory shifts; improving a bit each cycle; improving the product; adding more resources	Iterative learning for adaptive opportunity exploitation	**LEARN**

5. Discussion and Contributions

The findings moved lean startup approach beyond its conventional technology and commercial orientation by demonstrating that sustainable entrepreneurs engage in dual validation testing market viability and environmental effectiveness through the same iterative cycles. Existing scholarship conceptualises experimentation primarily as a mechanism for reducing market uncertainty and achieving product-market fit (Ries, 2011; Blank, 2013). The findings indicate that sustainable ventures validate ecological impact alongside commercial feasibility, operating under conditions of dual uncertainty in which environmental legitimacy functions as an evaluative criterion to market acceptance (Cohen and Winn, 2007; Dean and McMullen, 2007). The findings indicate that lean startup practices including bricolage give sustainable entrepreneurs a structured mechanism for developing sustainability-oriented ideas into viable ventures (Baker and Nelson, 2005; Ries, 2011; Shepherd and Gruber, 2021).

This contributes to the growing integration of lean startup and bricolage. Founders drew on resource recombination through locally available materials and informal partnerships (Baker and Nelson, 2005) consistent with bricolage approach. Founders combined bricolage for better application of lean startup experimentation in uncertainty (Reypens et al., 2021; Musona et al., 2020). The study therefore advances theory by showing that sustainable entrepreneurs use hybrid entrepreneurial logics in practice (Camuffo et al., 2020; Priyathee et al.,

2026) while bricolage enables experimentation to remain economically feasible under severe resource constraints (Baker and Nelson, 2005; Musona et al., 2020).

As validated learning accumulated through the measure and learn phases, founders retained and upgraded the combinations shifting towards selective bricolage (Baker and Nelson, 2005). This aligns with Fisher's (2012) call to examine how bricolage and other entrepreneurial behaviours complement one another.

The study further extends stakeholder-oriented perspectives into the lean startup approach, as the founders could not combine effectively commercial viability and environmental or social effectiveness into a single test; each MVP had to interrogate a sustainability hypothesis alongside the value and growth hypotheses of standard practice (Ries, 2011). Firstly, environmental positioning did not predict adoption, customers value sustainability but decided on cost, convenience and reliability, so behavioural signals proved more reliable than stated attitudes (Shepherd and Gruber, 2021). Second, evaluation extended beyond customers to other stakeholders, whose procurement standards and impact-evidence requirements shaped what founders had to measure and report. A demand-side and legitimacy pressure characteristic of sustainability-oriented ventures (Hockerts and Wüstenhagen, 2010).

6. Conclusion and Implications for Future Research

This study examined how lean startup approach support opportunity exploitation in sustainable entrepreneurship. The findings indicate that experimentation, stakeholder feedback, strategic resource management, and iterative learning collectively enable sustainable entrepreneurs to develop sustainability-oriented ideas into viable ventures. Moreover, the importance of resources in handling lean startup approach found to be significant. The findings indicate that, when adapted to sustainability conditions, lean startup practices provide a mechanism for navigating the uncertainty and resource constraints that characterise early-stage sustainable venturing.

The study has some limitations, firstly, it considers relatively small sample, limiting direct generalizability. Future research might extend this inquiry to other non-tech sectors or apply quantitative methods to examine relationships between lean startup practices and sustainable venture performance outcomes with bricolage as a moderating mechanism. Longitudinal designs could also capture how exploitation processes evolve as ventures mature beyond the early stage. Secondly, relying solely on founders' accounts leaving behind the perspectives of other stakeholders remain unrepresented, and future research can incorporate multiple informants would produce a more complete picture of the exploitation process. Third future research can also incorporate resource-based view, causation and effectuation theories as supporting variables while considering opportunity exploitation through lean startup for non-tech ventures.

Abstract: Artificial Intelligence (AI) is no longer just a tool that supports human decisions. It is becoming an active participant in the economy, one that negotiates, transacts, and coordinates autonomously with other AI agents at a speed and scale that no human organisation can match. This shift, from AI as assistant to AI as autonomous economic actor, represents one of the most significant innovations in how organisations operate, compete, and create value. Yet this innovation is outpacing governance. As AI agents increasingly interact with each other rather than with people, organisations are deploying autonomous systems without fully understanding when those systems should act independently, when they should defer, and when they should escalate to human oversight. Without answers to these questions, the promise of AI-driven innovation carries substantial and poorly managed risk. Supply chains are where this tension is most directly felt. They are already among the most complex environments organisations manage, and they are precisely where the cost of getting autonomous AI wrong is highest. Disruptions propagate fast, decisions must be made under uncertainty, and the consequences of miscalibrated autonomy can cascade across entire networks of operators, suppliers, and partners. This research proposes an innovative governance framework that addresses this challenge directly. By developing Trust-based thresholds that dynamically regulate how much autonomy an AI agent exercises depending on the reliability of its counterparts, the research introduces a new model for governing Agent-to-Agent interactions in high-stakes supply chain environments. The framework is grounded in empirical data from the European Gas Transmission Network and validated against the 2022 European Gas Supply Crisis, one of the most significant supply disruptions in recent European history. The expected outcome is both a theoretical contribution, an innovative framework for Trust-governed Autonomy in multi-agent systems, and a practical one: empirical evidence that supply chains governed by this model can recover from disruption autonomously, without continuous human intervention, opening new possibilities for resilient, AI-enabled supply chain innovation.

Keywords: Agentic AI, Supply Chain Resilience, Trust, Autonomy, Agent-to-Agent Economy, Innovation

1. Introduction

The deployment of Artificial Intelligence (AI) in operational environments has undergone a fundamental shift. What began as the automation of discrete, well-defined tasks has evolved into a qualitatively different paradigm: Agentic AI systems that perceive complex environments, reason across multiple variables, and act upon their conclusions with varying degrees of independence from human oversight (Bandi et al, 2025; Schrage & Kiron, 2025a; Al-Bashrawi et al, 2026). This transition carries profound implications for the organisations and sectors that adopt these systems, given that the conditions under which autonomous action is appropriate, and the mechanisms by which it should be governed, remain to a significant extent an open question in both research and practice (Geninatti Cossatin et al, 2026; Lee & See, 2004).

Supply chains represent one of the most consequential environments in which this question materialises. Modern supply networks are complex, globally interconnected systems in which disruptions do not remain localised but propagate across multiple tiers, amplifying in impact as they travel (Ivanov et al, 2014). The efficiency gains that have made these networks globally competitive, lean inventories, geographic specialisation, and tightly coupled logistics, are precisely the characteristics that render them vulnerable when disruption occurs (Manuj & Sahin, 2011). Conventional risk management approaches, built on static models that capture the network as a frozen snapshot, are structurally ill-suited to the speed and scale at which real-world disruptions unfold (Hosseini & Ivanov, 2020; Gupta & Gevaers, 2025).

Energy supply chains illustrate this vulnerability with particular acuity. The 2022 European Gas Supply Crisis (IEA, 2025) demonstrated how cascading failures across interconnected gas transmission networks can expose the fragility of systems optimised for efficiency rather than resilience, and the inadequacy of risk models that cannot adapt in real time to rapidly evolving conditions (Garvey et al, 2015). In high-stakes environments of this kind, where disruptions arrive with little warning and propagate faster than conventional decision cycles can

accommodate, the limitations of static risk modelling are not merely academic, they carry measurable operational and economic consequences (Camur et al, 2024; Song et al, 2024).

It is against this backdrop that the intersection of Agentic AI and Supply Chain Resilience becomes a critical area of inquiry. As AI systems grow more capable and more autonomous, a new dimension of complexity emerges: the Agent-to-Agent (A2A) Economy, in which AI agents transact, negotiate, and coordinate directly with other AI agents, rather than exclusively with human counterparts (Zhu et al, 2025; Kirshner et al, 2026). In these settings, Trust, a concept historically studied as a property of human-automation interaction, must be reconceptualised as a dynamic, probabilistic quantity that governs when one autonomous agent should rely on the decisions, signals, and outputs of another (Afroogh et al, 2024; Lee & See, 2004).

Innovation, broadly defined as the implementation of new or significantly improved processes, products, or organisational methods (OECD, 2005), spans a broad spectrum from technological and process innovation to supply chain innovation (Stundziene et al, 2024). The emergence of the A2A Economy represents precisely this kind of organisational innovation, one that is outpacing existing governance frameworks (Schrage & Kiron, 2025b). Unlike previous waves of digital transformation, where AI augmented human decision-making, this shift places autonomous agents at the centre of operational and economic exchange, creating governance challenges for which no established model yet exists. Addressing those challenges requires innovation not only in technology but in the frameworks used to govern it.

The existing literature has addressed many elements of this challenge in isolation. What it has not provided is a framework that connects Trust, Autonomy, and Supply Chain Disruption Modelling into a unified, empirically validated approach for governing autonomous agent behaviour under disruption. Two critical gaps define this space. The first concerns the Trust-based thresholds that probabilistically govern Autonomy transitions in Agent-to-Agent interactions. The second concerns the capacity of supply chain networks to recover from disruption automatically, what the literature refers to as Self-Healing Network Behaviour, without relying on human intervention at every decision point (Hosseini & Ivanov, 2020; Ojha et al, 2018).

This research, currently in progress as part of a doctoral study, addresses both gaps through an innovative governance framework for Trust-governed Autonomy in Agent-to-Agent supply chain networks, situated within the regulatory framework established by Article 14 of the European Union Artificial Intelligence Act (European Parliament & Council of the European Union, 2024).

2. Theoretical Framework

A systematic literature review was conducted across four databases - Scopus, Web of Science, ACM Digital Library, and arXiv -, covering the period from 2004 to 2026, restricted to English-language peer-reviewed publications across five thematic areas: Agentic AI, Trust in Automation, Supply Chain Resilience, Disruption Risk Modelling, and Agent-to-Agent Interaction. The review yielded a final corpus of 29 papers, organised across 17 thematic topics that together map the intellectual landscape from which this research emerges, as illustrated in Figure 1 below.

2.1 Agentic AI

Agentic AI systems are artificial intelligence systems capable of pursuing goals autonomously, reasoning across complex environments, and acting with minimal human direction (Bandi et al, 2025; Al-Bashrawi et al, 2026). This shift from reactive tools to autonomous actors represents a significant technological innovation, one that is transforming how organisations operate and compete, and that demands equally innovative implementation strategies grounded in context, human agency, and adaptive governance (Thomas et al, 2025).

The intellectual foundations of Agentic AI begin with the philosophical assumptions that shape how AI systems are designed and evaluated. Schrage and Kiron (2025a) argue that AI models are fundamentally shaped by what they aim to achieve, what counts as valid knowledge, and how they represent reality. When these assumptions are left unexamined, the result is misalignment: systems that optimise for the wrong goals or construct representations of reality that do not correspond to the environments in which they operate. Schrage and Kiron (2025b) extend this argument to organisational design, proposing that the value of AI is realised not through deployment alone but through the deliberate architecture of environments in which human and AI agents co-create strategic value, reframing the relevant unit of analysis from the individual model to the sociotechnical system in which it operates. Bandi et al (2025) provide a comprehensive taxonomy of Agentic AI architectures, defining autonomous agents as goal-driven systems that combine planning, persistent memory, tool use, and

multi-agent collaboration with varying degrees of human oversight, identifying orchestration style as the key architectural differentiator. Anjomshoae et al (2019) demonstrate that explainability, the capacity of an agent to explain its own behaviour, is foundational to the Trust placed in it, and identify a near-total absence of research on inter-agent explainability, a gap that becomes directly relevant when autonomous agents must decide whether to rely on each other's outputs in a shared operational environment.

2.2 Trust and Autonomy

Trust in automation has a well-established theoretical foundation. Lee and See (2004) define Trust as the attitude that governs reliance on an automated system under conditions of uncertainty, identifying three bases on which it is built - Performance, Process, and Purpose - and demonstrating that Trust evolves dynamically as experience accumulates. Critically, the authors flag an underexplored dimension: Trust not between a human and a machine, but between machines themselves. Canale and Thimmaraju (2025) extend this concern, proposing that Large Language Models may have inherited the same pre-cognitive vulnerabilities that social engineers exploit in people, a phenomenon they term Anthropomorphic Vulnerability Inheritance. Radanliev et al (2026) demonstrate that such vulnerabilities propagate across perceptual, cognitive, and executive layers of Agentic AI systems. Akkil et al (2026) show through large-scale multi-agent simulation that identical agents produce radically different macro-level outcomes depending on the population of agents surrounding them, establishing that the correct unit of safety analysis is not the individual model but the deployed system as a whole. The regulatory response is provided by the EU Artificial Intelligence Act (European Parliament & Council of the European Union, 2024), whose Article 14 establishes a spectrum of human oversight obligations for high-risk AI systems, from continuous monitoring to limited intervention rights. However, the EU AI Act does not specify how Autonomy levels should be governed dynamically as Trust and Risk evolve during operation. Afroogh et al (2024) identify calibrated Trust, the alignment between the Trust placed in a system and the Trust that system actually merits, as the central challenge in human-AI interaction, and flag the near-total absence of research on Trust in AI-to-AI interaction as one of the most significant gaps in the field. Qian and Wexler (2024) provide empirical grounding for this concern, demonstrating that access to a conversational AI affects demonstrated and perceived productivity in opposite directions, and that reliance behaviour diverges from stated intentions in ways that become even more consequential in Agent-to-Agent settings where no human is present to notice and correct the miscalibration. This is the first gap that the present research addresses.

2.3 Agent-to-Agent Economy

The emergence of the Agent-to-Agent Economy, in which AI agents transact, negotiate, and coordinate directly with one another rather than with human counterparts, marks a new frontier of economic innovation that is reshaping how supply chains operate. Supply chain innovation, defined as a multifaceted process designed to address environmental uncertainties, meet customer needs, and improve organisational processes through the adoption of new technologies (Stundziene et al, 2024), is increasingly driven by these autonomous agent interactions rather than by human-mediated decisions. Zhu et al (2025) characterise this Agent-to-Agent Economy through a large-scale negotiation experiment across nine Large Language Model families, demonstrating that autonomous agent negotiation is an inherently imbalanced game in which stronger models consistently secure better outcomes while weaker models exhibit higher rates of constraint violation, introducing systemic risks that do not exist in human-to-human negotiation. Kirshner et al (2026) benchmark LLM negotiators against human participants in a supply chain bargaining experiment adapted from the foundational human-subjects study of Davis and Hyndman (2021), finding that LLM agents are more agreement-prone but less fair, and that they do not exploit strategic ignorance when operating under private information conditions. At the implementation level, Xu et al (2024) provide one of the first working prototypes of autonomous supply chain management using multi-agent systems, explicitly identifying LLM-powered agents as the natural next step. Quan et al (2026) demonstrate that LLM-based risk severity scoring substantially outperforms rule-based approaches, while Kaur et al (2026) introduce carbon accountability into multi-agent supply chain decision-making, finding that while AI compute carbon is negligible relative to transport carbon for individual shipments, it becomes material at scale and must be measured alongside operational benefits.

2.4 Supply Chain Resilience

The application of AI to supply chain management represents one of the most consequential areas of operational innovation in recent years (Stundziene et al, 2024), offering capabilities in disruption detection and adaptive response that conventional models cannot provide.

Manuj and Sahin (2011) draw a critical distinction between supply chain structural complexity and decision-making complexity, demonstrating that well-designed information systems can substantially reduce perceived complexity even when objective network complexity remains high. Camur et al (2024) and Song et al (2024) establish that the supply chains most in need of intelligent disruption response are precisely those operating under the most severe informational and temporal constraints. The foundational contribution to disruption modelling is the Ripple Effect, formalised by Ivanov et al (2014) as the cascade of impacts that propagates through supply chain tiers when a significant event occurs at any one node. Hosseini and Ivanov (2020) demonstrate that Bayesian Networks are particularly well suited to supply chain risk analysis, capturing causal interdependencies and supporting both forward and backward inference, but identify the static nature of existing models as their principal limitation. Garvey et al (2015) formalise node-level risk propagation measures, validated by Ojha et al (2018) across thousands of simulation runs. Gupta and Gevaers (2025) identify a further limitation: existing models do not capture how multiple distinct risk types compound horizontally across the same tier, creating Super-Risk Events whose severity exceeds what any single-hazard model can anticipate. Singh and Singh (2019) show that big data analytics can convert past disruption experience into genuine resilience, while Hao et al (2025) demonstrate that AI-human collaboration in supply chains operates as a dynamic co-constitutive process requiring active management of epistemic asymmetry and temporal friction. Necula and Rieder (2025) demonstrate that AI can drive circular economy practices across supply chain stages, though the same AI systems introduce their own carbon cost (Kaur et al, 2026). Together, these limitations define the second gap the present research addresses.

Taken as a whole, the seventeen themes reviewed here establish both the urgency and the feasibility of the present research. What makes this contribution innovative is a combination of three characteristics that no existing framework has brought together: it operationalises Trust as a dynamic, probabilistic quantity governing Autonomy transitions in real time, rather than as a fixed property of a human-machine relationship; it grounds this model in empirical data from a real, large-scale supply disruption, making its validation testable and reproducible; and it situates the governance framework within the regulatory boundary conditions of the EU Artificial Intelligence Act, ensuring it is not only technically sound but legally accountable. Together, these characteristics define a contribution that is theoretically original, practically actionable, and responsive to the contextual complexity that effective innovation strategies must navigate (Thomas et al, 2025; Stundziene et al, 2024).

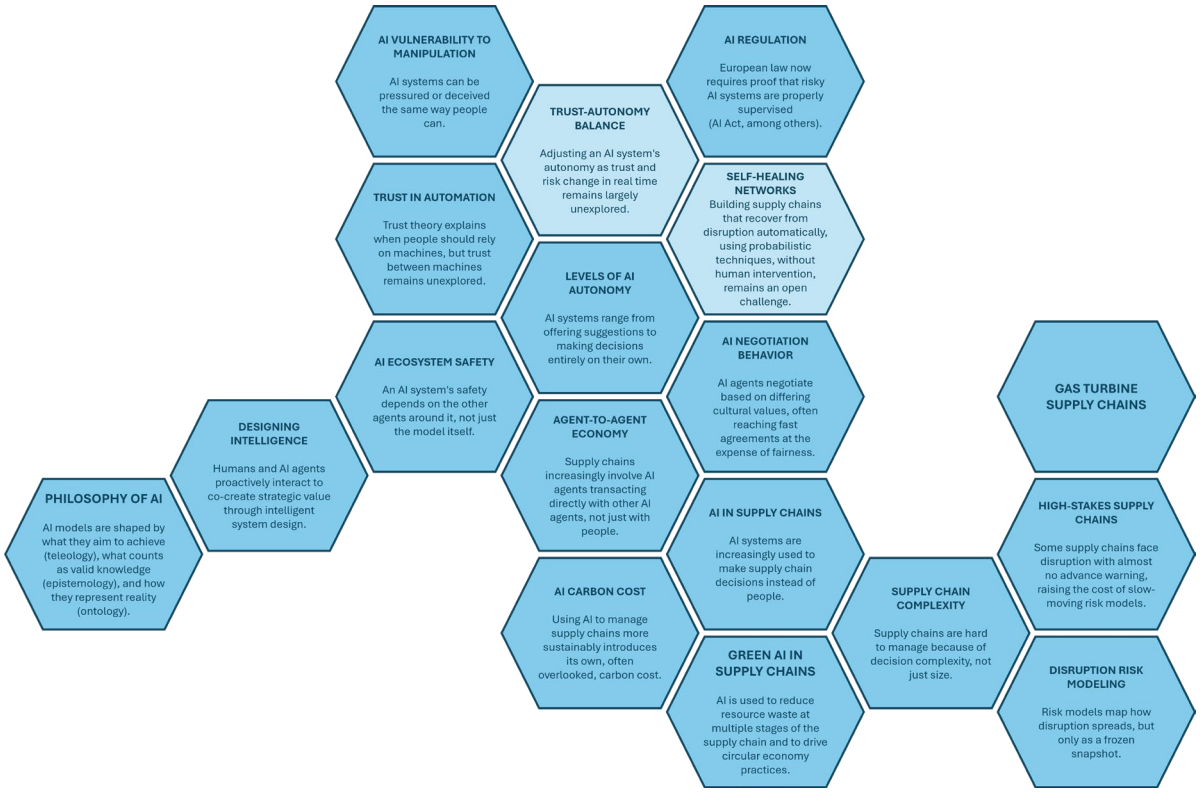

Figure 1: Affinity Map of the Literature Review - 17 Thematic Topics from Foundational Concepts to Research Gaps.

3. Research Questions

The two gaps identified in the literature arise from the intersection of two bodies of knowledge that have developed largely in isolation. Trust in automation provides the theoretical vocabulary for governing agent behaviour, but has not been extended to the dynamics of Agent-to-Agent interaction, where no human is present to recalibrate reliance in real time. Supply chain disruption modelling provides the quantitative tools for capturing network-level risk, but existing models remain static and unable to adapt as conditions evolve during an ongoing disruption. The convergence of these two limitations defines the research space this study occupies, giving rise to two formal research questions:

- RQ1 - What are the Trust-based thresholds that probabilistically govern Autonomy transitions in Agent-to-Agent interactions?
- RQ2 - How effective are these thresholds in Agent-to-Agent supply chain networks at minimising recovery time under disruption?

These two questions are not independent. RQ2 cannot be meaningfully answered without first resolving RQ1. The research is therefore organised sequentially, tracing a deliberate path from the micro, understanding how Trust governs the behaviour of two agents in interaction, to the macro, understanding how those same Trust-based mechanisms shape the resilience of an entire network under disruption.

4. Methodology

4.1 Research Design and Empirical Scenario

The 2022 European Gas Supply Crisis (IEA, 2025) serves as the primary empirical scenario, selected for its clearly identifiable onset, measurable propagation pattern across an interconnected network of operators, and a recovery trajectory that can be observed and quantified using publicly available data. The setting is the European Gas Transmission Network, operated by Transmission System Operators whose interactions are published through the ENTSOG Transparency Platform (ENTSOG, 2026). The simulation timeline spans 2019 to 2025, divided into three phases: a baseline period from 2019 to 2021 used to initialise agent Trust scores; the disruption year 2022; and a recovery and validation period from 2023 to 2025.

Three publicly accessible platforms provide complementary data layers: the ENTSOG Transparency Platform (ENTSOG, 2026) as the primary source for network structure, physical flows, and interruption events; the ENTSO-E Transparency Platform (ENTSO-E, 2026) for complementary energy generation data; and the Eurostat Energy Database (Cazzaniga, 2026) for country-level gas supply and consumption context. All three platforms provide data covering 2019 to 2025. The research operationalises disruption and recovery using statistically-derived thresholds applied to the 2019 to 2021 baseline data, grounded in empirical network behaviour and adapted from EU Regulation 2017/1938 (Council of the European Union, 2017).

4.2 Simulation Model

The research employs a Bayesian-Monte Carlo hybrid probability model (Bayes, 1763; Metropolis & Ulam, 1949). The Bayesian component governs Trust at the agent level, updating Trust scores after every interaction using Bayes' theorem, producing a Trust score that evolves continuously with the history of each agent relationship. The Monte Carlo component governs the simulation strategy at the network level, testing a large number of Trust threshold combinations across repeated simulation runs to identify the configurations that produce the fastest network recovery with statistical reliability.

Four Autonomy levels are proposed, ranging from full human oversight to full agent Autonomy, each grounded in the human oversight requirements established by Article 14 of the EU Artificial Intelligence Act (European Parliament & Council of the European Union, 2024). The framework is an academic interpretation of these requirements, not a reproduction of their legal text. For RQ1, a dyadic network is used to identify Trust-based thresholds in a controlled setting before scaling to the full network in RQ2. For RQ2, a set of agents is selected from the ENTSOG network based on their structural importance to the 2019 to 2021 baseline period, ensuring the simulation captures the most critical points in the European gas transmission network. Both agent sets are LLM-powered, with agent behaviour governed by Large Language Model reasoning rather than fixed rules.

4.3 LLM Integration

A commercially available Large Language Model (LLM), accessed via API with batch processing, serves as the reasoning engine powering agent behaviour throughout the simulation. For RQ1, a calibration approach is used before any simulation runs begin, establishing the decision logic that maps Trust and Risk levels to agent decisions. This decision logic is then applied consistently throughout all simulation runs, eliminating randomness from the threshold search and making results fully reproducible. For RQ2, a hybrid approach is used: agents rely on the calibrated decision logic for individual Trust-based Autonomy decisions, while live LLM calls are made only for Agent-to-Agent communication events during the disruption period, occurring at regular intervals.

5. Expected Results

The expected output of RQ1 is a set of empirically identified Trust-based thresholds that govern Autonomy transitions in Agent-to-Agent interactions, together with a characterisation of how these thresholds perform across the four Autonomy levels under the 2022 disruption scenario.

The expected output of RQ2 is a network-level validation of these thresholds under the 2022 European Gas Supply Crisis scenario (IEA, 2025), with recovery time measured and compared across Autonomy configurations. The research expects to demonstrate that supply chain networks governed by Trust-based Autonomy mechanisms recover from disruption more efficiently than networks operating under fixed Autonomy assumptions, providing empirical evidence for the feasibility of Self-Healing Network Behaviour in Agent-to-Agent supply chain systems, and producing a novel theoretical framework applicable beyond supply chains to any domain where autonomous agents must coordinate under uncertainty.

6. Conclusion

As AI agents move from supporting human decisions to making autonomous ones, governing when they should act independently, defer, or escalate to human oversight becomes one of the most consequential challenges organisations face (Lee & See, 2004; Afroogh et al, 2024). Supply chains represent the environment where this challenge is most acute and where the cost of miscalibrated autonomy is highest (Ivanov et al, 2014; Hosseini & Ivanov, 2020).

This research makes an innovative contribution across three dimensions. Its theoretical innovation is a novel framework for Trust-governed Autonomy in Agent-to-Agent interactions, the first to operationalise dynamic Autonomy transitions using probabilistic Trust thresholds grounded in empirical network data, addressing a gap the Trust in automation literature has identified but not resolved (Lee & See, 2004; Afroogh et al, 2024). Its practical innovation is a governance model organisations can implement to calibrate how much autonomy their AI agents exercise, grounded in context, adaptive governance, and measurable outcomes (Thomas et al, 2025), with direct relevance to supply chain innovation and the Agent-to-Agent Economy, an entrepreneurial frontier reshaping how organisations create and capture value (Al-Bashrawi et al, 2026; Stundziene et al, 2024; Zhu et al, 2025; Kirshner et al, 2026). Its regulatory innovation is the operationalisation of Article 14 of the EU AI Act as a dynamic governance mechanism, translating legal requirements into measurable, simulatable autonomy levels (European Parliament & Council of the European Union, 2024).

As with any research in progress, this study carries inherent limitations. The empirical validation is grounded in a single disruption scenario, which limits immediate generalisability to other supply chain contexts, and the framework's performance in supply chain types beyond gas transmission networks remains to be tested. Future research will extend the simulation to additional scenarios and network types, broadening the empirical basis of the Trust-Autonomy framework.

The research is currently in progress, with simulation construction underway. Future work will report the empirical results of the RQ1 dyadic threshold search and the RQ2 network-level validation, contributing to the growing body of evidence on how AI agents behave when interacting autonomously, and on how that behaviour can be governed effectively when the stakes are high.

Ethics Declaration

This research did not require ethical clearance. The study relies exclusively on publicly available datasets from the ENTSOG Transparency Platform, the ENTSO-E Transparency Platform, and the Eurostat Energy Database. No human participants were involved.

AI Declaration

In preparing this paper, the author utilised AI tools to assist with language refinement and structural organisation. All content was reviewed and verified by the author, who takes full responsibility for the final manuscript.

Iterative Stakeholder-Driven Commercialization Pathways in Academic Entrepreneurship and MVP Learning

Alexander Matrosov
LAB School of Business, LAB University of Applied Sciences, Lappeenranta, Finland

Alexander.matrosov@lab.fi

Abstract: Academic entrepreneurs (AEs) commercializing deep technologies operate under high uncertainty conditions, where technological advances precede clearly defined industrial applications. At low TRL, laboratory validation and demonstrations provide technical feasibility signals, yet problem definitions, user contexts, and system-level requirements remain narrow with limited perspective. Market information is fragmented and typically hard to translate into practical use. Under such conditions, commercialization unfolds as an iterative process of entrepreneurial framing, innovation learning, and external alignment. This study examines how AEs structure early commercialization through stakeholder engagement. Empirically grounded in a low TRL technology project, the research draws on expert interviews, internal team reflections, university support actors, workshops and a literature review. The literature provides a conceptual baseline against which emerging empirical themes are compared, refined, and structured. The analysis applies an inductive qualitative coding process, grouping findings into preliminary thematic categories such as entrepreneurial framing, iterative experimentation, business model development, technological advancement, and stakeholder alignment. Early-stage interactions within the team and university ecosystem played a critical role in articulating preliminary benefit hypotheses and shaping initial customer-oriented narratives. As engagement expanded to external stakeholders, effective progress depended on identifying actors with contextual authority and commercialization literacy. Rather than eliciting predefined requirements, exploratory questioning surfaced existing customer technical constraints. These dialogues enabled iterative reframing of problem–solution configurations, aligning technological competitive capabilities with differentiated customer contexts and value creation. Technical development progressed from proof-of-concept experimentation toward validated lab-scale feasibility, allowing more credible hypothesis testing regarding application-specific value propositions. The study conceptualizes early deep-tech commercialization as dialogical validation under time pressure and strategic risk. By integrating narrative stakeholder inquiry, structured analytical intelligence, and iterative technical experimentation, AEs can accelerate learning while managing uncertainty.

Keywords: Academic Entrepreneurship, Technology Commercialization, Opportunity Crafting, Lean Startup, Stakeholder Engagement

1. Introduction

Research commercialization is increasingly important because scientific discoveries often create wider economic and societal value only after they are translated into validated applications, business concepts, and market pathways. However, early-stage academic technologies frequently face a “Valley of Death”, where technical potential exists but commercial relevance, customer need, and follow-up resources remain uncertain. (Grünfeld *et al.*, 2026) This makes stakeholder engagement and MVP learning critical mechanisms for reducing uncertainty, testing opportunity assumptions, and shaping more credible commercialization pathways. Startup failures not always fail due to lack of finance, often many other factors, like skillset related to understanding of the business environments, contribute to lack of transition to commercial stage. (Gbadegeshin *et al.*, 2022) For this stakeholder fuelled review process around novel technology can possibly be one suitable way to anchor down the academic entrepreneurs (AE) towards successful venture.

From general perspective research breakthroughs follow similar innovation process than normal product development, difference is environment where companies conduct small experiments in near vicinity to customer interface and academics research happens much farther from commercial interaction layers. Academic Entrepreneur could understand differently technology readiness level (TRL) and raise funds at wrong time for improperly validated technology without validation systems. Certain process steps can be taken and adapted together for research commercialization as well, like stage gate models, Lean Startup and new product development theories suggest. Many universities have undertaken strategy to establish technology centre to increase stakeholder facilitations to share knowledge in the networks. (Kruachottikul *et al.*, 2023) Experimentations in startup early stages suffer still from improper learning from customer feedback and its impact on business model development. This involves active stakeholder engagement and balancing between various choices with limited resources. (Bocken and Snihur, 2020a) To find answers, following guiding research questions are set:

Main RQ: How does iterative stakeholder engagement shape early commercialization learning in low-TRL academic entrepreneurship? Support questions:

- What types of stakeholder input are most useful for refining early deep-tech commercialization assumptions?
- How do academic entrepreneurs translate fragmented stakeholder feedback into clearer problem–solution, customer, and value proposition hypotheses?
- How does stakeholder input interact with MVP-style experimentation, technical validation, and business model development?
- What criteria can be used to assess whether stakeholder engagement improves the commercialization pathway of an early-stage academic technology?

2. Literature Review

2.1 Academic Entrepreneurship, Deep-Tech Uncertainty and Experimentation

Commercialization of academic research is often characterized as high uncertainty, information asymmetry, unclear product applications and limited entrepreneurial capabilities. Academic entrepreneurship is broadly defined as activity conducted by researchers in research institutions. Activities contain collaborative research, consulting, startup creation and universality-industry partnerships development and networking. (Grimaldi *et al.*, 2011) Another common characteristic is closeness to small and young entrepreneurial ventures that work around deep-tech (DT) research concepts with so new concepts, grounding to market is challenging in early stages, possibly due to disruptive nature and novelty. Technologies in this field (eg. robotics, electronics) are commonly often highly regulated and require expertise to introduce or incorporate within existing value networks. Such high barriers can lead to high risk and research often remains in academic environments. (Micol, Leendertse and van Rijnsoever, 2026)

Experimentation can help academic entrepreneurs reduce uncertainty by testing assumptions before committing to a specific commercialization path. In deep-tech commercialization, several value creation and value capture options may appear possible, but limited resources prevent all alternatives from being pursued simultaneously. Experimentation therefore supports learning by comparing strategic options, reducing weaker choices, and informing decision-making. However, it also creates costs, since testing one path may consume scarce resources and partially close other alternatives. The aim is therefore not to identify a perfect numerical optimum, but to narrow uncertainty and select the most feasible strategic path based on available evidence and learning. (Gans, Stern and Wu, 2019) Indications show that those entrepreneurs who considers and experiment various options to pursue commercialization have higher chance of success, even more improved when involving mentorship guidance in decision process to absorb best possible alternative outcome. (Agrawal, Gans and Stern, 2020)

2.2 Stakeholder Engagement and Commercialization Networks

Commercialization is not only an internal firm activity, but a networked process in which external actors contribute to adoption, diffusion and market creation. Customers, users, suppliers, distributors, investors, public organizations, regulators and expert communities can perform practical commercialization tasks, provide credibility, support access to resources, shape adoption conditions and help create favorable market structures. (Aarikka-Stenroos, Sandberg and Lehtimäki, 2014) When dealing with academic based low TRL inventions it important to verify and validate through interaction means. Going to deep tech, markets are full of various impacting drivers like regulation which acts sometimes as market creation mechanism, followed by non-organized value chains and disorder formulating towards established business. As such stakeholders can enable academic entrepreneurs working mechanisms to refined assumptions and experiments from various market signals and approach problems with better aligned hypotheses of their idea value and solution. (Engez and Aarikka-Stenroos, 2023)

Commonly new ventures emerge through social interaction with actors such as financiers, customers, suppliers, employees and communities. For low-TRL AEs, stakeholder engagement is not only about listing relevant actors, but about refining and iterating the opportunity, identifying who has relevant power, legitimacy and urgency, and gradually enrolling actors whose contributions can turn an imagined opportunity into a credible venture pathway. (Mitchell *et al.*, 2021) In universities such early groups are often guided through advisory groups of the projects, comparable to board of directors, just with different angles, business vs research aspirations.

To draft successful opportunities from assumptions, AEs must consider wider stakeholder environment in their venture journeys. Typically, strongest voice is carried by customers whose needs AE should focus to satisfy via

opportunity-actualization perspective to filter out non-market stakeholders that might constrain success in some cases. Early engagement with most relevant stakeholders has its crucial role in low-TRL stages of AEs experimentation journey utilizing Lean methods or similar. (Ramoglou, Zyglidopoulos and Papadopoulou, 2021)

2.3 Lean Startup, MVP Learning and Entrepreneurial Experimentation

To further understand methods of venture creation Lean Startup (LS) and associated MVP learning needs to be understood. Starting from basis of LS, which entails Build-Measure-Learn feedback loop and its fast paced Minimum Viable Product thinking. (Ries, 2011) Especially interesting is to know how early TRL level experiments should be crafted when available information is scarce in nature and might be false, which is partial critique towards LS which was created for manufacturing incremental setups not radical deep teach environments often faced by AEs where communication towards customer is not yet developed enough. One main trait of LS is also to push external validation strongly and leave less for hypothesis drafting to push faster outputs and pivoting. (Felin *et al.*, 2020) Further criticism can lead to constructive suggestion in which specific areas AEs should implement LS methods, for which stakeholder input is often fragmented due to early nature of commercialization process. (Leatherbee and Katila, 2020)

Challenges remain with communication and experimentation culture, though practice can be seen to positively affect business model regeneration and creation activities in the startups via faster dialogue simultaneously contributing hypothesis drafting, but for deep tech orientation, research need to continue further in this domain. (Bocken and Snihur, 2020b) To gain better results AEs should increase use of front-end learning process in validation of MVP pivots, finding right market domain, opportunities and stakeholder groups to support better hypothesis formation and stronger business and commercialization impact. (Shepherd and Gruber, 2021)

3. Conceptual Framing

In this study academic entrepreneurship and deep tech commercialization validation via stakeholders is viewed as iterative learning process and not linear technology transfer process. Key characteristics is non fully clear market opportunity, and not yet fully understood applications for technology, early pivoting stage experimentations both in technology and business models. Study aims to better understand how stakeholder interaction impacts the process, based on studies effect is not always positive and failures happen. Improving background relevancy of stakeholder with right information should in theory lead to stronger validation paths. The conceptual framing connects three literature streams: academic entrepreneurship and deep-tech uncertainty, stakeholder engagement and commercialization networks, and Lean Startup / MVP experimentation.

The main theoretical argument is that stakeholder engagement functions as a front-end hypothesis refinement mechanism before meaningful MVP validation can occur. The case analysis should therefore classify stakeholders by their contribution to commercialization learning, not only list them as contacted actors. Each stakeholder category can be assessed by the type of input provided: technical feasibility, market need, adoption barrier, business model option, value-chain access, credibility, regulation/IP, or investment logic. This framing prepares the case description by showing why the empirical case is analysed as a sequence of stakeholder-driven learning cycles.

3.1 Methodology Structure

This study applies an exploratory qualitative single-case design. A case study design is appropriate when the aim is to examine a phenomenon in its real-life context and when multiple forms of evidence are needed to understand how the process unfolds. (Yin, 2009) The case was selected because it represents an early-stage academic deep-tech commercialization process where technical development, stakeholder engagement and opportunity framing occurred in parallel. Rather than examining commercialization as a completed outcome, the study focuses on how commercialization assumptions were formed, challenged and refined during the early stages of pre-venture development. This makes the case suitable for theory-building purposes, as case studies can be used to identify emerging constructs and relationships in underexplored phenomena (Eisenhardt and Graebner, 2007). The aim is analytical insight into how stakeholder-driven learning supports early commercialization pathway development.

The empirical material was collected from several complementary sources, including internal team reflections, expert interviews and statements, workshops, ecosystem interactions, and desk research. Internal reflections

captured the initial technical logic, perceived benefits and early value assumptions of the academic team. Expert interviews and statements provided technical, commercial, IP-related and market-oriented assessments. Workshops supported collective sensemaking and reframing of the opportunity. Ecosystem interactions included input from commercialization support actors, incubator representatives, investors, events and advisory actors. Desk research and literature review materials provided external comparison and theoretical grounding.

The analysis followed an abductive thematic logic. Empirical observations were first grouped around recurring commercialization issues such as technical constraints, customer problems, adoption barriers, stakeholder credibility, value proposition assumptions and business model options. These observations were then interpreted through broader themes including entrepreneurial framing, stakeholder alignment, MVP learning and technical-commercial translation. The stakeholder classification in the case description was used to show how different actor groups contributed to commercialization learning across project phases. The emerging interpretation was finally compared with prior literature on academic entrepreneurship, stakeholder networks and Lean Startup experimentation.

3.2 Project Case Description

The empirical setting is a university-based low-TRL technology commercialization case, based on decades of special material research translated into motion technology for robotics domain. (Kulagin *et al.*, 2022, 2024) The main concept idea was initially developed in a research environment, where technical potential had been demonstrated with small scale demos, but commercial use contexts, customer needs, adoption barriers and business model options were highly uncertain and required a project to advance commercial angle. The case therefore represents an early-stage academic entrepreneurship setting in which technical advancement precedes market clarity. In this case researchers are interpreted to be similar to academic entrepreneurs but not yet working in startup company. Early market validation showed promise of feasible business opportunities which led to project funding. Project length was two years (before, early, mid, late, post phases).

Table 1: Identified stakeholder groups, role, contribution type and project phase estimation during project.

Stakeholder Group	Role in MVP Development	Role in Commercialization	Contribution Type	Project Phases
Core Internal Project Stakeholder Landscape				
Academic entrepreneurs = core project team	Define PoC architecture, run experiments, modelling, integration	Frame value propositions, coordinate stakeholder engagement, business modelling	Technical + orchestration + framing	All phases
Technical researchers / engineers (PhD, MSc, specialists)	Technology design, simulation, control systems, validation	Translate technical features into application-level capabilities	Deep technical knowledge	Before, all phases
University ecosystem actors	Provide infrastructure, labs, procurement, support services	Support IP strategy, commercialization planning, funding alignment	Institu-tional + support	Early - mid phase
External research partners	Provide domain expertise (MSM materials, coils, modelling)	Increase credibility and validation for external stakeholders	co-deve-lopment	Early TRL valida-tion
Market-Facing and Validation Stakeholders				
Industrial companies (potential customers / OEMs)	Provide constraints for design such as performance and integration limits	Validate use cases and define application-specific requirements	Contextual validation	Mid phase / post-
Component suppliers (materials, coils, machining)	Enable physical PoC through materials and manufacturing	Define scalability constraints and cost structure	Supply chain + feasibility	Early - mid
System integrators / engineering partners	Help integrate actuator into larger systems	Enable pathway to industrial adoption	Integration capability	Mid late
End-user domain experts (aerospace, medical, robotics)	Provide indirect input through requirements and constraints	Identify high-value niche applications	Application knowledge	Mid phase

Stakeholder Group	Role in MVP Development	Role in Commercialization	Contribution Type	Project Phases
Industrial companies (potential customers / OEMs)	Provide constraints for design such as performance and integration limits	Validate use cases and define application-specific requirements	Contextual validation	Mid phase / post-
Commercialization and Funding Ecosystem				
Investors	Indirect influence through expectations on proof level	Validate business potential and define funding thresholds	Business validation + capital	Mid - late
External experts / consultants	Provide targeted insights on market, IP, and industry structure	Support positioning and competitive benchmarking	Analytical intelligence	Mid phase
IP service providers	Define invention technical boundaries	Enable protection strategy and white-space positioning	Legal / strategic IP	Early - mid
Funding bodies	Define reporting structure and KPIs	Shape commercialization pathways and expectations	Institutional validation	All phases
Ecosystem and Learning Stakeholders				
Events	Provide exposure to benchmarks and competing solutions	Support market sensing, networking, and positioning refinement	Ecosystem intelligence	Continuo us
Internal cross-functional team (business + tech)	Translate PoC into communicable concept	Align technical capability with market narratives	Iterative framing	All phases

The case process involved multiple input channels: internal team discussions, expert statements, university support services, workshops, investor discussions, possible customer and supplier contacts, public events, website-based interest collection, visual concept materials, patent and desk research, and MVP-oriented validation tools such as Lean Startup. These inputs were used to iteratively refine the value proposition and validate commercialization pathways for the novel technology.

4. Findings

Based on literature review and case context following comparison table have been drafted and findings per each identified core observation. These comparisons and findings are preliminary and should be investigated more further and deeply with further studies to increase credibility, currently providing limited perspective on one case study which has limited amount of special skills and team compositions as well as ecosystem and good example of highly novel material deep tech concept and attempt to commercialize it.

Table 2: Literature vs. case comparison & findings interpretation

Literature Expectation	Case Observation	Finding
Academic entrepreneurship involves uncertainty, unclear applications and limited commercialization capability (Grimaldi *et al.*, 2011; Micol, Leendertse and van Rijnsoever, 2026)	The case started from advanced material-based motion technology with technical promise but unclear commercial use context.	The case supports the literature: technical potential existed before market clarity.
Experimentation helps reduce uncertainty, but resources limit how many paths can be tested (Gans, Stern and Wu, 2019)	The project had to compare possible application domains, customer groups, MVP directions and business model options.	Stakeholder input helped narrow strategic options rather than produce one final answer.
Mentorship and external guidance can improve commercialization decision-making (Agrawal, Gans and Stern, 2020)	University support actors, experts, consultants, investors and ecosystem actors helped interpret commercial direction.	External input supported decision-making when it was connected to specific commercialization choices.
Commercialization is networked and depends on external actors such as customers, suppliers, investors and support organizations (Aarikka-Stenroos, Sandberg and Lehtimäki, 2014)	The case involved technical researchers, university actors, customers/OEMs, suppliers, investors, IP experts, events and support organizations.	The case confirms that early commercialization is distributed across a stakeholder network, not handled only by the academic team.
Stakeholders shape markets, adoption conditions and value-chain formation in	Various stakeholders contributed information about integration limits,	Stakeholder engagement helped translate the technology into

Literature Expectation	Case Observation	Finding
deep-tech settings (Engez and Aarikka-Stenroos, 2023)	supply-chain feasibility, application constraints, credibility and funding best practises.	possible market and value-chain positions.
Stakeholder identification is entrepreneurial action, not only stakeholder listing (Mitchell *et al.*, 2021)	Different stakeholders had different usefulness depending on timing and ability to provide actionable input for the moment.	The case shows that stakeholder quality matters more than stakeholder quantity.
Lean Startup emphasizes fast validation, but weak hypothesis formation limits learning (Ries, 2011; Felin *et al.*, 2020)	Low-TRL technology was difficult to present as a simple MVP because customers could not always evaluate the technical potential directly.	MVP learning required prior stakeholder-supported hypothesis formation.
Front-end learning strengthens business model and opportunity development (Bocken and Snihur, 2020b; Shepherd and Gruber, 2021)	Internal framing, workshops, expert input and stakeholder discussions helped convert technical capability into more specific value propositions.	The case supports the idea that stakeholder engagement functions as a front-end learning mechanism before MVP validation.

Based on the findings, clear trait for AEs is not having early defined market opportunity for which stakeholder exposure can be efficient tool or mechanism to bring technical concepts closer to the markets. Secondly, not all stakeholders are relevant to answer all questions and there should be systematic plan to divided certain themes like customer need to specific stakeholders like industrial partners and then technical validation questions to engineering stakeholders to maximize efficient process. Case project received a lot of input and feedback during all stages, from beginning concept was very limited, but by the end picture was formulating strongly and supporting evidence to make further decisions was possible to the level of business plan and possible spinout to specific market areas with specific value propositions. This was possible because of the input that shaped idea along the way, especially angles that emphasized commercial business logic and solving customer pains (from industrial advisory board stakeholders).

Fourth finding was technical oriented and required experimentation to figure out proper communication strategy to explain the benefits and viability of the concepts without having actual product. This included the most intensive knowledge transfer and synthesis from various stakeholders and multiple perspectives to find suitable angles, like power density or low voltage claims benefits. Even here it was hard to find business related logic at first, but eventually via interactions ideas started to formulate. As final findings, stakeholders and MVP building provided enough information to formulate efficient statements like product market fit, and which information needs to be gained / validated for next stages.

4.1 Answers to Research Question and Subquestions

RQ: Iterative & nonlinear stakeholder engagement shapes commercialization learning by turning an uncertain academic technology idea into a more structured commercialization pathway. In the case, stakeholder interaction helped the team refine application domains, identify market entry barriers, clarify value proposition assumptions, interpret technical constraints and adjust MVP/business model logic. Learning occurred through repeated cycles of internal framing, stakeholder exposure, feedback interpretation, technical-commercial translation and reframing.

