Figure 1: This is how a Figure Should Appear

For 3 distinguished factors, the maximum likelihood method with a VARIMAX rotation was used and, as a result, the following matrix of factor loadings of joint factors was obtained (Table 2).

Table 2: Rotated Factor Matrix for 3 Distingueshed Factors

Rotated Factor Matrix[a]			
	Factor		
	1	2	3
Size of the entity in the network	0.197	0.409	-0.022
Participant in the panel	0.611	0.474	0.171
Long-term activity	0.305	0.047	0.124
Provision of a job description	0.832	0.252	0.164
Involvement in the development of a competency profile	0.696	0.369	0.127
Sending job /apprenticeship /internship offers	0.579	0.200	0.392
Conclusion of a cooperation agreement	0.541	0.351	0.281
Activity in logging into the IT System	0.192	0.180	0.570
Adding the offer to the IT System	0.255	0.000	0.854
E-mailing activity	0.233	0.788	0.156
Phone call activity	0.176	0.528	0.060
Activity in direct meetings	0.112	0.638	0.148

The formation of the first factor defined as: "involvement in creating job reference descriptions/models" is most influenced by the following variables: participant in the panel, provision of a job description, involvement in the development of a competence profile, sending job /apprenticeship /internship offers, sending job /apprenticeship /internship offers, conclusion of a cooperation agreement, long-term activity. The second factor called “frequency of contacts” is most influenced by variables such as: e-mailing activity, phone call activity, activity in direct meetings, size of the entity in the network. The creation of the third factor referred to as "independent use of the system" is most influenced by variables such as: activity in logging into the IT System, adding the offer to the IT System. Figure 2 presents the Factor Plot in Rotated Factor Space for 3 distinguished factors.

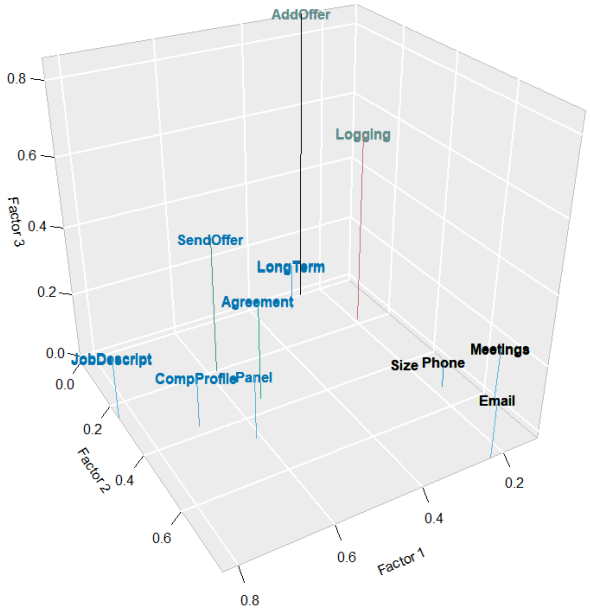

Figure 2: Factor Plot in Rotated Factor Space for 3 Distinguished Factors

In the next step, the Pearson correlation coefficient was analyzed to indicate key relationships between the studied variables. This approach is meant to help in the analysis of key and significant variables in determining the direction and key activities in maintaining relationships with entities in the network for the purpose of acquiring knowledge of competences.