SQ1: The most useful input was not general interest or opinion-based feedback, but contextual and actionable input. Useful stakeholder input included:

- Technical feasibility constraints
- Application-specific requirements
- Integration and system-level limitations
- Customer problem clarification (why would they buy the product?)
- Adoption barriers
- IP and freedom-to-operate signals
- Supplier and manufacturing feasibility (sourcing issues)
- Investor proof-level expectations
- Business model, earning and value-chain logic

SQ2: The case materials suggests that translation occurred through interpretation rather than direct adoption of feedback. Fragmented stakeholder input was processed through workshops, internal team discussions, expert comparison, desk research and business model tools. The team had to decide whether feedback should be accepted, rejected, parked or converted into a testable assumption.

SQ3: Stakeholder input influenced what should be tested technically and commercially. Technical validation made stakeholder discussions more credible, while stakeholder feedback helped define which technical demonstrations mattered commercially, or what pivot should be prioritized. Business model development was shaped by customer needs, integration requirements, supply-chain feasibility, investor expectations and IP positioning.

SQ4: Stakeholder engagement improves the commercialization pathway when it reduces ambiguity, creates testable assumptions, strengthens evidence for decision-making and helps the team choose the next feasible commercialization step.

Overall, the findings show that stakeholder engagement in low-TRL academic entrepreneurship should not be understood only as market validation. In the case, stakeholders acted as sources of contextual authority, technical-commercial translation, credibility and strategic filtering.

5. Conclusion and Results

Stakeholder validation in the academic entrepreneurship and low TRL MVP settings was examined in this study and how it shapes commercialization process. Starting from technical points and not market opportunity fits well academic setups with research findings and their early steps towards market readiness. To achieve successful ventures, AEs and other stakeholders within universities should pay attention to getting right feedback at a right time to ensure processes efficiency and spinout processes with relevant market product fit approaches and strategies to monetize on the inventions. For this, study has contributed to further identify stakeholders in one research to business process and how each actor contributes in the system towards successful commercialization which makes this attractive study addition to existing literature.

Remarks on the nature of stakeholder interaction is one main factor and how should be used strategically at a right time, to ensure right hypothesis are built with right stakeholders and the next step is targeted, and validation happens with again right stakeholder groups minimizing risks along the way. Quite often ventures fail to deliver proper product market fit with right value propositions either being positioned wrong or developed with non-sustainable fashion and this balancing mix with finding right steps is valuable strategic assets in decision making process for future AEs considering to spinout with their research ideas but lack proper knowledge and require this stakeholder interaction to verify statements.

5.1 Limitations and Future Research Directions

This study has several limitations. First, the analysis is based on a single deep-tech commercialization case, which limits statistical generalizability. The findings should therefore be interpreted as conceptual and processual insights into early commercialization learning rather than as general evidence of commercialization success. Second, the case was analysed during an early commercialization stage, meaning that final market outcomes, such as pilots, licensing, investment or spinout formation, could not yet be assessed. Third, stakeholder input was uneven, as some actors provided more detailed and actionable feedback than others. Researcher proximity to the case may also create interpretive bias, although the use of multiple data sources and comparison with prior literature partly reduces this limitation.

Future research should compare several academic deep-tech commercialization cases across different technology domains, institutional settings and TRL stages. Longitudinal studies would be especially useful for examining whether early stakeholder-driven assumptions later develop into validated pilots, investment decisions, licensing pathways or spinout creation. Further research should also develop clearer criteria for evaluating stakeholder input quality. Relevant criteria may include contextual authority, market relevance, technical relevance, decision impact and the ability to generate testable assumptions. Future work could also turn the proposed process model into a practical tool for supporting MVP, NABC and business model validation in academic commercialization projects.

Ethics Declaration

This study is based on professional discussion stored as project documentation, project reflections, workshops and stakeholder interactions related to an academic deep-tech commercialization case. The empirical material was analyzed at the project and stakeholder-group level, and no personal or sensitive data are reported in the paper.

AI Declaration

Artificial intelligence tools were used for language refinement, including sentence condensation, grammar correction and improvement of readability. AI was not used to interpret interview data, conduct the analysis, or generate the conclusions. All analytical decisions and final interpretations remain the responsibility of the authors.

Building Biodigital Clusters in Emerging Economies: A Conceptual Framework Integrating Technological Capabilities and Governance in the Pharmaceutical Sector

José Luis Meza de la Rosa and María del Rocío Soto Flores
Escuela Superior de Comercio y Administración, Unidad Santo Tomás, Instituto Politécnico Nacional, Ciudad de México, México

joseluis.mezad11@gmail.com
msotof@ipn.mx

Abstract: The emergence of artificial intelligence, biotechnology, advanced data analytics, and digital health technologies is transforming the pharmaceutical industry and reshaping the conditions under which innovation occurs. These developments are driving the formation of biodigital innovation ecosystems, where scientific knowledge, technological capabilities, governance arrangements, and institutional coordination become critical determinants of competitiveness and innovation performance. Despite the growing importance of biodigital convergence, existing literature has largely examined technological capabilities, innovation systems, cluster development, and governance as separate analytical domains. Limited attention has been devoted to understanding how these dimensions interact to support the emergence and consolidation of biodigital clusters, particularly in emerging economies characterized by institutional fragmentation, technological dependency, and uneven innovation capabilities. This paper presents the conceptual architecture of an ongoing doctoral research project that seeks to address this gap. The study proposes an integrative framework that combines three complementary perspectives: technological capabilities theory, governance theory, and innovation ecosystem approaches. The framework is designed to explain how technological capabilities and governance mechanisms jointly influence the development of biodigital clusters in the pharmaceutical sector. The proposed model conceptualizes technological capabilities as the ability of organizations and territories to acquire, absorb, adapt, generate, and reconfigure knowledge and technologies, while governance is understood as the set of coordination mechanisms that align actors, resources, institutions, and strategic objectives across multiple levels. The interaction between these dimensions is expected to facilitate knowledge flows, collaborative innovation, institutional learning, and ecosystem development. The research is particularly relevant in the context of emerging economies, where strengthening domestic innovation capabilities has become a strategic priority for technological sovereignty, industrial upgrading, and health resilience. Mexico provides a particularly interesting context due to recent efforts aimed at fostering innovation-driven industrial development and strengthening the pharmaceutical and biotechnology sectors.

Keywords: Industrial Clusters, Pharmaceutical Industry, Innovation Geography, Capabilities, Global Value Chains

1. Introduction

The pharmaceutical industry is undergoing a profound transformation driven by the convergence of artificial intelligence (AI), biotechnology, advanced data analytics and digital health technologies. Together, these advances are creating a biodigital paradigm in which biological knowledge and digital technologies reshape drug discovery, pharmaceutical research and industrial innovation, redefining the technological and institutional foundations of competitiveness.

This transformation reflects the broader dynamics of the Fourth Industrial Revolution, characterised by the integration of digital, biological and physical technologies into interconnected innovation processes. In pharmaceuticals, AI has become a strategic enabling technology for accelerating target identification, molecular design, toxicity prediction and clinical decision-making, while advances in genomics, synthetic biology, gene editing and precision medicine have expanded opportunities for therapeutic innovation. As a result, pharmaceutical innovation increasingly depends on the integration of diverse scientific and technological capabilities rather than on traditional research and development (R&D) activities alone.

Technological convergence is also reshaping the geography of innovation. Pharmaceutical innovation increasingly emerges within collaborative ecosystems involving universities, biotechnology firms, pharmaceutical companies, research institutes, regulatory agencies and digital technology providers. These interactions reinforce the strategic importance of industrial clusters as environments that facilitate knowledge exchange, collaborative learning and technological specialisation. However, in biodigital industries, geographical proximity alone is insufficient; effective innovation also depends on governance mechanisms, institutional coordination and strong technological capabilities.

For emerging economies, biodigital convergence offers opportunities for industrial upgrading, technological sovereignty and stronger health systems, while simultaneously exposing structural weaknesses associated with fragmented innovation systems and limited technological capabilities. Strengthening pharmaceutical competitiveness therefore requires integrated strategies that combine scientific investment with governance arrangements capable of coordinating multiple actors and supporting long-term capability development.

Although the literature has generated important contributions on technological capabilities, governance, industrial clusters and innovation ecosystems, these perspectives have largely evolved independently. Existing studies provide only partial explanations of biodigital transformation and offer limited understanding of how governance and technological capabilities jointly shape the emergence of biodigital pharmaceutical clusters, particularly in emerging economies. To address this gap, this paper proposes the Biodigital Cluster Framework (BCF), an integrative conceptual model combining technological capabilities theory, governance theory and innovation ecosystem perspectives. The framework conceptualises technological capabilities as dynamic processes through which organisations and territories acquire, integrate and reconfigure knowledge, while governance is understood as the multi-level coordination mechanisms that align institutions, actors and strategic objectives across pharmaceutical innovation ecosystems.

2. Literature Review

The transformation of the pharmaceutical industry reflects the convergence of artificial intelligence (AI), biotechnology, computational sciences and digital technologies into a new biodigital paradigm that is redefining innovation processes, industrial organisation and value creation. This transformation is consistent with Schumpeter's (1934) view of innovation as the engine of economic change and with Dosi's (1982) concept of technological paradigms, which explains how technological trajectories shape future innovation opportunities. Arthur (2009) further argues that technological evolution occurs through the recombination of existing technologies, providing a useful explanation for the integration of AI, biotechnology and computational biology in pharmaceutical innovation. Similarly, Perez (2002) interprets technological revolutions as systemic transformations that reshape production systems, institutions and industrial organisation. Recent OECD reports (2023; 2024) identify AI, synthetic biology and precision medicine as enabling technologies driving competitiveness, productivity and resilience. Nevertheless, current research continues to examine these technologies largely in isolation, providing only limited understanding of how their convergence reshapes territorial innovation dynamics.

The literature on technological capabilities explains why organisations differ in their ability to innovate by emphasising cumulative learning and knowledge accumulation. Lall (1992) defines technological capabilities as the competencies required to acquire, adapt and improve technologies, while Bell and Pavitt (1995) distinguish technological capabilities from production capabilities, arguing that innovation depends upon continuous learning rather than operational efficiency alone. Kim (1997), Figueiredo (2002; 2010) and Dutrénit (2004) demonstrate that these capabilities evolve progressively through learning, experimentation and interaction with external knowledge sources. Castellacci (2008) further conceptualises technological capabilities as multidimensional constructs integrating organisational learning, knowledge creation and innovation performance. More recently, Dynamic Capabilities theory (Teece, 2007; 2018) has extended this perspective by highlighting firms' ability to sense opportunities, seize emerging technologies and continuously reconfigure organisational resources. However, this literature remains largely focused on individual organisations and provides limited explanation of how capabilities are collectively developed within territorial innovation ecosystems.

Complementing this perspective, cluster and innovation ecosystem theories emphasise that innovation increasingly emerges through interactions among interconnected organisations rather than isolated firms. Porter (1998) highlights the competitive advantages of geographical agglomeration, while Regional Innovation Systems stress the importance of institutional interaction and regional learning (Cooke, 1998; Asheim and Gertler, 2005). Boschma (2005) further argues that innovation depends on multiple forms of proximity beyond geographical location, including cognitive, institutional and organisational proximity. More recent ecosystem approaches describe innovation as a dynamic process of value co-creation among interdependent actors (Autio and Thomas, 2014; Jacobides, Cennamo and Gawer, 2018), whereas Mazzucato (2018) emphasises the strategic role of governments in shaping innovation ecosystems through mission-oriented policies. Despite these advances, existing approaches provide only partial explanations of how AI, biotechnology and digital technologies jointly transform pharmaceutical innovation and territorial development.

Governance has consequently become a key concept for understanding how complex innovation systems coordinate heterogeneous actors operating across multiple institutional levels. Unlike hierarchical government, governance emphasises collaborative networks, institutional interaction and strategic coordination (Rhodes, 1997). Jessop (2002) further argues that governance evolves through the continuous interaction between institutional structures and strategic actors, enabling innovation systems to adapt to technological change. Importantly, governance extends beyond institutional coordination by encompassing the broader arrangements that shape collaboration, trust, decision-making and long-term ecosystem development. Although governance is widely recognised within innovation policy research, relatively few studies have explicitly examined how governance interacts with technological capability accumulation to explain the emergence of biodigital pharmaceutical clusters. This unresolved relationship constitutes the principal theoretical gap addressed by the conceptual framework proposed in this paper.

3. Conceptual Research Gap

The preceding literature review demonstrates that substantial theoretical progress has been achieved in understanding technological capabilities, governance, industrial clusters and innovation ecosystems. However, these research traditions have largely evolved as independent streams, each explaining a specific dimension of innovation while providing only limited insight into their interactions under conditions of biodigital technological convergence. The technological capabilities literature has generated robust explanations regarding how organisations accumulate knowledge, develop learning routines and strengthen innovation performance. Nevertheless, most capability-based studies focus primarily on firm-level learning processes and pay relatively little attention to the governance arrangements that enable capability accumulation across multiple organisations and institutions. Consequently, the broader ecosystem conditions supporting collective technological learning remain insufficiently theorised.

Conversely, governance literature has significantly advanced our understanding of institutional coordination, collaborative networks and public policy mechanisms. Yet governance studies generally conceptualise technological change as an external context rather than as a dynamic process that co-evolves with governance structures. As a result, the reciprocal relationship between governance and technological capability development has received comparatively limited theoretical attention. Research on industrial clusters and regional innovation systems has consistently demonstrated the importance of geographical agglomeration, knowledge spillovers and collaborative interaction in fostering regional competitiveness. However, much of this literature was developed before the emergence of artificial intelligence, computational biology and digital biotechnology as enabling technologies. Consequently, existing cluster theories only partially explain how technological convergence is reshaping spatial patterns of pharmaceutical innovation and creating new forms of biodigital ecosystems.

Finally, innovation ecosystem approaches have broadened the analysis beyond geographical proximity by emphasising value co-creation, complementarities and interdependence among heterogeneous actors. Nevertheless, current ecosystem frameworks frequently remain descriptive and provide limited analytical explanation regarding how technological capabilities, governance mechanisms and territorial conditions interact to produce sustained innovation performance within emerging biodigital industries. To synthesise the preceding discussion, Table 1 presents the principal theoretical contributions and limitations identified across the existing literature, thereby illustrating the conceptual fragmentation that underpins the need for an integrative biodigital cluster framework.

Table 1: Principal conceptual limitations in the existing literature

Literature Stream	Principal Contribution	Main Limitation for Biodigital Cluster Research
Technological capabilities	Explains organisational learning, knowledge accumulation and innovation capabilities	Primarily focuses on firms and pays limited attention to governance and ecosystem coordination.
Governance	Explains institutional coordination, collaborative networks and public policy	Does not explicitly incorporate technological capability accumulation or technological convergence.
Industrial clusters	Explains geographical agglomeration, knowledge spillovers and regional competitiveness	Developed largely before AI-driven pharmaceutical innovation and provides limited explanation of biodigital convergence.

Literature Stream	Principal Contribution	Main Limitation for Biodigital Cluster Research
Innovation ecosystems	Explains value co-creation, inter-organisational collaboration and ecosystem dynamics	Provides limited integration of territorial capabilities, governance and technological transformation within a unified analytical model.

4. Proposed Conceptual Framework

Building upon the conceptual gaps identified in the previous section, this paper proposes the Biodigital Cluster Framework (BCF) as an integrative conceptual model explaining how technological capabilities and multi-level governance interact to facilitate the emergence and evolution of biodigital pharmaceutical clusters in emerging economies. Rather than considering innovation as the outcome of isolated organisational efforts, the framework conceptualises biodigital clusters as complex adaptive systems in which organisations, institutions, technologies and territorial resources continuously co-evolve through collaborative learning and knowledge exchange. The proposed framework integrates four complementary theoretical perspectives. First, technological capabilities explain how organisations and territories accumulate, absorb and generate scientific knowledge. Second, governance theory explains how heterogeneous actors coordinate collective action through institutions, policies and collaborative arrangements. Third, innovation ecosystem theory provides the systemic perspective required to understand inter-organisational interactions. Finally, cluster theory contributes the territorial dimension through which geographical concentration facilitates knowledge spillovers and innovation dynamics.

Unlike previous conceptual models, the BCF assumes that technological capabilities and governance are mutually reinforcing rather than independent variables. Governance influences the development of technological capabilities by creating institutional conditions that facilitate collaboration, investment and knowledge exchange, while accumulated technological capabilities strengthen governance by increasing organisational maturity, collaborative capacity and strategic coordination. Consequently, biodigital clusters emerge through continuous feedback processes rather than through sequential stages of development. Figure 1 illustrates the proposed conceptual framework.

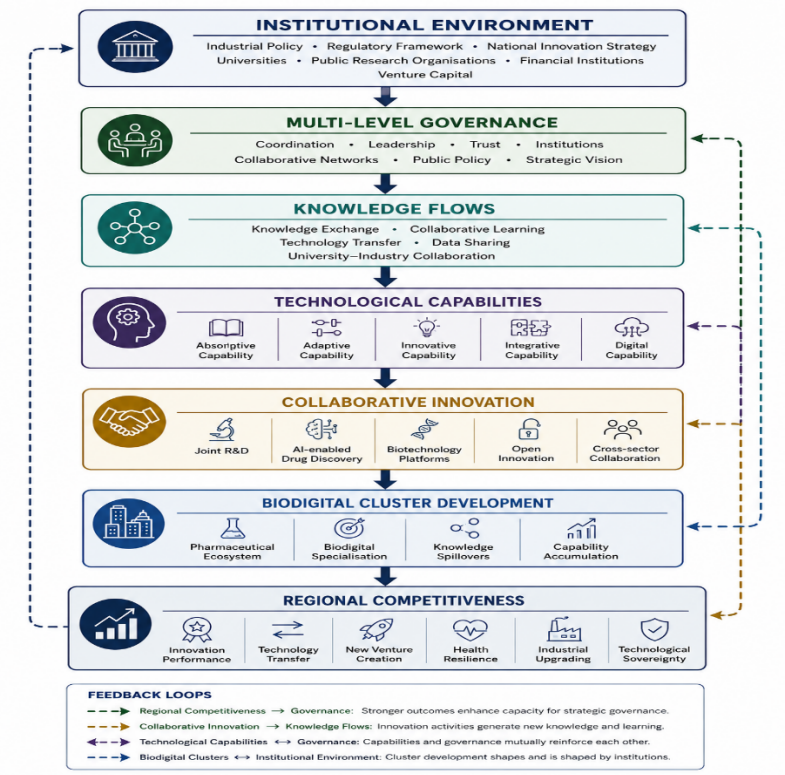

Figure 1: The Biodigital Cluster Framework (BCF): an integrative conceptual model for pharmaceutical innovation ecosystems in emerging economies.

Source: Authors' own elaboration using generative AI-assisted graphic design.

The framework assumes that biodigital innovation begins within a broader institutional environment composed of industrial policies, regulatory systems, universities, research organisations, financial institutions and public innovation agencies. These contextual conditions shape the opportunities available for collaboration, investment and technological learning. Rather than acting as passive background conditions, institutions actively influence the configuration and evolution of pharmaceutical innovation ecosystems.

4.1 Multi-Level Governance

Governance represents the central coordinating mechanism of the proposed framework. It is conceptualised as the set of formal and informal arrangements through which heterogeneous actors collectively organise strategic activities, allocate resources and coordinate innovation processes. Unlike traditional hierarchical governance models, biodigital governance is distributed across multiple organisational and territorial levels involving governments, universities, pharmaceutical companies, biotechnology firms, investors and regulatory agencies.

Five complementary dimensions characterise governance within biodigital clusters.

1. Coordination facilitates the alignment of strategic priorities among organisations with different objectives and capabilities.
2. Institutions provide stable formal and informal rules that reduce uncertainty, promote collaboration and support long-term investments.
3. Trust reduces transaction costs, facilitates knowledge sharing and strengthens collaborative relationships among ecosystem participants.
4. Public policy establishes strategic incentives, regulatory certainty and long-term industrial priorities that encourage technological investment.
5. Leadership enables collective vision-building, mobilises strategic resources and promotes ecosystem coordination around shared development objectives.

Together, these governance mechanisms create institutional conditions that support sustained innovation rather than isolated technological projects.

4.2 Knowledge Flows

Knowledge flows constitute the principal mechanism through which governance influences capability accumulation. Pharmaceutical innovation increasingly depends upon continuous exchanges of scientific knowledge among universities, biotechnology firms, pharmaceutical manufacturers, hospitals, regulatory agencies and digital technology providers. These interactions include collaborative research, data sharing, technology transfer, researcher mobility, open innovation initiatives and multidisciplinary learning processes. Within biodigital ecosystems, knowledge is simultaneously codified and tacit, requiring organisational capabilities capable of integrating biological sciences, computational methods, engineering, regulatory science and clinical expertise. Consequently, effective governance enhances both the quantity and quality of knowledge circulation throughout the ecosystem.

4.3 Technological Capabilities

Technological capabilities represent the endogenous innovation potential of organisations and territories. Consistent with capability theory, the framework conceptualises these capabilities as cumulative, dynamic and path-dependent processes that evolve through continuous learning and interaction.

Five complementary capability dimensions are incorporated into the model.

1. Absorptive capability refers to the ability to identify, acquire and assimilate external scientific and technological knowledge.
2. Adaptive capability reflects the capacity to modify existing technologies in response to changing scientific, regulatory and market conditions.
3. Innovative capability represents the ability to generate original products, technologies and scientific solutions through internal research and collaborative development.
4. Integrative capability refers to the ability to combine heterogeneous knowledge originating from biology, artificial intelligence, engineering, medicine and data science into coherent innovation processes.

5. Digital capability encompasses organisational competencies related to artificial intelligence, advanced analytics, cloud computing, digital infrastructures and computational modelling.

Collectively, these technological capabilities determine the capacity of organisations and regions to participate successfully in biodigital innovation ecosystems.

4.4 Territorial Conditions

The framework explicitly recognises that technological capabilities develop within specific territorial contexts. Biodigital clusters emerge where complementary actors coexist and interact through dense institutional networks.

Four territorial components are particularly important:

- **Universities and public research organisations** generate scientific knowledge and highly specialised human capital.
- **Pharmaceutical and biotechnology firms** transform scientific discoveries into commercial innovations while investing in technological development.
- **Government agencies** establish industrial policies, regulatory frameworks and public investment programmes that reduce uncertainty and encourage innovation.
- **Financial institutions** and venture capital organisations provide long-term funding required to commercialise emerging technologies and support high-risk innovation projects.

The interaction among these territorial actors generates cumulative knowledge spillovers that strengthen regional innovation performance over time.

4.5 Expected Outcomes

The final stage of the framework describes the expected outcomes associated with biodigital cluster development. These outcomes extend beyond firm-level innovation and encompass broader regional and societal impacts.

- **At the innovation level**, biodigital clusters increase collaborative research, interdisciplinary knowledge production and technological diversification.
- **At the industrial level**, stronger ecosystems facilitate technology transfer, accelerate AI-enabled drug discovery, stimulate the creation of biotechnology start-ups and strengthen participation in global pharmaceutical value chains.
- **At the territorial level**, biodigital clusters contribute to regional competitiveness through capability accumulation, employment generation, industrial upgrading and enhanced attractiveness for international investment.
- **At the societal level**, stronger biodigital ecosystems improve health resilience, accelerate responses to emerging public health challenges and reinforce technological sovereignty by reducing dependence on imported knowledge and critical technologies.

Taken together, the Biodigital Cluster Framework proposes that governance and technological capabilities should not be interpreted as separate determinants of innovation. Instead, they constitute interdependent and co-evolving processes embedded within territorial ecosystems that collectively shape the emergence, consolidation and long-term competitiveness of biodigital pharmaceutical clusters in emerging economies.

5. Implications and Conclusions

The Biodigital Cluster Framework (BCF) proposed in this paper contributes to the literature on pharmaceutical innovation by integrating theoretical perspectives that have traditionally evolved independently. While previous studies have examined technological capabilities, governance, industrial clusters and innovation ecosystems as separate analytical domains, the proposed framework conceptualises these dimensions as mutually reinforcing processes that collectively explain the emergence of biodigital pharmaceutical clusters in emerging economies. This integrative perspective responds to the increasing complexity of pharmaceutical innovation, where artificial intelligence, biotechnology and digital technologies are transforming not only research and development processes but also the institutional and territorial conditions under which innovation occurs.

From a theoretical perspective, the framework extends several established approaches. Unlike Porter's cluster theory, which primarily emphasises geographical concentration and competitive advantage, the Biodigital Cluster Framework highlights governance quality and technological capability accumulation as complementary determinants of cluster development. Likewise, although Regional Innovation Systems and Triple Helix models recognise the importance of institutional interaction, they provide only limited explanation of how emerging digital technologies reshape ecosystem dynamics. The proposed framework explicitly incorporates technological convergence and multi-level governance as endogenous mechanisms driving ecosystem evolution. Furthermore, it complements Dynamic Capabilities theory by extending the analytical focus from firm-level adaptation towards capability accumulation occurring across territorially embedded innovation ecosystems.

The framework also generates important implications for industrial and innovation policy. For emerging economies, strengthening pharmaceutical competitiveness requires moving beyond policies focused exclusively on research funding or scientific infrastructure. Instead, governments should promote integrated strategies that simultaneously reinforce technological capabilities, collaborative governance, regulatory quality and knowledge exchange among universities, firms, research organisations, financial actors and public institutions. Such systemic approaches may contribute to industrial upgrading, technological sovereignty and more resilient health systems.

From a managerial perspective, the framework suggests that pharmaceutical firms should increasingly regard innovation as an ecosystem-based process rather than an organisational activity undertaken in isolation. Developing absorptive and digital capabilities, participating in collaborative research networks and establishing strategic partnerships across scientific and institutional boundaries will become essential sources of long-term competitiveness within biodigital industries. As a conceptual study, this paper has inherent limitations. The Biodigital Cluster Framework has not yet been empirically validated and should therefore be interpreted as a theoretical architecture designed to guide future research rather than as a predictive model. Future studies should operationalise the proposed constructs and examine their relationships through structural equation modelling, comparative case studies and longitudinal analyses across pharmaceutical innovation ecosystems in different institutional contexts.

In conclusion, the Biodigital Cluster Framework provides a novel conceptual contribution to understanding pharmaceutical innovation by demonstrating that governance and technological capabilities should be interpreted as co-evolving processes embedded within territorial innovation ecosystems. By integrating these dimensions into a single analytical model, the framework offers a comprehensive perspective for explaining biodigital transformation and establishes a conceptual foundation for future empirical research on innovation policy, regional development and pharmaceutical competitiveness in emerging economies. Beyond its application to the pharmaceutical industry, the Biodigital Cluster Framework contributes to the broader field of Innovation Studies by proposing a conceptual lens through which technological convergence, governance and territorial capability accumulation can be understood as interdependent processes shaping industrial transformation. As artificial intelligence and biotechnology continue to redefine innovation across multiple sectors, the framework offers a transferable analytical foundation for future comparative research on biodigital ecosystems, industrial policy and regional development in emerging economies.

Ethics Declaration

This study is conceptual in nature and does not involve human participants, personal data, animal experimentation, or any procedures requiring ethical approval. Therefore, formal ethical clearance was not required.

AI Declaration

Artificial intelligence tools were used exclusively to support language refinement, structural organisation, editorial revision, and the graphical development of Figure 1 (Biodigital Cluster Framework) during manuscript preparation. The conceptual design of the framework, the theoretical integration, the interpretation of the literature, and all scientific arguments presented in this paper were entirely developed, critically reviewed, and validated by the authors.

Benefits Management Model in the Industry 5.0 Era

Liliana Anacleto Silva
ISCTE-IUL University Institute of Lisbon, Lisbon, Portugal

laccs@iscte-iul.pt

Abstract: The Industry 5.0 Era has introduced greater complexity across both business and technological domains, characterised by continuous evolution and an increasing emphasis on human and machine collaboration. In this context, organisations are required to enhance their capacity for rapid and innovative responses to emerging dynamics. Managers, therefore, rely on advanced technologies to strengthen analytical capabilities, enabling data-driven insights and timely, well-informed decision-making grounded in historical evidence. The integration of human expertise with augmented intelligence enhances organisational value creation and reinforces a human-centric perspective. What opportunities and challenges does this new context present for the methodology? Could Augmented Intelligence offer advantages by supporting managers in applying Benefits Management more effectively? The Cranfield School of Management's Benefits Management methodology offers a structured framework to guide strategic decision-making in complex projects, that is more focus on financial benefits, and, in Industry 5.0, it's a research gap because isn't focus on human centric. This research aims to explore the opportunities and challenges of this new context, proposing an enhanced Benefits Management model that prioritises human-centric value, sustainability, resilience, and continuous feedback, supported by augmented intelligence. The research will use the Preferred Reporting Items for Systematic reviews and Meta-Analysis Method in Literature Review and the Design Science Research Methodology to produce scientific knowledge by creating, developing, and evaluating one model. The model will be validated with people involved with Industry 5.0 and Benefits Management in organisations from different sectors (predominantly in the tertiary sector), for example, Decision Makers, Intermediate and Senior, Strategy and Innovations and Benefits Project Managers from sectors like Information and Communication Technologies, Finance and Banking, and Health. The data will be analysed, and the feedback will be incorporated into the model indicating the benefits identified, the different between the sectors, if exist and the opportunities that can be explored. It will be also suggestions future research that can be done and sector where the model can be applied. The expected contribution of this research is to have a Benefits Management Model improvement to provide an answer for the challenges of Industry 5.0.

Keywords: Industry 5.0; Benefits Management; Augmented Intelligence; Digital Transformation; Organisation Change.

1. Introduction

The way technology changes quickly and impacts humans, the way artificial intelligence automates repetitive processes, and the way we can learn more rapidly with artificial intelligence, motivate us to learn more and investigate these areas that can combine human intelligence and augmented intelligence. How can humans and machines collaborate to create value?

The emergence of Industry 5.0 has introduced a new paradigm centred on people, resilience, and sustainability, while the growth of augmented intelligence is profoundly transforming how organizations operate and make decisions. In this context, companies are challenged to rethink their business models and processes to ensure their relevance, efficiency, and value creation capacity.

Despite this transformation, there is a gap in how projects are evaluated and how benefits are identified, measured, and managed in environments characterized by high complexity, rapid change, and a strong technological component. Traditional Benefit Management approaches may prove insufficient to support rapid and informed decisions in this new context.

The problem arises of understanding how benefits management can be adapted or redefined in the context of Industry 5.0, to support more agile, effective decision-making oriented towards the creation of sustainable value in organizations. The Benefits Management Model expected to be improved with augmented intelligence processes that will increase the decision makers capacity to identify and control the Benefits Management project considering the Industry 5.0, adding the focus on Human-centric and resilience factors.

This research will be important for those conducting investigations in this area and for people who work in the Technology and Management areas, focusing on decision-makers and managers who need to determine project Benefits management.

2. Literature Review

This chapter describes the state of the art on the following topics: Industry 5.0, Augmented Intelligence, Benefits Management, and Industrial Sectors.

2.1 Industry 5.0

The evolution from Industrial 1.0 to Industry 5.0, from 1765 to 2020, Figure 1 (Kovari, 2024), starting with the use of Machinery in Industry 1.0, using Mass Production and Electricity in Industry 2.0, Computers & Automation in Industry 3.0, the Internet and Machine Learning in Industry 4.0 and Human Machine Co-operation and Cognitive System in Industry 5.0.

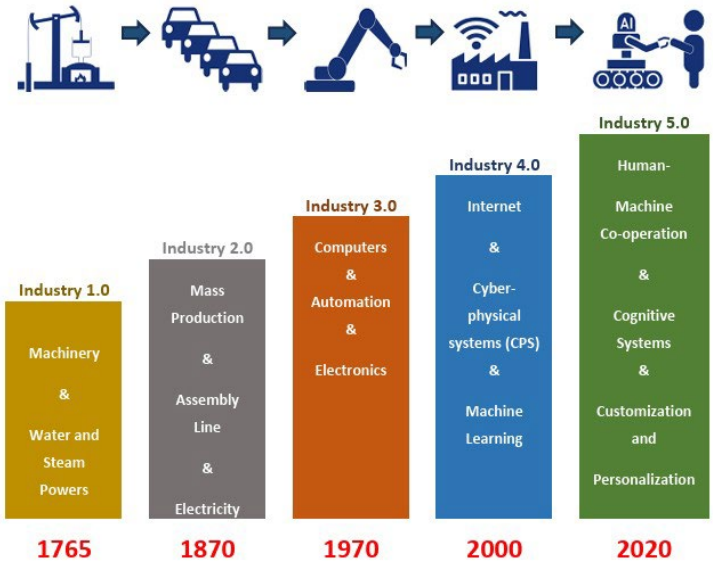

Figure 1: Industrial Revolution (Kovari, 2024)

According to Xu et al. (2021), Industry 4.0 is considered technology-driven, while Industry 5.0 is value-driven. Industry 5.0 centres around three interconnected core values: human-centricity, sustainability, and resilience (Figure 2).

Figure 2: Industry 5.0 (Xu et al., 2021)

It builds upon the advancements of Industry 4.0 by emphasising human well-being, environmental sustainability, and the creation of societal value beyond economic growth. People will develop new roles as a shift in value and need to upskill and reskill themselves for better career opportunities and work-life balance. Technology is to serve people and societies. Pinto et al. (2024) mention that it is critical to develop continuous learning and skills in emergency technologies, learning interdisciplinary skills, and contributing to multidisciplinary teams.

In the context of the Industry 5.0 paradigm, which advocates a human-centred approach to technological innovation, (Santos, Freitas and Fernandes, 2025), refer to the importance of balancing innovation, emotional resilience, cooperation, and social engagement skills and give relevance to continuous innovation, ethical considerations, and social and environmental sustainability are deeply intertwined, necessitating a balanced skill set that includes technological proficiency, creativity, emotional intelligence, adaptability, empathy, collaborative ability, effective communication, and leadership. Longo et al. (2020) mention that Industry 5.0 can be the Age of Augmentation, where Human-machine symbiosis enables collaboration in manufacturing (Figure 3).

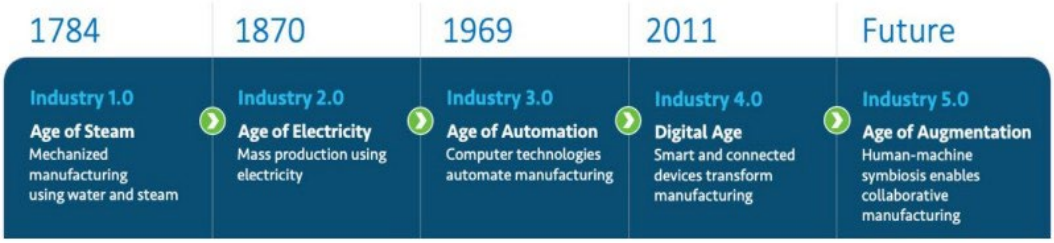

Figure 3: Fifth Industrial Revolution or Industry 5.0 (Longo et al., 2020)

Leng et al. (2022) mention that exploration of Industry 5.0 is still in an initial stage, and research findings are relatively scarce and less systematic. Piccarozzi et al. (2024) mention that there exists a relation between Industrial 4.0 and Industrial 5.0, emphasised by enabling technologies that will have challenges and opportunities. Industrial 4.0 creates the foundation for industrial 5.0, as it was done for the other previous industrial revolutions. Rieder and Schmuck (2024), in their article, refers that it was not possible to prove that Industry 5.0 will have an impact on companies' processes, but mention that Industry 4.0 had.

According to Ivanov (2023), Industry 5.0 is a combination of organisational principles and technologies to design and manage operations and supply chains as resilient, sustainable, and human-centric systems. Mention that the major technological principles of Industry 5.0 are collaboration, coordination, communication, automation, data analytics processing, and identification.

2.2 Augmented Intelligence

Augmented intelligence (also known as intelligence augmentation or cognitive augmentation) is the next level in artificial intelligence. The ultimate objective of augmented intelligence is to use machines to enhance the work, expertise, and experience of a human user or worker. Augmented intelligence is also known as intelligence amplification, cognitive augmentation, intelligence augmentation, machine augmented intelligence, or enhanced intelligence. It is essentially artificial intelligence (AI) with a twist. It refers to the creation of a close-to-human autonomous intelligence using modern technology. (Sadiku et al., 2021)

2.3 Benefits Management

A benefit is the advantage of a stakeholder or a particular group of stakeholders (Ward and Daniel, 2006). According to Ward and Daniel (2012), Benefits Management is an important process to ensure that the potential benefits of an implementation are identified and managed to achieve the objectives. It is important to organise and manage these benefits to maximise the positive results of technology implementation. The costs associated with investments in information systems should be identified, and the potential benefits and feasibility should be analysed (Oh, 2007).

Benefits Management complements and integrates with other areas and methodologies of Management, see Figure 4, such as Strategic Planning, Project, Program, and Portfolio, Investment Evaluation, Risk Management Techniques, Project Management Methodologies, Systems Development Methodology, and Change Management Methods.

Figure 4: Integration of Benefits Management (Ward and Daniel, 2006)

The Cranfield School's Benefits Management approach (Ward and Daniel, 2006) has 5 phases, which are represented in Figure 5.

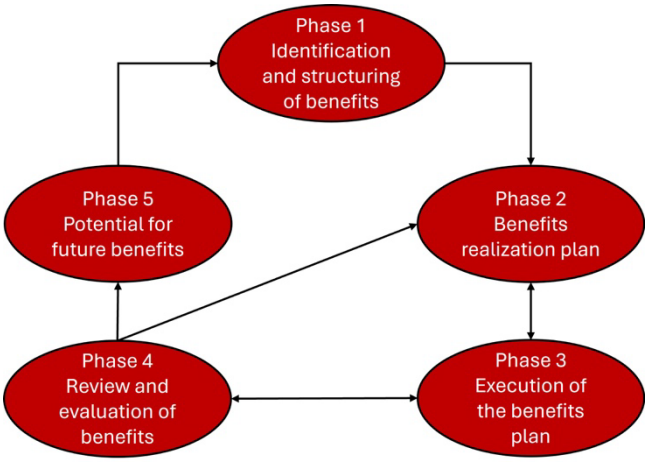

Figure 5: Benefits Management Process (Ward and Daniel, 2006)

2.4 Industrial Sectors

Industry 5.0 has impacted society, in different sectors and at different levels. Organisations must constantly innovate and adapt to emerging new technologies, adapting their organisational processes, the way they communicate with their customers, and becoming more competitive to meet the needs of increasingly demanding customers who want access to information and to make purchases at any time of day and from anywhere.

Covid forced companies to accelerate digital transformation because they had to reinvent their businesses, making them more digital to reach their customers more quickly and easily. Many businesses had to reassess their business processes, models, and systems. (Mihu et al., 2023).

Digital transformation has become a driver of business development, reshaping sectors and redefining the ways companies work. Companies are increasingly adopting digital technologies, such as Cloud, Artificial Intelligence, IoT, and data analytics (Big Data), to optimise operations, improve customer experience, and drive innovation (Joel et al., 2024).

The World Economic Forum (2026) presents the estimated industry growth potential by 2030, based on the World Economic Forum, Executive Opinion Survey 2025, and International Monetary Fund (IMF), indicate the sectors that will potential growth, such as IT Services, Medical and Healthcare Services, Financial Services, Professional Services, and Telecommunication.

Bartuś et al. (2025) have done research in five sectors (IT, automotive, industrial, service, and banking/financial) and defined the Model for implementing the assumptions of Industry 5.0 in organisations, with new insights into the practical implementation of Industry 5.0. Benefits such as improved product quality, increased production efficiency, and cost optimisation are primarily recognised by companies in the IT and industrial sectors. The research recommendations mentioned that there is space for more investigation in this area to explore in more detail.

Some sectors will be more impacted by Industry 5.0, with more transformation, whether due to technological intensity or the need to balance automation, human intervention or sustainability. Below are some transformations that have been happening in different sectors.

2.5 Financial Sector

Banks have also become digital, allowing people to conduct their transactions without having to go to a physical location. It is possible to perform all operations through an application on a cell phone or laptop, such as creating a savings account, term deposit, checking transactions, making transfers, contacting the account manager, sending documentation in digital format, consulting and purchasing insurance, real estate, and processing purchase and sale contracts.

New business areas have been developed, such as FinTech (Financial Technology), with the creation of digital financial products and services, investments, loans, and financial management, which currently use technologies such as artificial intelligence, data analysis, and automation. Another business area that has been developed is RegTech (regulatory technology), which allows companies to use technology to comply with regulations in an automated and efficient way (Osei et al., 2023).

2.6 Healthcare Sector

The healthcare sector has been undergoing a major digital transformation, using technology for research, platforms that provide comprehensive user information, centralised hospital information management, and staff work organisation, as well as hospital management of all products and services used (Kraus et al., 2021).

The Healthcare 5.0 brings the transformation of healthcare with the introduction of the Internet of Things (IoT), Artificial Intelligence and 6G Communication together under the principles of Industry 5.0, the human-centered, sustainable, and resilient. (Younesi et al., 2025)

2.7 Professional Services Sector

Many service organisations continue to use various Excel files and Microsoft Project to manage the day-to-day management of leads, business development, project management, and resource management. Professional Services Automation (PSA) platforms can help organisations centralise and standardise information (Sharif, 2002). According to Wang and Swanson (2007), a PSA platform proposes to help service-oriented organisations manage their projects and employees. PSA allows to automate a set of repetitive process activities that can take time away from professionals to focus on activities that require more skills (Sampson, 2021).

The organisational context needs to be prepared to have the human in the middle of a strategic decision. The correlation between machine and human tends to grow, and the business and human process needs to be optimised, being more agile in data analysis (Ladaga et al., 2025). With the Professional Service Automation tool, it will be more efficient the human resource management with more information regarding the projects, skills, and it's a tool that will help the economic and financial organisation context. Salvadorinho et al. (2024) suggest that organisations should have a platform with three pillars: Protean Career Attitude (empowering employee to take the responsibility for planning and advancing their professional careers); Learning Organisation (fostering knowledge sharing and collaboration while providing structured learning paths to drive growth and innovation), and participatory design (engaging employees in decision-making processes to innovate and create a more user-centred workplace). These pillars align with Industry 5.0 core pillars, resilience, human-centricity, and sustainability.

3. Conclusion of Literature Review

The Industry 5.0 brings changes to organizations which are more focused on human-centric and the cooperation between humans and machines. The Industry 5.0 is related with the augmented Intelligence, expanding the human capacity with more information, using technological tools, like professional service automation, helping organisations improving and be more efficiency, and prepare to capture benefits. The Benefits Management Model for Industry 5.0 can be derived designed from the Cranfield Benefits Management Model since it is a structured model with many years and that can be improvement with challenges and opportunities for Industry 5.0 focus on human centric and augmented intelligence.

The articles identified during the literature review were more focus on Industrial 5.0 in manufacturing and less on service organisation.

4. Objectives

The objective of the research is to design, develop, and evaluate a Benefit Management Model to foster the Industry 5.0 Era.

The research will have as sub-objectives the following points:

- Analyse the state of the art of Benefits Management in the context of Industry 5.0 Era, identifying the gaps and challenges of Benefits Management in the Industry 5.0 Era
- Define the guidelines for Integrating of Industry 5.0 dimensions into Benefits Management and incorporate Augmented Intelligence into Benefits Management Processes
- Design and develop a Benefits Management Model to incorporate Industry 5.0
- Demonstrate how the model supports Benefits Management in different sectors
- Evaluate the proposal Benefits Management Model in different sectors

4.1 Research Questions

The main objective of this study will be to provide answers as pertinent as possible to the following questions:

Which Benefits Management Model will be suitable for the Industry 5.0 Era?

The thesis will have as sub-questions that we would like to provide an answer to:

- What are the challenges and opportunities for the Benefits Management in context of Industry 5.0?
- What design principles should guide the development of the Benefits Management Model aligned with Industry 5.0?
- How can a Benefits Management Model be design and develop to address the Industry 5.0?
- How can the proposed Benefits Management Model be demonstrated in organisations context?
- How effective and useful is the proposed Benefit Management Model in supporting value realisation and decision-making within Industry 5.0 contexts?

5. Research Methodology

Industry 5.0 presents a set of both challenges and opportunities that are expected to reshape not only the nature of work but also the tools and technologies that underpin everyday activities. According to Rane (2023), the case of ChatGPT exemplifies this duality across Industry 4.0 and Industry 5.0 within different sectors. On the other hand, they raise significant concerns, particularly regarding the ethical implications of algorithmic decision-making. Nevertheless, they simultaneously create opportunities, such as strengthening fraud prevention mechanisms in the financial sector. The evolution of Industry 5.0 is closely linked to innovations enabled by augmented intelligence. Augmented intelligence integrates human and artificial agents within a socio-technological system, where both entities co-evolve by continuously learning and optimising decision-making processes. This interaction is increasingly facilitated through intuitive modalities, including conversational and voice-enabled interfaces (Bousdekis et al., 2025). The thesis will have a Literature Review to see the State of the Art regarding Benefits Management, Industry 5.0, and Augmented Intelligence. The Benefits management models that exist will be identified. A case study will be done in one organisation to apply the Benefits Management Model and evaluate the improvements that can be made to the model in the context of Industry 5.0, seeing what can be incorporated regarding resilience, human focus, and sustainability. This organisation is working on Industry 5.0, focusing on human and machine collaboration. To continue the doctoral research, the

universe of organisations and different sectors that are working on Industry 5.0 and the universe that makes sense for the thesis research. Afterwards, the challenges and opportunities that Industry 5.0 brings to Benefits Management for organisations from different sectors.

Based on the state of the art and the interviews that will be done with the organisations' representatives and other domain experts, a new Benefits management model will be proposed to incorporate the innovations related to Industry 5.0 and augmented intelligence. After, a Focus Group will be done with people from organisations from different sectors to validate the model and analyse what they have in common and what the differences are between them. The feedback received will be incorporated into the model.

5.1 Research Techniques

The Descriptive Method was used to compile the information collected on the state of the art. A Systematic Literature Review using the Preferred Reporting Items for Systematic reviews and Meta-Analysis (PRISMA) Method (Moher et al., 2010) will be made.

It was used indexed scientific databases to search for scientific articles, for example, Scopus and Web of Science, where we can find references for articles, conferences, and books related to science, technology, humanities, and other themes. We are planned to use the search strings like Industry 5.0 on Web of Science (https://www.webofscience.com/wos/woscc/summary/7a753cc0-f3cb-4edc-a8f3-55a9e0287047-019d0d4182/3bdca765-e051-47ad-bb17-6237b3a90d8b-019d0d4123/relevance/1); or string search by Industry 5.0 on Web of Science refine by Published Years between 2026 and 2022; Document Types: Review Article (https://www.webofscience.com/wos/woscc/summary/0b4202e9-fda4-446c-a534-3e4344c4670d-019d104b33/3bdca765-e051-47ad-bb17-6237b3a90d8b-019d0d4123/relevance/1). We are planned also to search by Benefits Management and join with Industry 5.0 and Augmented Intelligence. We will considering the latest articles, with peer review. The Literature Review will contribute with the state of the art and the gaps to support the research.

5.2 Case Study Methodology

According Njie and Asimiran (2014), the Case Study Methodology is a good choice in Quality Methodology because bring answers to the how and why of conundrums. Case study research involves a detailed and intensive analysis, and its focus is on a specific event, situation or organisation. (Schoch, 2020). A case study is an analysis made over a certain time period. Case studies tend to be selective, focusing on one or two issues that are fundamental to understanding the system being examined. (Tellis, 1997). The Case Study research has six steps: Plan, Design, Prepare, Collect, Analyse, and Share. These steps should be an iterative process to get more information. (Yin, 2009). In this research, a case study in one organisation will be applied to identify requirements to create a Benefit Management Model, incorporating the impact and the innovation of Industry 5.0 and the integration of Benefit Management in the 5.0 context.

5.3 Design Science Research Methodology

Design Science Research Methodology will be used to produce scientific knowledge by creating, developing, and evaluating of the proposal model. The Design Science Research methodology will follow the next six phases according to the approach of Peffers et al. (2007), which we can also see in Figure 6.

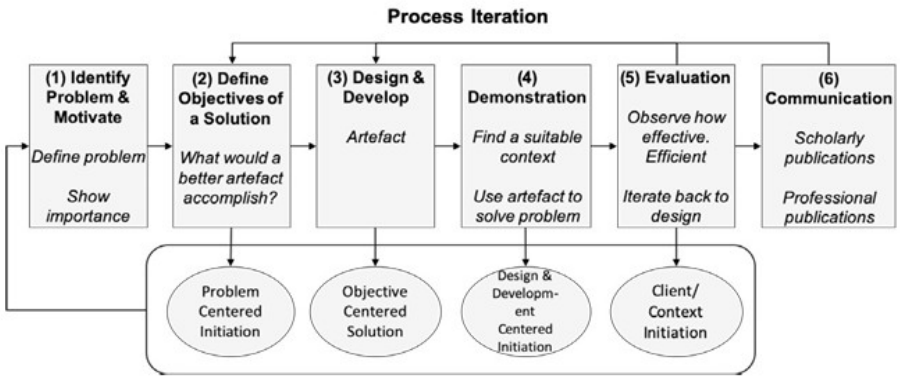

Figure 6: Design Science Research approach Peffers (Delport et al., 2024)

It was identified the problem and the motivation for this research. The Literature review helps to identify the gaps and challenges. The objectives and research questions were aligned with the Design Science Research Methodology. For the design and develop, we will analyse the Benefits Management model that already exists during the literature review and will design and develop a Benefits Management model for the Industry 5.0 era. After will demonstrate the proposal model in different sectors (predominantly in the tertiary sector), using the interview method. It will be identified at least two sectors that are in the listed-on top of potential grow sectors and that have the characteristics of Industry 5.0 and make projects, for example, Information and Communication Technologies, Finance and Banking, and Health. After, it will made the Model evaluation in different sectors using the Focus Group.

5.4 Qualitative Method

It will use qualitative design research using a descriptive method, interview, observation, and interpretation techniques.

5.5 Interview

Semi-structured interviews will be carried out, and prior preparation of the questions to be asked will be made. The interview technique will be used to obtain information from the areas involved and impacted. It is intended to identify information to evaluate the challenges and opportunities that Industry 5.0 causes in companies that have professional services and that use Benefits management processes. It will include questions regarding the use of the Benefits Management Model to evaluate and enrich the model with the improvements that make sense to incorporate.

It will be identified a company in the sector selected for the research and it will be selected the participant for the interviews that are involved with Industry 5.0 and Benefits Management in organisations, with the roles of Decision Makers, at Intermediate and Senior Level. The interviews will be scheduled in advance, indicating the purpose of the interview. The interview will be done face-to-face, in a one-on-one meeting, conducted by the researcher. (Creswell and Creswell, 2023). Each of the interviews will be recorded through Video and Audio, with authorisation requests, to be used later in data analysis. After collecting the data from the interviews, a qualitative analysis will be made using Gioia Methodology, to provide an answer to the research questions, bringing credibility to the research done and a structured approach to the research, to bring more academic knowledge and organisational knowledge, with the goal of generating a new model. It followed the Steps of Gioia methodology (Gioia et al., 2013): Research design, Data Collection, Data Analysis and Grounded Theory Articulation.

5.6 Focus Group

The Focus Group technique will be employed to validate the proposed Benefits Management Model and to collect further insights into Industry 5.0. This includes examining how organisations apply Benefits Management, the practices adopted, the challenges and opportunities that Industry 5.0 entails, and the emerging technologies that may be integrated within this paradigm to strengthen the model's validity. Participants will be drawn from organisations across different sectors that actively employ Benefits Management and are engaging with Industry 5.0, such as managers and decision-makers. Each Focus Group will comprise participants from a single sector, thereby ensuring sector-specific perspectives. Following the completion of the Focus Groups, the collected data and feedback will be systematically analysed to identify necessary improvements to the model and to compare both the commonalities and divergences across sectors.

6. Project Execution Plan

The research will be carried out over four academic years, starting in 2025/2026. During the project, we will have the Project Progress report every year to make the evaluation of the project with an Evaluation Panel to provide the progress of the activities that have been done and the activities that are planned. This work should be supervised by the advisor to ensure proper development.

6.1 Completed Activities

First curricular year activities; Identification of research topic; Identification of Commission Research Evaluation; Objectives and Research questions

6.2 In Progress Activities

Literature review, Methodology

6.3 Planned Activities

Identification of sectors; Interview, Focus Group, Design and Build the Conceptual Model. Evaluate the model and communication. The scientific dissemination in a refereed journal, and conferences.

7. Conclusion

This research aims to contribute to the investigation of Science and Technology, as it will develop knowledge in Technology and Management, bringing innovation to management, organisation, re-engineering, technology, and strategy. The research will contribute to increasing the knowledge in areas as Benefits management and Industry 5.0. The research will have limitations since will be only made the two sector and the evaluation of the Benefits Management Model for Industry 5.0 can be applied in more sector to be analysed and to have more or another conclusions. This research can be the knowledge base for future research.

Ethics Declaration

During the research, it will be requested to the organizations to conduct the case study for the doctoral research and to carry out the interviews and the focus group, with the understanding that the anonymity of the individuals and organizations will be maintained. Until this moment, the research doesn't have information related to any organization. It will have in the future.

AI Declaration

No AI tools were used to produce this document.

Exploring Digital Transformation in Organizations: A Typological Perspective

Mirela Andreea Tudose
National University of Science and Technology Politehnica, Bucharest, Romania

andreea.tudose04@gmail.com

Abstract: Due to its rapid expansion, as well as the numerous implications it has at the organizational level, digital transformation has become an increasingly discussed topic in studies and specialized works. However, it is often treated as a homogeneous phenomenon, leading to a limited understanding of the multitude of forms it can take. This paper aims to address this issue, referring to a specific typology of digital transformation - the one proposed by Hanelt et al (2021). Specifically, it conceptualizes digital transformation as a multidimensional phenomenon, structured into four categories – Technology Impact, Compartmentalized Adaptation, Systemic Shift and Holistic Co-evolution. From a methodological point of view, the paper has a literature-based approach, supported by the analysis of illustrative examples, for each category, of relevant international organizations. Thus, a better understanding of how the adoption of digital technologies has different impacts at the organizational level is facilitated, from limited effects related to the technological side, to profound transformations of the entire organizational structure simultaneous with those of the external environment. The main findings highlight that digital transformation is a complex, heterogeneous and context-dependent phenomenon. In other words, similar technologies can lead to significantly different outcomes depending on organizational conditions and specific factors. From a practical perspective, the article is useful for managers and practitioners, who can be supported in the effort to more effectively manage digital transformation processes within the organization, by clearly identifying the type of desired change and the level at which it manifests itself. Therefore, the proposed typological approach facilitates the analysis and observation of different digital transformation trajectories and provides a useful framework for future research.

Keywords: Digital Transformation, Organizational Change, Intra-Organizational Focus, Contextual Scope.

1. Introduction

Digital transformation has become an increasingly important topic for both researchers and managers and decision-makers at the organizational level. Since this complex and continuous process produces significant changes – positive or negative depending on how it is implemented and managed – in the way it works, attitudes, behaviors and performance level of employees, organizations are required to pay special attention to these aspects. In this sense, the first step is understanding the concept, characteristics, types and potential effects of digital transformation.

In response to this need, there are studies that address different perspectives of digital transformation, explaining and emphasizing its multidimensional character. An example in this sense is the typology proposed by Hanelt et al. (2021), which conceptualizes digital transformation as a process that can take different forms depending on its scale and impact within the organization and the environment in which it operates.

Considering all this, the main objective of this paper is to explore and illustrate with concrete case studies this typology in order to better understand how digital transformation manifests itself within organizations. The paper contributes to the existing literature by providing a synthesized and structured analysis of the typology under discussion, integrating its four categories into a unitary analytical framework. This article also aims to draw attention to the role that the internal context at the organizational level, but also the external one, of the sector/industry within which it operates, plays in establishing the direction of the organization's digital transformation. Last but not least, the present study could be useful for managers and practitioners who seek to deepen the phenomenon of digital transformation in order to make more informed and, therefore, more effective decisions, by explaining and exemplifying some possible types of digital transformation and their implications.

2. Methodology

This paper adopts a qualitative, exploratory approach, oriented towards theoretical clarification and exemplification, with the objective of illustrating different types of organizational digital transformation based on the specific classification developed by Hanelt et al. (2021). This classification is used as the main tool to structure the analysis, evaluating the type of digital transformation in the selected case studies according to the focus of intra-organizational processes and the breadth of the contextual scope.

This article is a conceptual work, which is mainly based on the existing literature – and in particular on the study by Hanelt et al. (2021) on the typology of digital transformation - and on a synthesized analysis carried out by the author on illustrative case studies from international organizations. The methodological approach of this paper does not involve the collection of primary empirical data, but aims to develop a coherent analytical perspective by integrating and interpreting established theoretical frameworks and secondary sources.

The selection of case studies was carried out using a theoretical sampling strategy, with the aim of illustrating in a relevant way the four types of digital transformation identified within the proposed classification. The cases were chosen so that each of them predominantly illustrates one of the analytical categories, allowing a clear comparison between distinct types of transformation.

The analysis is based on secondary data, published case studies, organizational analyses and public sources regarding the digital transformation processes of the selected organizations, being used to identify the dominant patterns of change relevant to the dimensions of the established framework. The actual process consisted of a comparative analysis of the case studies, carried out by relating each of them to the key dimensions of Hanelt and his colleagues' classification.

Given the heterogeneous nature of the phenomenon and the diversity of effects it implies on organizations, it is necessary to establish a clear conceptual understanding. In this context, this article is guided by the following research question:

How can the types of digital transformation at the organizational level be differentiated depending on the scale of the changes and the organization's relationship with the external environment in which it operates?

3. Understanding the Concept of Digital Transformation

In studies and specialized works, the terms “digital transformation”, “digitization” and “digitalization” are often used interchangeably. Although these concepts are closely related, they can (and should) be defined distinctly. Verhoef et al. (2021) consider that digital transformation consists of three phases/stages: digitization, digitalization and digital transformation itself. Although the three phases are not completely distinct and there may be overlaps, digital transformation can be considered the result of the first two, as it builds on the experience gained in the initial two stages.

Digital transformation, the broadest and deepest phase, involves fundamentally changing the way the organization uses digital technologies, in order to develop a new digital business model, based on the creation and exploration of sources of additional value (Verhoef et al., 2021). The process should focus on competitive advantage through the constant implementation of new technologies, in order to improve their user experience and reduce costs (Lamarre, 2023), including by integrating technologies such as artificial intelligence or cloud computing, which can increase the competitiveness of companies by streamlining their operations (Marr, 2023).

However, the definitions of digital transformation have undergone some changes with the chronological evolution of the phenomenon, as well as its understanding. In this sense, one of the first proposed definitions considers digital transformation to refer to “the changes that the digital technology causes or influences in all aspects of human life” (Stolterman & Fors, 2004, p. 689), while later definitions formulated by researchers focus on improving the organization as a result of implementing DT – “the changes that the digital technology causes or influences in all aspects of human life” (Fitzgerald et al, 2013, p. 2); “a new and modern term in business and technological literature is usually defined as integration of digital technology into business that results in, sometimes fundamental changes in business operation and delivery of value to customers” (Mićić, 2017); “a process that aims to improve an entity by triggering significant changes to its properties through combinations of information, computing, communication, and connectivity technologies” (Vial, 2019, p. 118); “A fundamental process of change, facilitated by the innovative use of digital technologies, accompanied by the strategic capitalization of key resources and capabilities, aimed at radically improving an entity” (Gong, & Ribiere, 2021, p. 12).

Nowadays, more and more organizations, regardless of state, industry or sector, are showing an increased interest in developing and adopting digital transformation, generally out of a desire to remain competitive, especially as a result of the use of digital tools such as Artificial Intelligence or Internet of Things (Bresciani, Ferraris, & Del Giudice, 2018). However, it is important to mention that although the changes brought about by digital transformation within organizations have entailed numerous benefits, such as increased productivity, flexibility and efficiency, they also imply a series of unintended side effects with negative impact (Tudose, 2025).).

4. Typology of Digital Transformation

Hanelt et al. (2021) discuss digital transformation using a four-perspective typology, as a result of analyzing and combining two dimensions – contextual scope (which refers to the scope of approach, from a narrow one focused on specific technologies or processes, to an extended one relating to the entire organization) and the change process within the organization (how focused the organization is on changes as a result of TD in its internal processes). Thus, the four proposed perspectives are: technological impact, systemic change, compartmentalized adaptation, and holistic co-evolution.

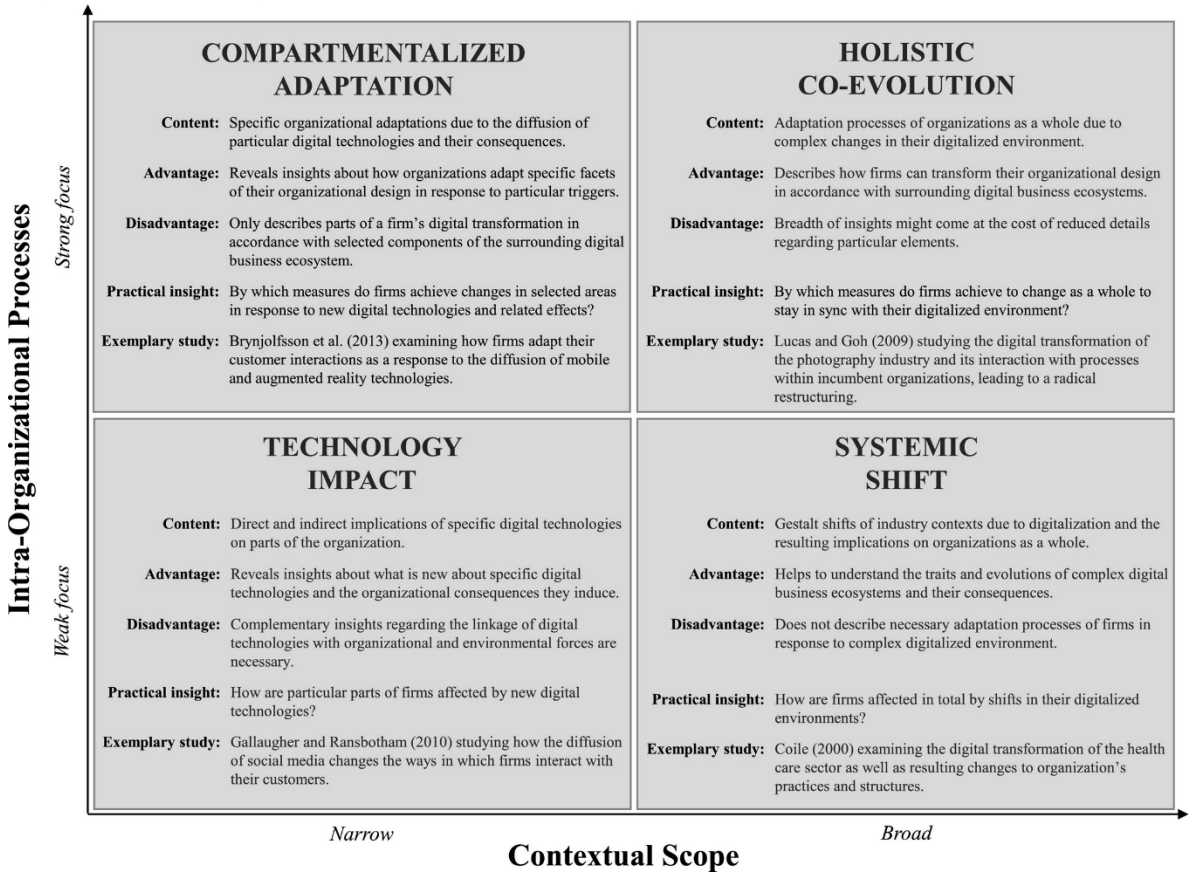

Figure 1: Typology of digital transformation perspectives

Source: Hanelt et al. (2021)

Technological impact is characterized by a narrow contextual scope and a reduced interest in changes to the organization's processes and involves direct and indirect effects of the adoption of digital technologies on some departments/parts of the organization, having the main advantage of identifying the novelties generated by the implementation of TD within the organization.

Compartmentalized adaptation involves a narrow contextual scope, but an increased interest in intra-organizational changes. This perspective analyzes how the organization adapts to digital transformation by changing certain processes or components of it accordingly, and its main advantage is that it shows concretely how organizations adopt certain changes in response to the emergence of new technologies.

Systemic change combines a broad contextual scope with little interest in internal change processes. This refers to the overall changes in a particular industry as a result of digital transformation, as well as the implications of these changes for organizations in that industry. The advantage of this perspective is that it facilitates a better understanding of the characteristics and trends of ecosystems undergoing digital transformation, not just at the level of a company, but as a systemic wave affecting all companies in an industry.

Holistic co-evolution represents the most integrated approach, referring to profound changes across the entire organization as a result of adopting digital transformation. These organizational changes occur simultaneously with changes in the entire system in which it operates – partners, customers, etc. Within this approach, the transformation is not an isolated one, but has an impact on the entire structure of the company, and the main

advantage is that it provides an overview of the changes that have occurred, as well as how organizations can become innovative and adaptable in a general context deeply impacted by digital transformation.

5. Results and Further Discussions

5.1 Technology Impact – Nike

For this category, an illustrative example is represented by the company Nike. Thus, the use of social networks has produced significant, but still limited, changes in terms of the channels and ways in which the company interacts with customers. Social media platforms, as specific digital technologies, have expanded and intensified the company-customer interaction in the case of Nike, especially by adopting specific marketing strategies and customer relationship management. In this context, the company has moved from predominantly unidirectional forms of communication to more complex, high-frequency, bidirectional interactions, with a strong message oriented towards engagement and real-time feedback, promoting the building of online communities around the brand.

The adoption of these digital practices does not imply, at least in the initial stages, radical changes in organizational processes or business model, although it significantly increases brand visibility and the degree of consumer involvement (Chai, 2024).

Therefore, the Nike case is representative of the Technology Impact category, highlighting the fact that digital tools can generate effects on some departments/parts of the organization.

5.2 Compartmentalized Adaptation – L'Oréal

L'Oréal is a good example of the compartmentalized adaptation category, more precisely through the integration of the ModiFace tool, a digital solution based on augmented reality that gives users (customers) the opportunity to virtually test the company's cosmetic products through a mobile application (Jessen et al., 2020).

Although this innovation has assumed a strong focus at the organizational level on the changes brought about by digital transformation, the area of approach (contextual scope) is narrow, oriented towards marketing processes, customer journey, product management and even brand communication. In other words, the implementation of the application aimed to improve the customer experience with the help of digital tools, quantified in increasing the company's profitability. Researchers have already discussed the benefits that can be brought by the use of augmented reality in the customer decision and purchase process (de Ruyter et al., 2020; Flavián et al., 2019), and companies such as L'Oréal have demonstrated that these solutions can be put into practice.

Therefore, the L'Oréal example shows how organizations can use digital tools to adapt specific internal processes or components, but in a limited context, without transforming the entire business model.

5.3 Systemic Shift – DBS Bank

Digital transformation in the banking sector represented an important systemic change, resulting from several factors such as the pressure exerted by FinTechs, new market contexts, rapid technological evolution, as well as openness from top management (Diener, & Špaček, 2021). Therefore, banks are under considerable pressure to digitally transform and adopt a more customer-centric approach in an effort to remain competitive.

In this context – of a banking industry marked by change – a concrete example for the Systemic Shift category is DBS Bank, one of Asia's leading financial services groups. DBS Bank has initiated a broad transformation process at the company level, which has gone beyond the boundaries of a single department/part thereof, implying a coherent reconfiguration of its organizational culture, processes and structure. In this sense, digital transformation involved the use of digital platforms, the modernization of IT infrastructure, as well as the implementation of agile methodologies in terms of decision-making, coordination and collaboration at the organizational level. Also, interaction with customers has been changed by integrating digital tools within banking operations (Shaaban, 2024).

Hence, the DBS Bank case shows how digital transformation can act as a catalyst for systemic change, generating important modifications at the organizational level, which are not limited to certain departments or processes, but reflect a systemic transformation triggered in response to changes at the industry level.

5.4 Holistic Co-evolution – Amazon

A representative example of the most comprehensive approach to digital transformation, holistic co-evolution, is the company Amazon, which has developed and implemented an intelligent virtual assistant based on cloud technology and artificial intelligence, Alexa. The evolution of this Amazon digital tool has coincided with that of the associated digital ecosystem, with mutual influences between internal changes occurring at the company level and general transformations in the environment in which it operates. Through this digital initiative, Amazon not only reorganizes its own structure, processes and organizational culture, but also contributes to building a system of relationships between users, developers and digital service providers. From the perspective of co-created value, the complex digital platform Alexa supports the creation of synergies, the integration of resources and the collaboration between stakeholders - such as service and product providers, application developers, end users - the added value being thus generated at the level of the entire ecosystem in which the company operates (Schmidt, Alt, & Zimmermann, 2026).

Therefore, the digital transformation in the case of Amazon, through the integration of the virtual assistant Alexa, does not only involve the adoption of a new digital technology, but also involves a profound change in the way it coordinates its activity, processes and collaborations with a series of key actors, in order to create a personalized and innovative experience. Simultaneously, this transformation has laid the foundations for significant developments in the interaction between developers, users and external partners, as well as in their interaction with the actual platform.

Ultimately, the Alexa case illustrates a holistic digital transformation, in the sense that changes at the organizational level as a result of adopting digital transformation and those occurring at the ecosystem level – increasingly digital – take place simultaneously, in a co-evolutionary process that has an impact on all actors involved.

The classification proposed by Hanelt and colleagues (2021) highlights that digital transformation is a complex phenomenon, which is not homogeneous, and can be classified into distinct categories depending on the area of approach to digital transformation at the organization level, the level at which it is focused on the changes that have occurred as a result of digital transformation in its internal processes, as well as the organization's relationship with its external environment. The table below represents a comparative synthesis in this regard, describing the main characteristics of each category, in order to better understand the conceptual and empirical differences between them.

Table 1: Summary of Digital Transformation Types According to Hanelt et al. (2021)

Typology	Main Level of change	Illustrative Case Study	Short Description
Technology Impact	Technological	Nike	Digital technologies generate specific effects on the channels and the way of communication and interaction with customers, without producing significant changes at the level of organizational structure or processes.
Compartmentalized Adaptation	Intra-organizational (localized – parts/departments)	L'Oréal (ModiFace tool)	Digital instruments adopted at the organizational level produce changes at the level of certain processes or its components, having a narrow area of approach, focused on specific technologies or processes.
Systemic Shift	Organizational and sector/industry level	DBS Bank	Changes at the sector/industry level as a result of the generally manifested digital transformation determine profound reconfigurations of organizational strategies, structures and processes.

Typology	Main Level of change	Illustrative Case Study	Short Description
Holistic Co-evolution	Organizational and ecosystemic	Amazon (Alexa intelligent virtual assistant)	Digital transformation impacts the entire organization, but it occurs simultaneously with the transformation (co-evolution) of the ecosystem in which it operates.

Source: Author's adaptation based on Hanelt et al. (2021)

6. Conclusion

In conclusion, this paper has conducted an analysis of the phenomenon of digital transformation in the organizational environment from a typological perspective, based on the classification proposed by Hanelt and collaborators. This refers to four categories – Technology Impact, Compartmentalized Adaptation, Systemic Change and Holistic Co-evolution – demonstrating that digital transformation is a complex, multidimensional phenomenon, with different impact depending on the level of application and the attention paid by the organization to these aspects.

The identification and analysis of representative empirical examples - case studies from internationally known companies - for each category of the typology supports a deeper understanding of digital transformation, showing the diversity of manifestations that it can take at the organizational level, as well as the importance of the internal situation of the organization and the sector/industry in which it operates. From a theoretical point of view, the analysis supports the usefulness of Hanelt et al.'s classification as a relevant tool for digital transformation research, and from a practical perspective, the described results support the fact that organizations have the opportunity to set the type of targeted change as a result of digital transformation if they understand and apply such a typology.

Future studies could explore the ways in which organizations can move from one category to another within the digital transformation typology, as well as the internal and external driving factors of these transitions.

This study has a number of limitations. The analysis is mainly based on the study of empirical examples from secondary sources, selected for illustrative purposes. Also, although useful from an analytical point of view, selecting a specific typology of digital transformation - in this case the one proposed by Hanelt and others - involves the risk of oversimplification regarding the multidimensionality of the digital transformation phenomenon and the multitude of situations in which organizations may find themselves on this journey.

Ethics Declaration

This paper contains a literature review and does not involve human participants, experiments, or the collection of personal data. Therefore, ethical approval was not required for this study. The research adheres to ethical guidelines for academic integrity, ensuring that all sources are cited and acknowledged appropriately. There are no known conflicts of interest related to this study.

AI Declaration

The author confirms that no artificial intelligence-based tools were used except for formal qualitative purposes, grammar and spelling checking, and formatting assistance. However, the final version of the manuscript has been reviewed and approved by the author to ensure accuracy, integrity and originality. Generative AI tools were not used to create or analyse the content of this work.

Entrepreneurial Innovation in Experimental Cinema: Digital Technologies, Immersive Media and New Educational Business Models

Adrian Zăvoianu
Business Engineering & Management National University of Science and Technology Politehnica Bucharest, Romania

ctmedia.zavoianu@gmail.com

Abstract: This paper examines entrepreneurial innovation at the convergence of experimental cinema, immersive media, and digital education, emphasizing how emerging technologies are reshaping creative industries and educational ecosystems. By integrating virtual reality (VR), augmented reality (AR), motion capture, artificial intelligence (AI), 360-degree filming, and large-scale immersive projections, experimental and avant-garde cinematic practices evolve into scalable educational and entrepreneurial ventures. The study explores how digital technologies enhance experimental film production for educational purposes by enabling immersive, interactive, and multisensory learning experiences that exceed traditional pedagogical approaches. These innovations foster increased learner engagement, deeper comprehension, and improved retention of complex information, positioning experimental cinema as a driver of educational innovation. Additionally, the paper analyzes the growth of immersive projection industries within the cultural and creative sectors, referencing prominent venues such as Atelier des Lumières (Paris), Bassins des Lumières (Bordeaux) and Carrières des Lumières (Les Baux-de-Provence). These cases illustrate how advanced projection technologies, spatialized sound, and 360° mapping enable new experience-based business models, transforming architectural spaces into interactive storytelling environments. From an entrepreneurial perspective, the research highlights how experimental cinema and immersive media act as innovation laboratories that stimulate cross-disciplinary collaboration among filmmakers, educators, technologists, and cultural entrepreneurs. The findings suggest that immersive digital tools not only redefine creative production and pedagogical methodologies but also democratize access to high-quality educational content and generate sustainable opportunities within the experience economy. This paper contributes to innovation and entrepreneurship scholarship by addressing an underexplored intersection between experimental film, educational technology, and immersive industries. Its originality lies in mapping the synergies between digital storytelling, education, and entrepreneurial innovation, offering valuable insights for creative entrepreneurs, educators, cultural institutions, and policymakers seeking to expand the boundaries of interactive learning and creative enterprise.

Keywords: Entrepreneurial Innovation; Experimental Cinema; Immersive Media; Digital Education; Creative Industries; Experience Economy

1. Introduction

The accelerated transformations driven by digital and emerging technologies - such as virtual reality (VR), augmented reality (AR), and artificial intelligence - have profoundly redefined both the creative industries and contemporary educational practices. In this dynamic context, the boundaries between art, technology, and entrepreneurship are becoming increasingly permeable, facilitating the emergence of hybrid forms of cultural production and knowledge transmission. Experimental cinema, traditionally associated with aesthetic exploration, nonconventional languages, and avant-garde discourses, acquires new dimensions through the integration of immersive media, which transform the viewer into an active participant and redefine the narrative experience.

This convergence between experimental film and immersive technologies creates a fertile framework for innovation, not only at the artistic level but also in education and entrepreneurship. Immersive media enable complex simulations, interactive experiences, and exploration-based learning, opening new perspectives on how knowledge can be constructed and internalized. At the same time, the experience economy fosters the development of business models centered on interactivity, personalization, and emotional engagement, where creative content becomes a key driver of economic value.

However, the central problem motivating this research lies in the lack of an integrated approach that correlates experimental cinema, immersive media, and digital education within a coherent entrepreneurial framework. Although each of these fields has been extensively studied independently, their intersection remains insufficiently theorized and applied in practice. This fragmentation limits innovation potential and reduces the capacity of stakeholders in these sectors to capitalize on existing synergies.

In this regard, the paper aims to contribute to the development of a conceptual and applied framework that integrates these dimensions.

The main objectives of the study are:

1. To analyze the role of immersive technologies in transforming cinematic practices, particularly in the experimental domain;
2. To explore the educational potential of these technologies, with an emphasis on experiential and interactive learning;
3. To highlight emerging entrepreneurial models that leverage the convergence between art, technology, and education in the context of the digital economy.

The paper also examines the evolution of immersive projection industries within the cultural and creative sectors, with reference to emblematic spaces such as *Atelier des Lumières*, *Bassins des Lumières* and *Carrières des Lumières*. These case studies illustrate how advanced projection technologies, spatialized sound, and 360° mapping facilitate the emergence of experience-centered business models, transforming architectural spaces into interactive narrative environments.

Building on these objectives, the research is guided by a series of fundamental questions: How do immersive media transform teaching and learning processes? In what ways can experimental cinema function as a tool for educational innovation? What types of entrepreneurial models emerge from the integration of immersive technologies into the production and distribution of artistic content? And, ultimately, how can this intersection contribute to the development of sustainable creative ecosystems?

By addressing these questions, the study aims not only to analyze an emerging phenomenon, but also to provide both theoretical and practical reference points for researchers, educators, and entrepreneurs interested in harnessing the transformative potential of immersive technologies in the fields of experimental cinema and contemporary education.A central issue addressed by this study is the role of immersive technologies in transforming contemporary filmmaking, particularly experimental cinema. Technologies such as virtual reality, augmented reality, AI-generated imagery, and immersive projection systems redefine cinematic language by expanding the spatial, sensory, and participatory dimensions of audiovisual storytelling. In this context, experimental film provides a relevant framework for examining the convergence between immersive media, creative innovation, and new forms of artistic production.

2. Literature Review

Experimental cinematography is characterized by its rejection of traditional narrative conventions and its exploration of innovative visual and sensory forms. It represents an domain of cinematic practice, defined by its opposition to the narrative and aesthetic conventions of mainstream film and by its exploration of the possibilities of the moving image. In specialized literature, it is frequently associated with the terms "*avant-garde*" or "*underground cinema*", characterized by non-narrative, abstract forms and an approach oriented toward formal and perceptual experimentation. In *Visionary Film: The American Avant-Garde, 1943–2000*, Adams Sitney defines experimental cinematography as a form of expression focused on the exploration of subjectivity, perception, and the formal structures of the image, in contrast to the narrative conventions of classical cinema (Sitney, 2002). In *Experimental Cinema in the Digital Age*, Le Grice analyzes the transformations generated by the transition from analog to digital media, emphasizing that experimental cinematography retains its exploratory function while expanding its means of expression. Le Grice argues that with the emergence of digital media, the emphasis shifts from the final result to the process, stating that "*it is not the final product that matters, but the program*" and the way it generates the visual experience (Le Grice, 2002). A complementary perspective is offered by David Bordwell and Kristin Thompson in *Film Art: An Introduction*, where experimental film is analyzed as a form of cinema that expands language through the use of unconventional techniques of editing, composition, and the relationship between sound and image. They emphasize that, although marginal from an industrial perspective, experimental cinematography has had a significant influence on mainstream cinema, particularly in terms of visual styles and the aesthetics of music videos, advertisements, and auteur films (Bordwell et al., 2010). Experimental cinematography can be understood as a "*laboratory*" of cinematic language, in which forms of visual expression and ways of engaging the spectator are tested. It contributes not only to the development of film aesthetics but also to the redefinition of the viewer's role, who becomes an active participant in the process of meaning-making.

Immersive media and emerging technologies - the development of digital technologies, such as virtual reality, augmented reality, artificial intelligence, and 360° filming, has led to the emergence of immersive media, which offer interactive, multisensory, and highly personalized experiences. These technologies fundamentally transform the way users interact with digital content, shifting from a passive model of consumption to an active, participatory one. A central concept in understanding immersive media is "*presence*", defined by Mel Slater and Sylvia Wilbur as the extent to which a technological system succeeds in creating the convincing illusion that the user is situated in a virtual environment. The authors distinguish between technological immersion, determined by system characteristics (resolution, field of view, interactivity), and psychological presence, which reflects the user's subjective experience (Slater et al., 1997). Janet H. Murray, in *Hamlet on the Holodeck*, analyzes new digital media as emerging narrative spaces characterized by interactivity, immersion, and agency. Murray emphasizes that the user is no longer a mere spectator but becomes an "*agent*" capable of influencing the unfolding of the narrative (Murray, 2003). This transformation is also supported by the early research of Frank Biocca, who explores communication in virtual reality environments and highlights how these technologies fundamentally alter the relationship between body, space, and identity. Biocca argues that immersive media extend the user's sensory capacities and create new forms of "*mediated presence*" in which the boundaries between the real and the virtual become increasingly blurred (Biocca, 1992). More recently, Jeremy Bailenson, in *Experience on Demand*, demonstrates the significant impact of virtual reality on users' behavior and cognitive processes. Bailenson highlights VR's ability to generate empathy and influence attitudes and behaviors by simulating experiences impossible to live in physical reality. Users can experience social situations or alternative perspectives, contributing to the development of understanding and sensitivity toward diverse human contexts (Bailenson, 2018).

Digital education and immersive learning increasingly rely on interactive and experiential models, in which technology facilitates the shift from passive to active learning. Immersive learning represents an emerging paradigm that leverages the potential of virtual environments to create authentic, interactive, and user-centered educational experiences. A foundational contribution in this field is that of Richard E. Mayer, who, in *Multimedia Learning*, formulates the theory of multimedia learning. This theory posits that the learning process is more effective when information is presented through a coherent combination of visual and auditory elements, rather than relying solely on text (Mayer, 2002). Chris Dede argues that immersive environments create unique opportunities for learning-by-doing, a pedagogical model based on direct experience. Dede emphasizes that immersive interfaces allow the simulation of complex situations that would be difficult or impossible to recreate in traditional educational settings (Dede, 2009). Recent research by Makransky and Petersen provides empirical evidence on the effectiveness of using virtual reality in education. The authors show that VR environments can significantly enhance students' motivation, engagement, and interest due to their interactive and captivating nature (Makransky and Petersen, 2019). However, they caution that merely introducing the technology does not guarantee superior educational outcomes.

Entrepreneurship in the creative industries - the contemporary economy is undergoing a transformation, shifting its focus from the production of goods and services to the creation of meaningful experiences for consumers. Cultural and creative industries are becoming fertile ground for entrepreneurial development, offering opportunities based on creativity, technology, and audience engagement. A key reference for understanding this phenomenon is Joseph Pine II and James Gilmore's *The Experience Economy*, in which the authors argue that the modern economy is evolving from goods and services toward experiences. In this paradigm, economic value is no longer determined solely by functional utility, but by the capacity to generate emotional engagement and memorability (Pine and Gilmore, 1998). This economic transformation is also supported by Richard Florida's theory of the creative class. Florida emphasizes that the economic development of contemporary societies is linked to their ability to attract and sustain creative individuals - artists, designers, developers, researchers - who generate ideas, innovations, and cultural content (Florida, 2002). Henry Jenkins introduces the concept of participatory culture in *Convergence Culture*, highlighting the transformation in the relationship between producers and consumers. In the digital era, the audience is no longer a passive receiver but becomes an active participant and even a co-creator of content (Jenkins, 2006).

3. Methodology

This paper is built on an exploratory qualitative approach, suitable for investigating an emerging field at the intersection of immersive technologies, digital education, and the creative industries. By combining the analysis of specialized literature with the examination of relevant case studies and the interpretation of current industry

trends, the research aims to provide a coherent and multidimensional perspective on how immersive projections are transforming cultural and educational experiences.

This methodological triangulation ensures both a solid theoretical foundation and an applied openness toward new innovative models generated within the digital economy.

3.1 Critical Analysis of Academic Sources and Industry Reports

The critical analysis of academic sources and industry reports represents one of the central methods of the research, aiming to provide both theoretical and contextual grounding for the investigative approach. This stage involved the identification, selection, and rigorous evaluation of relevant literature in the fields of immersive technologies, digital education, and creative industries.

The selection of sources was based on criteria such as thematic relevance, academic impact (citations), currency of information, and methodological validity.

The critical analysis involved not only synthesizing existing information but also comparatively evaluating theoretical perspectives and empirical findings. Thus, convergences and divergences among different authors were identified regarding the effectiveness of immersive technologies in education, their impact on cognitive processes, and their role in fostering creativity. This triangulation of information enhances the validity of the research and supports the formulation of conclusions relevant to both academic and entrepreneurial environments.

3.2 Examination of Representative Immersive Cultural Spaces

The second method employed in the research consists of the qualitative analysis of relevant case studies, represented by immersive cultural spaces that integrate advanced digital technologies into artistic and educational experiences. This approach allows for the investigation of how theoretical concepts identified in the literature are applied in real-world contexts.

The selection of case studies was based on criteria such as international recognition, degree of technological innovation, diversity of experiential formats, and relevance to the convergence of art, technology, and education. In this regard, the analysis focused on emblematic spaces such as *Atelier des Lumières, Bassins des Lumières* and *Carrières des Lumières*.

The analytical criteria were selected based on both immersive media theory and the operational characteristics of contemporary immersive exhibitions, as they reflect the core dimensions through which immersion, audience engagement, and experiential learning are generated in digital cultural environments. The use of immersive projection technologies, spatialized sound, interactive elements, narrative architectural spaces, audience participation, and educational components was considered essential for evaluating how immersive environments create multisensory experiences, transform spectatorship into active participation, and function not only as entertainment formats, but also as platforms for cultural mediation and informal learning.

The analysis of these spaces considered several dimensions:

- the use of immersive projection technologies (video mapping, 360° projections, multi-screen systems);
- the integration of spatialized sound and interactive elements;
- the configuration of architectural space as a narrative environment;
- the types of experiences offered to the public and the level of active participation;
- the educational and interpretative components of the exhibitions.

3.3 Interpretation of Emerging Trends in the Creative Industries

The third method focuses on interpreting emerging trends in the creative industries, with emphasis on the impact of digital transformation and immersive technologies on models of cultural production, distribution, and consumption.

This analysis is based on correlating information extracted from academic literature and industry reports, aiming to identify major directions of development.

These include:

- the shift from passive consumption to participatory and interactive experiences;

- the development of the experience economy;
- the integration of artificial intelligence and extended reality (XR) into creative processes;
- the emergence of new business models based on immersion, personalization, and digital storytelling.

The interpretation of these trends involves an interdisciplinary approach, combining perspectives from fields such as media studies, creative economy, and experience design. In this context, concepts such as *"immersive storytelling"*, *"digital transformation"* and *"creative entrepreneurship"* are analyzed to highlight how they are reshaping contemporary cultural ecosystems.

The method also involves identifying entrepreneurial opportunities generated by these transformations, including the development of hybrid spaces (immersive exhibitions, digital museums), interactive educational platforms, and cultural products based on emerging technologies. The focus is on how these initiatives leverage the convergence of art, technology, and education to create both economic and social value.

3.4 Case Study - Analysis of the AMIEX® Model (Art & Music Immersive Experience)

Complementing the methodological framework, the research integrates an in-depth analysis of the AMIEX® (Art & Music Immersive Experience) model, developed by Culturespaces, as a representative case study for investigating immersive projections in cultural and educational contexts. This approach enables a direct link between the theoretical dimension of the research and the manifestations of immersive technologies in contemporary institutional practices.

The AMIEX® model emerged in 2012 as an initiative for reinterpreting artistic presentation, initially implemented at *Carrières des Lumières* and later expanded to *Atelier des Lumières* and *Bassins des Lumières*. The development of this model reflects a shift in the valorization of cultural heritage, transforming industrial or historical spaces into multisensory exhibition environments capable of supporting visual narratives.

From a methodological perspective, the analysis is based on the examination of its technological, curatorial, and experiential components. The AMIEX® concept employs digital projections, computer animation, and immersive sound design, configured into a system that enables audiovisual experiences. Images are generated using digital techniques that preserve the visual structure of original artworks while recontextualizing them within an expanded spatial framework, where architectural surfaces become supports for visual storytelling.

A central element of the analysis is the curatorial dimension, which marks a departure from the traditional museum paradigm. Within AMIEX® exhibitions, original artworks are replaced by digital reproductions, shifting the focus from material authenticity to the experience of perception. This transformation indicates a reconfiguration of the museum's role from a space of preservation to a medium of cultural mediation adapted to the digital society.

The analysis of audience experience highlights a shift in the relationship between spectator and artwork. In the AMIEX® context, visitors are no longer passive observers but participants, moving within projections and developing a bodily relationship with the images. This sensory interaction generates an affective experience, differing from the static contemplation typical of traditional museums, and fosters cognitive and emotional engagement.

The AMIEX model represents a standardized system for exploiting immersive art at an architectural scale, where spatial variables, projection density, audience capacity, and narrative structure are calibrated in a repeatable way across locations. The analysis of three venues - *Atelier des Lumières, Carrières des Lumières*, and *Bassins des Lumières* - reveals relationships between projection surface, technical infrastructure, and annual audience performance, confirming the existence of an operational model rather than isolated artistic installations.

Table 1: Comparative data of physical and technical parameters

Location	Projection area (m²)	Exhibition area (m²)	Video projection systems	Sound systems	Visitors/year
Atelier des Lumières	3.300	1.300	140	50	~1.200.000
Carrières de Lumières	7.000	3.500	100	30	~560.000
Bassins des Lumières	3.400	1.600	90	40	~500.000

Source: AMIEX documentation

The data show that absolute projection surface size is not the determining factor for audience volume; rather, it is the ratio between projection area, projector density, and spatial compactness that influences immersive intensity and visitor turnover. For example, although *Carrières des Lumières* has the largest projection surface (7,000 m²), it does not generate the highest number of visitors, being significantly surpassed by *Atelier des Lumières*, which has half the surface but higher technological density and spatial compactness.

In order for the analysis to go beyond the descriptive level of raw data - such as surface areas, number of projectors, number of speakers, or annual visitor volume - and to achieve scientific relevance, it is necessary to introduce derived indicators capable of expressing functional relationships between these variables. Only by relating technical parameters to spatial dimensions and visitor performance can the technological and spatial efficiency of each venue be objectively evaluated, revealing not how large the installations are, but how intensively and productively they use the available infrastructure to generate immersion and audience capacity.

Table 2: Derived efficiency indicators

Location	m² Projection/Projector	m² Exhibition/Projector	Visitors/m² Projection	Visitors/Projector
Atelier des Lumières	23,6	9,3	364	8.571
Carrières de Lumières	70,0	35,0	80	5.600
Bassins des Lumières	37,8	17,8	147	5.555

Source: AMIEX documentation

The data clearly show that *Atelier des Lumières* operates in a regime of technological hyper-density, with nearly three times more projection coverage per unit area than *Carrières de Lumières*. This density explains its exceptional audience performance, indicating that immersive perception is directly correlated with image granularity and visual omnipresence, rather than the raw monumentality of the space. A second critical element is the standardized narrative model of the shows, identical across all locations: a main exhibition of approximately 35 minutes, followed by a short 4 - 7 minutes sequence created by contemporary artists, with a new set produced annually. This format creates an optimal temporal unit of around 40 minutes, allowing for controlled audience flow rotation and predictable daily capacity, effectively transforming the artistic experience into a programmable system similar to a cinematic cycle, but within an open space - without seating and without a prescribed path.

Table 3: Standardized AMIEX digital exhibition model

Component	Duration	Functional Role	Production Frequency
Main Exhibition	~35 min	Classical artistic narrative, full immersion	Annual
Short Exhibition	4–7 min	Contemporary intervention, rhythmic variation	Annual
Full Cycle	~40 min	Visitor rotation unit	Permanent

Source: AMIEX documentation

This temporal structure, combined with the density of the equipment, explains why these venues can handle hundreds of thousands to over a million visitors annually without creating the sense of typical museum overcrowding.

Table 4: Final comparative synthesis

Key Indicator	Atelier des Lumières	Carrières de Lumières	Bassins des Lumières
Experience Type	Dense, compact immersion	Monumental, cavernous	Balanced
Spatial Efficiency	Very high	Low	Medium
Technological Efficiency	Maximum	Minimum	Medium
Audience Yield	Maximum	Medium	Medium
Exhibition Model	Identical AMIEX	Identical AMIEX	Identical AMIEX

Source: AMIEX documentation

From a methodological perspective, this dimension is interpreted in relation to the concepts of immersion, presence, and experiential learning, highlighting the fact that such environments can function as tools of informal education. The experiences generated within AMIEX® stimulate emotional memory and empathy, facilitating a form of learning based on direct participation and sensory engagement, in contrast to traditional models of knowledge transmission.

Another relevant aspect of the analysis is the role of new media technologies as tools of cultural mediation. Digital projections and sound design create an accessible interpretative framework that allows the general public to interact with artworks without requiring prior knowledge. In this sense, the AMIEX® model can be interpreted as a form of an "augmented museum," in which technology facilitates the reinterpretation of artistic heritage and its adaptation to new forms of perception specific to the digital society.

The analysis also highlights the contribution of this model to the democratization of access to art. AMIEX® exhibitions attract a heterogeneous audience, including categories that do not usually frequent traditional museums, such as young people, families, or individuals without formal artistic education. The removal of symbolic barriers associated with classical museum institutions and the adaptation of presentation formats to contemporary visual languages contribute to expanding audiences and diversifying cultural consumption.

The democratization potential of the AMIEX® model is supported by both audience scale and accessibility dynamics observed in immersive exhibition spaces. Venues such as Atelier des Lumières attract over one million visitors annually, indicating the capacity of immersive environments to reach broader audiences than many traditional exhibition formats. Furthermore, the multisensory and non-specialized nature of immersive exhibitions reduces symbolic and educational barriers commonly associated with conventional museums. Large-scale projections, immersive soundscapes, free circulation within the space, and experiential storytelling contribute to attracting heterogeneous audiences, including young people, families, and visitors without formal artistic education. These characteristics suggest that immersive exhibition models facilitate broader public engagement with artistic content and expand cultural participation.

At the same time, integrating a critical perspective into the methodological analysis allows for an evaluation of the model's limitations. The success of immersive exhibitions is accompanied by debates regarding the risk of transforming art into a spectacle primarily oriented toward entertainment and emotion, to the detriment of critical reflection and the direct relationship with the original artwork.

By integrating this case study into the methodology, the research gains a solid applied dimension, enabling the correlation of theoretical concepts with real practices in the creative industries. The AMIEX® model effectively illustrates the convergence of art, technology, and education, highlighting how immersive technologies can generate new forms of cultural experience and support the development of entrepreneurial models based on the experience economy.

Finally, the interpretation of emerging trends has enabled the integration of the obtained results into a broader framework, highlighting the directions of evolution within the creative industries and the entrepreneurial opportunities they generate. The correlation of the three methods ensures a coherent and multidimensional perspective on the studied phenomenon, facilitating the identification of connections between technology, education, and entrepreneurship.

4. Results and Discussion

The research results highlight a significant transformation in the relationship between technology, art, and education, confirming the hypothesis that immersive technologies act as a catalyst for innovation in the creative industries and learning environments.

Beyond their technical novelty, immersive technologies fundamentally transform experimental filmmaking by redefining the relationship between image, space, and spectatorship. Unlike traditional cinema, immersive environments such as VR and 360° film replace passive viewing with spatial and interactive participation, requiring filmmakers to rethink narrative structure, montage, and audience positioning. At the same time, artificial intelligence and real-time rendering systems introduce adaptive and interactive dimensions that expand sensory experimentation and audience engagement. As a result, immersive filmmaking evolves into a hybrid audiovisual form situated at the intersection of cinema, digital art, interactive media, and game design.

The integration of data derived from literature analysis, case studies, and the examination of the AMIEX® model developed by Culturespaces allows for the formulation of coherent conclusions regarding the impact of these technologies on film production, education, and contemporary business models.

The integration of immersive technologies into experimental cinema leads to a profound transformation of cinematic language and of the modes of production and reception. New technologies - virtual reality (VR), augmented reality (AR), and artificial intelligence (AI) - further amplify this direction, extending film beyond the traditional screen and moving beyond linear narrative structures. In this context, contemporary experimental cinema can be understood as a hybrid medium, situated at the intersection of film, digital art, and interactive experience.

The impact on education represents a central dimension, as the use of immersive environments generates significant effects on the learning process, primarily by increasing learner engagement. The interactive, engaging, and multisensory nature of these experiences simultaneously stimulates visual, auditory, and kinesthetic channels, fostering active participation and emotional involvement.

This openness supports the development of informal and extended education, in which cultural spaces and immersive exhibitions become extensions of the traditional educational environment, contributing to the development of cultural and creative competencies in an accessible and attractive way for a diverse audience.

The results demonstrate that the integration of immersive technologies is not merely a technological evolution, but a structural transformation in the way cultural and educational content is created, distributed, and experienced.

5. Conclusions and Perspectives

The paper highlights the essential role of immersive technologies in transforming experimental cinema and digital education, demonstrating that they are not merely technological tools, but structural drivers of change within the cultural and creative industries.

By integrating theoretical perspectives with applied analyses, the research emphasizes the emergence of a new cultural ecosystem, characterized by interactivity, participation, and interdisciplinary convergence.

One of the study's main contributions lies in the interdisciplinary integration of three major fields - cinematography, education, and entrepreneurship - highlighting how they influence one another within the context of digital transformation. The analysis shows that experimental cinema is increasingly adopting immersive formats, while education leverages these technologies to create more effective and engaging learning experiences.

Regarding future perspectives, a clear direction is emerging toward the development of integrated ecosystems in which cinema, education, and technology converge to create hybrid experiences. The integration of artificial intelligence, extended reality (XR), and interactive platforms will continue to expand the boundaries of these fields, generating new forms of artistic expression and new educational models.

In conclusion, the paper demonstrates that immersive technologies are not merely technological tools, but catalysts of cultural and educational transformation. By harnessing their interdisciplinary potential, they can contribute to the development of innovative, sustainable, and relevant practices for contemporary society.

Ethics Declaration

This research was conducted in accordance with applicable international and national ethical standards. Ethical approval was not required as the study did not involve human subjects or sensitive personal data.

AI Declaration

I hereby declare that this work has been created solely through human effort, without the use of artificial intelligence (AI) tools for generating, drafting, structuring, or reviewing the content.

All ideas, formulations, and conclusions included in this work are the result of my personal effort and have not been assisted by software applications utilizing natural language processing technologies or similar AI models.

This declaration reflects my commitment to academic and professional integrity.

shahabgheysari@gmail.com

Abstract: Entrepreneurship Support Organisations (ESOs) need metrics to evaluate ventures within entrepreneurial ecosystems, but assessing startup readiness remains difficult. Current practice relies mainly on descriptive indicators that are hard to measure and to reproduce, and little is documented about how these indicators are operationalised or how well they perform. The Open Innovation Framework for Pitch Competitions (OIF-PC) (Movahedian Attar et al., 2025) takes a systems-thinking view in which entrepreneurial support is treated as a funnel whose design parameters shape venture development. Its constructs, however, are defined at programme level and have not yet been expressed as measurable attributes. Expressing them at venture level would give programmes a more useful basis for evaluation. This study therefore operationalises the OIF-PC orientation as measurable attributes of startups and examines whether these attributes are associated with observed outcomes. A secondary dataset of 923 records describing 922 unique ventures, with 45 raw attributes covering funding, milestones, networks, and the ecosystem, was analysed using Logistic Regression, Random Forest and XGBoost. SHAP (SHapley Additive exPlanations) was used to interpret model outputs and to quantify the contribution of original and derived variables to the assessed readiness score. Access to resources is associated with more favourable outcomes. How those resources are used, and how actively a venture engages with its entrepreneurial environment, account for a comparable share of the model's attribution, with network connectivity the single most influential attribute. This indicates that ecosystem constructs of the OIF-PC type can be operationalised through venture-level variables, but it is not a validation of the framework itself. On this basis, the study introduces the Startup Success Readiness Index (SSRI), which combines four pillars (Relational Strength, Milestone Achievement, Investor Diversity and Funding Efficiency) into a weighted score using SHAP-derived attribution. The SSRI gives ESOs a transparent readiness measure that they can use to profile ventures, find capability gaps and inform programme design.

Keywords: Startup Success Assessment; Entrepreneurship Support Organisations (ESOs); Open Innovation Framework for Pitch Competitions (OIF-PC); Machine Learning; Startup Success Readiness Index (SSRI); SHAP

1. Introduction

Entrepreneurial ventures contribute to innovation, job creation and economic growth. A large share of them close early in their development, and many of the remainder never reach a sustainable scale. Support programmes have grown in number in response, with the aim of developing and scaling promising ventures.

These programmes offer entrepreneurs mentorship, funding opportunities, professional networks and strategic guidance. Identifying which ventures have strong growth potential is harder. Selection decisions are commonly based on expert opinion, scattered indicators or short-term measures that may not reflect longer-term outcomes well, leaving support organisations without a clear account of which venture characteristics matter most.

The role of entrepreneurial ecosystems has attracted increasing attention in this context. Startup performance is associated with the internal characteristics of the firm and also with the interaction between entrepreneurs, investors, mentors, institutions and support organisations. These relational aspects, however, are rarely measured at the level of the individual venture.

This study therefore asks whether venture characteristics can be measured from observable data and used to assess how closely a venture resembles those that were ultimately acquired rather than closed. It is framed as assessment rather than prediction: the dataset is cross-sectional and the outcome is already observed, so all findings are reported as associations. The study makes two contributions. First, using interpretable machine learning, it operationalises ecosystem constructs of the OIF-PC type as measurable attributes and identifies which of them are associated with observed outcomes. Second, it introduces the Startup Success Readiness

Index (SSRI), a transparent composite score derived from SHAP attribution that allows ESOs to profile ventures on four pillars and to locate capability gaps.

2. Literature Review

2.1 Startup Success and Entrepreneurial Ecosystems

Research on new venture success initially concentrated on success factors, including entrepreneur traits and the financial, market and technical competences of new ventures (Song et al., 2008; Giardino et al., 2014). Evidence at this level is uneven, however. Song et al. (2008) find that only a subset of the frequently proposed firm-level factors is consistently associated with outcomes, which suggests that firm-level attributes alone leave much of the variation unexplained. More recent research has therefore shifted towards the ecosystem, examining the role of networks, institutions, entrepreneurs, incubators, policy-makers and the surrounding society in a new venture's development (Isenberg, 2010; Stam, 2015; Spigel, 2017).

A related stream has examined incubators, accelerators and pitch competitions as mechanisms for developing entrepreneurs' skills, networks and access to resources (Cohen, 2013; Pauwels et al., 2016; Hallen et al., 2020). The findings of this stream are mixed. Interventions differ considerably in design and selection practice, and the benefit associated with participation varies from programme to programme. This variation points to evaluation approaches that focus on the underlying design parameters rather than on programme participation as a single indicator.

This stream also treats open innovation, which depends on external interaction and collaboration between firms, as one of the mechanisms associated with entrepreneurial success (Chesbrough et al., 2006; West and Bogers, 2014). Despite this conceptual progress, the ecosystem perspective has rarely been translated into measurable indicators that can support explanatory analysis and the design of interventions. This gap is the starting point for the present study.

2.2 Support Programmes and Evaluation Challenges

Support services have grown quickly over the last decade and are widely used to stimulate innovation and to help new businesses develop (Cohen, 2013; Pauwels et al., 2016). Their effectiveness is nonetheless difficult to demonstrate (Hallen et al., 2020). Evaluations commonly rely on indicators such as participation rates, budgets achieved, or short-term results. These describe programme activity, but they do not give a clear picture of how support mechanisms relate to longer-term business development.

Many frameworks identify observable outcomes but provide little guidance on which ecosystem conditions or support mechanisms would need to be improved to obtain better outcomes. Evaluation therefore tends to describe what a programme did rather than indicate what its managers should change.

2.3 OIF-PC as a Structured Ecosystem Evaluation Framework

Recent work has proposed more structured ways of accounting for support activities within innovation ecosystems. One of these is the Open Innovation Framework for Pitch Competitions (OIF-PC) (Movahedian Attar et al., 2025), which sets out how support mechanisms relate to business development.

OIF-PC treats pitch competitions as one piece of the larger ecosystem rather than as isolated events. It adopts a systems-thinking perspective in which the entrepreneurial path is modelled as a funnel: from an initial idea, through mentorship and incubation, to a pitch competition and an operating company. Its design parameters include mentorship duration, mentor and team diversity, and financial support, and its output is a set of successful or discontinued ventures. On this basis, the framework proposes three indicators: an Innovation Alignment Index (IAI), a Funnel Diversity Score (FDS), and a Post-Competition Funding Index (PCFI). The three indicators are intended to reflect the quality of support activities and their relation to business progress.

Because these indicators are defined at the level of a funnel, they cannot be computed directly for an individual venture observed outside such a programme. In this study, OIF-PC is therefore used as a conceptual orientation only: it motivates which families of venture attributes are worth measuring, and the analysis does not test the framework itself.

2.4 Machine Learning for Evaluation

Machine learning is widely used in data analysis because of its ability to capture patterns, non-linear relationships, and interactions among variables (Kuhn and Johnson, 2013). Most studies applying these methods in an entrepreneurial context focus on individual firms rather than on the broader ecosystem. A further limitation is interpretability (Doshi-Velez and Kim, 2017). Such models can reach high accuracy while giving little insight into which conditions are associated with the outcome. Post-hoc explanation methods, which attribute a model's output to its individual inputs, have been developed in response, SHAP among them (Ribeiro et al., 2016; Lundberg and Lee, 2017; Molnar, 2022).

3. Methodology

3.1 Data Description

This empirical study is based on a secondary dataset of 923 records describing 922 unique ventures (one exact duplicate was removed) and 45 attributes representing different dimensions of entrepreneurship. It covers financial attributes (venture capacity and investment activity), temporal attributes (growth trajectory and funding timelines), industry and geographical attributes, and network metrics for ecosystem connectivity; the Appendix lists all attributes with short descriptions. The target variable is derived from the recorded venture status, which takes exactly two values here: acquired (n = 596, 64.6%) and closed (n = 326, 35.4%), coded as successful (1) and unsuccessful (0) respectively. No operational category is present in the data. The classes are moderately imbalanced, so evaluation measures that are not distorted by class proportion are required.

The sample contains only ventures whose trajectory has resolved into acquisition or closure; ventures still operating at the time of collection are absent by construction. The observed 64.6% acquisition share is therefore a property of the sampling frame, not a base rate for startups in general. The analysis concerns which of the two resolutions occurred, given that the venture resolved at all, and the framework is positioned as a readiness assessment instrument rather than a prediction model.

Missingness is concentrated in a small number of attributes. Missing closure information is fully determined by the outcome, and this attribute is therefore excluded. Missing milestone information (18.3% and 17.2%) is more common among younger ventures, which probably reflects their stage of development and reporting behaviour, and is handled as described in Section 3.2.

3.2 Feature Engineering and Preprocessing

The modelling feature set was derived from the 45 attributes of the working file under a selection rule fixed before any model was fitted. Attributes that encode the outcome were removed: labels, an exact copy of the recorded status, and closed_at, whose presence identifies closed ventures. Also removed were identifiers, high-cardinality text fields already represented by indicator variables, one duplicated column, and one external ranking whose measurement date could not be established. Two derived variables were constructed: the natural logarithm of total funding, which reduces a strong right skew, and a binary indicator of whether any milestone was recorded, which is also the missing-data indicator for the milestone dates. No composite ratio or index was created at this stage, because each candidate composite was a deterministic function of attributes already retained; composition into the four readiness dimensions is performed on model contributions rather than on raw attributes (Section 4.4). This yields 28 features: 16 assigned to the four readiness dimensions and 12 sector and location controls (Appendix A).

Preprocessing was implemented as a single pipeline fitted on the training partition only. The four attributes with missing values were median-imputed because the median is less sensitive than the mean to the long right tails of the time-to-event variables. The nine continuous and count features were standardised, which the coefficient-based model requires and which leaves the tree ensembles unchanged. The 19 binary indicators passed through untransformed. Class rebalancing was tested rather than assumed to be necessary. SMOTE (Chawla et al., 2002), SMOTE-NC and class weighting were each compared against the untreated training set in repeated cross-validation. None improved ranking performance, so no resampling was applied.

3.3 Temporal Scope, Leakage Control and Interpretive Limits

One limitation of the data is that several features, especially those related to funding and milestones, represent information that becomes available at later stages of the venture life cycle. These variables therefore describe

a venture's observed trajectory to date rather than its characteristics at founding. The framework is scoped accordingly: it assesses ventures on what has already been observed, and attributes generated by the resolution event itself are excluded from the analysis.

Leakage was controlled at two levels. The risk is that information from the held-out ventures reaches the model and inflates the reported performance. Attributes that encode the outcome were removed before modelling (Section 3.2), and every fitted transformation was contained in a pipeline estimated on the training partition alone. No quantity computed from the 185 held-out ventures, whether an imputation median or a scaling constant, was available to the model at any stage.

The results are interpreted as statistical associations rather than causal evidence: they indicate which venture characteristics correspond to observed outcomes, not that those characteristics produce them. Establishing causal claims would require a longitudinal design in which venture attributes are recorded before the outcome is realised.

3.4 Model Development

Three algorithms were compared: Logistic Regression as an interpretable linear baseline, and Random Forest (Breiman, 2001) and XGBoost (Chen and Guestrin, 2016) for their ability to represent non-linear relationships and interactions between features. A majority-class classifier was included as a null reference, so that the reported figures can be judged against what is obtainable without any model.

The 922 ventures were split once, using a fixed random seed, into 737 training and 185 held-out test ventures, stratified on the outcome so that both partitions carry the same acquired/closed proportion. Hyperparameters were tuned by exhaustive grid search (105 configurations across the three learners), evaluated by 5-fold stratified cross-validation on the training partition only; the test partition was not used at any point during model development. To verify that the selected configuration is not an artefact of tuning and reporting on the same folds, the entire tuning procedure was re-run inside a nested cross-validation, which placed the resulting optimism at 0.002–0.004 ROC-AUC. The searched grids and the selected settings are reported in the Appendix.

3.5 Evaluation Metrics

Model performance was assessed using Accuracy, Precision, Recall, F1 score, ROC-AUC and PR-AUC. Accuracy is sensitive to class imbalance and is therefore reported only against the majority-class baseline. Precision is the proportion of ventures assessed as successful that were in fact acquired, and so reflects false positives; Recall is the proportion of acquired ventures that were identified, and so reflects false negatives. The F1 score balances the two.

Because the framework orders ventures by assessed readiness rather than classifying them at a fixed cut-off, ROC-AUC was specified in advance as the primary metric: it evaluates ranking across all decision thresholds and is unaffected by the class proportion (Fawcett, 2006). PR-AUC is reported alongside it because it concentrates on the positive class and disregards true negatives (Saito and Rehmsmeier, 2015); as acquired ventures are the more frequent class here, PR-AUC must be read against the 0.646 baseline of an uninformative ranking. Threshold-dependent measures are reported at a stated operating point (Section 4.2).

4. Results

4.1 Bivariate Associations

Point-biserial correlations between each attribute and the outcome are consistently positive but modest. Network connectivity shows the strongest association (relationships, $r = 0.36$, $p < 0.001$), followed by milestone count ($r = 0.33$), total funding on the logarithmic scale ($r = 0.30$), age at last milestone ($r = 0.26$), number of funding rounds ($r = 0.21$) and average investors per round ($r = 0.19$). No coefficient reaches $|0.40|$, indicating that no single attribute accounts for the outcome on its own.

Two features of these associations shaped the modelling. First, the rank correlation exceeds the linear one for several attributes, most clearly for relationships ($\rho = 0.47$ against $r = 0.36$). This indicates a monotone but non-linear relationship, and it is evidence, obtained before any model was fitted, that non-linear learners should perform better than a linear baseline. Second, the temporal attributes are correlated with each other. The strongest pair is age at last funding and age at first milestone ($r = 0.72$), and the maximum variance inflation

factor is 8.0. Multicollinearity of this magnitude destabilises coefficient-based interpretation in the Logistic Regression baseline but leaves the tree ensembles, which split on one attribute at a time, unaffected.

4.2 Model Performance

Table 1 reports performance on the 185 held-out ventures. Both tree ensembles outperform the linear baseline across all measures, and all three models exceed the majority-class reference. XGBoost attains the highest ROC-AUC (0.858) and PR-AUC (0.912) and is adopted as the reference model for interpretation, since the framework ranks ventures by readiness.

The margin over Random Forest is small. In repeated cross-validation on the training partition, the two ensembles differ by 0.006 ROC-AUC, which does not reach conventional significance (paired *t*-test, $p = 0.060$) and is smaller than the fold-to-fold variation of either model. XGBoost is adopted because it leads on both pre-specified metrics, but the findings that follow do not depend on that choice: the attribution ranking is reproduced under Random Forest (Section 4.3). The figures in Table 1 correspond to the default 0.5 cut-off; because the operating point is a policy decision rather than a property of the model, it is reported explicitly and can be shifted, at a known cost, to favour recall on closed ventures.

Table 1: Test-set performance on 185 held-out ventures (positive class = acquired)

Model	Accuracy	Precision	Recall	F1-score	ROC-AUC	PR-AUC
Majority-class baseline	0.649	0.649	1.000	0.787	0.500	0.649
Logistic Regression	0.714	0.782	0.775	0.778	0.797	0.861
Random Forest	0.789	0.800	0.900	0.847	0.838	0.892
XGBoost (adopted)	0.778	0.811	0.858	0.834	0.858	0.912

4.3 Attribution Analysis

For each venture, SHAP assigns to every attribute the amount by which that attribute moved the model's output away from the average output. The contributions for a venture therefore sum exactly to its assessed readiness. Averaging the absolute contributions over the training ventures gives each attribute's share of total attribution mass.

Attribution is concentrated. Relationships alone carry 24.8% of the total, followed by age at last milestone (12.7%), total funding (12.6%), milestone count (12.4%) and average investors per round (11.0%). These five attributes account for roughly three-quarters of all attribution, and the twelve sector and location controls together carry 5.4%. Each of the five is oriented in the expected direction, with higher values corresponding to higher assessed readiness (Figure 1).

Aggregated by dimension, the shares are Funding Efficiency 27.9%, Milestone Achievement 26.1%, Relational Strength 24.8% and Investor Diversity 15.7%. The number of attributes in each dimension affects these totals. Funding Efficiency reaches its share through four attributes, whereas Relational Strength reaches a comparable share through one. Per attribute, Relational Strength is more than three times as influential as any other dimension (0.558 against 0.157 for Funding Efficiency), so the ordering of dimensions reflects how many attributes each one contains as much as how much each contributes. The ordering of individual attributes is stable across learners; the ordering of dimension totals is not, and per-attribute values are therefore reported alongside dimension totals throughout.

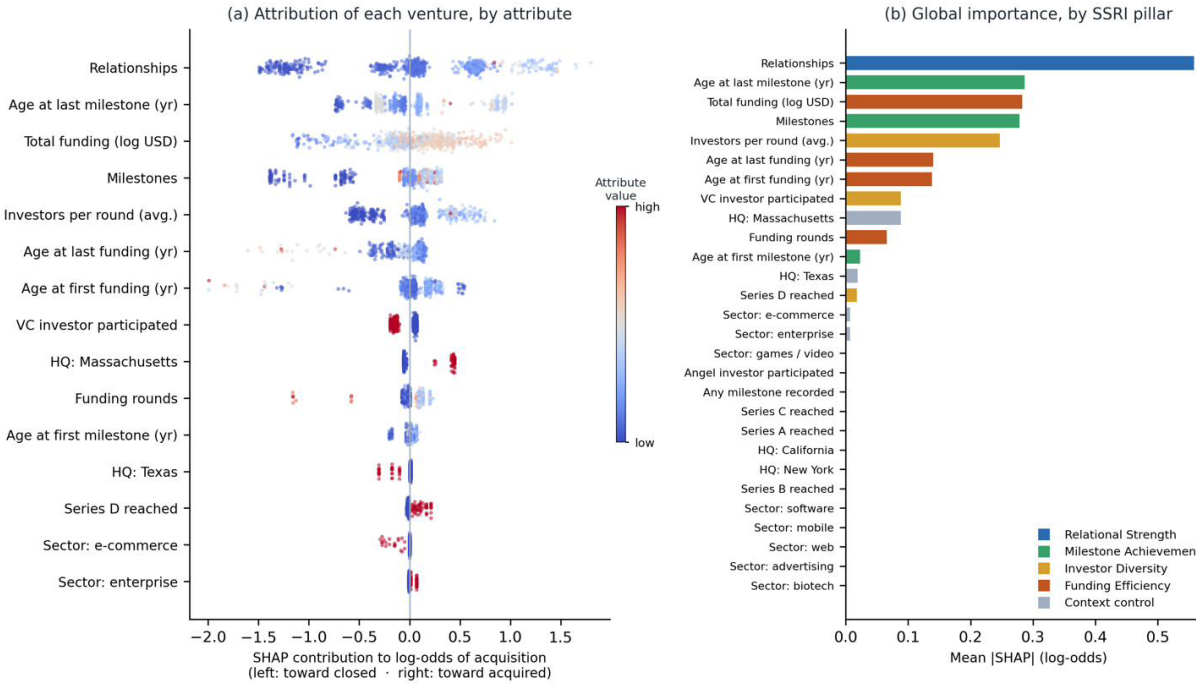

Figure 1: Attribute contributions to assessed readiness (SHAP)

4.4 Startup Success Readiness Index (SSRI)

The assessed readiness score is the model's output for a venture, a probability-scaled quantity that requires the fitted model to compute. The SSRI is a transparent composite index on a 0–100 scale that reproduces the model's reasoning in one line of arithmetic and can be computed on paper. The index is intended for programme use, where a score that cannot be inspected is of limited value.

Its construction proceeds in three steps. Each attribute is first rescaled to a common scale by min–max normalisation using bounds taken from the training partition only, and oriented so that a higher value always corresponds to higher readiness. For attribute j on venture i, with training bounds L_j and U_j and direction $\sigma_j \in \{+1, -1\}$:

$\tilde{x}_{ij} = \text{clip}((x_{ij} - L_j) / (U_j - L_j), 0, 1)$, $z_{ij} = \tilde{x}_{ij}$ if $\sigma_j = +1$, otherwise $1 - \tilde{x}_{ij}$

Second, each attribute is weighted by its share of attribution mass. Writing s_j for the mean absolute SHAP value of attribute j and S_p for the sum over the attributes of dimension p, the within-dimension weight is $w_{j|p} = s_j / S_p$ and the dimension weight is $W_p = S_p / \Sigma S$. The dimension sub-score and the composite are then:

$P_{ip} = 100 \times \Sigma_{j \in p} w_{j|p} \cdot z_{ij}$

$SSRI_i = \Sigma_p W_p \cdot P_{ip} = 0.2949\, P_{FE} + 0.2764\, P_{MA} + 0.2624\, P_{RS} + 0.1662\, P_{ID}$

The construction has three consequences. First, the weights are not chosen: they are the model's own attribution shares, so an attribute the model does not use receives weight zero automatically. Five of the sixteen attributes receive exactly zero weight, and the index therefore rests on eleven attributes. Second, since $W_p \cdot w_{j|p} = s_j / \Sigma S$, the two-level structure is algebraically identical to weighting every attribute by its plain share of total attribution mass; the dimension structure determines how a score is explained but has no effect on its value, and reassigning attributes between dimensions leaves every venture's SSRI unchanged. Third, the twelve sector and location controls are excluded from the index by design, since they are not levers available to a programme designer, and the weights of the remaining attributes are renormalised accordingly.

Table 2: Dimension weights derived from attribution mass

Dimension	Active/total attributes	W_p
Funding Efficiency (FE)	4 / 4	29.49%
Milestone Achievement (MA)	3 / 4	27.64%
Relational Strength (RS)	1 / 1	26.24%
Investor Diversity (ID)	3 / 7	16.62%

5. Discussion

5.1 Operationalising Ecosystem Constructs

This study asked whether ecosystem constructs can be mapped onto computable metrics that can be examined empirically. The results support this in a limited sense. OIF-PC defines its indicators at the level of a support programme, not the individual venture; what this analysis shows is that the constructs behind them have venture-level counterparts that are measurable and associated with observed outcomes. The framework itself is not tested here.

The attribution results show three correspondences. Funding attributes speak to the concern behind the Post-Competition Funding Index: ventures with larger and more frequent funding histories receive higher assessed readiness. Milestone attributes speak to the concern behind the Innovation Alignment Index, since milestone achievement records the conversion of intentions into observable progress rather than innovation as such. Relationship intensity is a venture-level counterpart to the Funnel Diversity Score(FDS): FDS was proposed for competition cohorts, but the number of recorded ties reflects the breadth of a venture's interaction with ecosystem actors, and it is the single most influential attribute in the model. These correspondences are interpretive rather than empirical equivalences, and give a basis for further work rather than measurement validation.

5.2 Validation of the Startup Success Readiness Index (SSRI)

The index was evaluated on the 185 reserved ventures, which were used neither for model fitting nor for any weight or normalisation bound. SSRI is positively associated with the outcome (point-biserial $r = 0.432$, $p = 8.2 \times 10^{-10}$; Spearman $\rho = 0.472$) and orders the reserved ventures with ROC-AUC = 0.785. Mean SSRI is 38.8 for acquired ventures against 29.3 for closed ventures (Cohen's $d = 1.00$). When ventures are ranked by SSRI and divided into quintiles, the observed acquisition rate falls from 86.5% in the highest quintile to 29.7% in the lowest. Figure 2 shows the two distributions. They overlap substantially but differ clearly in location.

Three qualifications apply. First, the index is measurably weaker than the model it summarises: the difference in ROC-AUC is 0.073 (95% CI 0.022 to 0.126), so transparency is obtained at a measurable cost in ordering quality. Second, relationships used alone are not statistically distinguishable from the full composite (difference 0.033, 95% CI −0.027 to 0.090); the index is therefore justified by the diagnostic profile it gives across four dimensions, not by better discrimination. Third, attribution weighting is not distinguishable from equal weighting at this sample size (difference 0.030, 95% CI −0.001 to 0.060), so the weights should be read as the model's measured emphasis, not as a demonstrated improvement over a simple average.

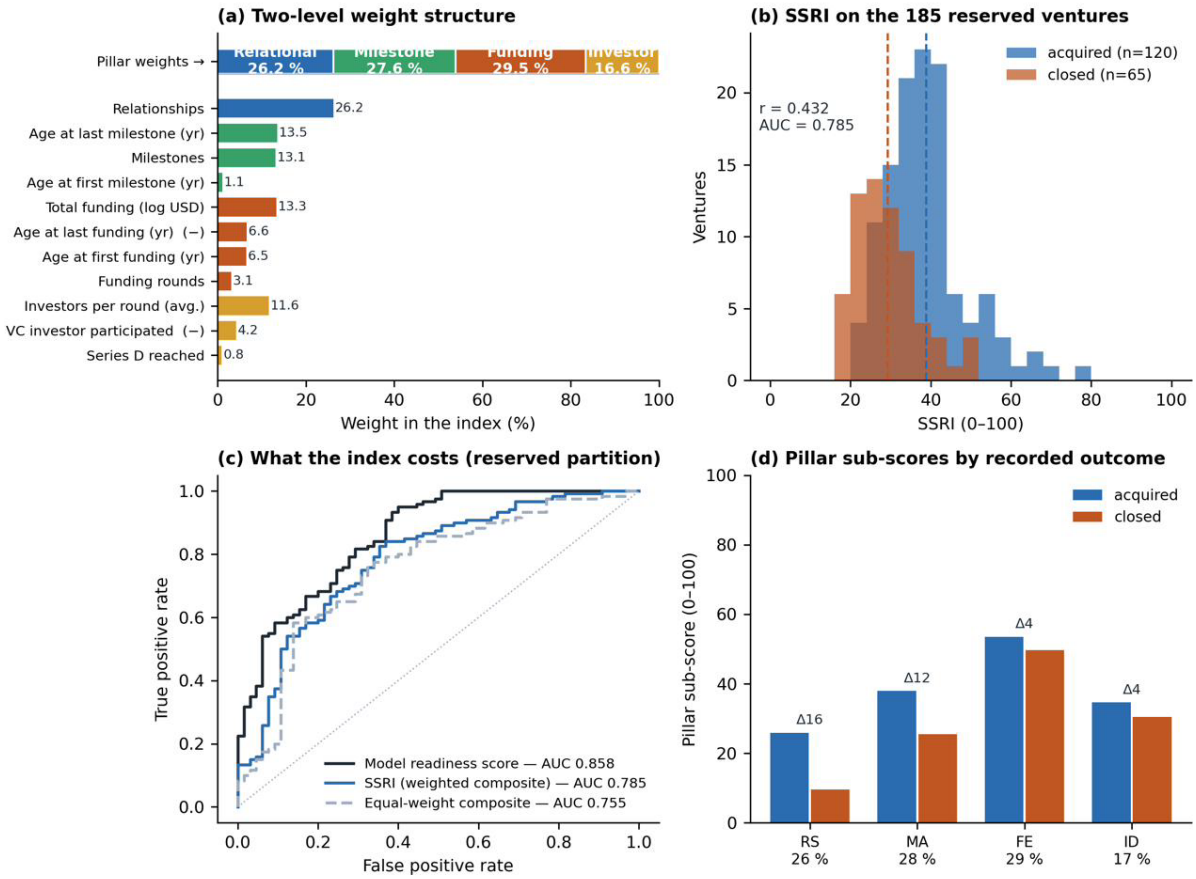

Figure 2: Distribution of SSRI by observed outcome

5.3 Interpretation and Practical Implications

The attribution results point to how resources are used rather than to how much of them a venture holds: in this sample, capital is associated with favourable outcomes when it appears together with relational and execution attributes rather than on its own. Three implications follow for support programmes, subject to the associative nature of the evidence. First, relational activity (deliberate connection to mentors, investors and industry partners) is the dimension with the highest attribution per attribute and the most direct programme lever. Second, progress is better represented by several recorded intermediate milestones than by a single terminal assessment. Third, support directed at how capital is deployed is a plausible lever alongside support directed at raising more of it. In the funnel logic that motivated the study, these are design parameters of a support programme rather than properties of a venture.

6. Conclusion

Motivated by the funnel logic of OIF-PC, this study expressed ecosystem characteristics as measurable venture attributes and examined them with interpretable machine learning models. These attributes are associated with observed outcomes, network connectivity most strongly. The study contributes the Startup Success Readiness Index, a transparent composite that translates model attribution into a score programmes can inspect and act on. Its limits are equally clear: the evidence is associative, the sample contains only resolved ventures, and the index summarises the model at a measurable cost in ordering quality.

Ethics Declaration

No ethical approval was required for this study. It did not involve human participants, animals or sensitive personal data, and it used only publicly available information and secondary sources.

AI Declaration

Artificial intelligence (AI) tools were used to help with language editing and to improve the clarity of the text. The authors reviewed, edited and verified every suggestion before it was included.

Appendix A: Model attributes

The model uses 28 attributes: 16 assigned to the four readiness dimensions and 12 sector and location controls. Weights are the attribution shares used in the SSRI; a weight of 0.00 indicates the attribute was not used by the model.

Attribute	Dimension	Description	Weight
relationships	RS	People and organisations	26.24%
age_last_milestone_year	MA	Years from founding to most recent milestone	13.48%
log_funding_total_usd	FE	log(1 + total capital raised, USD)	13.29%
milestones	MA	Count of recorded milestone events	13.10%

Reframing the Ecosystem: Ranking Organizations as Emerging Stakeholders in Entrepreneurial Ecosystems

Abstract: Entrepreneurial ecosystems are increasingly assessed through global ranking systems that claim to measure innovation capacity, competitiveness and startup activity. Yet little is known about how these rankings influence and shape the very environments they evaluate. This study addresses this gap by examining ranking organizations as influential actors within entrepreneurial ecosystems. Drawing on stakeholder theory and based on seventeen semi-structured expert interviews, the study applies the Gioia methodology to explore how rankings affect perceptions, strategies and governance processes. The analysis identifies five mechanisms through which ranking organisations exert influence: structural data constraints, methodological ambiguity, stakeholder-oriented interpretation, interaction with ecosystem actors and legitimacy building effects. Our results show that the influence of rankings derives less from empirical precision than from their interpretive use, perceived legitimacy and public visibility. The findings further indicate that the understanding and use of rankings develops through ongoing dialogue between producers and users, resulting in an emerging interpretive form of co creation. Building on these findings, we introduce the concept of meta-stakeholders, defined as actors that evaluate entrepreneurial ecosystems while simultaneously influencing their development. The study demonstrates the performative power of measurement and its role in shaping entrepreneurial legitimacy and policy agendas. It contributes to research on entrepreneurial ecosystems by advancing a relational and interpretive perspective on evaluation processes and by conceptualising ranking organisations as meta-stakeholders that actively shape ecosystem dynamics.

Keywords: Entrepreneurial Ecosystems, Ecosystem Rankings, Stakeholder Theory, Ranking Organizations, Ecosystem Stakeholder

1. Introduction and Motivation

Entrepreneurial ecosystems are often described as dynamic constellations of startups, investors, universities, and public institutions that collectively drive innovation and competitiveness (Feld 2020). In recent years, a new and largely overlooked group of actors has gained influence over how these ecosystems are perceived, governed and resourced: the global ranking organisations. Although existing research discusses how measurement systems can shape behaviour and frame collective expectations, relatively little is known about the mechanisms through which ecosystem rankings exert influence on the environments they describe.

Entities such as Startup Genome, StartupBlink, the Global Entrepreneurship Monitor (GEM), and the World Intellectual Property Organization (WIPO) have become influential actors that not only observe or measure entrepreneurial ecosystems but also shape their narratives and priorities. Through the production of data-driven comparisons, they draw attention to specific indicators, enhance the visibility of certain regions, and may indirectly influence where public and private actors allocate resources or focus strategic efforts (see also (Espeland & Sauder 2007; Kornberger et al. 2017; Harima et al. 2024)). Rankings therefore function as more than diagnostic instruments. They produce simplified and highly visible representations of complex realities that can guide policy decisions, investment strategies and ecosystem positioning.

Building on stakeholder theory (Freeman 1984), this paper argues that ranking organisations qualify as meta stakeholders, meaning actors that not only evaluate entrepreneurial ecosystems but also participate in shaping them through their evaluative authority, interpretive influence and symbolic legitimacy. Their activities create feedback loops in which measurement, perception and strategic decision making become intertwined. As the empirical findings show, the relationship between producers and users of rankings is characterised by ongoing interpretive engagement and selective collaboration, resulting in an emerging form of co creation that contributes to the evolving meaning of ranking outcomes. To investigate these dynamics, this study addresses two research questions:

1. How do ranking organizations operate as influential actors within entrepreneurial ecosystems?

2. Through what mechanisms do rankings shape ecosystem actors' perceptions, strategies, and governance practices?

This paper has two complementary aims. The first aim is to identify empirically the mechanisms through which ranking organisations influence ecosystem perceptions, strategies and legitimacy. The second aim is to develop a conceptualisation of ranking organisations as meta stakeholders, thereby integrating them into broader discussions on evaluation, governance and the performative effects of metrics. To avoid conceptual overlap, these two dimensions are examined separately. Section 4 presents the mechanisms derived from the empirical material, while Section 5 synthesises these findings into the conceptual contribution.

2. Conceptual Background and Research Gap

While research (Fubah & Moos 2021; Mason & Brown 2014; Stam & van de Ven 2021; Wurth et al. 2022) conceptualises entrepreneurial ecosystems as interconnected networks of firms, universities, financial institutions, and policy actors, it largely overlooks the role of ranking organisations.

Existing literature on quantification and governance suggests that metrics can become performative: they influence the realities they claim to measure (Espeland & Sauder 2007; Infantino & Bussani 2023; Mingers & Willmott 2013). From this perspective, entrepreneurial ecosystem rankings may not only reflect existing ecosystems but also construct them by signaling which attributes are considered most relevant: innovation capacity, funding intensity, or startup density. By defining, evaluating, and at times actively collaborating with governments and development agencies to improve these ecosystems, ranking organisations position themselves as quasi-policy actors that both measure and shape entrepreneurial environments.

Hence, the research gap addressed here is twofold:

1. Conceptual: The lack of integration of ranking organizations into stakeholder frameworks.
2. Empirical: The limited understanding of how rankings influence ecosystem actors and are, in turn, influenced by them.

3. Methodology and Empirical Foundation

To investigate how ranking organizations influence entrepreneurial ecosystems and how their legitimacy and impact are perceived, seventeen semi-structured expert interviews were conducted between December 2024 and February 2025. To ensure that the interviews captured both the production and user perspectives of ecosystem rankings, participants were selected through purposive sampling. Representatives of ranking organisations were identified through desk research based on their direct involvement in producing or managing one of the seven rankings analysed in this study. The selection of the seven rankings followed a purposive sampling logic based on criteria such as recency, geographical scope, and thematic focus on entrepreneurial ecosystems. At the same time, the final set of rankings reflected variation in methodologies, data sources, and institutional backgrounds, enabling a more comprehensive understanding of how ranking practices shape entrepreneurial ecosystems. Ecosystem researchers, policymakers, and practitioners were chosen for their academic or professional expertise related to entrepreneurial ecosystems, innovation policy, or ranking use. Potential interviewees were contacted via email or LinkedIn. This approach ensured that all participants possessed substantial, relevant knowledge of the phenomenon under investigation.

The sample comprised seven representatives of ranking organisations and ten ecosystem experts. Interviews were conducted in both online and in-person formats and lasted between 14 and 53 minutes, with an average duration of approximately 34 minutes. In total, the dataset comprises approximately 9.5 hours of recorded interview material. The full interview guides used for both ranking organizations and ecosystem experts are provided in the Appendix.

All interviews were recorded, transcribed, and analyzed using the Gioia methodology (Gioia et al. 2013). In line with more recent methodological developments, the Gioia approach combines inductive and abductive reasoning, allowing iterative linking between empirical insights and existing theory (Magnani and Gioia 2023). The analysis followed the three-stage coding process of identifying first-order concepts, developing second-order themes, and aggregating these into overarching dimensions. First-order concepts remained closely tied to informant-centric terms, while second-order themes reflect emerging theoretical interpretations developed by the researchers. This structured approach enhances transparency by making explicit how empirical observations are translated into theoretical insights.

4. Findings: Mechanisms of Influence

This section presents five mechanisms through which ranking organisations influence entrepreneurial ecosystems. The analysis revealed mechanisms that emerged across both interview groups. These mechanisms synthesise the dominant second order themes identified in the data. Figure 1 presents an overview of these themes.

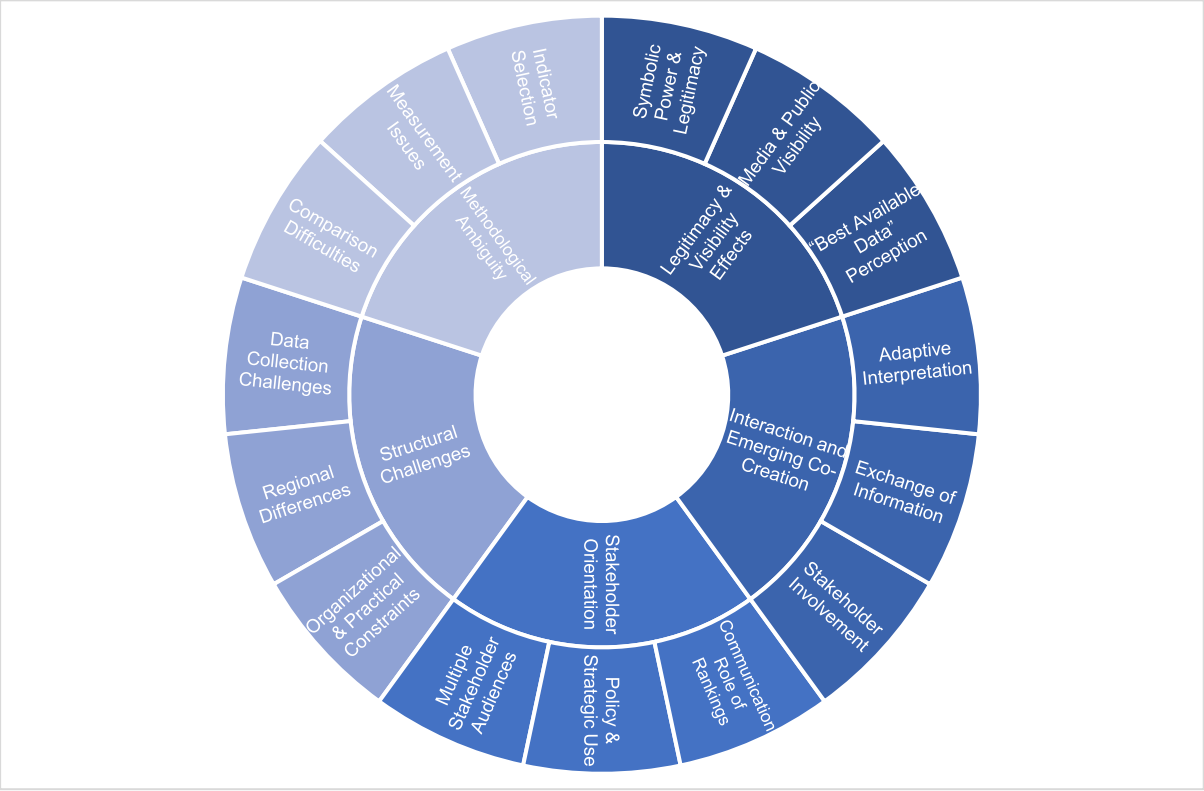

Figure 1: Selected Mechanisms Through Which Ranking Organisations Influence Entrepreneurial Ecosystems

4.1 Structural Challenges

The first mechanism relates to the structural constraints surrounding the data on which rankings rely. Interviewees consistently described challenges arising from heterogeneous, overlapping, and incomplete data sources. Ranking organisations typically draw on multiple large-scale databases such as Crunchbase, PitchBook, and Dealroom, as well as survey-based inputs, which often capture the same events in parallel. This leads to duplication issues and requires significant data processing efforts. As one respondent explained, "all three data sources are going to show that they got the funding. So, if you just process this in a straight way, you get a lot of duplicates […]. We built our in-house technology through which we are removing the duplicates from all three data sources and then picking the main one." (I 1.3)

Beyond duplication, interviewees highlighted broader challenges related to integrating and harmonising multiple data sources. Ranking organisations rely on combining diverse datasets to construct comprehensive representations of entrepreneurial ecosystems. As one respondent noted, "we pull from a lot of different data sources […] for example trade registers […] and then you get a bunch of information that helps populate the data." (I 1.2) This illustrates that rankings are based on the aggregation and enrichment of fragmented data inputs rather than on a single consistent data source.

In addition to technical inconsistencies, geographic variation in reporting practices creates asymmetries in data quality. Smaller and emerging ecosystems often exhibit incomplete reporting infrastructures, while others benefit from more systematic data collection. As one interviewee noted, "we should account better for the fact that data of provider x is probably of higher quality in the UK than in other countries in Europe." (I 1.6) Another interviewee explained, "it depends on the region's willingness to provide the information… some countries are better at providing information… and they tend to benefit" (I 2.2). This suggests that differences in data coverage

and reporting quality can create structural advantages for some ecosystems while reducing the visibility of others.

Organisational constraints also limit the extent to which ranking producers can validate information or refine methodologies. Ranking organisations often operate with relatively small teams and limited resources. As one interviewee noted, “we are a small team […] if I count our fellows […] we are eight people.” (I 1.1) This suggests that the scope for extensive data validation and methodological refinement may be constrained by available organisational resources.

Taken together, these structural constraints demonstrate that ranking outcomes are not solely the result of neutral measurement processes, but are shaped by the availability, quality, and integration of underlying data. As a result, differences in data infrastructures can translate into systematic differences in how ecosystems are represented and compared.

4.2 Methodological Ambiguity

While structural challenges relate to data availability and infrastructure (Section 4.1), this second mechanism focuses on the methodological choices through which such data is interpreted and operationalised. Interviewees highlighted that indicator selection is shaped by a combination of conceptual considerations and practical constraints, including data availability, the historical evolution of ranking models and the need to maintain longitudinal comparability. These factors contribute to diversity across rankings in terms of which dimensions of entrepreneurial activity are emphasised and how they are operationalised. As one ranking producer explained, “you have this theoretical construct… what is the best way to measure each of these… there’s no perfect data… you try to go as close to that as possible” (I 1.3), highlighting that methodological design involves continuous trade-offs between conceptual ideals and empirical feasibility.

Participants also pointed to several measurement-related challenges, such as gaps in available indicators, differences in taxonomies across data providers or delays in updating certain datasets. In particular, interviewees highlighted that many dimensions of entrepreneurial ecosystems cannot be directly measured and therefore require the use of proxies. As one respondent noted, “we always use proxies… we were not able to measure the real quality” (I 1.6), indicating that operationalisations often only approximate the underlying constructs. While these issues do not fundamentally undermine the usefulness of rankings, they can influence how specific ecosystems appear in comparative assessments.

Furthermore, variations in ecosystem size, maturity and structural characteristics can make direct comparisons difficult. Interviewees emphasised that the relevance of ranking criteria depends on context and user perspective, suggesting that ecosystem performance cannot be assessed through a single universal framework. As one respondent stated, “how thriving the ecosystem is, depends on the person who needs this information” (I 2.9). This highlights that rankings inevitably simplify complex realities and may privilege certain models of success over others.

Finally, interviewees noted that even small methodological adjustments may shift rank positions, which underscores the interpretive nature of these exercises. The construction of rankings involves discretionary choices that can significantly shape outcomes. As one expert critically observed, “if you pick the right variables… you can create a ranking to make yourself look good” (I 2.5). Overall, the interviews suggest that ranking methodologies require a series of informed decisions and trade-offs rather than representing purely mechanical measurement processes.

4.3 Stakeholder Orientation

The third mechanism highlights the diverse set of stakeholders who use and interpret ranking outputs. Interviewees emphasised that rankings are consumed by multiple stakeholder audiences, including policymakers, investors, entrepreneurs and ecosystem builders. Each of these actors engages with rankings in different ways, reflecting their specific informational needs and strategic priorities. As one respondent explained, “one of the biggest stakeholders are policymakers,” but rankings are also relevant to “venture capitalists, family offices or business incubators as well as entrepreneurs deciding where to be based“ (I 2.4). This suggests that ranking outputs do not address a single audience, but circulate across a heterogeneous set of actors with different expectations and uses.

In particular, rankings are frequently used for policy and strategic purposes. Policymakers draw on rankings to communicate progress, guide strategic decisions and justify interventions, while ecosystem builders and support

organisations use them for benchmarking and partner selection. As one interviewee noted, “often entrepreneurship support organization apply for European fundings, then yeah, they might consider looking at the ranking to identify potential partners” and policymakers may look for ecosystems with “similar geographical characteristics” in order to find comparable examples (I 2.9). Rankings therefore function not only as descriptive tools, but also as strategic reference points in ecosystem development and policy learning.

Beyond their instrumental use, rankings also fulfil an important communicative function. Interviewees stressed that rankings shape public narratives by directing attention towards particular indicators or dimensions of entrepreneurial activity. Through media communication, reports and public announcements, rankings influence how ecosystems perceive themselves and how they are perceived externally. As one policymaker put it, rankings are often “a marketing aspect” (I 2.10). This communicative role broadens their relevance beyond measurement alone and contributes to their continued presence in policy and strategy discourses.

4.4 Interaction with Ecosystem Actors

The fourth mechanism concerns the informal and at times more structured interactions between ranking organisations and ecosystem actors. Interviewees reported that policymakers, analysts and local ecosystem agencies frequently reach out to ranking producers to clarify unexpected results, indicator definitions or contextual factors that might influence a region’s position. These enquiries illustrate that ranking outputs require ongoing interpretive work and that stakeholders are actively involved in making sense of the results. As one respondent noted, stakeholders often “come back with questions” when results are unclear or surprising, particularly when rankings do not align with local expectations (I 1.5).

Several interviews also indicated that ecosystem actors provide additional contextual information, such as local data or explanations of region-specific developments. Although such material is not systematically integrated into ranking methodologies, respondents noted that it can shape how ranking organisations communicate results or respond to questions. As one interviewee explained, “sometimes they share additional data or context with us which helps to better understand specific ecosystem dynamics, even if it is not directly incorporated into the ranking model” (I 1.4).

In some cases, these exchanges extend beyond ad hoc clarification. Individual interviewees pointed out that certain ranking organisations periodically engage with governments in a more formal capacity, offering analytical support or policy-oriented insights that resemble consulting activities. As one respondent described, “we also work with governments […] providing more detailed analysis and insights,” indicating that ranking organisations may assume an advisory role alongside their evaluative function (I 1.6). While these collaborations are not part of the core ranking process, they illustrate that ranking organisations sometimes act as intermediaries in ecosystem development.

The interviews do not suggest structured co-development, but reveal a pattern of recurring interpretive interactions and selective collaboration through which meaning-making occurs via dialogue rather than a one-directional flow of information.

4.5 Legitimacy and Visibility Effects

The final mechanism concerns the symbolic dimension and public visibility of rankings. A first aspect relates to the perception of rankings as the “best available” source of comparative information. Interviewees noted that rankings maintain influence because stakeholders rely on them pragmatically, even when their limitations are acknowledged. This was particularly evident among municipal representatives. As one ecosystem manager explained, rankings are “absolutely not 100%, but from time to time you have to admit that it’s the best available data […]. It’s not an official statistic, but it’s the best available thing” (I 2.9). This is further reinforced by the observation that “each is imperfect… it is consistency of the rankings that we look at” (I 2.2), suggesting that users rely on rankings despite known limitations.

A second aspect concerns the symbolic power and legitimacy of rankings. Interviewees indicated that rankings are often treated as authoritative reference points, even though their construction could have subjective and methodological choices. As one respondent critically noted, “they maybe have even political agenda… how bias free is it?” (I 2.9) This highlights that rankings derive influence not only from their empirical content but also from their perceived legitimacy and authority within public and policy discourses.

Finally, visibility further amplifies these effects. Governments and ecosystem agencies frequently publicise favourable outcomes to strengthen international positioning and attract investment and talent. Interviewees

described rankings as a tool for external communication and image-building, particularly when results are positive. As one respondent noted, when outcomes are favourable, they become "a nice thing to do some celebration on media" (I 2.10).

5. Conceptualising Ranking Organisations as Meta Stakeholders

Building on the five mechanisms identified in Section 4, this section addresses the first research question by conceptualising how ranking organisations operate as influential actors and evaluative intermediaries within entrepreneurial ecosystems. Taken together, the findings demonstrate that ranking organisations do not merely observe entrepreneurial ecosystems but actively shape how they are evaluated, interpreted, and represented. Their influence derives not from direct participation in entrepreneurial activity, but from their ability to define evaluative categories, structure interpretive contexts, and produce symbolic signals that guide strategic decision-making.

The empirical findings suggest that ranking organisations occupy a position that extends beyond that of conventional stakeholders. Through their evaluative practices, they influence how ecosystem actors perceive performance, allocate attention, and communicate legitimacy. We introduce the concept of meta-stakeholders, defined as actors that evaluate entrepreneurial ecosystems while simultaneously shaping the criteria, interpretations, and narratives through which these ecosystems are understood. In this role, ranking organisations influence not only outcomes within ecosystems but also the evaluative frameworks that guide how these outcomes are assessed and interpreted.

5.1 Evaluative Authority

The mechanisms related to structural data challenges and methodological ambiguity show that ranking organisations possess considerable authority in establishing the frameworks through which entrepreneurial ecosystems are assessed. By selecting indicators, defining measurement criteria and constructing comparative models, they shape understandings of what constitutes performance, maturity or success. Even when these choices are influenced by data availability or operational constraints, they nonetheless have a structuring effect on how entrepreneurial activity is conceptualised. This evaluative authority positions ranking organisations as actors who, through their methodological decisions, implicitly set standards for ecosystem performance.

5.2 Interpretive and Strategic Influence

The interviews also highlight the interpretive influence that arises from the diverse ways in which stakeholders engage with rankings. Policymakers draw on ranking results to communicate progress, justify interventions and orient strategic development efforts. Investors and ecosystem builders interpret rankings as signals of potential, while entrepreneurs often use them selectively when considering locations or assessing global trends. These interpretive dynamics illustrate that rankings shape how information is framed and understood within entrepreneurial ecosystems. Their influence extends beyond technical measurements and enters the realm of strategic sensemaking, reinforcing the position of ranking organisations as actors who contribute to public narratives and policy orientations.

5.3 Symbolic Legitimacy

The mechanism related to legitimacy and visibility demonstrates that rankings generate symbolic value that extends beyond empirical accuracy. Stakeholders often regard rankings as the most accessible comparative information available, even when they acknowledge their limitations. This pragmatic acceptance reinforces the legitimacy attributed to ranking outputs and enables them to function as recognised signals in public communication and decision-making. National and local governments frequently reference favourable ranking results to strengthen their international positioning and attract investment, as illustrated by Singapore's public communication regarding its improved position in the Global Startup Ecosystem Index 2025 (Enterprise Singapore 2025). Rankings thus serve not only as evaluative instruments but also as legitimacy-building tools that ecosystem actors strategically employ to signal progress and credibility (Toepler et al. 2025).

5.4 The Meta Stakeholder Role

Taken together, the findings demonstrate that ranking organisations shape evaluative criteria, structure interpretive contexts, and contribute to the production of legitimacy within entrepreneurial ecosystems. Their

influence does not stem from direct participation in entrepreneurial activity, but from their capacity to define how such activity is measured, interpreted, and communicated.

Unlike traditional stakeholders, who directly participate in value creation processes within ecosystems, ranking organisations operate at a meta level. They do not produce entrepreneurial outcomes themselves but instead shape the frameworks through which these outcomes are evaluated and understood. Through their methodological choices, they influence what is considered relevant performance. Through their visibility and communication, they affect how ecosystems are perceived externally. Through their interaction with stakeholders, they contribute to the ongoing interpretation and contextualisation of ranking results.

This positioning enables ranking organisations to act as *meta stakeholders*: actors that evaluate entrepreneurial ecosystems while simultaneously influencing their development through evaluative authority, interpretive engagement, and symbolic legitimation. Their influence emerges through the circulation and use of their evaluations, creating feedback loops in which measurement, perception, and strategic action become intertwined. As a result, ranking organisations do not merely reflect entrepreneurial ecosystems but actively participate in shaping their trajectories.

6. Conclusion

This study examined how ranking organisations influence entrepreneurial ecosystems and how this influence can be conceptualised within a stakeholder-theoretical perspective. Through seventeen expert interviews, the analysis identified five mechanisms that describe how ranking organisations shape evaluative standards, interpretive environments and symbolic meaning within ecosystems. These insights support a broader conceptualisation of ranking organisations as meta stakeholders whose influence emerges from evaluative authority, interpretive impact and symbolic positioning.

6.1 Conceptual Contribution

The findings contribute to stakeholder theory by suggesting that ranking organisations can be understood as influential actors and evaluative intermediaries within ecosystem governance. Their influence arises from the capacity to define what is measured, shape how information is interpreted, and generate signals that contribute to legitimacy. By conceptualising ranking organisations as meta-stakeholders, the study further contributes to research on entrepreneurial ecosystems and the governance of markets through metrics, highlighting how evaluation itself becomes a source of influence in complex socio-economic systems.

6.2 Mechanistic Contribution

The empirical analysis identified five mechanisms that explain how rankings influence entrepreneurial ecosystems. Structural data challenges and methodological ambiguity reveal how evaluative frameworks are constructed. Stakeholder orientation demonstrates how diverse actors use and interpret ranking outputs. Interaction with ecosystem actors illustrates the iterative dialogues through which meaning is negotiated, while legitimacy and visibility effects highlight the symbolic dimensions that amplify ranking influence. Together, these mechanisms show that the impact of rankings emerges less from empirical precision than from their role in structuring interpretation, communication and perceived legitimacy.

6.3 Practical Implications

The findings have several implications for key stakeholders within entrepreneurial ecosystems. For policymakers, rankings should be used as complementary rather than definitive tools. They should critically assess underlying methodologies and interpret results in light of local data and context, particularly when responding to small rank changes. For ranking organizations, the results highlight the need for greater transparency regarding indicators, weighting, and methodological changes. Clearer communication can support more informed use and interpretation of rankings. For ecosystem builders and support organizations, rankings can be useful for benchmarking and external positioning, but should not be relied on in isolation. Greater focus on underlying indicators and consistent data contribution may improve both strategic use and representation. For researchers, the study highlights the relevance of evaluative intermediaries and the need for complementary approaches that capture dimensions not reflected in rankings.

6.4 Outlook

Future research could explore how digital data infrastructures, algorithmic evaluation systems, and new forms of public–private data collaboration reshape the relationship between measurement and influence in entrepreneurial ecosystems. These developments may further illuminate the evolving authority of rankings and the growing role of evaluative actors in shaping strategy, legitimacy, and governance. Ultimately, rankings do not merely measure entrepreneurial ecosystems but actively contribute to their construction.

Ethics Declaration

Ethical clearance was not required for this study. All participants provided informed consent and participated voluntarily.

AI Declaration

AI-based tools were used to support the writing process, including language refinement, editing, and formatting. All core ideas, analyses, and interpretations presented in this paper are the authors' own. The use of AI tools did not influence the research design, data collection, analysis, or the substantive contributions of the study.

Patent Portfolio Management in Utility Organizations: An Innovation-to-Value Framework for Transforming Invention Disclosures into Strategic Organizational Assets

Mariam Alqasimi
Innovation & Intellectual Property Management, Utility Sector

Abstract: Patent portfolio management has evolved beyond the traditional role of intellectual property protection and increasingly serves as a strategic mechanism for supporting innovation, organizational competitiveness, and value creation. Despite growing investments in research and development, many utility organizations continue to face challenges in systematically transforming invention disclosures into measurable organizational outcomes. Existing literature predominantly focuses on patent protection, valuation, and commercialization as independent domains, while limited attention has been given to an end-to-end management framework that connects invention generation, intellectual property protection, portfolio optimization, and strategic value realization. This paper proposes an Innovation-to-Value Patent Management Framework (IVPMF) designed specifically for innovation-intensive utility organizations. Drawing upon more than seven years of professional experience in intellectual property portfolio management, innovation governance, patent strategy, and technology transfer, the framework demonstrates how organizations can transition from reactive patent filing practices toward proactive portfolio management approaches that align innovation activities with organizational objectives. The proposed framework consists of nine interconnected stages: opportunity identification, invention disclosure, technical validation, prior-art intelligence, patentability assessment, strategic portfolio prioritization, protection strategy, commercialization readiness, and strategic value creation. The framework is supported by practitioner observations derived from the management of more than one hundred patentability assessments, fifty to sixty patent filings, twenty granted patents, and twenty-three commercialization support and internal deployment pathways across multiple technology domains. The findings suggest that organizations can significantly improve innovation outcomes when patent portfolio management is integrated into broader innovation governance structures rather than treated as an isolated legal function.

Keywords: Patent Portfolio Management; Innovation Management; Intellectual Property Management; Technology Transfer; Utility Innovation; Knowledge Management; Innovation Governance; Strategic Value Creation; Patent Strategy; Commercialization.

1. Introduction

Innovation has become a critical determinant of organizational competitiveness, particularly within utility organizations operating in increasingly dynamic technological, environmental, and regulatory environments. Historically, utility organizations focused primarily on operational reliability, infrastructure management, and service continuity. However, the global transition toward digitalization, sustainability, decarbonization, smart infrastructure, artificial intelligence, and advanced energy technologies has significantly increased the importance of research, development, and innovation activities within the sector.

As innovation activities expand, organizations generate increasing volumes of intellectual assets in the form of inventions, technical know-how, proprietary methodologies, software solutions, and emerging technologies. Intellectual property protection, particularly through patents, plays a fundamental role in safeguarding these innovations and enabling organizations to maintain competitive advantages while maximizing returns on research and development investments.

Despite growing awareness of intellectual property importance, many organizations continue to view patent management primarily as a legal or administrative activity focused on filing applications and securing protection rights. Such an approach often results in fragmented decision-making processes, inefficient allocation of resources, underutilized patent portfolios, and limited connections between innovation activities and strategic organizational objectives.

The limitations of traditional patent management approaches have led scholars and practitioners to advocate for more strategic portfolio management models. Rather than evaluating inventions individually, organizations are increasingly encouraged to manage intellectual property as a portfolio of strategic assets capable of supporting technology leadership, competitive positioning, commercialization opportunities, partnerships, and long-term organizational growth.

Within utility organizations, this challenge becomes particularly significant due to the multidisciplinary nature of innovation activities. Research initiatives frequently span renewable energy systems, advanced materials, smart grids, digital technologies, artificial intelligence applications, water technologies, automation systems, and

sustainability solutions. Managing such diverse innovation outputs requires structured processes capable of balancing technical merit, commercial potential, strategic relevance, and resource constraints.

Furthermore, innovation success is not determined solely by the number of patents filed or granted. The true value of intellectual property emerges when inventions contribute to organizational objectives through commercialization, technology deployment, strategic partnerships, operational improvements, knowledge creation, or competitive differentiation. Organizations therefore require mechanisms that connect invention generation with value realization throughout the innovation lifecycle.

While extensive literature exists regarding patent valuation, patent strategy, technology transfer, and innovation management, relatively limited attention has been devoted to developing integrated frameworks that connect invention disclosure management, patent portfolio governance, commercialization readiness, and strategic value creation within utility-sector environments. This gap creates a need for practical and transferable approaches capable of supporting innovation-intensive organizations.

This paper addresses this challenge through the development of the Innovation-to-Value Patent Management Framework (IVPMF). The framework proposes a structured pathway through which organizations can systematically transform invention disclosures into strategic organizational assets while aligning intellectual property activities with broader innovation objectives. It draws upon practitioner experience accumulated through intellectual property portfolio management, patentability assessments, invention disclosure evaluation, portfolio strategy development, technology transfer support, and commercialization readiness activities.

The remainder of this paper is organized as follows. Section II reviews relevant literature on patent portfolio management, innovation governance, and technology transfer. Section III outlines the methodology used to develop the framework. Section IV introduces the Innovation-to-Value Patent Management Framework and its supporting figures. Section V discusses practical implementation insights and organizational implications. Section VI presents conclusions and recommendations for future research and practice.

2. Literature Review

2.1 Evolution of Patent Portfolio Management

Intellectual property has become an increasingly important organizational asset within knowledge-intensive industries. Historically, patent management was viewed as a legal function focused on securing exclusive rights to inventions and protecting technological developments from unauthorized use. Early practices emphasized patent filing volumes, geographical coverage, and legal enforceability as the primary indicators of success.

Over time, however, organizations recognized that patents represent more than legal instruments. Patents embody codified organizational knowledge, technological capabilities, and innovation outcomes that can influence competitive positioning, market access, collaboration opportunities, and long-term organizational performance. As a result, patent portfolio management has evolved into a strategic management discipline that integrates intellectual property considerations into broader business and innovation strategies.

Granstrand (1999) argued that intellectual property portfolios should be managed as strategic assets that contribute to value creation rather than as isolated legal protections. Similarly, Teece (1986) highlighted the importance of complementary assets and organizational capabilities in transforming technological innovations into economic value. More recent open innovation research has reinforced this shift by showing that intellectual property decisions increasingly operate within broader innovation ecosystems, collaboration models, and knowledge flows rather than within purely legal boundaries (Gassmann et al., 2010; Bogers et al., 2018). These perspectives collectively move attention from individual patents toward the management of patent portfolios as interconnected collections of innovation assets.

Modern patent portfolio management therefore encompasses invention disclosure management, patentability assessment, portfolio optimization, filing strategy development, patent valuation, commercialization support, technology transfer, and portfolio governance. It is also increasingly informed by patent analytics and evidence on patent quality, citation impact, and strategic positioning (Hall et al., 2005; World Intellectual Property Organization [WIPO], 2024). Organizations seeking to maximize returns on research and development investments must ensure that patent activities align with strategic objectives rather than operate independently from innovation management functions.

2.2 Intellectual Property as a Strategic Asset

The resource-based view of the firm (Barney, 1991) suggests that sustainable competitive advantage arises from valuable, rare, difficult-to-imitate, and non-substitutable resources. Intellectual property often satisfies these criteria because it protects unique technological capabilities while creating barriers to imitation. Subsequent research has further shown that well-managed intellectual property portfolios contribute to reputation, bargaining power, market signaling, and innovation positioning, especially in environments characterized by collaboration and open innovation (Reitzig, 2004; Hall et al., 2005; Bogers et al., 2018).

Reitzig (2004) proposed that patents provide value through multiple pathways, including exclusion of competitors, licensing opportunities, negotiation leverage, and signaling effects. More recent global evidence also indicates that intellectual property is increasingly embedded in national and organizational innovation strategies, making portfolio quality and strategic coherence as important as filing volume (WIPO, 2024). Within utility organizations, this strategic role is especially significant because innovation activities often require high capital investment, long development cycles, infrastructure integration, and multidisciplinary collaboration.

2.3 Innovation Management and Value Creation

Innovation management literature emphasizes the systematic transformation of ideas into valuable outcomes. Innovation processes generally involve idea generation, evaluation, development, implementation, and value realization. Schumpeter (1934) highlighted the role of new combinations of knowledge, technologies, and resources in driving economic development. Contemporary scholars such as Tidd and Bessant (2020) and Trott (2021) describe innovation management as the process of organizing resources, learning mechanisms, and capabilities to create and capture value from innovation activities, while the OECD (2018) provides an updated policy-oriented definition of innovation that includes both products and business processes.

Utility organizations face unique innovation challenges because they must simultaneously pursue operational reliability, sustainability objectives, technological modernization, regulatory compliance, and customer expectations. Patent portfolio management can therefore play a critical role within innovation management systems by supporting decision-making, protecting innovation outputs, and facilitating value realization. Nevertheless, many organizations continue to manage innovation and intellectual property as separate functions, limiting opportunities for knowledge integration and reducing the strategic benefits that can be derived from coordinated innovation governance (Tidd & Bessant, 2020; Trott, 2021).

2.4 Technology Transfer and Commercialization

Technology transfer refers to the movement of knowledge, technologies, capabilities, or innovations from one context to another for practical application and value creation. Bozeman (2000) argued that technology transfer effectiveness should be evaluated based on outcomes rather than transfer activities alone. Later work by Bozeman et al. (2015) further demonstrated that technology transfer should be assessed through contingent effectiveness, public value, and organizational context rather than by narrow commercialization metrics alone. Multiple pathways therefore exist through which innovations generate value, including licensing, partnerships, joint ventures, spin-offs, internal deployment, and commercialization initiatives.

Within utility organizations, commercialization may occur through multiple mechanisms. Some innovations generate value through external partnerships or licensing arrangements, while others create value through internal deployment, operational improvements, cost reduction, sustainability enhancement, or service optimization. Technology transfer and commercialization readiness should therefore be viewed as integral components of patent portfolio management rather than downstream activities separated from portfolio decision-making (Bozeman, 2000; Bozeman et al., 2015).

2.5 Knowledge Management and Intellectual Capital

Nonaka and Takeuchi (1995) describe knowledge creation as a dynamic process involving interaction between tacit and explicit knowledge. Patent documentation represents a form of knowledge codification that transforms technical expertise into protected organizational assets. More recent work has further highlighted the bidirectional relationship between knowledge management and intellectual capital, showing that organizations create stronger innovation outcomes when knowledge capture, codification, and reuse are systematically linked to strategic capabilities (Garcia-Perez et al., 2020). Organizations that effectively manage intellectual capital are

therefore better positioned to preserve technical knowledge, support organizational learning, and facilitate knowledge sharing across boundaries.

2.6 Innovation Governance and Portfolio Decision-making

Cooper et al. (2001) emphasize that portfolio management enables organizations to prioritize projects, allocate resources effectively, and maintain strategic balance. Similar principles apply to patent portfolios, where organizations must determine which inventions justify protection, commercialization efforts, or additional investment. Recent innovation management literature also stresses that portfolio decisions should connect governance, learning, risk, and value creation rather than rely solely on technical screening (Tidd & Bessant, 2020; Trott, 2021). Strategic portfolio governance therefore requires evaluation criteria that extend beyond technical novelty; commercial potential, strategic relevance, competitive positioning, implementation feasibility, and long-term organizational impact must all be considered.

2.7 Research Gap

Although substantial literature exists on patent strategy, innovation management, technology transfer, commercialization, and knowledge management, these domains are frequently examined independently. Existing research rarely provides a unified framework that connects invention disclosure management, patentability assessment, portfolio governance, commercialization readiness, and strategic value creation within a single innovation lifecycle model, particularly in utility-sector settings. Current studies on open innovation, knowledge integration, and portfolio governance provide valuable insights (Bogers et al., 2018; Garcia-Perez et al., 2020), yet they do not offer an end-to-end practitioner-oriented framework tailored to infrastructure-intensive utility environments. The literature therefore reveals a need for a practical and transferable framework, which forms the foundation of the Innovation-to-Value Patent Management Framework proposed in this paper.

3. Methodology

3.1 Research Approach

This paper adopts a practitioner-based qualitative research approach to develop a practical framework for patent portfolio management within innovation-intensive utility organizations. The study is grounded in professional experience accumulated through more than seven years of involvement in intellectual property portfolio management, patent strategy development, innovation governance, technology transfer support, and commercialization readiness activities. Practitioner-based qualitative inquiry is appropriate when the purpose is to interpret processes, identify recurring patterns, and develop analytically transferable insights from real-world contexts (Creswell & Poth, 2018; Yin, 2018). The objective is not to evaluate a specific organization's performance, but to identify recurring practices, governance mechanisms, and decision pathways that can be generalized into a transferable management framework.

3.2 Data Sources

The framework was developed through observations derived from professional involvement in:

- Management of more than 100 patentability assessments.
- Support of approximately 50–60 patent filings.
- Contribution to approximately 20 granted patents.
- Support of 23 commercialization and internal deployment pathways.
- Invention disclosure management activities.
- Prior-art intelligence and patent landscape assessments.
- Patent prosecution support and filing strategy development.
- Portfolio analytics, reporting, and technology transfer support activities.
- Innovation awareness and inventor engagement programs.

The experience covered multiple technology domains including digital technologies, sustainability-related innovations, advanced engineering systems, artificial intelligence applications, smart infrastructure solutions, and emerging technology platforms.

3.3 Framework Development Process

The proposed Innovation-to-Value Patent Management Framework was developed through three stages. First, patent portfolio management activities were reviewed to identify common processes occurring throughout the innovation lifecycle, consistent with qualitative framework development approaches that move from patterned observation to conceptual synthesis (Creswell & Poth, 2018). Second, the identified activities were grouped according to their contribution to innovation progression, intellectual property protection, portfolio optimization, and value creation. Third, the activities were synthesized into a nine-stage framework representing the progression from invention generation to strategic organizational value creation, reflecting the portfolio logic emphasized in innovation governance literature (Cooper et al., 2001; Tidd & Bessant, 2020).

3.4 Limitations

The framework is based primarily on practitioner observations and therefore reflects experiences within innovation-intensive utility environments. While the framework is intended to be transferable across industries, future empirical studies may further validate its applicability within alternative organizational contexts. No confidential organizational information is disclosed in this paper.

4. The Innovation-to-Value Patent Management Framework (IVPMF)

4.1 Framework Overview

The Innovation-to-Value Patent Management Framework (IVPMF) proposes that patent portfolio management should be viewed as a strategic innovation process rather than a legal protection process. The framework integrates innovation management, intellectual property management, technology transfer, commercialization readiness, and portfolio governance into a single lifecycle model consisting of nine interconnected stages. This integrative view is consistent with research emphasizing the strategic coordination of innovation portfolios, knowledge flows, and value capture mechanisms rather than isolated legal or administrative actions (Tidd & Bessant, 2020; Trott, 2021). Figure 1 illustrates the overall framework.

Figure 1: Innovation-to-Value Patent Management Framework (IVPMF).

4.2 Stage 1: Opportunity Identification

Innovation opportunities originate from multiple sources including research activities, operational challenges, emerging technologies, sustainability objectives, customer needs, and strategic priorities. Organizations that

actively identify innovation opportunities create stronger pipelines of invention disclosures and improve portfolio quality. Opportunity identification should therefore be considered the starting point of patent portfolio management rather than an activity external to the process.

4.3 Stage 2: Invention Disclosure

The invention disclosure stage serves as the formal entry point into the intellectual property management process. Effective disclosure systems encourage inventors to document innovation outputs while providing sufficient technical detail for evaluation. Organizations should establish structured disclosure mechanisms capable of capturing technical, strategic, and commercial information.

4.4 Stage 3: Technical Validation

Technical validation assesses whether an invention is technically feasible and sufficiently mature for intellectual property evaluation. This stage typically involves inventor interviews, technical reviews, feasibility assessments, and clarification of innovation objectives. Technical validation reduces uncertainty and improves decision-making quality during subsequent stages.

4.5 Stage 4: Prior-Art Intelligence

Prior-art intelligence extends beyond traditional novelty searches. This stage incorporates patent landscapes, technology scouting, competitor intelligence, and research trend analysis. It contributes to novelty assessment, identification of technology gaps, strategic positioning, competitive awareness, and future research direction.

4.6 Stage 5: Patentability Assessment

Patentability assessment evaluates inventions according to established intellectual property criteria including novelty, inventive step, and industrial applicability. However, the proposed framework argues that patentability should not be evaluated solely from a legal perspective, strategic considerations should also influence assessment decisions.

4.7 Stage 6: Strategic Portfolio Prioritization

Strategic portfolio prioritization represents one of the most important contributions of the proposed framework. Many organizations focus exclusively on patentability while neglecting strategic portfolio considerations. This stage evaluates inventions according to strategic alignment, commercial potential, technology maturity, organizational impact, resource requirements, and competitive positioning.

4.8 Stage 7: Protection Strategy

Protection strategy determines how intellectual property rights will be secured and maintained. Key considerations include jurisdiction selection, filing route selection, budget allocation, portfolio balance, and technology lifecycle. Organizations should avoid applying identical filing approaches to all inventions; instead, protection strategies should reflect strategic objectives and portfolio priorities.

4.9 Stage 8: Commercialization Readiness

Commercialization readiness assesses the organization's ability to transform protected innovations into practical value. Potential pathways include internal deployment, licensing, strategic partnerships, technology transfer, operational integration, and future commercialization opportunities. Commercialization readiness should be evaluated before protection decisions are finalized whenever possible.

4.10 Stage 9: Strategic Value Creation

The final stage focuses on value realization. Value creation may occur through revenue generation, cost reduction, operational improvement, sustainability enhancement, strategic partnerships, competitive advantage, knowledge transfer, and organizational reputation. The framework emphasizes that patents achieve their greatest value when integrated into broader innovation ecosystems rather than remaining isolated legal assets.

4.11 Strategic Patent Decision Matrix

Figure 2 presents a strategic decision matrix that supports prioritization decisions for invention disclosures and patent assets. The matrix evaluates inventions along two dimensions: strategic value and commercial potential. The resulting quadrants guide appropriate management actions, ranging from accelerated commercialization to limited protection or strategic abandonment.

Table 1: Strategic Patent Decision Matrix.

	Commercial Potential	
	High	Low
Strategic Value High	Accelerate & Commercialize	Strategic Protection & Monitoring
Strategic Value Low	Selective Commercialization	Limited Protection or Abandonment

4.12 Utility Intellectual Property Maturity Model

Figure 3 introduces a five-level intellectual property maturity model designed to help utility organizations benchmark their current capabilities and progress toward innovation-driven intellectual property management.

Table 2: Utility Intellectual Property Maturity Model.

Level 1 Reactive	Level 2 Structured	Level 3 Managed	Level 4 Strategic	Level 5 Innovation-Driven
Patent filing occurs only when requested.	Basic invention disclosure and filing procedures established.	Portfolio reviews and patentability assessments integrated.	IP portfolio aligned with organizational innovation strategy.	IP actively supports commercialization and value creation.

4.13 Patent Portfolio Optimization Model

Figure 4 presents the portfolio optimization model that supports continuous improvement of intellectual property assets. The model emphasizes feedback between strategic impact and the upstream innovation pipeline.

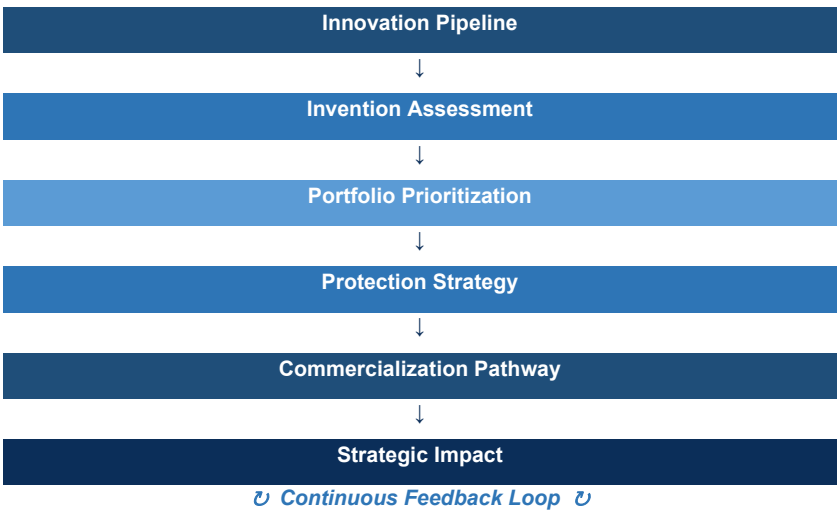

Figure 2: Patent Portfolio Optimization Model.

5. Discussion

5.1 Reframing Patent Portfolio Management as an Innovation Governance Function

A central contribution of the IVPMF is the repositioning of patent portfolio management from a predominantly legal activity to a strategic innovation governance function. While traditional approaches emphasize patent filing, prosecution, and maintenance activities, the proposed framework suggests that intellectual property management should be integrated into the broader innovation ecosystem. Existing literature acknowledges this strategic importance, yet practical implementation often remains fragmented, particularly when knowledge creation, portfolio governance, and commercialization responsibilities are dispersed across separate functions (Gassmann et al., 2010; Tidd & Bessant, 2020). Innovation teams, research groups, intellectual property specialists, commercialization units, and senior management frequently operate within separate structures, creating discontinuities throughout the innovation lifecycle.

The IVPMF addresses this challenge by establishing clear connections between invention generation, technical validation, strategic prioritization, protection decisions, and value realization. This integration enables organizations to make more informed decisions regarding resource allocation, portfolio composition, and innovation investment. The framework therefore supports a shift from "patent-centric management" toward "innovation-centric portfolio governance."

5.2 Strategic Portfolio Decision-Making

Research organizations often generate more invention disclosures than can realistically be pursued through comprehensive patent protection strategies. The proposed framework introduces strategic portfolio prioritization as a dedicated stage within the innovation lifecycle. This stage extends beyond traditional patentability assessments by incorporating broader organizational considerations such as strategic alignment, technology maturity, commercialization potential, competitive positioning, resource requirements, and long-term organizational impact. Rather than asking whether an invention can be patented, organizations should also ask whether the invention should be patented and whether protection contributes to broader strategic goals, a distinction that is consistent with portfolio decision principles discussed by Cooper et al. (2001) and later innovation management work (Trott, 2021).

5.3 The Role of Prior-Art Intelligence Beyond Novelty Assessment

Patent databases represent one of the world's largest sources of technical information and innovation knowledge. The proposed framework advocates for a broader interpretation of prior-art intelligence, encompassing technology trend identification, competitor monitoring, white-space analysis, research direction validation, collaboration opportunity identification, and strategic technology forecasting. Organizations that utilize patent intelligence solely for novelty assessment may overlook significant opportunities for strategic decision-making, particularly because citation and patent information can reveal technological trajectories, knowledge diffusion, and strategic positioning (Hall et al., 2005; WIPO, 2024).

5.4 Commercialization Readiness as a Missing Element in Traditional Patent Management

Many organizations evaluate inventions primarily from technical and legal perspectives while postponing commercialization considerations until later stages. This separation often creates challenges when inventions demonstrate strong patentability potential but limited pathways toward implementation. The proposed framework argues that commercialization readiness should be evaluated much earlier in the innovation lifecycle. Within utility organizations, value may emerge through internal technology deployment, operational efficiency improvements, sustainability enhancement, reliability improvements, cost optimization, service quality enhancement, and strategic partnerships, which is consistent with the broader outcome-oriented view of technology transfer advanced by Bozeman (2000) and Bozeman et al. (2015).

5.5 Knowledge Management Implications

The proposed framework also contributes to knowledge management literature by emphasizing the role of intellectual property as a mechanism for knowledge capture, preservation, and utilization. Patents serve as repositories of technical knowledge and organizational learning. By integrating intellectual property management and knowledge management practices, organizations can create stronger innovation ecosystems

capable of generating sustainable value over time, consistent with the knowledge-creation perspective of Nonaka and Takeuchi (1995) and the more recent synthesis offered by Garcia-Perez et al. (2020).

5.6 Implications for Utility Organizations

Utility organizations operate within environments characterized by long technology development cycles, infrastructure-intensive operations, regulatory requirements, sustainability objectives, and rapid technological transformation. These characteristics create unique challenges for innovation management and intellectual property governance. The proposed framework offers several practical implications: (i) organizations should establish structured invention disclosure systems capable of capturing innovation outputs across diverse technology domains; (ii) intellectual property activities should be integrated into innovation governance structures rather than operating independently; (iii) portfolio decisions should consider strategic and commercial factors in addition to legal patentability criteria; (iv) commercialization readiness assessments should occur early in the innovation lifecycle; and (v) organizations should adopt value-oriented performance indicators that extend beyond patent filing and grant statistics.

5.7 Performance Measurement and KPIs

Traditional intellectual property metrics often focus on patent counts, filing volumes, and grant rates. While important, such indicators provide limited visibility into the strategic contribution of intellectual property. Organizations should therefore adopt balanced performance indicators including invention disclosure quality, portfolio strength, commercialization readiness, deployment outcomes, technology transfer activities, innovation adoption rates, strategic partnerships, and organizational impact. A balanced scorecard approach (Kaplan & Norton, 1996) enables management to evaluate intellectual property performance from financial, innovation, stakeholder, operational, and learning perspectives.

5.8 Contribution to Theory and Practice

From a theoretical perspective, the framework integrates concepts from innovation management, intellectual property management, technology transfer, knowledge management, and innovation governance into a holistic perspective that addresses limitations of fragmented approaches found within existing literature. From a practical perspective, the framework provides innovation managers, intellectual property professionals, technology transfer practitioners, and organizational leaders with a structured approach for managing innovation assets. Unlike purely conceptual models, the framework is grounded in practical observations derived from real-world portfolio management activities and therefore offers direct applicability within innovation-intensive environments.

6. Conclusion and Future Work

This paper proposed the Innovation-to-Value Patent Management Framework (IVPMF), a practitioner-oriented framework designed to support organizations in transforming invention disclosures into strategic organizational assets. The study responds to growing recognition that intellectual property management should extend beyond legal protection activities and become an integrated component of innovation governance systems. Existing literature has frequently examined patent strategy, innovation management, technology transfer, and knowledge management as separate domains. The proposed framework addresses this fragmentation by providing a structured model that connects invention generation, patentability assessment, strategic prioritization, protection strategy, commercialization readiness, and value creation.

The framework consists of nine interconnected stages: Opportunity Identification, Invention Disclosure, Technical Validation, Prior-Art Intelligence, Patentability Assessment, Strategic Portfolio Prioritization, Protection Strategy, Commercialization Readiness, and Strategic Value Creation. Collectively, these stages represent a comprehensive pathway through which organizations can maximize the impact of innovation investments and strengthen the contribution of intellectual property portfolios to organizational objectives.

The findings suggest that organizations achieve greater innovation value when patent portfolio management is integrated into broader innovation governance structures rather than treated as an isolated legal function. Strategic prioritization, commercialization readiness, and knowledge management considerations emerge as critical factors influencing portfolio effectiveness.

Future research may validate the IVPMF through empirical research across multiple sectors including utilities, manufacturing, healthcare, transportation, and digital industries. Researchers may also investigate quantitative relationships between portfolio maturity and innovation outcomes, the role of artificial intelligence in patent intelligence, and the effectiveness of commercialization readiness assessments. Additional research could explore maturity assessment models, benchmarking methodologies, and innovation governance mechanisms that support strategic value creation from intellectual property assets. Ultimately, the proposed framework supports a broader view of intellectual property management, one in which patents are not merely instruments of protection, but strategic assets that contribute to innovation, competitiveness, knowledge creation, and long-term organizational value.

Acknowledgements

Abstract: Entrepreneurship education has traditionally framed opportunity validation as a rational, market-oriented process centred on analytical reasoning and persuasive argumentation. However, validation scenarios in real entrepreneurial contexts are cognitively demanding and emotionally charged, requiring students to regulate their attention, manage stress, and adapt their communication under uncertainty. Despite growing interest in brain-driven approaches to entrepreneurial learning, the cognitive-emotional dynamics underpinning opportunity validation remain underexplored in entrepreneurial pedagogy. This work-in-progress paper proposes a brain-driven redesign of opportunity validation grounded in cognitive performance, emotional regulation, and embodied learning. Adopting a Design-Based Research (DBR) methodology, the study implemented and iteratively refined a multimodal pedagogical framework across two student groups in an undergraduate entrepreneurship programme at a private Mexican university. The intervention integrated four design principles: authentic validation contexts using real target-market audiences; neurophysiological observation tools including EEG headbands and eye-tracking glasses; emotional design assessment grounded in the visceral-behavioural-reflective model proposed by Norman (2005); and guided reflection protocols to support metacognitive processing under pressure. Rather than focusing solely on market feasibility, the framework reconceptualises desirability as a cognitive-emotional construct, positioning validation as an embodied interaction among the entrepreneur, audience, and opportunity. Preliminary qualitative observations suggest improvements in communicative clarity, strategic argumentation, and empathic connection with the audience, dimensions rarely captured by conventional evaluation instruments. Quantitative data collected using neurophysiological devices are currently being analysed and will inform future empirical publications. By bridging brain-driven entrepreneurship and educational design, this study contributes a replicable framework for rethinking opportunity validation in higher education.

Keywords: Brain-driven Entrepreneurship, Opportunity Validation, Design-based Research, Emotional Regulation, Cognitive Performance

1. Introduction

Opportunity validation in entrepreneurship education has predominantly been assessed through rational, market-oriented criteria: feasibility analysis, competitive positioning, and logical argumentation. Yet in authentic entrepreneurial settings, validation is a high-stakes cognitive-emotional event. The entrepreneur must simultaneously regulate attentional demands, manage stress responses, and adapt communication in real time before an audience with genuine expectations. These dimensions, encompassing cognitive load, emotional regulation, and embodied interaction, are rarely visible through conventional assessment instruments.

Despite growing interest in brain-driven entrepreneurship (Silitonga et al., 2025) and the neurophysiological dimensions of learning and emotion regulation (Egana-delSol et al., 2023; Rehman et al., 2025), the pedagogical design of validation experiences in higher education has not kept pace. Most pitch exercises remain evaluator-centred and outcome-focused, overlooking how students regulate their cognitive-emotional performance in real time.

This paper presents a work-in-progress, design-based intervention addressing this gap. Developed within the Bachelor in Entrepreneurship at Tecnológico de Monterrey, the framework repositions opportunity validation as a brain-aligned, emotionally intentional pedagogical event that can be observed, reflected upon, and iteratively redesigned.

2. Theoretical Background

Brain-driven entrepreneurship proposes that entrepreneurial behaviour is fundamentally shaped by cognitive and affective processes: attention regulation, neuroplasticity, emotional resilience, and embodied decision-making (Silitonga et al., 2025). This aligns with Lackéus (2020), who argues that emotionally significant learning events produce deeper entrepreneurial competencies than content-centred instruction alone.

The present work draws on three theoretical pillars. First, the emotional design model proposed by Norman (2005) identifies three levels of user response: visceral (immediate affective reaction), behavioural (functional interaction), and reflective (attributed meaning). Applied here, desirability is reconceptualised as a cognitive-emotional construct shaped by the quality of interaction between entrepreneur, idea, and audience, rather than as a binary market judgment.

Second, Fredricks, Blumenfeld and Paris (2004) conceptualise student engagement as multidimensional, encompassing behavioural, cognitive, and emotional components. This framework informs both the design of the intervention and its observational strategy, since neurophysiological tools allow these dimensions to become simultaneously visible.

Third, Design-Based Research (DBR) (McKenney and Reeves, 2012) provides the methodological rationale for iterative educational design informed by practitioner observation and theory. DBR legitimises work-in-progress contributions because the value lies in the progressive refinement of the design, not solely in its final outcomes.

3. Methodology

The intervention was implemented within the unit "Evaluation and Communication of Opportunities" (fourth semester, Bachelor in Entrepreneurship, Tecnológico de Monterrey). Twenty-eight students across two groups participated, organised into teams of three to four members. The brain-driven validation framework is structured around four interconnected design principles, summarised in Table 1.

Table 1: Four design principles of the brain-driven validation framework

Design Principle	Component	Instrument / Tool	Function
Authentic Context	Real target-market audience	External stakeholder recruitment	Simulates genuine validation pressure
Neurophysiological Observation	EEG (presenters); eye-tracking and physiological sensors (audience)	Muse 2; Tobii Pro Glasses 3; Empatica Embrace Plus	Captures EEG-derived attentional activity, gaze fixation patterns, electrodermal activation, and physiological arousal; processed to estimate cognitive-emotional performance indicators
Emotional Design Assessment	Visceral, behavioural, reflective dimensions (audience); vigor, dedication, absorption (students)	Norman (2005) desirability instrument; UWES-S 9 (Schaufeli et al., 2002)	Assesses perceived desirability from the audience and engagement from student presenters
Guided Reflection Protocol	Metacognitive processing post-event	Structured prompts and post-activity questionnaire	Supports self-regulation and iterative learning

The activity unfolded in three phases: preparation (40 min) for device installation, consent, and protocol explanation; execution (110 min) of team presentations up to seven minutes with real-time audience feedback; and closure (30 min) for collective reflection and post-activity questionnaire administration. All sessions took place in the Living Lab Experiential Classroom (Morán et al., 2025).

Qualitative data collection involved four faculty members who documented student performance using predefined reflective categories aligned with Norman's (2005) emotional design dimensions and Fredricks et al.'s (2004) multidimensional engagement framework. Observational notes were consensually validated through structured post-session debriefs. Data triangulation drew on three sources: faculty observations, audiovisual recordings of student-audience interactions, and two post-activity self-report instruments. Student presenters

completed the Utrecht Work Engagement Scale, Student version (UWES-S 9; Schaufeli et al., 2002), capturing vigor, dedication, and absorption (n=23; 100% response rate). Market-audience participants completed a desirability instrument based on Norman's (2005) visceral, behavioural, and reflective levels, with guided verbal feedback. Both instruments were adapted and validated by the IFE Experiential Classroom research team at Tecnológico de Monterrey. Quantitative neurophysiological data are under analysis and will inform a forthcoming publication.

4. Preliminary Findings

4.1 Student Dimension

Across the three qualitative data sources, preliminary patterns emerged in two interrelated areas: perceived engagement and observed performance during validation. Relocating the activity to the Experiential Classroom produced a notable shift in student disposition, with participants describing the environment as more professional and cognitively demanding than conventional routines. Several students reported heightened awareness of the mind-body-communication connection when equipped with EEG devices, consistent with Silitonga et al. (2025). In some cases, device use appeared to provoke mild performance anxiety, identified by the teaching team as a target for iterative redesign.

Faculty observations, corroborated by audiovisual review, suggested patterns of structured argumentation, reduced reliance on memorised scripts, and increased responsiveness to audience feedback. The independent recruitment of real market representatives appeared to function as a formative experience in itself, prompting students to practise proactivity and value communication beyond the classroom. UWES-S 9 self-reports will be triangulated with these observations in subsequent cycles to examine whether perceived vigor, dedication, and absorption align with externally observed performance.

4.2 Faculty Dimension

The intervention required substantive pedagogical reconfiguration. Aligning learning objectives, formative evaluation criteria, and technical protocols demanded interdisciplinary coordination across academic, research, and technical staff. Faculty reported a qualitative shift in their observational capacity, noticing how students managed stage anxiety, adjusted verbal and non-verbal communication, and responded emotionally under validation pressure. These observations align with Nabi et al. (2017), who argue that entrepreneurship education must integrate content, context, and process in a unified pedagogical logic.

5. Discussion and Implications

This study reframes opportunity validation in entrepreneurship education as a cognitive-emotional performance shaped in real time, rather than as a rational and market-oriented process. The framework contributes on two interrelated levels. Theoretically, it extends the concept of desirability beyond market fit by positioning it as a cognitive-emotional construct that requires the entrepreneur to engage with the audience at the visceral, behavioural, and reflective levels (Norman, 2005; Fredricks et al., 2004). Methodologically, it offers a replicable design that can be adapted by educators with varying levels of technological access, provided the core principles of authenticity, emotional intentionality, and reflective practice are preserved.

A key implication is that opportunity validation can be redesigned to generate richer formative data without requiring full technological infrastructure. Neurophysiological tools function as observation instruments, not as ends in themselves. Educators in resource-constrained settings can preserve the framework's logic by substituting digital tools with structured observational protocols and emotionally grounded rubrics.

Ongoing analysis of neurophysiological data will enrich the qualitative account with empirical evidence of cognitive and emotional patterns during student performance. Consistent with Egana-delSol et al. (2023), who showed that neurophysiological markers capture programme impact missed by self-reported measures, this study positions physiological observation as a complement to conventional assessment. As a work-in-progress study, findings are based on triangulated qualitative observations, while neurophysiological data remain under analysis. Subsequent cycles will examine the relationship between neurophysiological indicators, communication quality, and perceived desirability.

6. Conclusion

This work-in-progress paper proposes a brain-driven, design-based framework for reconceptualising opportunity validation in entrepreneurship education. By integrating authentic validation contexts, neurophysiological observation, emotional design assessment, and guided reflection, the framework is designed to make visible dimensions of student performance, including cognitive load, emotional regulation, and empathic communication, that conventional instruments rarely capture. It offers educators and researchers a replicable model for brain-aligned validation in higher-education entrepreneurship programmes. Rather than evaluating whether an idea is convincing, this framework enables educators to understand how students become convincing under real cognitive and emotional pressure.

Ethics Declaration

Ethical clearance was obtained from Tecnológico de Monterrey prior to data collection. All student participants and invited audience members provided written informed consent. The neurophysiological data collection protocol received institutional approval under the Novus Experiential Classroom 2024 grant (Project ID 833146). Participant anonymity and data confidentiality have been maintained throughout, with data stored securely under institutional policy.

AI Declaration

AI-assisted writing tools were used for language editing and structural feedback. All theoretical framing, design decisions, data collection, and arguments were developed by the authors. The pedagogical intervention and research design were carried out independently.

Acknowledgements

The authors thank the Novus Experiential Classroom 2024 advisory team at Tecnológico de Monterrey for institutional support, and the Living Lab Experiential Classroom research team for their technical, logistical, and methodological collaboration.

From Empathy to Impact: Examining Opportunity Recognition for Impactful, Socially Relevant Entrepreneurship

Moses Faleafaga
Faculty of Technology, Amsterdam University of Applied Sciences/Vrije Universiteit, The Netherlands

m.h.j.a.faleafaga@hva.nl

Abstract: Entrepreneurship education (EE) aims to develop students' ability to identify, evaluate and act on opportunities, yet opportunity identification receives little structured attention. It is shaped by prior knowledge, experience and networks, which can limit students to familiar markets and problems. This creates an innovation blind spot in unfamiliar or underserved domains such as ageing, disability or accessibility, where socially relevant entrepreneurship is needed but user knowledge is less accessible. Empathy-based methods, such as empathic interviewing, perspective-taking, observation and immersion, offer a promising path but remain under-researched in entrepreneurship education. This working paper presents a PhD project that conceptualises entrepreneurial empathy as a teachable capability: an epistemic bridge through which students access, interpret and translate deeper user knowledge into higher-quality opportunities. Opportunity quality is multidimensional, spanning problem depth, user alignment, innovativeness, social relevance and impact potential. The research asks to what extent empathy-based methods enable students to identify higher-quality opportunities grounded in deeper understanding of user needs. It comprises four studies: a cross-disciplinary typology of empathy-based methods; an AI-supported scaffold for empathic interviewing; a randomised comparison of trained and conventional interviewing; and a study of physical immersion. Together they combine conceptual development, educational design and empirical evaluation to strengthen inclusive, socially relevant entrepreneurship education.

Keywords: Entrepreneurship Education, Opportunity Identification, Entrepreneurial Empathy, Empathy-Based Methods, Empathic Interviewing, Socially Relevant Entrepreneurship

1. Introduction

Entrepreneurship education (EE) fosters entrepreneurial mindsets and develops students' ability to identify, evaluate and act on opportunities and create value through innovative action (Fayolle and Gailly, 2008; Shane and Venkataraman, 2000). Despite the growth of EE research, little attention is paid to the earliest entrepreneurial stage: opportunity identification. Most programmes emphasise ideation, business modelling, validation and pitching, assuming students will arrive at meaningful ideas. Yet identification is neither automatic nor evenly distributed: it is shaped by prior knowledge, lived experience, disciplinary background and networks (Shane, 2000; Baron, 2006). Effectuation theory suggests entrepreneurs build on who they are, what they know and whom they know (Sarasvathy, 2001), mechanisms that can keep students close to familiar markets, users and problems.

This creates a pedagogical challenge: how can EE help students identify high-quality opportunities grounded in user needs, particularly when those needs are unfamiliar, hidden or poorly articulated? The challenge is sharpest in underserved domains such as ageing, disability,

chronic illness, homelessness or poverty, where socially relevant entrepreneurship is needed yet students lack direct knowledge or networks. Empathy-based methodologies offer a path: empathic interviewing, immersion, perspective-taking and contextual inquiry can broaden students' perspectives, uncover unarticulated needs and reframe problem spaces (Kouprie and Sleeswijk Visser, 2009). Evidence in entrepreneurial contexts suggests they lead to more original, user-aligned opportunity framing (Prandelli, Pasquini and Verona, 2016; Khalid and Sekiguchi, 2018).

Yet these methods remain underutilised and under-researched in EE. A systematic review of students' opportunity identification capability found that, across 44 empirical studies, only two used empathy-based techniques (Farrokhnia et al, 2026); a review of opportunity recognition in EE similarly finds the capability scarcely researched (Cárdenas-Figueroa and Olmedo-Navarro, 2024). A review of empathy across entrepreneurship and engineering reports a similar imbalance: entrepreneurship studies empathy mainly in relation to outcomes such as entrepreneurial intentions, mostly outside educational settings, while engineering research has paid more attention to empathy as a teachable, developable capability (Litvinov et al, 2023). This working paper presents a PhD project that addresses this gap by examining empathy-based opportunity identification and developing scaffolds for its rigorous, scalable use. The project therefore contributes by

specifying and empirically testing how empathy-based methods can expand students' access to user knowledge and improve the quality of opportunities identified in unfamiliar problem spaces.

2. Conceptual Framing

To address this gap, the project is organised around two central constructs: entrepreneurial empathy as a developable capability and opportunity quality as the principal outcome. The project conceptualises empathy-based methods as teachable epistemic bridges for opportunity identification, and entrepreneurial empathy as an overarching learnable capability through which students access, interpret and translate deeper user knowledge into higher-quality opportunities. Following Packard and Burnham (2021), empathy is treated not as a stable trait but as a trainable capability through which students engage with users' lived experiences, needs, constraints and contexts to support the identification, framing and development of meaningful opportunities. In effectuation terms, it lets students deliberately expand what they know and whom they know beyond their familiar starting point. Opportunity quality is treated as multidimensional, spanning problem depth, user alignment, innovativeness, social relevance and impact potential, and these dimensions serve as the shared evaluative criteria across the studies. The framing is especially relevant for socially relevant, impactful and regenerative EE, where underserved or marginalized groups such as older adults or people with chronic illness or disabilities have needs that are hard to identify through desk research or superficial contact. Entrepreneurial empathy may help students slow down before committing to a solution, question assumptions and attend more carefully to users and their lived experience.

3. Main Research Question

To what extent do empathy-based methods enable students to identify higher-quality entrepreneurial opportunities grounded in a deeper understanding of user needs?

4. Research Design

The question is addressed through four interrelated studies combining conceptual development, educational design and empirical evaluation.

4.1 Study 1: Typology of Empathy-based Methods

Study 1 develops a cross-disciplinary typology of empathy-based methods, combining a literature-based method review across fields such as entrepreneurship, design, ethnography, psychology and social sciences with expert interviews. It categorises methods by mechanism, educational purpose, type of user insight, difficulty and relevance for different contexts, and provides the overview from which the later studies draw: empathic interviewing is the core, scalable method for Studies 2 and 3, while the immersive methods in Study 4 come from the same typology.

4.2 Study 2: AI-supported Interview Scaffold

Study 2 develops and evaluates an AI-supported scaffold for empathic interviewing. Interviewing is widely encouraged in EE and innovation, but difficult to train and practice effectively, leading to students often interviewing superficially: they ask leading questions, pitch too early, seek confirmation and fail to probe and dig deeper. Using a design science approach, the study builds a voice-to-voice training environment with believable AI personas that prepares students for, rather than replaces, real interactions and develops their empathic interviewing capability. AI enables repeated practice in a standardised, low-risk setting and scalable training and assessment beyond human role-play alone. After a pilot, 400–500 students across several cohorts will complete pre-post simulations, rubric-based assessment and student reflections. The rubric covers active listening, open and non-leading questioning, probing, perspective-taking and responsiveness to user cues. This sample supports reliable estimates of improvement and exploratory comparisons across disciplines.

4.3 Study 3: Trained Versus Conventional Interviewing

Study 3 tests whether trained empathic interviewing improves opportunity identification beyond conventional interviewing. Approximately 60 students working in duos, producing around 30 teams, will take part in a standardised opportunity-identification sprint, with approximately 15 teams per condition. Given its exploratory nature, the study is intended to provide an initial indication of whether trained empathic interviewing improves

opportunity quality and to inform the design of larger follow-up research. The control group receives a standard interview briefing typical of many EE settings; the intervention group receives intensive empathic-interview training supported by the Study 2 tool. Both groups then interview the same user group for equal time and produce an anonymised opportunity dossier (user profile, problem and opportunity statement, preliminary value proposition, and reflection on how their understanding changed). Social relevance is built into the task and criteria. Outputs are assessed by condition-blinded expert and user juries using rubrics covering problem depth, user alignment, innovativeness, social relevance and impact. Opportunity quality will be operationalised as blinded rubric scores across the five predefined dimensions of problem depth, user alignment, innovativeness, social relevance and impact potential. An exploratory component compares business and STEM cohorts.

4.4 Study 4: Physical Immersion

Study 4 examines physical immersion and situated identification. Some needs and constraints are not accessible through interviews alone: people normalise workarounds, struggle to articulate tacit routines, or overlook systemic constraints. This small-scale, high-depth study uses observation, shadowing, contextual inquiry, accessibility audits and structured reflection in real settings to examine what immersion adds beyond interviews and how situated engagement shapes opportunity framing, depth, novelty and user alignment. It is especially relevant for unfamiliar or underserved contexts, and user groups will be selected with attention to accessibility, participant burden and ethics.

5. Expected Contributions and Implications

The project is expected to make four contributions. Conceptually, it will develop entrepreneurial empathy as a teachable capability and epistemic bridge into unfamiliar problem spaces. Methodologically, it will produce a cross-disciplinary typology of empathy-based methods for opportunity identification. Empirically, it will test whether trained empathic interviewing improves opportunity quality. Educationally, it will develop pedagogical scaffolds and assessment rubrics for entrepreneurship education.

The broader implications concern the integration of empathy-based opportunity identification into entrepreneurship curricula, particularly in STEM contexts where students may possess strong technical capabilities but require greater support in understanding users and framing problems. The project may also support more inclusive, resilient and socially relevant innovation by helping students engage systematically with underserved user groups. Outputs are expected to include openly accessible educational materials alongside academic publications. Overall, the project seeks to establish whether empathy-based methods can provide a practical and scalable means of helping students discover more meaningful opportunities beyond the limits of their existing knowledge and networks.

Ethics Declaration

No empirical data have yet been collected. The planned studies involve human participants and will proceed only after approval by my university's research ethics committee.

AI Declaration

A generative AI assistant was used to support language editing, restructuring and reference formatting; it was not used to generate the research design or any findings. All output was reviewed and verified by the author, who takes full responsibility for the paper.

Entrepreneurial Temporal Design: Reframing the Sustainability Intention-Action Gap in Food Waste

Marwa Gad Mohsen
College of Business and Economics, United Arab Emirates University, Al Ain, United Arab Emirates

m.gmohsen@uaeu.ac.ae

Abstract: Persistent gaps between sustainability intentions and food consumption behaviour remain poorly explained by attitudinal or informational accounts alone. Food-waste research shows that planning, shopping, and storage routines are often more proximate predictors of household waste than stated intentions, while information-based interventions tend to have limited and weakly sustained effects. This paper argues that part of the problem is temporal misalignment; sustainable food practices are often organised around institutional or retail rhythms that do not match how households plan meals, manage uncertainty or coordinate consumption. Entrepreneurship research has examined time as a resource that ventures manage internally, but less as a design variable through which ventures shape customer practices and sustainability outcomes. New ventures are particularly relevant because they can build temporal structure into an offering from the outset, before legacy channel arrangements, operating routines and customer expectations constrain redesign. The paper therefore develops a framework of entrepreneurial temporal design for sustainable food consumption. It identifies three mechanisms; rhythm alignment, which structures provision around household consumption patterns; communal synchronisation, which coordinates edible surplus with demand before discard; and routine embedding, which anchors low-waste practices into recurring behaviour. Secondary examples from food-sharing and meal-planning ventures provide compact illustrations of these mechanisms. Four propositions connect temporal design to reduced food waste, more durable behaviour change, and competitive differentiation from incumbents whose established routines make equivalent redesign costly. By shifting attention from persuasion to temporal fit, the paper contributes an entrepreneurial and temporal-psychology-informed conceptualisation of food-waste reduction that complements attitude- and information-based accounts. By positioning temporal design as an entrepreneurial strategy that closes a sustainability gap that policy and awareness campaigns have not while offering new ventures a basis for competitive differentiation, it offers a focused agenda for empirical research on how ventures can design timing, rhythm, and routine as pathways to sustainable consumption.

Keywords: Entrepreneurial Temporal Design; Sustainable Consumption; Food Waste; Intention-Action Gap; Competitive Differentiation

1. Introduction

Sustainability research has long documented a gap between consumers' pro-environmental intentions and their consumption behaviour (Joireman et al 2012). The persistence of household food waste across contexts (UNEP and WRAP 2024) indicates that awareness, affluence and policy commitment alone are insufficient. Explanations for this gap have often prioritised awareness, attitudes, and other individual-level drivers, yet food-waste research increasingly shows that household waste emerges from interacting routines and situational constraints rather than from information deficits (Schanes et al 2018). Planning, shopping, and storage routines are consequential predictors of waste generation (Stancu et al 2016), while information-based interventions on their own show limited and often weakly sustained effects (Ran et al 2025). This points to a structural explanation that remains underdeveloped: sustainable behaviours are often designed around temporal rhythms – shopping cycles, delivery schedules, institutional calendars – that do not correspond to how households actually plan, purchase and consume food. Emerging work on shopping frequency under uncertainty reinforces this point, showing that the waste-minimising rhythm depends on household variability rather than on any single ideal schedule (van Rooijen et al 2025).

This paper reframes the gap as an entrepreneurial design opportunity. New ventures can build temporal structure into offerings from the outset, whereas incumbents are constrained by established routines and customer relationships. Drawing on entrepreneurship research and temporal psychology, the paper links temporal design to sustainable food outcomes and venture differentiation. *Oddbox*, *Too Good To Go*, and *Olio* provide compact illustrations of how ventures can design timing, rhythm, and routine into sustainable food consumption rather than empirical cases.

2. Theoretical Background

Entrepreneurship research has examined time extensively as a resource ventures manage internally – identifying and acting within opportunity windows, pacing growth, and sequencing resource commitments (Levesque and Stephan 2020). Yet, time has not been systematically studied as a design variable through which ventures shape

customer practices and downstream sustainability outcomes. Existing work in sustainable entrepreneurship shows that organisational design and business model choices matter for venture viability (Parrish 2010), but the emphasis remains largely on venture development rather than on how ventures intentionally structure customers' temporal environments. McMullen and Dimov (2013) note that entrepreneurial processes are themselves shaped by time in ways still poorly understood, a gap that becomes especially consequential where the customer behaviour a venture is trying to influence is itself governed by temporal pressures.

Two further literatures explain why this gap matters specifically for food consumption. Temporal psychology shows that time pressure shifts decision-making from deliberative to automatic processing (Dhar and Nowlis 1999), and that future time orientation is associated with more sustainable behaviour (Joireman et al 2012). Social acceleration theory explains why modern consumption occurs under conditions of chronic time scarcity; technological and social change compress the time available for planning even as objective efficiency improves (Rosa 2013), so that sustainable choices requiring additional planning time are structurally disadvantaged relative to convenient alternatives. Relatedly, practices that disrupt an established routine tend to be abandoned once initial motivation fades, since behaviours not anchored into existing habitual sequences carry a persistent cognitive cost (Wood and Neal 2009).

What is missing, then, is an account of how entrepreneurial ventures can convert temporal design into a source of both sustainability impact and venture-level advantage. New ventures retain greater freedom than incumbents to configure offerings, interfaces, and interaction rhythms from the outset, without the inertia of legacy routines or channel structures. This positions ventures, rather than households or policymakers, as the primary site for closing the gap through redesign rather than persuasion.

3. A Temporal Framework for Sustainable Food Consumption

We propose that entrepreneurial ventures can help close the intention-action gap and simultaneously build a more differentiated market position. The proposed framework identifies three temporal design mechanisms, each addressing a specific way that time and sustainable food behaviour are currently misaligned (Figure 1). Rhythm alignment addresses the mismatch between irregular household planning and rigid retail cycles, by structuring provision around predictable consumption rhythms rather than one-off transactions. *Oddbox* illustrates this mechanism through offering recurring rescued fruit and vegetable boxes (Oddbox n.d) that help households plan around a predictable supply rhythm rather than isolated shopping trips, permitting customers to switch, swap or pause them. Communal synchronisation addresses the coordination problem in surplus redistribution, where edible food becomes waste largely because supply and demand are not temporally aligned at the point of surplus. *Too Good To Go* illustrates this mechanism by matching surplus food from stores, cafés and restaurants with consumers through time-bounded collection windows, coordinating reservation with a specified collection time, while *Olio* extends the logic through neighbour-to-neighbour and volunteer-supported surplus sharing (Too Good To Go n.d.; Olio n.d.). Routine embedding addresses the durability problem in sustainable behaviour; many interventions produce short-term compliance but do not survive once novelty fades, because the behaviour has not been anchored into an existing daily or weekly routine. Practices are more likely to persist when they become part of recurring household or community routines rather than one-off acts of goodwill.

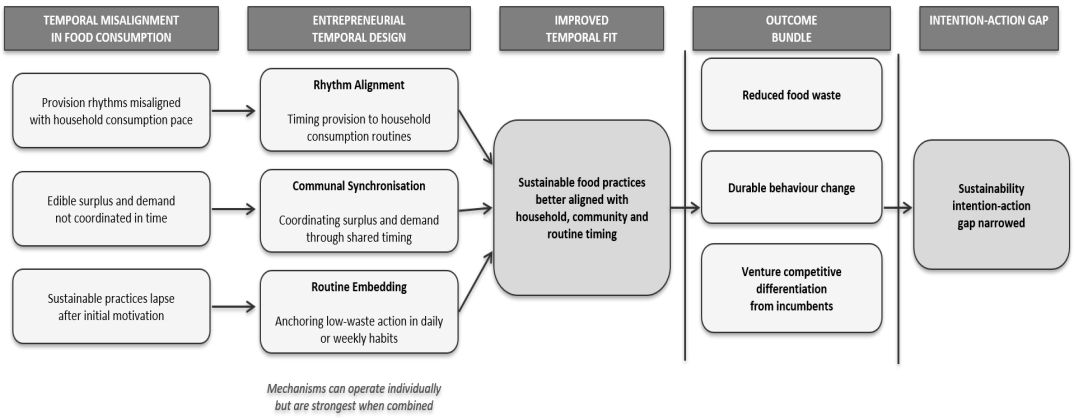

Figure 1: Entrepreneurial temporal design mechanisms linking venture strategy to sustainability and competitive outcomes

Together, these examples show how ventures can fit sustainable action to household and community rhythms rather than add another deliberative task. Table 1 summarises the three mechanisms, venture illustrations and expected outcomes.

Table 1: Entrepreneurial temporal design mechanisms for sustainable food consumption

Mechanism	Temporal Problem Addressed	Venture Illustration	Primary Outcome Pathway
Rhythm alignment	Provision cycles misaligned with household consumption pace	*Oddbox*: recurring rescued-produce boxes	Less over-purchasing and spoilage
Communal synchronisation	Edible surplus and demand not coordinated in time	*Too Good To Go*: timed pickup windows; Olio: local surplus exchange	More edible surplus used before discard
Routine embedding	Sustainable practices lapse after initial motivation	*Olio*: recurring neighbourhood and volunteer sharing	More durable low-waste behaviour

Successful deployment should reduce food waste and strengthen the durability of low-waste behaviour. When built into the core offering, these mechanisms may also differentiate ventures from incumbents whose established routines constrain temporal redesign.

4. Research Propositions

These illustrations motivate four propositions for future empirical testing.

- P1: Ventures that align provision rhythms with actual household consumption patterns (rhythm alignment) will achieve greater reductions in food waste than ventures offering temporally undifferentiated access to the same products.
- P2: Ventures that synchronise surplus redistribution around shared community collection rhythms (communal synchronisation) will achieve higher rates of surplus utilisation than platforms relying on ad hoc, uncoordinated exchange.
- P3: Sustainable food practices embedded within existing daily or weekly routines (routine embedding) will demonstrate greater behavioural durability over time than practices requiring ongoing deliberate choice.
- P4: Ventures that build temporal design mechanisms into their core offering, rather than treating timing as an operational afterthought, will differentiate more clearly from incumbent providers because established routines and customer relationships make equivalent temporal redesign costly to replicate.

5. Conclusion

This paper reframes the sustainability intention-action gap in food consumption as an entrepreneurial temporal design opportunity. By identifying three mechanisms through which entrepreneurial ventures can align provision with household temporal rhythms, coordinate surplus redistribution, and embed sustainable practices into daily routines, the framework offers a focused conceptual basis for future empirical work. It contributes to entrepreneurship and sustainability research by showing that temporal design choices are not merely operational details but a source of competitive differentiation for new ventures entering markets where sustainability and convenience currently pull in opposite directions. It shifts attention from persuading households to designing offerings around the temporal realities of food consumption. Future research should test the propositions using primary case evidence across regions and examine whether the temporal mechanisms extend to other sustainable consumption domains.

Top 100 Global Sustainable Solutions: Ten years on

Christopher J Moon
Middlesex University, UK

c.moon@mdx.ac.uk

Abstract: The Sustainia100 report (2016) was published ten years ago and provided the results of the top 100 most innovative sustainability solutions from across the globe judged by an international panel of experts. This paper reviews these top 100 from 2016 ten years on. The analysis is comprehensive as it provides a unique data set on the global top 100 from 2016, and which companies are still successful ten years later.

Keywords: Sustainability, Triple Bottom Line, Social Innovation, Financial Viability, SDGs.

1. Introduction

The original data set of 100 globally most innovative sustainability solutions was compiled by Sustainia (2016), a leading Sustainability consultancy from Copenhagen, in conjunction with the Global Compact and Monday Morning. The 2016 report was published not long after the 17 United Nations Sustainable Development Goals (SDGs) were agreed by world leaders in 2015 (Moon, 2017, 2018). Each business was originally evaluated on its availability, scalability, positive environmental impact, financial viability, and improving the quality of life. In fact, each project included a Triple Bottom Line review. Thus, ten years on this paper explores to what extent the Triple Bottom Line concept continues to demonstrate financial success and positive social and environmental impact in the long term.

The paper also provides insights into the focus on the SDGs, as 2016 was the only year that the top 100 projects were all mapped by Sustainia against the SDGs, and whether there is now ongoing support for the original contention that 'new mindsets and innovative thinking businesses' have delivered on everything from good health and well-being, affordable and clean energy, to improved infrastructure and sustainable urban development, including financial viability in the long-term (Sustainia, Ibid). In fact, the initial research covered 10 sectors and 188 countries of deployment. The sectors included were Buildings, Food, Fashion, Transportation, IT, Education, Energy, Health, Cities, Resources.

2. Background

Peters and Waterman (1982) identified core attributes of 'excellent' companies that foster innovation and enduring performance. However, of the original companies in the research 9 of 30 companies (30%) had failed by 2002 (McKinsey, 2017). Then, 3 of 15 companies (20%) identified by Collins and Poras (1994) had failed by 2014 (McKinsey, 2017). Further, 3 of 8 companies (37.5%) identified as Good to Great by Collins (2001) had failed by 2016 (McKinsey, 2017). The McKinsey study (Ibid) of these 50 companies acknowledged that performance is affected by external trends and forces. However, further research by Eccles et al (2014) found 'High Sustainability' related to better corporate financial performance, a study now cited by 6680, and Friede et al (2015) cited evidence from more than 2000 empirical studies (1970s to 2014) finding that ESG (Environmental, Social and Governance) factors were positively related to corporate financial performance in 90% of the studies. Thus, 'sustainability' may be a better predictor of long-term company performance than the other measures cited above. The following Research Questions are thus posed:

> RQ1: How many of the original Sustainia projects from 2016 are still active in 2026?
>
> RQ2: Is there any indication that their original Triple Bottom Line evaluation in 2016 is still evident in their 2026 performance?

3. Methodology

As it is now ten years on it is timely to review the top 100 solutions from Sustainia (2016) and determine which of the projects were successful and whether this validates their emphasis on sustainability. The analysis is based on desk research including the checking of the original 100 url's from the Sustainia (2016) report and identifying which url's are still active by the same companies. And if not, checking to see if the company had a new url, or had changed its name, or had gone out of business.

Further, by reviewing the performance of each company since 2016, this provides insights into the success of the TBL concept in the longer term. The findings are displayed in Tables 1-10 below by sector (see Appendix). With new url's highlighted in blue and underlined, and companies 'out of business' highlighted in red and underlined.

4. Findings and Discussion

The first finding of this new research is that the majority of the 100 projects in the Sustainia100 (2016) globally most innovative solutions have been sustained for over ten years. In fact, only 11% of the original projects are now cited as being specifically out of business. This result is similar to the finding of Friede et al (Op Cit).

The initial trawl of url's revealed that 49% of the original url's cited by Sustainia were still active. However, this result was slightly skewed with the fact that 10% of the original cited projects (government) did not have url's associated with them, and that 41% of url's had changed for various reasons. Thus, some companies have changed their name or merged or been acquired during the last ten years.

This means that 87% of the original projects identified by Sustainia have been found to be 'successful' after ten years. Whilst this success cannot be directly attributed to 'sustainability' alone, each of the original sample of 100 companies were evaluated on their Triple Bottom Line performance by an international panel of experts, and the author of this paper has found evidence of continuing strong emphasis on 'sustainability' in this regard (see appendix).

5. Limitations of the Research

The research is limited by the fact that this desk research may not be 100% accurate. However, the author double-checked the original Uniform Resource Locators (url's) provided by Sustainia at least twice to confirm whether the initial url's were still active pertaining to the original projects. Thus, where the original urls were no longer active the author undertook google searches to determine if the project was out of business or had been acquired by another company or simply changed its url. In numerous cases this was confirmed. However, due to the difficulty in tracking all projects precisely, the most up-to-date status or data may not be available. Further, for the original government cited projects urls were not cited in the 2016 report at all, and current data on the performance of most of these projects was hard to find. Data that was not available is marked as NA in the table.

6. Conclusions

This study is of 100 projects that were analysed in 2016 as being globally most innovative, ten years hence. As the original 100 were initially evaluated on their Triple Bottom Line impact, the sample provided a unique data set to study ten years hence to see how many projects/organisations were still active and successful. 87% were found to be 'successful' based on the data cited in the Appendix, tables 1-10.

There can be a range of factors governing the success or failure of a company. However, this prima facie evidence is compelling. Further, the results will be of interest to teachers, researchers and practitioners. The author has used the original sample in his teaching for many years and students always appreciate the innovative and inspiring examples cited from the original Sustainia100 report. As this is the only year that Sustainia mapped all the projects against the SDGs the exercise is also useful for teaching about the SDGs in practice, and the TBL concept in practice.

At the very least this research updates the information on these 100 projects. However, researchers can also now look more closely at the individual projects that have been successful, or by sector.

Ethics Declaration

Ethics approval was not required for this research as it is scholarly research based on desk research only.

AI Declaration

AI was not used in the research for this paper other than to provide a second check on whether companies identified by Sustainia (2016) were still in business. Thus, Google was used for the desk research and Google Scholar to check references.

Regulatory Designation and Knowledge Dynamics in Pharmaceutical Innovation: Evidence From Breakthrough Therapy Designation

Abstract: Innovation in the pharmaceutical sector is shaped not only by scientific discovery but also by regulatory mechanisms that influence the direction, speed, and priorities of technological development. In science-based industries such as pharmaceuticals, where innovation depends heavily on the accumulation of scientific knowledge, regulatory frameworks play a central role in shaping innovation trajectories. Among these, the U.S. Food and Drug Administration's Breakthrough Therapy Designation (BTD), introduced under the Food and Drug Administration Safety and Innovation Act (FDASIA) in 2012, represents a mechanism designed to accelerate development of promising drugs. While prior research has focused on BTD effects on development timelines, approval outcomes, and firm-level investment, less attention has been given to its relationship with scientific knowledge production. This study examines how BTD is associated with patterns of scientific publication activity across disease areas, focusing on leukemia, lymphoma, and multiple myeloma. Using FDA approval and Web of Science bibliometric data, we construct a group of BTD and comparable non-BTD drugs and analyze publication trends before and after designation using a difference-in-differences approach. The results show that the BTD group shows higher trend of increase in publication activity following designation compared to the non-BTD. Log-transformed trends indicate stronger relative growth for BTD-designated drugs, with a positive DiD. However, the DiD estimate is not statistically significant. These findings suggest that regulatory designation may be associated with increased production of scientific knowledges. Further research is needed to extend the analysis of regulation-induced innovation into knowledge dynamics.

Keywords: Pharmaceutical Innovation, Porter Hypothesis, Regulatory Incentive, Scientometrics, Knowledge Dynamics

1. Introduction

Innovation in the pharmaceutical sector is shaped not only by scientific discovery but also by regulatory mechanisms that influence the speed, direction, and priorities of technological development (Dosi, 1982; Nelson and Winter, 1985; Freeman, 1994). In science-based industries such as pharmaceuticals, innovation depends heavily on the production, accumulation, and integration of scientific knowledge across multiple stages of research and development (R&D) (Pavitt, 1984; Freeman and Soete, 1997). Because pharmaceutical R&D is characterized by high uncertainty, long development timelines, and significant financial risk, regulatory arrangements constitute a key institutional factor shaping R&D costs, incentives, and the direction of innovation in drug development (Grabowski and Vernon, 2000; Nightingale and Mahdi, 2006; Pisano, 2006; Sampat and Lichtenberg, 2011; DiMasi et al., 2016). Regulation should therefore be understood not merely as a constraining factor, but also as an accelerating and directional mechanism.

A distinctive example is the U.S. Food and Drug Administration's breakthrough therapy designation (BTD), introduced under the Food and Drug Administration Safety and Innovation Act in 2012. BTD accelerates the development and review of therapies that may offer substantial improvement over existing treatments (Sherman et al., 2013; Kesselheim et al., 2015). Unlike earlier FDA pathways such as fast track, breakthrough therapy designation emphasizes early recognition of promising innovations and prioritizes development through enhanced regulatory engagement (Baird et al., 2014). It combines procedural acceleration with early prioritization.

BTD can influence innovation by shaping firms' R&D behavior and directing effort toward more promising therapies (Thomas, 1990; Eisenberg, 2006). In sectors where scientific publication is a key form of knowledge production, regulatory designation may influence outcomes beyond approval timelines. BTD may therefore be associated with changes in scientific publication patterns.

Existing research has examined regulatory incentives in terms of approval speed, development timelines, and firm-level investment. However, the relationship between regulatory designation and scientific knowledge production remains less understood. Few studies have focused on the association between regulatory mechanisms and patterns of scientific publication activity.

This study examines how BTD relates to scientific knowledge production across disease areas. Specifically, it investigates whether BTD is associated with changes in scientific publication activity relative to comparable non-designated drugs.

2. Literature Review

2.1 Regulation and Innovation

Innovation emerges from interactions among firms, institutions, knowledge infrastructures, and policy environments (Freeman, 1994; Breschi et al., 2000; Lundvall, 2007). In science-based sectors such as pharmaceuticals, innovation depends heavily on scientific knowledge (Pavitt, 1984). Regulation is a critical institutional mechanism shaping innovation by governing clinical trial standards and the validation of safety and efficacy (Cockburn and Henderson, 1998; 2001; Orsenigo et al., 2001; Pisano, 2006).

The Porter Hypothesis suggests that regulation can incentivize firms to develop new technologies (Porter, 1990; Porter and Vanderlinde, 1995). Empirical findings indicate that these effects vary across contexts (Wagner, 2003). Most research has focused on economic outcomes such as patents and firm performance (Lanoie et al., 2011; Ambec et al., 2013), with limited attention to scientific knowledge dynamics.

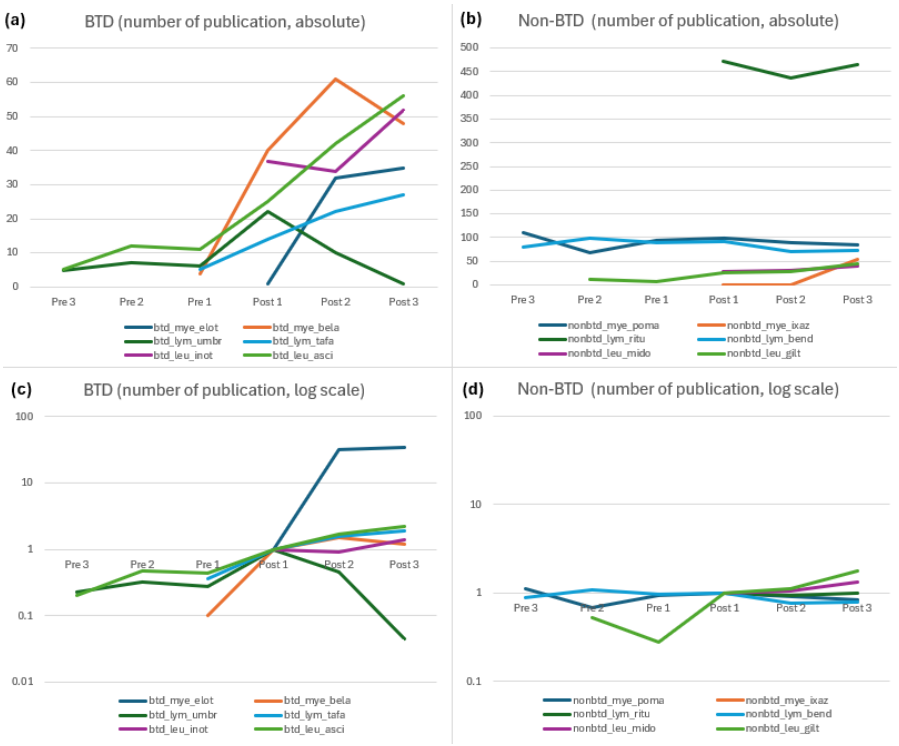
This gap is important in pharmaceuticals, where innovation depends on the accumulation and use of scientific evidence (Eisenberg, 2006). Understanding how regulation influences knowledge production extends existing research.

2.2 Breakthrough Therapy Designation as a Regulatory Incentive

Regulatory frameworks have incorporated expedited mechanisms to accelerate drug development under uncertainty. FDA programs such as Fast Track, Priority Review, and Accelerated Approval improve access to therapies (Kesselheim et al., 2015; Haffner, 2016).

Breakthrough Therapy Designation is granted when preliminary evidence indicates substantial improvement over existing therapies (Sherman et al., 2013; Baird et al., 2014). It involves early interaction between regulators and firms, reducing uncertainty and supporting efficient development.

Existing research has examined its effects on development timelines and investment (Shea et al., 2016; Chandra et al., 2026). Less attention has been paid to its relationship with scientific knowledge dynamics. This study addresses this gap by examining publication activity.



3. Methods

To examine the association between regulatory designation and scientific knowledge dynamic, BTD data were obtained from the FDA database, which provides information on approved drugs and indications. A total of 303 approvals were granted between 2013 and 2024.

The dataset was refined using a 10-year window (2013–2023), including only original treatment approvals, yielding 73 cases. The analysis focuses on leukemia, lymphoma, and multiple myeloma. For each, matched non-BTD drugs were selected based on similar indications and approval timing using the FDA Orange Book.

Scientific knowledge production is measured using publication activity. Annual publication counts were collected from the Web of Science Core Collection using *Title [drug name] AND All field [disease name].*

A three-year pre and post designation window was applied. Publication counts were log-transformed. An event-time difference-in-differences (DiD) model was used with drug and relative-period fixed effects:

where Y_{it} is the publication count for drug i in period t; BTD_i indicates treated drugs; and $Post_t$ denotes post-designation periods. The model includes drug fixed effects (α_i) and relative-period fixed effects (δ_t).

4. Results

BTD-designated drugs show remarkable increase in publication activity following designation compared to non-BTD drugs (Figure 1). After log transformation to account for absolute differences, the DiD is positive (+0.85), indicating higher relative growth in BTD (Table 1). This suggests that regulatory designation is associated with increased scientific knowledge production. However, the DiD estimate is not statistically significant (β = 0.116, SE = 0.569), indicating no robust causal evidence.

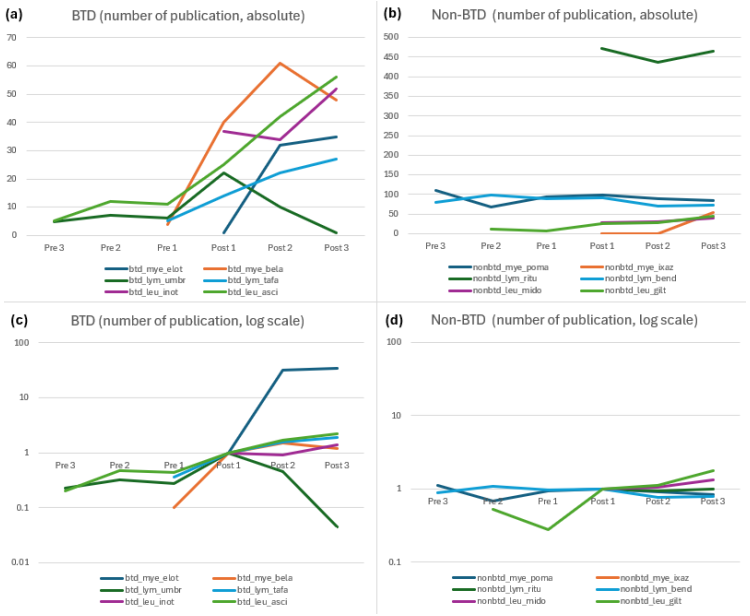


Figure 1: Publication Trends of BTD and Non-BTD (Absolute and Log Scales)

Table 1: Group Means of Log-Transformed Publication Counts (Pre- and Post-Designation)

Group	Pre (Log Mean)	Post (Log Mean)	Change
BTD	1.39	3.33	**+1.94**
Non-BTD	3.24	4.33	**+1.09**
DiD	-	-	**+0.85**

5. Discussion and Conclusion

The findings suggest that BTD is associated with trend of increased scientific publication activity. Although not statistically significant, the positive trend indicates that regulatory signals may influence knowledge production.

This aligns with research showing that regulation can promote innovation (Wagner, 2003). The results extend this perspective by focusing on knowledge dynamics.

This study contributes by examining regulation-induced innovation beyond traditional outcomes such as patents and development speed. It highlights the role of regulation in shaping scientific activity.

The small sample size is limitation of this research; therefore, further research should expand the larger dataset and examine knowledge networks and structures.

Abstract: This article aims to assess and benchmark the state of technology transfer and innovation processes (TTIP) in Higher Education Institutions (HEIs) across Central and Eastern Europe (CEE), focusing on how institutional and stakeholder-related knowledge transfer is shaped by regional contexts. The study is grounded in established theories of university–stakeholder interaction and innovation systems, with particular attention to the methodological approaches that dominate TTIP research and practice in CEE HEIs. Methodologically, the research combines an empirical comparative analysis with the development of a comprehensive mixed-methods survey framework. The proposed methodology employs stratified sampling across institutional employee types and research areas, integrating quantitative survey data with qualitative insights and administrative records related to technology transfer activities. The survey targets academic staff, researchers, administrative personnel, and doctoral students, who are identified as the primary actors in university technology transfer processes. The findings highlight that HEIs in CEE operate within distinct historical, institutional, and economic conditions that generate persistent challenges, including weak university–industry linkages, underdeveloped innovation ecosystems, limited and discontinuous funding, and uneven institutional support structures compared to Western European counterparts. Despite these constraints, technology transfer activities are shown to operate across diverse institutional environments through multiple mechanisms, including technology transfer offices (TTOs), collaborative research projects, intellectual property management, start-up creation, and academic spin-offs. The added value of this study lies in its integrated analytical and methodological contribution. First, it offers a contextualized benchmarking of TTIP performance in CEE HEIs that accounts for regional specificities often overlooked in pan-European analyses. Second, it introduces a robust and replicable survey-based methodology for capturing individual-level perspectives on technology transfer, enabling more nuanced performance measurement beyond institutional indicators. Finally, the study provides evidence-based insights to inform policymakers and university managers seeking to strengthen innovation systems in CEE higher education while respecting national and institutional diversity.

Keywords: Technology Transfer, Innovation System, Higher Education Institution, Benchmarking

1. Introduction

The transformation of Higher Education Institutions (HEIs) into engines of economic growth through technology transfer and innovation (TTI) has become an important trend in European policy over the past 10 years, alongside the development of international indicator frameworks for measuring innovation, for example, the Global Innovation Index (GII) and the European Innovation Scoreboard. Nowadays, this topic and its evolution are particularly critical in Central and Eastern European Countries (CEE), where universities are expected to be more involved than in the past, switching their position into playing a pivotal role in bridging the innovation gap, thereby contributing to regional economic development and competitiveness (Kergroach et al., 2018). The CEE region, comprising countries that joined the European Union (EU) in successive waves from 2004 to the present, presents a unique context for analyzing technology transfer dynamics. These nations share many traits, such as historical legacies, institutional reforms, and receipt of structural funds for investment in research and development (R&D) and innovation infrastructure (Barjak et al., 2016). Besides the characteristics of being part of the EU, the CEE countries could be divided into the following subregions: Central Europe (Poland – PL, Czech Republic – CZ, Hungary – HU, Slovakia – SK), the Baltic states: (Estonia – EE, Latvia – LV, Lithuania – LT), Eastern Europe: (Romania – RO, Ukraine – UA, the Republic of Moldova – MD, Belarus - BY), and South-Eastern Europe: (Bulgaria – BG, Serbia – RS, Slovenia – SI, Bosnia & Herzegovina - BA , Croatia – HR, Albania – AL, Montenegro – ME, North Macedonia – MK, Kosovo - XK). While this article is mainly focusing on CEE universities part of the EU and ERASMUS+ programme, all universities need more attention and research in this TTIP area.

Despite funding and support, CEE HEIs from the EU and ERASMUS+ programme, continue to face challenges in translating research outputs into commercial use and real-world applications, establishing fewer effective

linkages between academia and industry, and working harder in creating sustainable innovation ecosystems (Lacka et al., 2023). The performance of technology transfer varies significantly both between and within countries, reflecting differences in institutional capacity, policy frameworks, and entrepreneurial culture (Birkner et al., 2022). Understanding these variations and identifying the characteristics that distinguish high-performing institutions from low-performing ones is essential for policymakers, university administrators, and innovation practitioners seeking to strengthen the region's innovation capacity.

This article addresses the need for a comprehensive benchmarking analysis of TTIP awareness and engagement across HEIs in CEE countries, including Romania. The study analyses the historical evolution of TT understanding among HEIs, develops a methodology based on publicly shared best practices from universities, and provides detailed country-specific assessments through a survey.

The main objectives of the present study are to contextualize the HEI technology transfer processes for CEE countries within the global innovation landscape; providing a comparative country-level analysis of innovation performance, TTO structures, strengths, challenges and recent trends; proposing a comprehensive survey methodology for primary data collection that operationalizes key variables from the literature; developing actionable recommendations tailored to different stakeholders groups (researchers, professors, TTO officers, students, policymakers.

The article is organized to provide insights in the following structure and order: first, a comprehensive literature review covering the historical evolution of HEI technology transfer processes in CEE; comparative metrics for benchmarking; the theoretical framework; key concepts in university technology transfer; innovation ecosystems; and knowledge transfer mechanisms. Then, it presents a detailed country-by-country comparative analysis of the target nations, describes the research methodology employed in the present study, and proposes a comprehensive survey methodology framework for primary data collection. Finally, it concludes with a discussion of the data and implications, providing a ground for different stakeholders' groups and future research directions.

2. Literature Review

The technology transfer and innovation landscape for CEE HEIs is continuously changing. In countries that joined the EU in waves, universities have been forced to undergo a greater transformation. The immediate integration period to the EU involved the adoption of legal and policy frameworks to support university-industry collaboration and technology commercialization. Often, young EU member states adopted models from Western European countries (Anderson et al., 2018) that did not address the needs of their local specificities or industries.

2.1 Theoretical Foundations of Technology Transfer in HEIs

There is still an uneven approach to technology transfer at the HEI level, encompassing a range of activities that shape how academic outputs are translated into commercial use and societal benefits.

There has been a switch in time from the traditional university missions of teaching and research to "the third mission", translated into engaging directly with stakeholders and contributing to societal development, as mentioned by Pinheiro et al. (2015). This "third mission" implies three main dimensions: knowledge transfer and commercialization, continuous education and lifelong learning, and societal engagement and civic responsibility (Garcia et al., 2018; Berghaeuser et al., 2020).

It can be argued that this "third mission" considers levels of definitional ambiguity and variation across contexts. In European discourse, "third mission" has become prominent in education policy, though in Latin American contexts it is more often emphasized as an extension of the current policy (Dassoler et al., 2023).

Particularly in the European Research Area, it is strongly emphasized that adopting "the third mission" requires new organizational structures (such as TT structures) and, in turn, cultural change in how academics perceive their roles and how HEIs allocate resources and recognition.

In the CEE context, the third mission represents a significant evolution from the historical role of universities, which were focused primarily on teaching and secondarily on research, often conducted by separate academic institutes (Marozau et al., 2026).

Table 1 presents the EU status of the CEE countries in correlation to the number of HEIs and the innovation ranking. For the innovation ranking, the European Innovation Scoreboard for 2025 is considered the official EC composite score, based on 32 indicators, for measuring national or regional innovation.

It can be argued that EU membership adds value to HEIs, as CEE countries that are part of the EU are beyond the emerging-innovator status. However, just one of the CEE countries is considered a strong innovator – EE, four countries are considered moderate innovators – CZ, LT, HR, and SI, and the rest of the countries, EU members or not, are considered emerging innovators. Among EU members, HR, PL, SK, LV, BG, and RO are emerging innovators.

Table 1: Benchmarking technology transfer and innovation potential for CEE countries

Country	Acronym	EU status	Sub-region	No. HEIs	ERASMUS+ Charter	Innovation ranking EIS
Czech Republic	CZ	EU member	Central Europe	62	73	Moderate
Hungary	HU	EU member		64	56	Emerging
Poland	PL	EU member		361	302	Emerging
Slovakia	SK	EU member		35	32	Emerging
Estonia	EE	EU member	Baltic	18	18	Strong
Latvia	LV	EU member		22	44	Emerging
Lithuania	LT	EU member		22	28	Moderate
Belarus	BY	Non-EU	Eastern Europe	51	0	Not applicable (N/A)
Republic of Moldova	MD	Non-EU		16	0	Emerging
Romania	RO	EU member		80	78	Emerging
Ukraine	UA	Non-EU		207	0	Emerging
Albania	AL	Non-EU	South-Eastern Europe	35	17	Emerging
Bosnia & Herzegovina	BA	Non-EU		28	23	Emerging
Bulgaria	BG	EU member		51	53	Emerging
Croatia	HR	EU member		47	45	Moderate
Kosovo	XK	Non-EU		7	11	N/A
Montenegro	ME	Non-EU		17	4	Emerging
North Macedonia	MK	Non-EU		23	27	Emerging
Serbia	RS	Non-EU		32	49	Emerging
Slovenia	SI	EU member		44	86	Moderate

Source: ENIC-NARIC (2023), UniRank (2026), Erasmus (2021), EIS (2025)

As shown in Table 1, there is a mismatch between the country's size and its innovation output. For example, Romania, with 80 declared HEIs, is an emerging innovator, while Estonia, with 18 HEIs, is a strong innovator.

Moving further, it can be emphasized that HEIs in CEE countries play a critical role in National Innovation Systems (NIS), serving as primary generators of research outputs and human capital, and potential providers of technology transfer to industry. Lower national innovation performance is consistently associated with weaker measurable technology-transfer outputs from HEIs.

In most cases, knowledge flows from universities are conditional on public R&D investments and strong interaction between universities and industry (Runiewicz-Wardyn, 2014). The dependence on public funding, rather than on market-driven sources, highlights structural weaknesses associated with the status of a moderate or emerging innovator. HEIs in countries with lower EIS rankings tend to have weaker university-industry collaboration rates, less-developed TTOs, and lower success in valorisation and commercialization metrics, such

as spin-off creation and licensing revenues. The ERASMUS+ Charter column is emphasizing the membership in the ERASMUS+ Programme, being one of the most coherent exchange and mobility programme at the EU level.

Technology transfer still lacks a universally accepted definition. The concept of technology transfer varies across national and regional contexts (Wahab et al., 2011). Technology transfer is the process of translating research outcomes from an HEI into a market solution, typically in at least one industry. This is why it would be very relevant for each HEI to have a Technology Transfer and Innovation-related entity to raise awareness, provide guidance, and evaluate how TT is acquired at the HEI level and translated into industry (Bozeman, et al.,2000). A general term for this entity is usually the Technology Transfer Office (TTO). At the institutional level, a TTO serves as a boundary, a structural mediator between academic researchers, professors, PhD students, and industry partners, reducing bureaucratic noise, keeping information consistent, and making knowledge exchange transaction cost-relevant (Siegel et al., 2005; Debackere et al., 2005).

Critically, TT is not a linear process; it is highly dynamic, with a multi-directional flow of knowledge shaped by all the actors involved and by the culture of each HEI and country. The capacity to absorb knowledge is addressed by many theories, such as the Quadruple Helix context, which argues that universities, industry, government, and society actors must build Intentional interactions and complementary processes to enable effective innovation diffusion and knowledge transfer (Militaru et al., 2025). Therefore, TT mechanics cannot work efficiently without a human and cognitive foundation.

2.2 Technology Transfer Mechanism in CEE HEIs

Technology transfer from universities to industry serves multiple critical functions for CEE countries. Firstly, provides a mechanism for translating publicly funded research into economic and social value, strengthening the need for continuous investment in higher education and R&D (Stankeviciene et al., 2017). Secondly, maintains university-industry linkages, creating feedback loops that improve academic research's responsiveness to market needs and challenges (Serbanica et al., 2015). Thirdly, it contributes to regional economic development by creating high-value workplaces, fostering an entrepreneurial mindset, and providing opportunities for researchers and graduates to commercialize ideas locally rather than migrating to more developed national innovation systems (Stoicovici et al., 2017; Birkner et al., 2022).

There are 20 countries in CEE; hypothetically, if each university has one TTO, that would result in more than 1,000 TTOs. Taking this potential into account, HEIs in CEE could build a foundation for technology transfer outputs at the regional and national levels.

Characteristics such as the ability of local markets and industries to recognize, assimilate, and apply knowledge generated by universities, as well as organizational capabilities for technology transfer in HEIs, influence the dynamics of technology transfer and innovation capacity (Runiewicz-Wardyn, 2014). From the analysis of several HEIs included in the primary study, both *institutional mechanisms* such as TTOs, formal procedures, intellectual property (IP) management, incubators/accelerators, and *relational mechanisms* based on networks among academic staff, interpersonal connections, affiliation to science and technology (S&T) parks, were identified (Miller et al., 2016).

Table 2 provides an overview of the TT institutional and relational mechanisms found on the HEIs' websites shared by respondents in the primary dataset.

Table 2: TT institutional-relational framework overview

TT Institutional characteristics (TTIC)		TT relational characteristics (TTRC)	
Name	**Definition**	**Name**	**Definition**
IC1. Dedicated TTO/innovation structure	Established TTO, innovation/knowledge transfer unit/center	RC1. International networks	Part of international research networks
IC2. Formal TT regulations/procedures	Existing internal procedural frameworks	RC2. Industry partnerships	Shared programs, visible partnerships
IC3. IP management	Explicit mention of patent filing, IP registration, licensing	RC3. Academic exchange and mobility programmes	Bilateral exchange, ERASMUS+

TT Institutional characteristics (TTIC)		TT relational characteristics (TTRC)	
Name	**Definition**	**Name**	**Definition**
IC4. Research infrastructure	Existing research labs, dedicated physical Innovation spaces	RC4. External funding	External funding support (EU projects, national research grants) available to academic staff
IC5. Performance metrics	Explicit metrics for valorisation and commercialisation	RC5. Regional/national innovation roles	Explicit affiliation to high-tech parks, regional innovation hubs

Source: author's structure developed

The institutional-relational framework is relevant for benchmarking TT in the CEE context because HEIs face challenges both in building internal infrastructure and in integrating into European and global research and innovation networks.

3. Methodology

The methodology for the current study focuses on both secondary and primary analyses. The secondary research consists of an analysis of several databases, such as the OECD and local university websites, as well as a literature review. The primary research consists of an applied survey covering several variables related to technology transfer and innovation absorption at the university, as perceived by HEI staff. The applied survey reached around 150 persons from CEE HEIs and gathered 31 responses, 29 from CEE HEIs, one from Hungary, and one from Türkiye.

This study establishes a pilot benchmarking methodology to assess the current state of technology transfer in HEIs across CEE. Table 3 shows the variables available in the dataset and their description. The study deliberately excluded TTO officers to capture the academic side of TT processes at the HEI institutional level.

Table 3: Research variables

Research Objective	Research Variables	Variable Role Measurement
RO1 Defining TTO structures	TTO existence	Whether there is a TTO or an innovation-related structure within HEI
	Authority linkages and autonomy	Identifying the type of communication between academic staff and TTO
	Strategic planning	Identifying local regulations available for TTI
RO2 Measuring perception of academic staff over TTO involvement	Academic staff reach	Understanding the awareness about TTI
	Visibility	Identifying available TT opportunities
	Communication channels	Understanding the communication means
	Academic recognition	Whether there is a way to recognize involvement in TTI activities
RO3 Benchmarking the technology transfer and innovation indicators at the HEI level	Performance metrics	Understanding relevant indicators to measure TTI, and which ones are tracked
	Succes stories	Whether there are heard or/and experienced

Source: author's structure developed

The study was conducted among academic staff from 10 CEE countries, nine EU, one Non-EU, and Türkiye. The roles answering the study were professors, PhD students (doctoral students), researchers, and administrative staff. All respondents agreed to give permission for the use of their data for research purposes.

The applied survey consisted of 20 questions: 19 mandatory, closed-ended, and one non-mandatory, open-ended. The first questions covered demographics such as role in academia, home HEI, and country. The interpretation and graphical elements of the current study were developed in Microsoft Forms, JAMOVI, and Microsoft Excel. Table 4 consists of 39 JAMOVI variables derived from 20 survey items; Q5 and Q20 are missing from the Table 4 dataset because they gathered the websites where the TT information was available for each HEI.

4. Results and Discussions

The primary data frame an exploratory database of N31 across 9 countries, a quite small sample, with a geographic concentration in CEE countries. Table 5 presents a matrix of the sample's demographic profiles. Each row represents a country and an HEI, with the values indicating the number of respondents from that institution who answered the survey.

The 31 universities are showing the following roles and count: 4 administrative staff, 7 PhD students, 19 professors, and one researcher. As main observations, RO was the most-represented country, with 16 responses across 5 HEIs, 10 professors, and 5 PhD students. POLITEHNICA Bucharest has the highest percentage of respondents, 12. MD responses came from three different HEIs in the professor role, in total 61% responses for geographic concentration.

HR responses came from two administrative staff members and one researcher.

BG, CZ, EE, LV, and PL each have only 1-2 responses, indicating that survey penetration and engagement on the topic were quite low. Hungary and Türkiye are not CEE countries; however, they are neighbouring them, and the respondents could have a close perception, which will be further analysed.

The role distribution is important because it shows a clear interest among professors in the topic (61% of respondents), while administrative staff and researchers (12%) are underrepresented, indicating that TT awareness is present among professors and less among researchers and administrative staff (other than TTO officers).

Table 5: Dataset distribution among respondents

Source: author's structure developed

The underrepresentation of administrative staff and researchers could be considered a red flag regarding the TT's interest and capacity; therefore, researchers show low engagement in TT processes. Consistent with the study, the professors show the highest awareness of TT regulations, the PhD students show the lowest, and the administrative staff are divided in their opinions; the descriptive statistics suggest greater uncertainty about institutional TT infrastructure among early-career academics. Only 39% of the respondents were aware of the local HEI regulations for TT. The most common TT documentation, which only 26% of the respondents were aware of and took into consideration, was the Rector's action plan, and the IP local policy, with 17% of the respondents.

Table 6 highlights correlations among Jamovi variables. There is a statistically significant, moderate positive correlation between Q8XQ10. There is a direct connection between the resources available to learn about TT

and interaction with their TTO, which seems natural; only 16% of respondents confirmed that they are aware of the resources to learn about TT.

Table 6: Correlation matrix Jamovi Q8, Q10, Q14

Q8.resourceTT_HEI x Q10.interactionTTO_HEI	Q8.resourceTT_HEI x Q14.academicrecognition_TT	Q10.interactionTTO_HEI x Q14.academicrecognition_TT
Spearman's rho 0.331	Spearman's rho 0.700	Spearman's rho 0.259
p-value 0.069	p-value <0.001	p-value 0.159

Source: author's structure developed

On the other hand, there is a large positive correlation between the resources available to learn about TT and academic recognition (incentives or other) for the involvement in activities related to TT and innovation (Q8XQ14). This structural relationship is confirmed by local practice, as active patents and licensing are taken into consideration when advancing in the academic hierarchy within CEE HEIs, and, at the same time, the correlations show that where resources are available, academics are more likely to have their TT activities recognized.

The third correlation between Q10XQ14 is not statistically significant; the interaction with TTO employees does not necessarily guarantee that interacting with TTO employees is also motivated to get involved in the process and hence obtain academic recognition.

The survey examined academic staff perceptions of TT indicators across CEE HEIs. The reliability analysis of the Q17 indicators collectively indicates a reliable and consistent scale for measuring the relevance of the indicators, as evidenced by Cronbach's α in Table 7. It can be suggested that the respondents perceive the TT indicators as a holistic, interconnected set rather than independent ones. Figure 1 - The correlation heatmap confirmed strong positive inter-item correlations across all pairings.

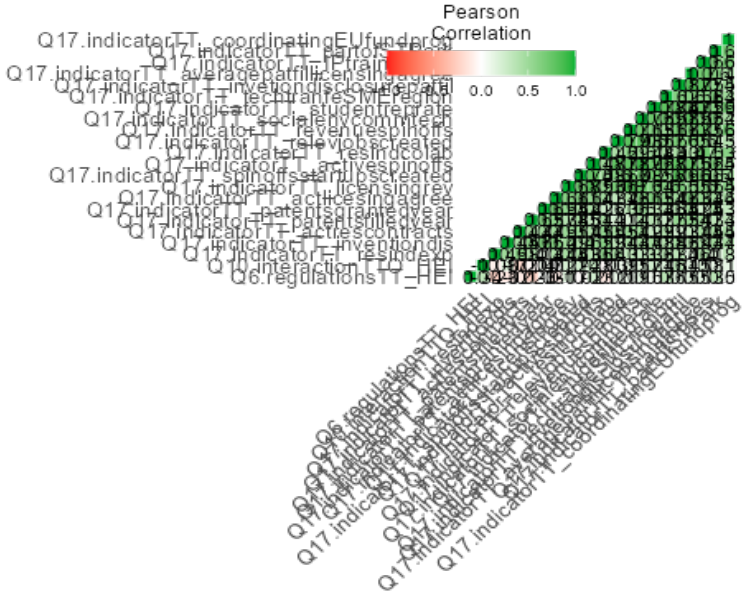

Figure 1: Correlation Heatmap Pearson Q6-Q10-Q17 variables

For CEE HEI respondents, the following indicators were considered as already part of their practice: 14% - number of researchers with industry collaboration, 14% - number of active research with industry, 14% - coordinating EU research-funded programs, 9% number of patents granted per year, 7% number of research industry collaboration agreements signed, and 6% of the total highlighted that there is none indicators used by their HEI to track TT processes. After analyzing the data, although all respondents considered the 20 indicators measured at Q17 to be, to some degree, relevant, their real-life application is quite scarce in CEE HEIs, given the pilot sample. 74% of respondents reported not knowing any success stories related to TT and innovation at their university.

To benchmark the CEE HEIs in the study, the synthesized characteristics from Table 2 were used, and calculations were applied to the 10 characteristics based on the primary data gathered. Table 8 presents the comparative analysis.

Table 8: TTO website characteristics comparative analysis

Source: author's structure developed

Legend: 1 – present characteristic confirmed on the HEI/TTO's website; 0 – absent characteristic not found on the website, N/A – respondent did not identify any TTO.

Score interpretation (1-10): sum of (IC1 -RC5), 1-5 minimum/emerging, 6-10 developing/moderate.

There are some characteristics that all universities tick, for example, being part of international networks and organizing academic exchange, which are most of the time visible on the university's International Relations page, not on the TT office/department sections. Some characteristics are lacking in some universities because there are no TT structure and local regulations, which make the activity hard to access.

Most HEIs in Central Europe demonstrate strong institutional and relational characteristics, with scores ranging from 7 to 9 out of 10. The Baltic countries are interested in implementing TT processes using locally developed models. Moldova demonstrates an emerging character, with significant fresh involvement in this area. Bulgaria and Romania show significant institutional heterogeneity, reflecting the diversity of HEIs.

5. Conclusions

The analysis of the technology transfer HEI characteristics was based solely on publicly available website information; it may not fully reflect the true state of practice in internal TT processes. However, it is a starting point for a more in-depth analysis of CEE and Romanian HEIs. This study reveals significant heterogeneity in both institutional and relational TT characteristics. This institutional-relational framework has important implications for primary research of TT on HEI academic staff.

The absence of TTO officers' responses was a design decision, not a limitation, defining the demand side of TT rather than the supply side. The academic awareness of TT processes is concentrated mostly in the professors' layer rather than the researchers' layer, where intellectual property usually originates.

The present study provides a comprehensive basis for understanding the state of technology transfer and innovation across a diverse sample of CEE universities, introduces a novel framework for benchmarking HEIs, and uses primary data to emphasize the need to improve both structural and relational TTI at the HEI level in CEE countries.

This study can be considered by fellow academic staff for research design development to strengthen TTI in CEE, and by fellow stakeholders to understand the innovation system and improve connections with the HEI.

Abstract: Muslim-majority economies face a challenge where Micro Small and Medium Enterprises (MSMEs) are constrained by a lack of access to formal financial services. This constrains MSMEs ability to innovate and create economic value. Islamic crowdfunding is a promising alternative that is technology-driven and Shariah compliant. There has been interest in the field of MSME financing in entrepreneurial ecosystems for the past twenty years but there has been no comprehensive bibliometric study. This paper presents a systematic bibliometric study with respect to Islamic crowdfunding between the years of 2006 to 2026. Following the PRISMA 2020 framework 1452 records were taken from Scopus, where 130 articles were identified for analysis. Using VOSviewer, five major themes were identified based on the analysis of the co-occurrence network of the articles: (1) technology and investor behaviour, (2) Shariah compliance and governance of the platforms, (3) financing of entrepreneurship and MSMEs, (4) the environment of entrepreneurship and regulatory issues, (5) innovation in financial markets. It was noted that the articles focused on the platforms and the Investors, and that the studies were primarily cross-sectional in nature.

Keywords: Islamic Crowdfunding, Bibliometric Analysis, Systematic Literature Review, SME Financing, Financial Technology.

1. Introduction

In emerging economies, the foundation of productive capacity is the MSME sector and the backbone of its growth and innovation is entrepreneurship. MSMEs in almost all Muslim countries experience formal financing constraints yet there is a greater challenge for MSME entrepreneurs seeking Shariah-compliant financing (Abdeldayem & Aldulaimi, 2023; Fasano et al., 2025; Muneem et al., 2025; Abdulkadir et al., 2024). This financing gap illustrates the lack of equilibrium in the alignment of formal financing mechanisms and the ethical frameworks of Muslim entrepreneurs (Hassan et al., 2022). Where risk and uncertainty are predominant along with ethical frameworks and the prohibition of riba, gharar, and maysir, Islamic crowdfunding has emerged as a viable alternative financing mechanism (Hendratmi et al., 2019; Marwa et al., 2023). Its rapid growth in countries such as Indonesia, Malaysia, and the Middle East, combined with the regulatory interest from the OJK and Bank Negara Malaysia (Al-Mulla et al., 2022; Ishak et al., 2024; Otoritas Jasa Keuangan, 2025; Market Data Forecast, 2025; Irawati, 2020), reflects its importance in the markets. It is playing a more strategic role in financial inclusion and sustainable development (Hasna et al., 2022; Khan et al., 2023; Ramdani et al., 2025).

Research has progressed significantly over the past couple of decades. The Shariah Law legitimacy phase (2006–2015) and the digital contracts phase were the foundational work. Phase two of the research (2016–2026), originated due to the advancement of Islamic fintech. This phase is characterized by the development of the platforms and the regulation of Islamic fintech (Hendratmi et al., 2020; Qudah et al., 2023). Even with the mapping of the related fields which include Islamic Finance, (Qudah et al., 2023), green crowdfunding (Ramdani et al., 2025), and conventional equity crowdfunding (Gupta et al., 2024; Camilleri & Bresciani, 2024), none of the studies comprehensively analyzed Islamic crowdfunding's intellectual structure. This includes MSME financing in entrepreneurial ecosystems. There is a notable lack of research on the integration of entrepreneurial ecosystems in Islamic Equity Crowdfunding and the interactions between the investors and the entrepreneurs (Brown et al., 2018, 2019; Giudici et al., 2020; Sendra-Pons et al., 2024; Buttičè & Vismara, 2022; Lukkarinen et al., 2022; Figueiredo & Bendelá, 2024). Although there has been a notable advancement in Islamic equity crowdfunding, the same cannot be said for Islamic crowdfunding (Abdeldayem & Aldulaimi, 2023; Muneem et al., 2025). Operating in this gap is bound to benefit researchers, developers and policymakers who want to enhance Islamic Crowdfunding as an open financing channel (Bank Indonesia, 2024; Otoritas Jasa Keuangan, 2025). Using Scopus, this study analyzes Islamic Crowdfunding from 2006–2026 to answer six research questions. These include the trends in publications, the analysis of productivity, the patterns of keywords, the relationships in collaboration

2. Methodology

This study uses a systematic bibliometric analysis of the Scopus database to understand the intellectual structure of Islamic crowdfunding research from 2006 to 2026. The search string used was: (TITLE-ABS-KEY (Islamic AND crowdfunding) OR TITLE-ABS-KEY (Shariah AND crowdfunding) OR TITLE-ABS-KEY (Islamic AND ("equity crowdfunding" OR "crowdfunding financing"))). Due to its position as the largest peer-reviewed abstract and citation database in the world, and its automated bibliographic data export, Scopus was selected as the sole primary data source (Carè et al., 2025; Farah et al., 2025; Qudah et al., 2023). As the majority of Web of Science literature that is pertinent to this research area is included in Scopus, the use of a single, comprehensive database does not significantly affect the representativeness of the corpus.

Methodological rigor and reproducibility in accordance with PRISMA 2020 were strictly adhered to during the processes of data extraction and selection (Figure 1). At the conclusion of the first search, 1,452 records were identified. After applying predetermined inclusion and exclusion criteria restricting the remaining dataset only to publications that were written in English, contain peer-reviewed content which is relevant to Islamic crowdfunding as well as financing of MSMEs, all duplicate entries (n = 216), and entries that were off-topic (n=199), were systematically removed from the total data set; thus, resulting in 130 articles being included in the final analysis. The period of the articles included was between 2009-2026 and, therefore, are classified into 2 separate analytical phases; the emergence phase (2006-2015) and the growth phase (2016-2026).

Bibliometric analysis was conducted using two well-established software tools: Bibliometrix R Studio (Aria & Cuccurullo, 2017) and VOSviewer (Van Eck & Waltman, 2010). Descriptive statistics reflecting the annual production of scientific literature, the productivity of authors, contributions by countries/institutions, source title contributions, and frequency of keywords were evaluated using Bibliometrix. VOSviewer was used for conducting network-based visualizations (e.g. keyword co-occurrence mapping, co-authorship networks, and thematic clustering) (Figure 1). Together, these two software tools allow for a thorough review of both quantitative aspects of the literature and the relational structures that constitute the field's intellectual development. Descriptive statistics were used to address RQ 1-3; network statistics were used to answer RQ 4; and a synthesis of the descriptive, network and content analyses were utilized to answer both RQ 5 and RQ 6.

3. Results

3.1 Dynamic Trends Observed in the Literature on Islamic Crowdfunding (2006–2026) and Authors

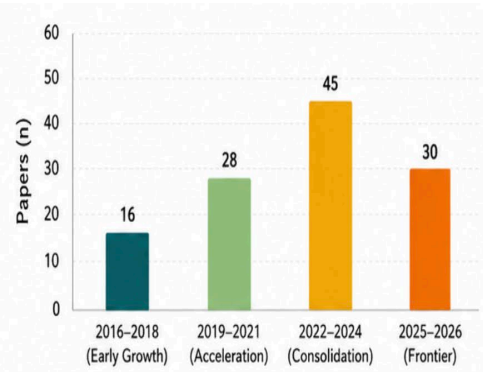
The chronological pattern revealed by 130 publications across 17 years indicates an increasing rate of research in the realm of Islamic crowdfunding. The research was previously defined by isolated instances of conceptual research on Islamic crowdfunding. This research trajectory has quickly transitioned from conceptual research to a growing research field, as indicated by the phased development presented in Table 1, which outlines the encompassing distribution of the various phases of the research and bibliometric parameters of the overall corpus of islamic crowdfunding research.

Table 1: Bibliometric Overview of the Islamic Crowdfunding Literature (2006 -2026

Period / Phase	Papers (n)	Cumulative	Phase %	Total Citations	Avg Cit./Paper	h-index (partial)
Conceptual/ Emergence Phase (2006–2015)	11	11	8.5%	761	69.2	—
Growth Phase (2016–2026)	119	130	91.5%	2,475	20.8	—
Total Corpus	**130**	**130**	**100%**	**3,236**	**24.89**	**31**

Source: Authors' elaboration from merged Scopus export (May 2026, n = 130 articles).

3.1.1 Phase I – Conceptual and Emergence Phase (2006–2015)



Phase I (2006–2015) – Conceptual and Emergence The Emergence Phase of Islamic crowdfunding research (2006–2015) only contains 11 publications, averaging less than two publications per year. The scholarly work produced during this phase has focused on three major themes: The shariah principles of financial intermediation (waqf, zakat, mudarabah, musharakah), MSME issues in terms of funding in Muslim countries, and into comparisons of conventional banks versus Islamic banks. There was no mention of the term "crowdfunding" in any of the key words associated with any of the publications that were published in Phase I, confirming that the research field was not stable enough for the term "crowdfunding" to be associated with projects related to islamic crowdfunding. There are many important papers associated with Phase I of this research that had above-average citation rates (69.2); including: Beck et al. (2011), Irwin and Scott (2010), and Yoshino and Taghizadeh-Hesary (2015). The US Jobs Act (2012) and Malaysia's implementation of an equity crowdfunding framework (2015), were significant institutions that provide the impetus for the Phase II explosion of islamic crowdfunding research.

3.1.2 Phase II – Growth Phase (2016–2026)

The Growth Phase, which spans from 2016 to 2026, represents the overwhelming majority of the corpus (119 out of 130 or 91.5%) and the number of citations (%) for this entire corpus; 2,475 of 3,236 (76.5%), respectively. For further understanding of the growth trajectory's internal dynamics, Table 1b breaks down the Growth Phase into four sub-periods.

The early growth period of 2016-2018 produced 16 total articles with an average number of 40.4 citations per paper demonstrating long-lasting academic impact of the articles created during this time. Of the articles included in the corpus, Block et al. (2018) held the record for the most cited paper with 507 total citations. This paper described a theoretical framework of the new players in entrepreneurial finance and described crowdfunding as an alternative to bank financing which provided the subsequent vocabulary for Islamic crowdfunding researchers in their research.

Table 2: Sub-period Analysis within the Growth Phase (2016–2026)

Sub-period	Papers (n)	Cumulative	Total Citations	Avg Cit./Paper	Key Catalyst
2016–2018 (Early Growth)	16	16	646	40.4	Global CF platform boom
2019–2021 (Acceleration)	28	44	747	26.7	Reg. frameworks; COVID-19
2022–2024 (Consolidation)	45	89	930	20.7	Islamic ECF / P2P maturation
2025–2026 (Frontier)	30	119	152	5.1	IR 5.0; e-Waqf; AI fintech

Source: Authors' elaboration from merged Scopus export (May 2026).

The second phase of research from 2019-2021 (acceleration phase) produced 28 publications about Islamic equity crowdfunding (IECF) and peer-to-peer (P2P) that were built on the advancement of IECF platforms in Malaysia (Nusa Kapital, pitchIN) and Indonesia (Ethis, Kapital Boost) and accelerated through the COVID-19 pandemic; COVID-19 made evident the fragility of bank financing for micro, small, and medium enterprises (MSMEs) and further advanced the adoption of digital financial platforms (Octaviani et al., 2021). The third phase of research (consolidation phase) from 2022-2024 produced a total of 45 articles which shows that the market for Islamic ECF research has matured; the paper collection includes formal Shariah governance frameworks, hybrid instrument-platform design, gender-disaggregated studies on adoption rates, and bibliometric analysis of the field as a whole (Mohd Kassim et al., 2024; Herawati, 2024; Sarfraz et al., 2023; Ramli et al., 2023). The fourth and final phase is identifiable by research from 2025-2026 (partial) that identifies IR 5.0, e-waqf integration into Islamic fintech platforms, and the use of UTAUT^2 as the adoption model applied to MSMEs in Indonesia (Ashari & Abdul-Rahman, 2025) and represents an approximate annualized output ten times greater than the average outputs produced in Phase I.

3.2 Most Cited Works and Foundational Contributions

The ten highest cited articles in the corpus are illustrated in Figure 3. They serve as the base literature upon which Islamic crowdfunding research is systemically organized. The ten highest cited articles in the corpus provide the field's intellectual foundation (refer to Figure 3). Notably, the broader entrepreneurial finance and MSME finance publication representation dominates the publication representation in the corpus, rather than publications exclusive to Islamic crowdfunding research. Block et al. (2018) has 507 total citations and provides the theoretical vocabulary for research on information asymmetry, platform economics and investor heterogeneity that Islamic crowdfunding researchers have systematically adapted. Eldridge et al. (2021) has 98 total citations and presents the best rigorous causal evidence that equity crowdfunding has a positive effect on MSME innovation and growth. This finding can be directly applied to research on Islamic equity crowdfunding (ECF) but has yet to be scientifically validated using data from Islamic equity crowdfunding platforms. Bu et al. (2024) has 81 total citations within one year of publication and examines digital inclusive finance as a tool for providing MSMEs financing indicating a strong likelihood that digitally focused Islamic crowdfunding research will be increasingly impactful in the future regarding financial inclusion.

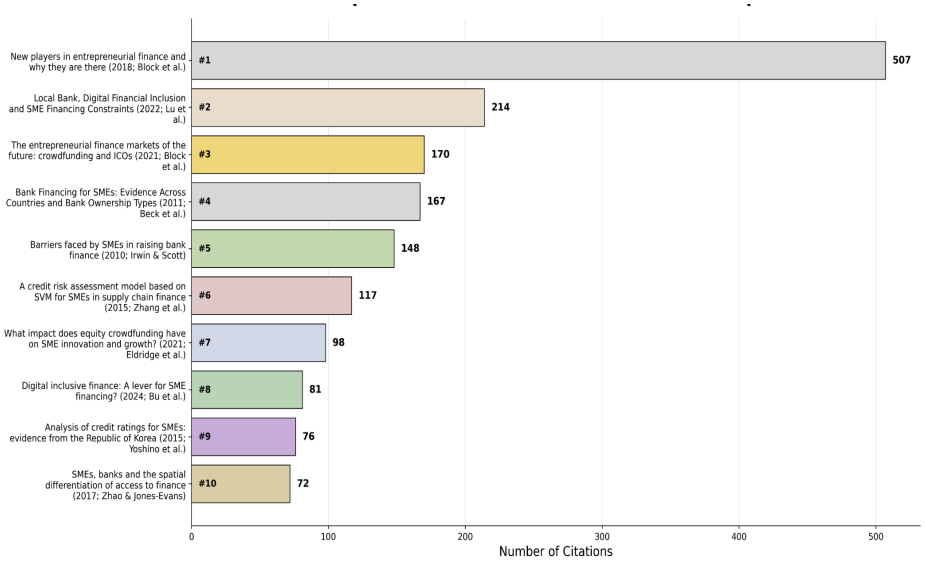


Figure 3: Top 10 Most-Cited Publications in the Corpus

Source: Authors' elaboration from Scopus (May 2026). Citations as of export date.

3.3 Most Productive Authors, Countries, Institutions, and Sources

Publication counts for both Table 3 and Table 4 show the top five authors in terms of the number of publications produced (the "global" authors). There are two main groups of authors that can be defined based on how they have contributed to the broader SME financing and entrepreneurial finance academic literature and therefore provide a theoretical basis for researching Islamic crowdfunding; and the "independent" group of authors, who have authored articles on Islamic crowdfunding and are unique to the field have published very little compared to the "global" authors.

Table 3: Top 10 Most Productive Authors in the Corpus

Rank	Author	Publications	Institutional Affiliation	Key Thematic Focus
1	Vismara S.	3	University of Bergamo, Italy	Equity crowdfunding, IPO
2	Ishak M.S.I.	3	Universiti Utara Malaysia	Islamic crowdfunding, governance
3	Wu J.	3	Hunan University, China	Digital finance, SME credit
4	Wang Y.	3	Renmin University, China	SME financing, bank credit
5	Li H.	3	Hunan University, China	Digital inclusive finance

Source: Authors' elaboration from merged Scopus export (May 2026).

Table 4 shows a breakdown of productivity by author affiliation by country. The UK has 59 author affiliations, which reflects the UK's current status as the centre for research in both entrepreneurial finance and MSME finance globally. Indonesia and Malaysia together account for 56 author affiliations, which is the largest combined author affiliation output of all Muslim majority countries in the world. Of the total 59 author affiliations, only 29 were from Indonesia and 27 were from Malaysia.

Table 4: Top 5 Most Productive Countries by Author Affiliation

Rank	Country	Affiliations	Region	Islamic CF Role	Phase
1	United Kingdom	59	Europe	Comparative/theoretical anchor	Both
2	China	46	East Asia	Digital finance comparator	Growth
3	Italy	31	Europe	Equity CF/ECF platform research	Growth
4	Indonesia	29	Southeast Asia	Core Islamic CF producer	Growth
5	Malaysia	27	Southeast Asia	Core Islamic CF producer	Growth

Source: Authors' elaboration from merged Scopus export (May 2026).

3.4 Keyword Analysis and Conceptual Architecture

Keyword co-occurrence analysis is a method for mapping conceptual framework of a subject area through determining the keyword clusters that exist to create systematic groupings of scholarly articles within a specified domain. An example of co-occurrence of keywords can be found in Table 6, which shows the top 20 most used author-assigned keywords in this corpus according to thematic cluster and timeframe of existence. Three thematic clusters were identified. The first cluster, "SME Finance," consisting of the terms "SME financing" (34), "SMEs" (25), "financial constraints" (5), "bank financing" (5), is the primary area of research focus within the literature surrounding SME financing, clearly identifying Islamic crowdfunding as a primary source of financing for SME financial access and inclusion.

The second thematic cluster, "Alternative Digital Finance," contains keywords of "crowdfunding" (21), "equity crowdfunding" (9), "fintech" (9), "entrepreneurial finance" (9), "venture capital" (4), "blockchain" (3) and "alternative financing" (3). This cluster only appears at the later Growth Phase (<2016); this indicates that this intellectual sub-area has developed post 2016. The co-occurrence of keywords "fintech" and "Islamic crowdfunding" creates an emergence of a new sub-area of "Islamic fintech" (i-fintech) within the literature, providing a unique overlap of Islamic compliance and financial access and use of digital platforms.

3.5 Co-Occurrence, Collaboration, and Co-authorship Patterns

Table 7 summarises the bibliometric indicators of the corpus's co-authorship structure. The field exhibits strong collaborative norms: only 15 papers (11.5%) are single-authored, while 88 papers (67.7%) involve three or more co-authors. The average of 3.08 authors per paper is above the typical norm for business and social science research (Glänzel and Schubert, 2004), suggesting that Islamic crowdfunding scholarship is characterised by team-based inquiry a pattern consistent with the multidisciplinary demands of a field bridging Islamic jurisprudence, financial economics, digital technology, and entrepreneurship.

Table 5: Co-authorship and Scientific Impact Indicators of the Corpus

Bibliometric Indicator	Value	Interpretation
Total publications	130	Filtered corpus
Single-authored papers	15 (11.5%)	Collaborative norm established
Two-authored papers	27 (20.8%)	Dyadic collaboration common
Three-authored papers	40 (30.8%)	Dominant collaboration size
Four or more authors	48 (36.9%)	Multi-author groups increasing
Average authors per paper	3.08	Above social science norm
Internationally co-authored papers	52 (40.0%)	High globalisation of scholarship
Dataset h-index	31	Scientifically recognised impact threshold
Total citations	3,236	Cumulative scholarly influence
Average citations per paper	24.89	Strong per-paper impact

Source: Authors' elaboration from merged Scopus export (May 2026).

3.6 Thematic Evolution Across Phases

The two phases were compared systematically according to six analytical axes of publication volume, citation patterns, thematic keywords, geographical distribution, methodological approaches, and theoretical frameworks in Table 6.

Table 6: Comparative Analysis of Research Themes: Emergence vs. Growth Phase

Dimension	Conceptual / Emergence Phase (2006–2015)	Growth Phase (2016–2026)	Delta (Δ)	Trend
Publications	11	119	+108	↑↑↑
Average citations/paper	69.2	20.8	−48.4	↓ (recency)
Papers with Islamic themes	0	21	+21	↑↑↑
Dominant methodology	Quantitative regression	Mixed (quant + qualitative SEM)	—	Diversifying

Dimension	Conceptual / Emergence Phase (2006–2015)	Growth Phase (2016–2026)	Delta (Δ)	Trend
Dominant geography	Europe, Sub-Saharan Africa	Global (SE Asia dominant)	—	Globalising
Key theoretical frame	Credit rationing; info. asym.	UTAUT/TAM; platform theory; Shariah gov.	—	Expanding

Source: Authors' elaboration from merged Scopus export (May 2026). ↑↑↑ = substantial increase; ↓ (recency) = natural bibliometric decline due to publication date.

During its Growth Phase, five thematic transitions occurred during this period: (1) Platform Economics & Crowdfunding Theory (2016-2019), (2) Islamic FinTech Formalisation (2020-2022), (3) Shariah Governance & Regulatory Analysis (2023-2024), (4) Integrating Social & Philanthropic Instruments (Waqf, Zakat, etc) (2023-2024) (Amri et al., 2024), and (5) Modelling Adoption Behaviours (UTAUT, TAM, Theory of Planned Behaviour)(2021-2026) for use by researchers developing theoretical constructs of social finance eco-systems through adoption behaviours leveraging UTAUT, TAM, and Theory of Planned Behaviour and integrating the constructs into their own research where applicable.

3.7 Future Research Agenda: Islamic Crowdfunding as a Driver of SME Financing in Entrepreneurial Ecosystems (RQ6)

Figure 5 provides an organized agenda for future research on Islamic crowdfunding using the framework of the five-phase thematic analysis and the bibliometric findings related to unexplored research areas. There are ten priority areas for future research based on the lack or absence of empirical data, methodological limitations, or geographical blind spots found.

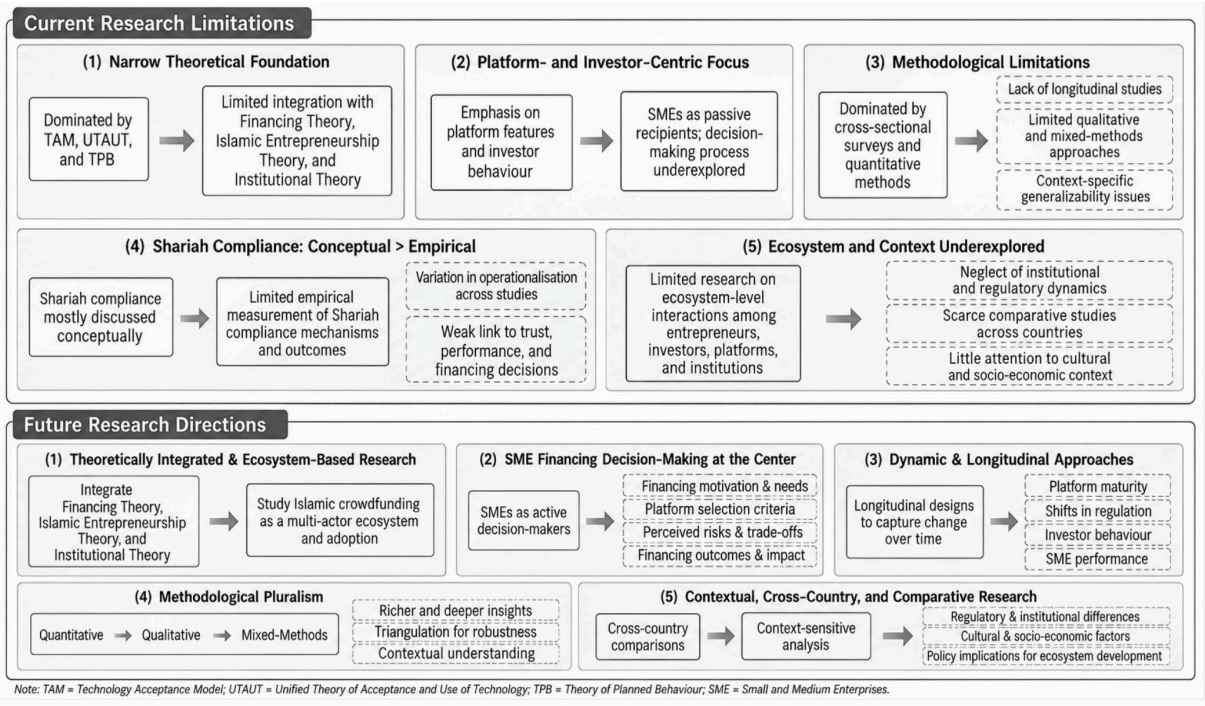

Figure 5: Future Research Agenda

The summaries of the four cross-cutting priorities arise in the literature. The lack of internationally recognized standards for Shariah governance is a barrier; more comparative studies need to be conducted across Malaysia, Indonesia, UAE, and Nigeria. The use of UTAUT/TAM has only been applied to adoption intention for banking or SME financing and rarely to actual use of a platform, so longitudinal and platform-specific studies need to be conducted to measure the actual impact. The entrepreneurial ecosystem approach remains relatively

unexplored in this area; lawyers should have the opportunity to consider ecosystem-based research examining interactions between Islamic crowdfunding platforms, Islamic banks, zakat and waqf institutions, and regulators as a way to create knowledge regarding entrepreneurship and Islamic finance. The development of Islamic crowdfunding platforms using the IR 5.0 technologies (AI, blockchain, smart contracts, and e-Waqf) represents a new area of research that needs further examination due to the need for determining Shariah compliance with AI-based credit scoring and the tokenization of sukuk using blockchain.

3.8 Practical Implications and Recommendations

The evidence carries four practical implications. For platform operators, the absence of internationally recognised Shariah governance standards is an operating risk as much as a research gap: operators should publish their screening criteria, Shariah board composition, and contract structures (murabahah, mudarabah, musharakah, or qard al-hasan) as standing disclosures rather than case-by-case assurances.

For SMEs and entrepreneurs, the "SME Finance" keyword cluster positions Islamic crowdfunding as a complement to, not a substitute for, bank financing: fundraisers should treat campaigns as one stage of a financing pathway that builds a documented repayment record, and select platforms whose contract type matches the venture's cash-flow profile. For regulators, the literature's focus on adoption intention rather than realised use cautions against reading survey optimism as market readiness: sandboxes and licensing regimes should require platform-level reporting of completed campaigns, default rates, and investor concentration. Given the corpus's South-East Asian concentration, Malaysian and Indonesian models should be adapted rather than transplanted elsewhere.

Finally, the underexplored link between platforms, Islamic banks, and zakat and waqf institutions is a design opportunity: blended structures in which zakat or waqf funds absorb first-loss exposure on qard al-hasan campaigns would let platforms serve borrowers excluded on credit-risk grounds. Where AI-based credit scoring or blockchain tokenisation supports such structures, Shariah compliance should be established at the design stage and documented for auditability.

4. Conclusion

The evolution of Islamic crowdfunding research appears to have moved quickly from just discussing how small and medium-sized enterprises (SMEs) can be financed through creative means to a diverse and evolving body of work that includes new financial technology, governance through Shariah compliance, the impact of people's behaviours on adoption of these types of businesses, and the various social finance instruments that can be used. Bibliometric evidence shows that there is increasing interest within the academic community in researching this area, geographic diversity as to who is studying it, and increasing overall complexity in the academic literature available on this subject. However, there are still large gaps such as using an ecosystem-based analysis; standardising governance; longitudinally assessing the impact of this type of business; and integrating emerging technologies. For practice, the same evidence base points to transparent Shariah governance disclosure by platform operators, staged use of crowdfunding by SMEs alongside bank financing, supervision grounded in realised rather than intended platform use, and blended structures linking platforms with zakat and waqf institutions. Therefore, future studies should use an interdisciplinary, comparative, and ecosystem-based approach to further develop theory and practice related to Islamic crowdfunding as an inclusive financing mechanism for SMEs in developing countries.

Acknowledgements

The authors would like to express their gratitude to Institut Teknologi Bandung and all scholars and institutions whose indexed publications contributed to this bibliometric study. Appreciation is also extended to colleagues and reviewers for their valuable feedback and academic support during the development of this research.

Ethics Declaration

This study did not involve human participants, personal data collection, or experimental procedures requiring formal ethical clearance. The research was conducted using secondary data obtained from the Scopus database and publicly available scientific publications.

AI Declaration

Artificial Intelligence (AI) tools were utilised in a limited capacity to support language refinement, grammar checking, paraphrasing, and visualisation design during the preparation of this manuscript. The authors reviewed, validated, and revised all AI-assisted outputs to ensure the accuracy, originality, and academic integrity of the final paper.

Building Entrepreneurial Resilience Through Islamic Social Finance and Microfinance

Vania Nur Rizqi R., Wawan Dhewanto and Sri Herliana

sri.herliana@sbm-itb.ac.id

Abstract: Microentrepreneurs in vulnerable households face a distinctive problem: business capital doubles as household survival capital, so any shock forces capital to be diverted from productive use toward consumption. Existing entrepreneurship and microfinance research has concentrated heavily on capital access, leaving this household-level antecedent underexplored. This paper proposes a prescriptive conceptual framework showing how household resilience functions as an enabling condition for entrepreneurial resilience, allowing microentrepreneurs to protect productive capital, access Islamic microfinance, and sustain business development rather than merely survive economic shocks. The framework integrates four sequential and cyclical layers: Islamic Social Finance (ISF) as resource mobilisation; household buffer support as protection against shocks; Islamic microfinance as a connectivity mechanism providing capital, social capital, and capacity building; and microenterprise development as transformation, through which beneficiaries move from aid recipients (*mustahiq*) toward productive entrepreneurial actors and, eventually, *zakat* payers (*muzakki*). Grounded in *Maqasid al-Shariah* as its normative foundation and drawing on Hanisch's (2024) prescriptive theorising approach, the framework engages entrepreneurial resilience, entrepreneurial ecosystem, and social entrepreneurship literature to derive five higher-level, theoretically testable propositions, together with opportunity and risk mechanisms that anticipate outcomes such as mission drift and poverty traps. Evidence drawn from prior empirical studies indicates that productive *zakat* programmes combined with mentoring significantly strengthen business growth and *mustahiq* welfare, and that coordinated ISF models outperform unintegrated ones in reducing poverty. By repositioning household buffer support as the mechanism connecting Islamic social finance to entrepreneurial outcomes, the paper contributes to entrepreneurship theory by proposing how household resilience may enable entrepreneurial resilience beyond capital access alone, in vulnerable Muslim-majority contexts. The paper closes with theoretical, entrepreneurship-practice, and policy implications for entrepreneurs, microenterprise support organisations, *zakat* institutions, *waqf nazhir*s, Islamic microfinance providers, and regulators in Indonesia and Malaysia, and outlines a future research agenda centred on empirical testing of the proposed propositions.

Keywords: Entrepreneurial Resilience, Household Buffer, Islamic Social Finance, Islamic Microfinance, Microenterprise Development, *Maqasid al-Shariah*

1. Introduction

Microenterprises are central to entrepreneurship and economic development, comprising over 97 percent of Indonesia's business units and absorbing 89 percent of its workforce (Maulina et al., 2023b). Yet entrepreneurs in vulnerable households face a problem rarely addressed by conventional financing interventions: business capital and household survival capital are the same pool of resources. When a shock occurs, illness, crop failure, or a sudden loss of income, that capital is withdrawn from the business to protect the family, halting entrepreneurial momentum rather than merely delaying it. Limited capital access alone therefore keeps Indonesia's entrepreneurship rate around 3 percent, far below the 14 percent average in developed economies and below Malaysia's 4 percent, while 70 percent of microentrepreneurs still struggle to access adequate financing (Maulina et al., 2023b).

Existing microfinance and entrepreneurship interventions have concentrated heavily on capital provision, while household resilience, the entrepreneur's capacity to keep productive assets intact through a crisis, remains theoretically underexplored. Islamic Social Finance (ISF) instruments, *zakat*, *waqf*, *infaq*, and *sadaqah*, hold documented potential to address this problem: national *zakat* potential in Indonesia reaches Rp 327 trillion, yet only about 10 percent was realised in 2023. However, the transmission mechanism from ISF institutions to household resilience and, in turn, to sustainable entrepreneurial outcomes remains fragmented and largely unmapped (Maulina et al., 2023a; Ma and Sukmana, 2025). Iskandar et al. (2021) confirm a long-term relationship between ISF collection and poverty reduction that depends on distribution architecture rather than volume, reinforcing that the problem is one of design, not of resource scarcity.

The practical stakes are significant: well-intentioned ISF and microfinance programmes can produce dependency traps and mission drift instead of transformation (Bacq et al., 2025; Tamanni and Haji Besar, 2019). When ISF is

designed with productive components and structured mentoring, however, beneficiaries can become entrepreneurs capable of eventually contributing back to the ISF ecosystem (Widiastuti et al., 2022a).

This paper therefore proposes an integrative, prescriptive framework connecting ISF, household buffer support, Islamic microfinance, and microenterprise development, and positions household resilience as the enabling condition for entrepreneurial resilience: the capacity of microentrepreneurs to protect productive capital and adapt their businesses through shocks rather than being forced to liquidate them. The paper has three objectives: to explain, through a coherent theoretical architecture, why household resilience must precede sustainable microenterprise growth and how Islamic microfinance connects the two; to classify the opportunity and risk mechanisms underlying this architecture; and to formulate five higher-level, theoretically testable propositions.

The paper adopts prescriptive theorising (Hanisch, 2024) as its methodological approach, addressing normative questions, how entrepreneurial support should be designed, and instrumental questions, how desired outcomes can be achieved, an approach suited to grand challenges such as persistent poverty and financing gaps that require an actionable roadmap rather than only a diagnosis. The literature base was developed through a targeted review using keywords including Islamic social finance, entrepreneurial resilience, entrepreneurial ecosystem, social entrepreneurship, household resilience, and microenterprise development, prioritising empirical studies, systematic reviews, and grounded conceptual frameworks from 2017 onwards; earlier references were retained only where foundational to the argument (e.g., Coleman, 1988; Carter and Barrett, 2006; Sen, 1999).

2. Literature Review and Theoretical Foundation

2.1 Islamic Social Finance as an Entrepreneurship Support Mechanism

ISF instruments, *zakat*, *waqf*, *infaq* and *sadaqah*, and *qardh hasan*, form a redistribution ecosystem whose transformative potential depends on how funds flow, not merely how much is collected (Ascarya, 2021; Maulina et al., 2023a). ISF is an established poverty-alleviation instrument, but whether and how it should function as entrepreneurship support, building the conditions under which recipients can start and sustain a business, remains theoretically unclear. Ma and Sukmana (2025) find that the transmission mechanism from ISF institutions to household and enterprise levels remains a black box in the literature, which is the central gap this framework addresses.

2.2 Household Resilience and Productive Capital Protection

Microenterprises cannot grow sustainably while their households remain vulnerable. Carter and Barrett's (2006) asset-based poverty trap explains why: below a critical asset threshold, accumulated capital is pulled toward consumption during shocks, meaning entrepreneurs from poor households repeatedly divert business capital to family needs instead of reinvesting it. Household buffer support, the capacity to absorb shocks without liquidating productive assets, interrupts this cycle. In this framework, household buffer support refers to the intervention mechanism, the financial, social, and adaptive-capacity components that ISF and related programmes provide, whereas household resilience refers to the resulting capacity of the household to absorb shocks without liquidating productive assets; this distinction is used consistently throughout the paper. Diagne et al. (2025), using panel data from 3,367 households in two Southeast Asian countries, found that resilience capacity significantly mitigates the impact of shocks on wellbeing, meaning buffered households can face crises without sacrificing business continuity. ISF can build this buffer directly: productive *zakat* programmes significantly increase *mustahiq* business growth and welfare (Widiastuti et al., 2021a), and mentoring, a non-transfer component, significantly enhances that growth further (Widiastuti et al., 2022b). An effective buffer is multidimensional, combining financial reserves, activatable social networks, and adaptive capacity (Lade et al., 2017); interventions that ignore these dimensions risk reinforcing poverty rather than alleviating it. This literature, however, treats household resilience mainly as a welfare outcome in its own right; it stops short of asking what that resilience enables for the entrepreneur running the household's business, a link Section 2.3 develops.

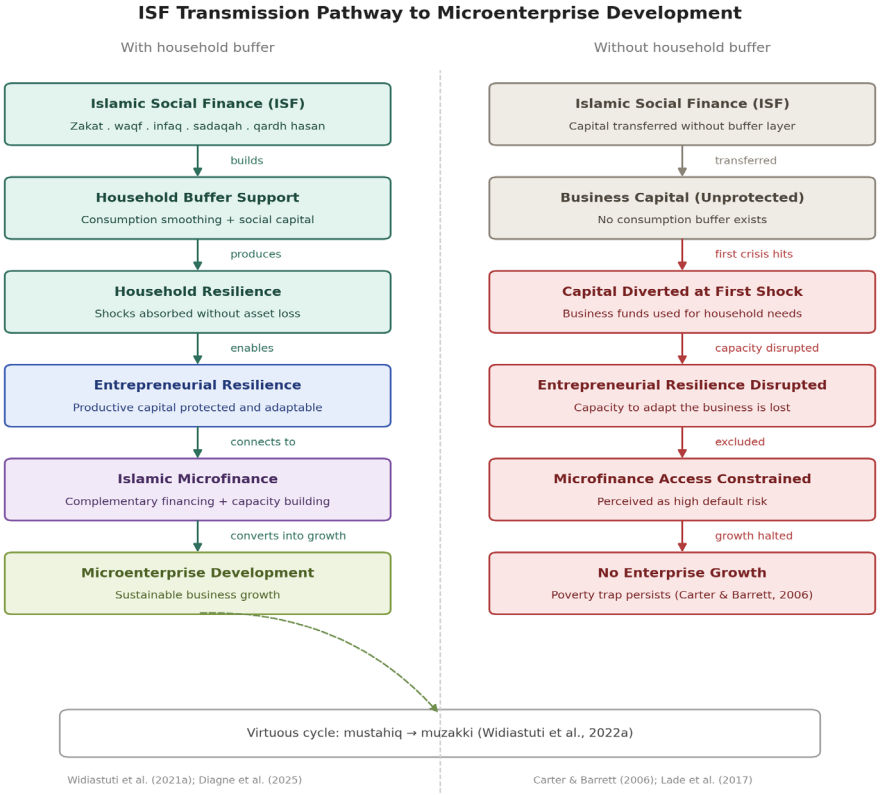

Figure 1: The ISF-household buffer-entrepreneurial resilience-Islamic microfinance-microenterprise pathway, with and without a buffer layer

2.3 Entrepreneurial Resilience and Social Entrepreneurship

Positioned this way, household buffer support is not only a protective welfare mechanism but an enabling condition for entrepreneurial resilience, the capacity of entrepreneurs to maintain and adapt their businesses when shocks occur, rather than treat the business as a liquidity source of last resort. Where household needs are unmet, a shock forces business capital out and disrupts the enterprise; where a household buffer exists, productive capital is protected and the entrepreneur can continue operating and adapting. This reframing connects ISF-based interventions to entrepreneurship theory rather than treating them purely as poverty-alleviation transfers. It also connects to social entrepreneurship: ISF institutions share characteristics with social-mission organisations balancing beneficiary welfare against financial sustainability, a tension that, if poorly managed, produces exactly the mission drift and dependency traps documented in social entrepreneurship research (Bacq et al., 2025). A supportive entrepreneurial ecosystem, encompassing innovation, networks, and institutional support, is likewise a key condition for the sustainability of ISF-based enterprises such as *waqf* businesses (Maulina et al., 2025b), and drives inclusive outcomes when embedded in community and digital ecosystems (Napitupulu et al., 2026).

This perspective extends entrepreneurial resilience research, more commonly examined in relation to firm-level resources and external shocks, by highlighting a household-level antecedent that is particularly salient for microentrepreneurs in vulnerable settings: sustained entrepreneurial activity depends not only on firm resources but on whether household consumption needs can be buffered without drawing down productive business capital.

2.4 Islamic Microfinance as an Entrepreneurial Development Mechanism

Where a household buffer allows a business to withstand shocks, Islamic microfinance is the mechanism that converts that resilience into growth, providing working capital, capacity building, and social networks through sharia-compliant contracts (Baber, 2021). Its role differs functionally from ISF: ISF is largely a one-way redistribution instrument, whereas Islamic microfinance offers revolving financing paired with ongoing development, consistently improving welfare across economic, social, and spiritual dimensions (Martiana and

Rahmanto, 2021). Evidence for its entrepreneurial value is accumulating: Abd Hamid et al. (2024) find that capital access is only one of five success factors for *asnaf* entrepreneurs, alongside record-keeping, employee management, marketing, and digital capability, meaning financial capital alone will not produce growth. Kakembo et al. (2021) extend this finding to Uganda, and at Baitul Misykat Aceh, *qardh hasan* financing combined with strict selection, supervision, and spiritual guidance produced significant economic empowerment for small traders (Hasnita et al., 2025). Without such non-financial components, mission drift looms, as financial pressure pushes institutions toward more financially capable clients (Tamanni and Haji Besar, 2019). Social Capital Theory (Coleman, 1988; Putnam, 1993) explains a further reason microfinance cannot be replaced by transfers alone: institutions such as *Baitul Maal wa Tamwil* mobilise bonding, bridging, and linking social capital that gives entrepreneurs access to markets and networks otherwise out of reach. What this literature does not clarify is how microfinance access relates to the household-level resilience established in Section 2.2; this paper treats Islamic microfinance as the connectivity mechanism that converts an already-buffered household into a growing enterprise, rather than as a substitute for that buffer.

2.5 Microenterprise Development and Capability

Microenterprise development is the transformative layer in which beneficiaries shift from aid recipients into productive economic actors. Structural capital barriers remain severe: only 30-40 percent of Indonesian MSMEs are bankable (Maulina et al., 2023b), against a global MSME financing gap estimated at around USD 5.7 trillion (IFC, 2024), making trust-based, collateral-free Islamic microfinance a highly relevant bridge. Consistent with the Capability Approach (Sen, 1999), development should be measured through the expansion of real capabilities, to innovate, access markets, and build networks, rather than income growth alone; Widiastuti et al. (2021a) operationalise this using *Maqasid al-Shariah* dimensions. Microenterprise development is not an endpoint but a turning point in a cycle: successful entrepreneurs generate surplus that allows them to pay *zakat*, becoming *muzakki*, an outcome achievable through properly designed ISF programmes (Widiastuti et al., 2022a). This capability-based view of success is well established, but it is rarely traced back to its household-level preconditions; this paper supplies that missing upstream link.

2.6 Maqasid al-Shariah as Normative Foundation

Maqasid al-Shariah provides the normative foundation integrating this framework. Its universal principles, preserving religion, life, intellect, lineage, and property (Chapra, 2008), have direct operational relevance here: preserving life requires fulfilling basic household needs before productive capital is exposed to risk, justifying the buffer-first logic of Layer 2; preserving intellect supports the capacity-building components embedded in Islamic microfinance. *Maqasid al-Shariah* plays four operational roles: establishing a hierarchy of priorities, buffers before business capital; an anti-harm orientation mitigating mission drift and dependency traps; distributive justice toward the most vulnerable; and accountability, since weak governance transparency remains the largest obstacle to donor participation (Maulina, 2022). Prior applications of *Maqasid al-Shariah* have mainly measured beneficiary welfare after the fact; this paper instead uses it prospectively, to justify the sequencing of the four-layer framework itself.

3. Prescriptive Theorising Approach

Unlike descriptive research explaining why phenomena exist, prescriptive theorising addresses normative questions, how things should be, and instrumental questions, how desired states can be achieved (Hanisch, 2024). This approach is well suited to persistent poverty and financing gaps in Muslim-majority countries, where practitioners need an actionable roadmap rather than only a diagnosis. Development of the framework followed three steps. First, the theoretical arguments and empirical evidence reviewed in Section 2 were synthesised to identify the theoretical relationships between ISF, household resilience, entrepreneurial resilience, Islamic microfinance, and microenterprise development. Second, this synthesis was organised into the opportunity and risk mechanisms presented in Sections 4.2 and 4.3, distinguishing pathways that the literature shows can be leveraged from those that must be anticipated and mitigated. Third, each mechanism was translated into a higher-level proposition in Section 4.4, pairing a normative desired state with an instrumental pathway for achieving it, so that the framework remains open to future empirical testing rather than functioning only as description.

4. Integrative Conceptual Framework

4.1 Four-Layer Architecture

The framework comprises four sequentially and cyclically connected layers: ISF as resource mobilisation, collecting and distributing *zakat* and *waqf* funds; household buffer support, which uses these funds to build resilience so that productive capital need not be liquidated during shocks; Islamic microfinance, which connects buffered households to business financing and capacity-building support; and microenterprise development, which converts financing and mentoring into business growth and, eventually, the transformation of beneficiaries into *zakat* payers who replenish Layer 1. Household resilience and entrepreneurial resilience function as intervening mechanisms operating within and between these four layers, rather than as additional institutional layers in their own right; Figure 1 depicts them as intermediate stages precisely to make this mediating role explicit. The connecting logic follows Carter and Barrett (2006): sequencing consumptive support before productive capital prevents business capital from being consumed at the first crisis, while buffered households may face lower default risk and can focus on business development rather than survival, which is why microfinance without adequate household resilience may be less effective in sustaining productive investment. From microfinance to enterprise growth, financial, social, and human capital jointly convert access into outcomes; Dela Cruz et al. (2025), reviewing over a thousand MSME finance interventions, confirm that combining financial access with non-financial support consistently outperforms financial interventions alone.

4.2 Opportunity Mechanisms

Four opportunity mechanisms operate across the framework. Resource mobilisation is strengthened by donor segmentation, since upper-middle-class and general-class Muslim donors show different motivations for cash *waqf* contribution, meaning a single fundraising approach underperforms. Household resilience is measurably enhanced by two-layer ISF distribution combined with mentoring, which raises both business growth and multidimensional *mustahiq* welfare (Widiastuti et al., 2021a; 2022b; Diagne et al., 2025), with coordinated ISF models around 12 percent more effective at poverty alleviation than unintegrated ones (Widiastuti et al., 2022a). Entrepreneurial development is accelerated where Islamic microfinance bundles capital with the non-financial success factors entrepreneurs need (Abd Hamid et al., 2024; Hasnita et al., 2025; Kakembo et al., 2021). Sustainable transformation is achievable through an entrepreneurial ecosystem that supports innovation and community, enabling the *mustahiq*-to-*muzakki* cycle (Widiastuti et al., 2022a; Maulina et al., 2025b; Napitupulu et al., 2026).

4.3 Risk Mechanisms

Four risk mechanisms must be actively anticipated. Mission drift and governance failure arise when financial pressure pushes institutions away from the poorest clients and when weak transparency undermines donor trust (Tamanni and Haji Besar, 2019; Maulina, 2022), sometimes producing dependency traps typical of poorly governed social enterprises (Bacq et al., 2025). A poverty and dependency trap persists where ISF distribution fails to push households beyond the minimum asset threshold (Carter and Barrett, 2006; Lade et al., 2017). A microfinance trap occurs when clients cycle through borrowing and repayment without reaching a genuine growth point (Martiana and Rahmanto, 2021). Institutional and regulatory constraints, particularly misalignment between *waqf* and Islamic banking regulation, restrict the scale at which integrated models can operate (Maulina et al., 2023b).

4.4 Higher-Level Propositions

Following Hanisch (2024), each proposition below combines a normative statement with an instrumental statement.

4.4.1 P1: ISF and Household Resilience

Sequenced ISF distribution that builds household resilience before productive capital provision is expected to strengthen the protection of productive capital during household shocks. Normative: ISF distribution should be sequenced to build household resilience before productive business capital is provided. Instrumental: *zakat* institutions should secure basic consumption and a minimum resilience buffer before activating productive capital and mentoring; this sequencing is supported by evidence that mentored productive *zakat* programmes

significantly raise business growth and welfare (Widiastuti et al., 2021a; 2022b) and that resilience capacity mitigates shock impacts (Diagne et al., 2025).

4.4.2 P2: Household Buffer and Entrepreneurial Resilience

Normative: household buffer support should be designed explicitly to protect productive capital from household shocks, strengthening entrepreneurs' capacity to maintain and adapt their businesses. Instrumental: ISF institutions should combine minimum financial reserves with community-based social capital activities, such as peer savings groups, and adaptive-capacity support as standard components of household buffer programmes; these components can reduce the need to draw down productive business capital during shocks (Coleman, 1988; Putnam, 1993; Lade et al., 2017), while programmes ignoring socio-cultural dimensions risk reinforcing poverty instead.

4.4.3 P3: Islamic Microfinance and Entrepreneurial Development

Normative: Islamic microfinance institutions should treat business training, supervision, and mentoring as standard financing components, integrating financial and non-financial support to convert household resilience into sustainable enterprise development. Instrumental: institutions should bundle financing disbursement with mandatory mentoring and monitoring, as capital access is only one of several success factors for entrepreneurs (Abd Hamid et al., 2024) and integrated non-financial support is the primary antidote to mission drift (Hasnita et al., 2025; Tamanni and Haji Besar, 2019).

4.4.4 P4: Integrated ISF-Microfinance Ecosystem

Normative: ISF and Islamic microfinance institutions should operate as complementary, coordinated mechanisms rather than isolated instruments, supported by social capital and appropriate ecosystem infrastructure. Instrumental: institutions should design shared referral pathways from ISF beneficiary status into microfinance access, supported by digital platforms that improve transparency and reach (Maulina, 2022).

4.4.5 P5: Sustainable Transformation and Maqasid

Normative: microenterprise development should be evaluated as a multidimensional capability and transformation process, including the potential transition from *mustahiq* to *muzakki*, under *Maqasid al-Shariah*. Instrumental: programme designers should adopt Maqasid-based welfare measurement covering religion, life, intellect, lineage, and property, supplementing income-only indicators (Widiastuti et al., 2021a), and sustain entrepreneurial ecosystem support, since support and culture, not capital alone, determine whether transformation is genuine (Maulina et al., 2025b; Napitupulu et al., 2026).

5. Discussion and Implications

The findings discussed below are conceptual: they are propositions and mechanisms synthesised from prior theoretical and empirical literature, not statistical results from primary data collected for this paper. Their value lies in reorganising existing evidence into a coherent, testable architecture, which Section 5.4 identifies as a priority for future empirical research.

5.1 Theoretical Contributions

This framework offers four contributions. First, it proposes household resilience as an antecedent, enabling condition of entrepreneurial resilience for microentrepreneurs in vulnerable households, addressing the transmission gap identified by Maulina et al. (2023a) and Ma and Sukmana (2025). Second, it suggests that entrepreneurial development depends on integrated resources, financial, human, and social capital, combined with household protection, rather than on financing considered in isolation. Third, it clarifies the complementary, non-substitutable functions of ISF and Islamic microfinance within a single entrepreneurial ecosystem. Fourth, it proposes grounding entrepreneurial success in *Maqasid al-Shariah*, measuring outcomes through capability, welfare, and transformation rather than income alone.

5.2 Implications for Entrepreneurship Practice

For entrepreneurs and microenterprise support organisations, the framework implies that resilience-building, not only capital access, should be an explicit programme objective; mentoring and peer networks should be

treated as core services rather than optional add-ons. For BMTs and Islamic microfinance institutions, non-financial components should become standard operating procedure, both to accelerate growth and to guard against mission drift.

5.3 Policy Implications

For regulators, harmonising *zakat*, *waqf*, and Islamic banking regulation carries the greatest systemic potential, since current misalignment is a key bottleneck restricting integrated, scalable models. Regulatory sandboxes allowing supervised piloting of integrated ISF-microfinance products, coordinated by bodies such as Indonesia's OJK and BWI and Malaysia's BNM, would let this framework's propositions be tested under real institutional conditions before full implementation.

5.4 Future Research Agenda

Priority agendas include: quasi-experimental testing of the layered causal architecture in Indonesia and Malaysia; longitudinal study of the *mustahiq*-to-*muzakki* transformation; cross-country testing of the framework's boundary conditions; and research on digitalisation's role in extending Islamic microfinance to underserved and women entrepreneurs (Ma and Sukmana, 2025; Napitupulu et al., 2026).

6. Conclusion and Limitations

This paper proposes a four-layer prescriptive framework connecting Islamic Social Finance, household buffer support, Islamic microfinance, and microenterprise development, positioning household resilience as the enabling condition for entrepreneurial resilience among vulnerable microentrepreneurs. Its contribution lies in explaining why resilience must precede capital, why Islamic microfinance can function as a complementary bridge between resilience and enterprise development rather than a substitute for either, and why entrepreneurial transformation requires a Maqasid-based, multidimensional measure of success. The framework yields five higher-level propositions and identifies opportunity and risk mechanisms grounded in prior empirical evidence. Limitations include: the propositions remain empirically untested; the evidence base is concentrated in Indonesia and Malaysia; moderating variables such as urbanisation and regulatory quality are not yet integrated; and gender dimensions, despite women's prominence among ISF beneficiaries and microentrepreneurs, are not explicitly addressed. These limitations point toward substantial opportunities for future empirical and comparative research.

Ethics Declaration

This study is a conceptual paper based on the synthesis of published secondary literature and did not involve primary data collection from human or animal subjects; ethical clearance was therefore not required.

AI Declaration

Generative AI tools were used in preparing this paper for language editing, wording refinement, and word-count reduction, as well as some assistance with drafting and structuring specific passages; the conceptual framework, propositions, and arguments are the authors' own.

Abstract: Climate change is forcing organisations to innovate their governance structures, risk management practices, and strategic decision-making processes to address the growing physical and transition risks associated with a changing climate. Within the energy sector, corporate climate resilience has emerged as an organisational innovation capability that enhances long-term competitiveness, strengthens responsible business practices, and creates sustainable value. Despite increasing regulatory expectations and sustainability reporting requirements, empirical evidence on how firms in emerging economies develop and embed climate resilience remains limited. This study assesses the level and evolution of corporate climate resilience among Malaysian energy firms using the Climate Change Risk and Adaptation Strategies Index (CCRASI), a multidimensional framework comprising 64 indicators across four dimensions, (i) climate risk assessment, (ii) adaptation strategies, (iii) carbon risk management, and (iv) governance and stakeholder engagement. Using content analysis, the annual and sustainability reports of 28 publicly listed Malaysian energy firms covering the period 2019-2024 were analysed. The results indicate a moderate level of corporate climate resilience, with an average score of 44.85%. However, resilience performance improved substantially during the study period, increasing from 25.06% in 2019 to 68.86% in 2024, representing an overall improvement of approximately 175%. Governance and stakeholder engagement recorded the highest score (59.55%), reflecting stronger board oversight, climate governance, stakeholder engagement and organisational accountability. In contrast, climate risk assessment recorded the lowest score (36.88%), indicating limited adoption of advanced practices such as quantitative climate risk assessment, climate scenario analysis, stress testing, and financial impact analysis. Carbon risk management and adaptation strategies also recorded moderate scores, suggesting that firms have made steady progress in strengthening carbon reduction initiatives and operational adaptation measures. This study contributes to the innovation and entrepreneurship literature by positioning corporate climate resilience as a strategic organisational innovation capability that strengthens organisational adaptive capacity, supports responsible business practices, and promotes sustainable value creation. It also demonstrates the applicability of the CCRASI as a practical assessment framework for evaluating organisational resilience and supporting continuous improvement. The findings provide practical guidance for business leaders and policymakers seeking to strengthen climate governance, improve organisational resilience, and accelerate the transition towards a competitive, low-carbon economy.

Keywords: Climate Governance, Climate Resilience, Climate Risk, Corporate Adaptability, Energy Firms, Sustainable Development.

1. Introduction

Climate change has emerged as one of the most significant challenges facing the global energy sector. According to the Intergovernmental Panel on Climate Change (IPCC, 2023), the frequency and intensity of climate-related events, including floods, heatwaves, droughts, storms, and sea-level rise, have increased considerably in recent decades. Such events pose significant risks to energy infrastructure, operational continuity, and energy security. At the same time, energy firms must also respond to increasing transition risks arising from evolving climate regulations, carbon pricing mechanisms, technological innovation, and rising stakeholder expectations associated with the transition to a low-carbon economy. Furthermore, the Sixth Assessment Report by the IPCC highlights that climate impacts and cascading risks disproportionately affect organisations with weak governance structures and limited adaptive capacity (IPCC, 2022). Against this backdrop, climate resilience is increasingly recognised as a strategic capability that enables firms to innovate, enhance organisational sustainability and remain competitive in an increasingly carbon-constrained business environment.

The energy sector is pivotal to the economic and social development of Malaysia and still the main source of greenhouse gas (GHG) emissions. It is therefore an important sector for the country's decarbonisation and transition to cleaner energy. Recent initiatives like the National Energy Transition Roadmap (NETR), Bursa

Malaysia Sustainability Reporting Requirements, and the National Sustainability Reporting Framework (NSRF) have increased the bar for firms to enhance their climate governance, climate-related disclosures, and their resilience to climate-related risks. This is in line with global trends, as investors, regulators, and financial institutions increasingly demand more transparency regarding climate-related risks and opportunities (Garrido-Merchán et al, 2026). In addition, climate-related risks are increasingly integrated into corporate risk management and strategic decision-making encouraging firms to adopt more responsible business practices and innovative governance approaches (Kumarasiri et al, 2026).

Despite growing interest in responsible business practices and corporate sustainability, limited empirical evidence exists on how Malaysian energy firms strategically develop climate resilience as part of their long-term organisational innovation capability and business sustainability. Much of the existing research has concentrated on areas like sustainability reporting, carbon disclosure, environmental performance, and climate-related governance. However, there has been a noticeable lack of attention to assessing firms' overall resilience to climate-related risks (Kumarasiri et al, 2026). Additionally, previous studies tend to look at individual aspects of climate management in isolation, providing limited insight into the multidimensional nature of organisational resilience, adaptive capacity, and climate preparedness (Lyle et al, 2026; Saha et al, 2026). Recent findings indicate that effective climate resilience assessment requires the integration of multiple dimensions to capture organisational preparedness, vulnerability, adaptive capacity, and risk management capability more comprehensively. As a result, there remains a lack of evidence regarding the extent to which energy firms are prepared to identify, manage, and adapt to climate-related risks.

To address this gap, this study aims to evaluate climate resilience as an indicator of responsible business practice by assessing how Malaysian energy firms integrate climate governance, risk management, adaptation strategies and stakeholder engagement into their sustainability strategies. For this purpose, we introduce and employ a multidimensional climate resilience index, so-called, the Climate Change Risk and Adaptation Strategies Index (CCRASI). This index comprises climate risk assessment, adaptation strategies, carbon risk management, and governance and stakeholder engagement. Unlike earlier research that mainly zeroes in on climate disclosure, carbon reporting, or governance mechanisms, this study offers a more comprehensive assessment of how well firms are equipped to recognise, manage, and adapt to climate-related risks. Specifically, the study assesses the current level of climate resilience, tracks its development from 2019 to 2024, and pinpoints the strongest and weakest dimensions of climate resilience among Malaysian energy firms.

2. Methodology

This study employs a quantitative content analysis approach to assess the climate resilience practices of Malaysian energy firms. The study utilised a sample of 28 energy firms listed on Bursa Malaysia from 2019-2024, comprising 168 firm-year observations. Data were collected from the annual and sustainability reports sourced from Bursa Malaysia and corporate websites. We employed the CCRASI to assess climate resilience, consisting of 64 indicators distributed across four dimensions: climate risk assessment, adaptation strategies, carbon risk management, and governance and stakeholder engagement. The CCRASI was developed from existing literature on climate resilience, climate risk management, sustainability reporting, and climate adaptation. Its multidimensional framework reflects contemporary perspectives that conceptualise organisational resilience as a multifaceted capability requiring the integration of multiple risk and resilience dimensions (Lyle et al, 2026; Saha et al, 2026). To evaluate climate resilience practices, this study adopts an unweighted index methodology, where each indicator is assigned equal importance. Each disclosed item receives a score of one (1), resulting in a maximum possible score of 64. The overall CCRASI score is then expressed as a percentage, with higher scores indicating stronger climate resilience practices and greater organisational readiness.

3. Results and Discussion

3.1 Overall Climate Resilience Performance

The mean CCRASI score is 44.85%, indicating that energy firms in Malaysia exhibit moderate resilience to climate change. Scores varied from 0% to 100%, with a standard deviation of 29.24, signifying substantial variation in climate resilience practices amongs firms. This moderate score aligns with recent evidence that organisations vary in their levels of readiness, adaptive capacity, and climate risk management capabilities, mainly due to their specific resources, governance structures, and strategic priorities (Lyle et al, 2026; Saha et al, 2026). The wide range of scores suggests that climate resilience practices are not uniformly adopted among energy firms, and

the degree to which climate-related risks are integrated in organisational decision-making differs significantly. These differences may be due to the different levels of organisational commitment and technical expertise and the extent to which climate-related risks are embedded in governance and enterprise risk management systems (Kumarasiri et al, 2026).

3.2 Trend of Climate Resilience Performance

The findings indicate that Malaysia's energy firms have substantially enhanced their climate change resilience practices throughout the study period. Figure 1 illustrates that the average CCRASI score increased from 25.06% in 2019 to an impressive 68.86% in 2024, signifying a total increase of approximately 175%. From 2020 and 2022, climate resilience strategies and risk management practices accelerated. This progress is expected to be propelled by heightened awareness of climate-related risk, rising stakeholder expectations, better practices in sustainability reporting, and greater support from national and international policy toward climate action and energy transition initiatives.

The persistent rise in CCRASI scores throughout 2023 and 2024 indicates that climate resilience has transcended mere compliance and is increasingly integrated into organisational governance, strategic planning, and operational decision-making processes. This improvement shows that energy firms are increasingly aware of the importance of tackling both physical and transition risks posed by climate change, thus facilitating wider decarbonisation and energy transition objectives.

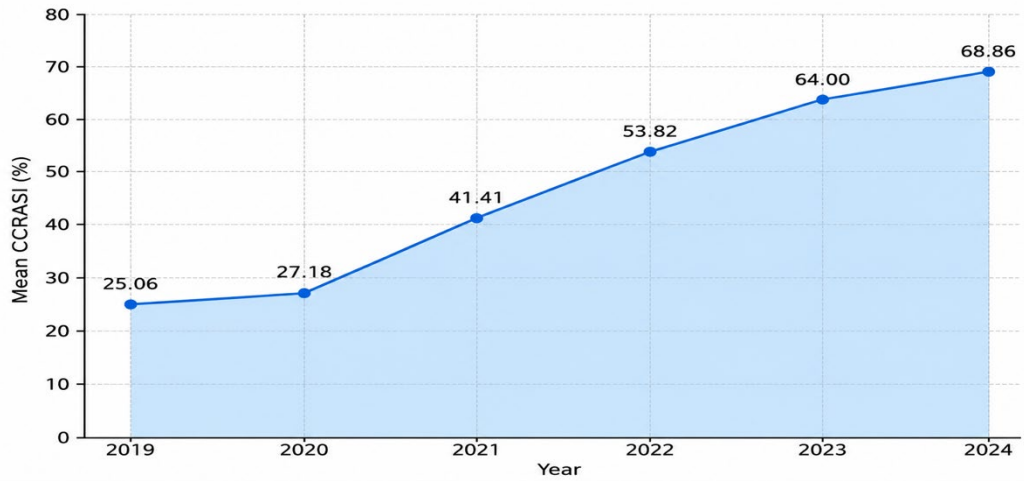

Figure 1: Trend of CCRASI Scores (2019–2024).

These results indicate a gradual yet significant enhancement of climate resilience capabilities among Malaysian energy firms. The upward trend indicates improvement across the four CCRASI dimensions: climate risk assessment, adaptation strategies, carbon risk management, and governance and stakeholder engagement; signifying a more proactive and strategic response to climate-related challenges. Furthermore, these findings provide valuable insights for the execution of NSRF by pinpointing deficiencies in climate resilience practices that necessitate enhanced focus in disclosure, monitoring, and strategic management.

3.3 Analysis by CCRASI Dimension

Figure 2 displays the average scores for the four dimensions of CCRASI for Malaysian energy firms during the period 2019-2024. The findings indicate significant variability across these dimensions, suggesting that the advancement of climate resilience practices is inconsistent throughout all aspects of climate risk management.

Governance and stakeholder engagement emerged as the strongest dimension, recording the highest average score of 59.55%. This finding suggests that most Malaysian energy firms have established climate-related governance structures, board oversight mechanisms, sustainability policies, and stakeholder engagement initiatives. The relatively high score reflects the widespread integration of climate considerations into corporate policies and enterprise risk management, supported by regular climate-related reporting to the board, dedicated climate leadership, board training, and internal awareness programmes. Collaboration in enhancing national climate adaptation and mitigation initiatives is growing, evidenced by partnerships with governmental bodies.

These practices reflect the rising incorporation of climate governance into corporate management and strategic decision-making.

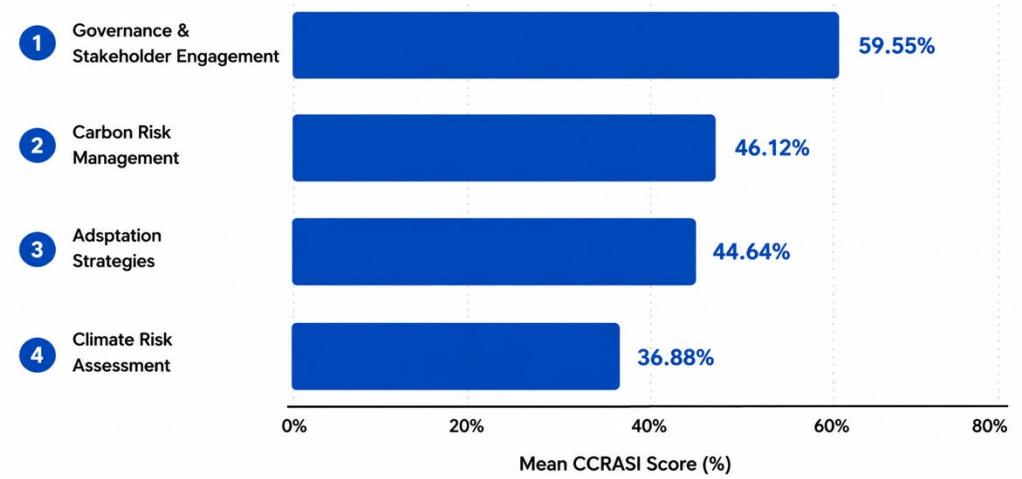

Figure 2: Average CCRASI Dimension Scores among Malaysian Energy Firms (2019–2024).

This evolution signifies that climate governance is increasingly becoming a strategic business practice instead of a mere reporting obligation, indicating a deeper integration of sustainability into corporate decision-making. The heightened score signifies a growing emphasis on climate accountability, transparency, and sustainability governance among Malaysian energy firms. The significant performance of this dimension likely reflects the growing impact of global climate-related reporting frameworks, including the Task Force on Climate-related Financial Disclosures (TCFD) and the International Sustainability Standards Board (ISSB). These frameworks are prompting companies to strengthen their governance frameworks and refine climate-related disclosures. As investors and regulators increasingly prioritise climate-related information, companies are under intensified pressure to demonstrate accountability in managing climate-related risks (Garrido-Merchán et al, 2026). The discovery aligns with prior studies indicating that climate-related and ESG disclosures can reduce information asymmetry and bolster stakeholder confidence (Perera et al, 2026). This interpretation is further supported by evidence indicating that climate-related reporting often emphasises governance, oversight, and disclosure mechanisms, as these elements are more readily articulated and face increased regulatory scrutiny (Saha et al, 2026). As a result, companies typically perform better in governance-related aspects than in technically challenging fields like climate risk evaluation and long-term adaptation strategies. This might explain why governance and stakeholder engagement scored the highest, whereas climate risk assessment lagged behind as the weakest dimension in the CCRASI framework.

Carbon risk management ranked second, with an average score of 46.12%. This suggests that Malaysian energy firms are increasingly strengthening carbon management through the measurement of Scope 1 and Scope 2 GHG emissions, the adoption of energy-efficient equipment, and the implementation of smart monitoring technologies. The findings also indicate growing integration of carbon reduction objectives into business planning, supported by dedicated carbon strategy task forces, alignment with international climate commitments, and increasing investment in renewable energy systems. Collectively, these initiatives demonstrate that many firms are embedding sustainability into their core business strategies by improving operational efficiency, enhancing carbon management practices and supporting the transition towards a low-carbon economy. The finding is consistent with previous studies that highlight the importance of carbon-related disclosure and emissions reporting as an essential tool for managing climate-related risks (Choi et al, 2026). Additionally, there is evidence that climate risk disclosure can drive green innovation and promote investments in low-carbon technologies and sustainability initiatives, which are crucial for reducing emissions and achieving long-term decarbonisation (Peng et al, 2026). The growing focus on carbon management aligns perfectly with Malaysia's goal of achieving net-zero emissions and the implementation of national initiatives like the NETR. However, the moderate score highlights that there are plenty of opportunities for Malaysian energy firms to enhance their carbon reduction strategies and better align with global best practices.

The overall score for adaptation strategies is 44.64%, indicating a moderate level of preparedness to respond to the impact of climate change. The findings suggest that Malaysian energy firms have placed greater emphasis on operational measurs, particularly water efficiency initiatives, business continuity planning, and the protection

of water resources, whic recorded the highest levels of implementation. Firms also demonstrated moderate progress in monitoring and maintaining climate-resilient infrastructure and collaborating with government agencies on climate adaptation initiatives. However, more proactive and long-term adaptation measures remain less widely adopted. In particular, infrastructure planning against extreme weather events, the use of climate-resilient materials, early warning systems, rainwater harvesting, and green infrastructure development recorded relatively low levels of implementation. These findings suggest that, while firms are strengthening operational resilience, greater investment in strategic and long-term adaptation measures is required to enhance climate resilience across the sector. These findings are consistent with previous studies, which indicate that organisations are increasingly adopting climate adaptation and risk management practices to strengthen resilience against climate-related disruptions (Perera et al., 2026). Similarly, Malaysian energy firms have demonstrated greater progress in operational adaptation measures than in long-term adaptation planning. Furthermore, investment in climate-resilient infrastructure and adaptive management practices has been recognised as an important means of enhancing organisational resilience and adaptive capacity (Zhu et al., 2026). Nevertheless, the moderate Adaptation Strategies score suggests that adaptation efforts remain less developed than governance and disclosure-related activities. This observation reinforces previous studies showing that organisations, particularly in emerging economies, often prioritise climate mitigation over long-term adaptation because of financial, technological, and institutional constraints that limit investment in adaptive capacity.

Climate risk assessment recorded the lowest average score (36.88%), making it the least developed dimension of climate resilience among Malaysian energy firms. While most firms disclosed climate-related information in their annual and sustainability reports and acknowledged the importance of transition risks, the adoption of advanced analytical approaches remained limited. In particular, quantitative estimation of physical and transition risks, financial impact analysis, climate scenario analysis, and climate stress testing were reported by relatively few firms. Although some organisations have started integrating climate-related risks into enterprise risk management, systematic and forward-looking climate risk assessment has yet to become common practice across the sector. These results are consistent with earlier studies, which highlight that incorporating systematic climate risk assessment into corporate decision-making remains a major challenge despite growing awareness of climate-related risks (Kumarasiri et al, 2026). Likewise, Lyle et al (2026) found that many organisations continue to face difficulties in quantifying climate-related risks, even as their exposure to climate hazards increases. As reporting frameworks such as the TCFD, the ISSB, and Malaysia's NSRF place greater emphasis on scenario analysis, quantitative risk assessment, and resilience planning, the findings suggest that Malaysian energy firms are still developing these analytical capabilities. Although climate-related disclosure has improved considerably, further progress depends on strengthening quantitative risk assessment, scenario-based planning, and the integration of climate risk into strategic decision-making and enterprise risk management.

Figure 2 illustrates clear differences in performance across the four CCRASI dimensions, demonstrating that climate resilience practices among Malaysian energy firms are progressing at different rates. Governance and stakeholder engagement achieved the highest average score (59.55%), reflecting considerable progress in climate governance, board oversight, stakeholder collaboration, and organisational awareness. By contrast, climate risk assessment recorded the lowest average score (36.88%), largely because advanced practices such as quantitative risk assessment, climate scenario analysis, stress testing, and financial impact assessment remain relatively uncommon. The 22.67 percentage-point gap between these two dimensions highlights that firms have made substantially greater progress in strengthening governance and disclosure practices than in developing analytical capabilities for climate risk assessment. Carbon risk management (46.12%) and adaptation strategies (44.64%) recorded similar levels of implementation, suggesting that organisations are making steady progress in carbon mitigation, operational resilience, and business continuity planning. However, the relatively weaker performance in quantitative climate risk assessment and long-term adaptation measures indicates that forward-looking resilience planning has yet to become fully embedded within organisational practices. Collectively, these findings suggest that Malaysian energy firms are gradually integrating climate resilience into their governance and operational activities. Nevertheless, strengthening analytical risk assessment, scenario-based planning, and long-term adaptation strategies will be essential to achieving a more comprehensive and integrated approach to climate resilience management.

3.4 Implications

The findings indicate that climate resilience is increasingly vital to responsible business practices in the Malaysian energy sector. The relatively strong performance in governance and stakeholder engagement suggests that

many firms have successfully embedded climate governance, board oversight, stakeholder engagement, and organisational awareness into their business operations. Simultaneously, the moderate efficacy of carbon risk management and adaptation strategies suggests that companies are advancing in enhancing carbon reduction efforts, operational resilience, and business continuity planning. The CCRASI framework offers organisations a pragmatic instrument for assessing climate resilience, identifying capability gaps, and prioritising strategic actions to improve sustainability performance. Integrating climate resilience into corporate governance, enterprise risk management, and long-term strategic planning, enables organisations to strengthen adaptive capacity, enhance organisational resilience, and create sustainable long-term value.

However, the comparatively low performance of the climate risk assessment dimension highlights an important area requiring further attention. The findings suggest that Malaysian energy firms should strengthen quantitative climate risk assessment through greater adoption of financial impact analysis, climate scenario analysis, stress testing, and vulnerability assessments. Strengthening these forward-looking analytical capabilities would enable organisations to better anticipate both physical and transition risks, support more informed strategic and investment decisions, improve infrastructure resilience, enhance operational continuity, and reinforce long-term energy security.

At the policy level, greater institutional support is required to strengthen climate resilience assessment and reporting. Although Malaysia has introduced the National Sustainability Reporting Framework (NSRF), sector-specific guidance that incorporates climate risk assessment, adaptation measures, scenario analysis, and resilience indicators would improve the consistency, comparability, and decision-usefulness of climate-related disclosures. However, strengthening climate resilience requires more than improving disclosure requirements; it also depends on integrating climate considerations into organisational capabilities, governance structures, enterprise risk management, and business planning (Lyle et al, 2026). High-quality climate and ESG disclosures also play a critical role in reducing information asymmetry, strengthening stakeholder confidence, and supporting informed decision-making on climate-related risks and opportunities (Garrido-Merchán et al, 2026; Perera et al, 2026). Taken together, these measures can accelerate the transition towards a more competitive, sustainable, low-carbon, and climate-resilient energy sector while supporting Malaysia's long-term economic development and energy security goals.

4. Conclusion

This study assessed the climate resilience practices of Malaysian energy firms utilising the CCRASI from 2019 to 2024. The findings indicate a significant enhancement in climate resilience, as evidenced by the average CCRASI score increasing from 25.06% in 2019 to 68.86% in 2024, reflecting a growing organisational commitment to addressing climate-related risks. Among the four dimensions, governance and stakeholder engagement recorded the highest average score, indicating significant advancement in climate governance, board oversight, stakeholder collaboration, and organisational awareness. Carbon risk management and adaptation strategies exhibit moderate performance, indicating that firms are increasingly adopting carbon reduction initiatives, business continuity planning, and operational adaptation measures. In comparison, climate risk assessment was the least advanced dimension, mainly due to limited adoption of quantitative risk assessment, financial impact analysis, climate scenario analysis, and stress testing. The findings demonstrate that Malaysian energy firms have significantly advanced in governance and operational resilience. Nonetheless, additional focus is required on enhancing predictive analytical capabilities and formulating long-term climate adaptation strategies.

This study contributes to the responsible business and sustainability literature by demonstrating that corporate climate resilience can be understood as an organisational innovation capability that supports strategic decision-making, responsible business practices, and long-term organisational sustainability. The proposed CCRASI framework builds on existing approaches to climate resilience assessment by offering a comprehensive multidimensional tool for evaluating climate governance, carbon management, adaptation strategies, and climate risk assessment within a single framework. Beyond its academic contribution, the framework provides a practical benchmark for organisations, policymakers, and regulators to identify capability gaps, monitor progress, and strengthen climate resilience in support of Malaysia's transition towards a low-carbon economy.

Several limitations should be acknowledged. The study focuses solely on publicly listed Malaysian energy firms and utilises publicly accessible annual and sustainability reports, which may not comprehensively reflect actual organisational climate resilience practices. Secondly, the assessment relies on corporate disclosures and consequently does not assess the efficacy of the reported practices or their implementation in practice. Finally, the study encompasses solely the timeframe from 2019 to 2024. Future research may extend this work by

examining other industries, performing cross-national or cross-sector comparisons, exploring the relationship between climate resilience and organisational performance, and examining the impact of evolving sustainability reporting frameworks on corporate climate resilience over time.
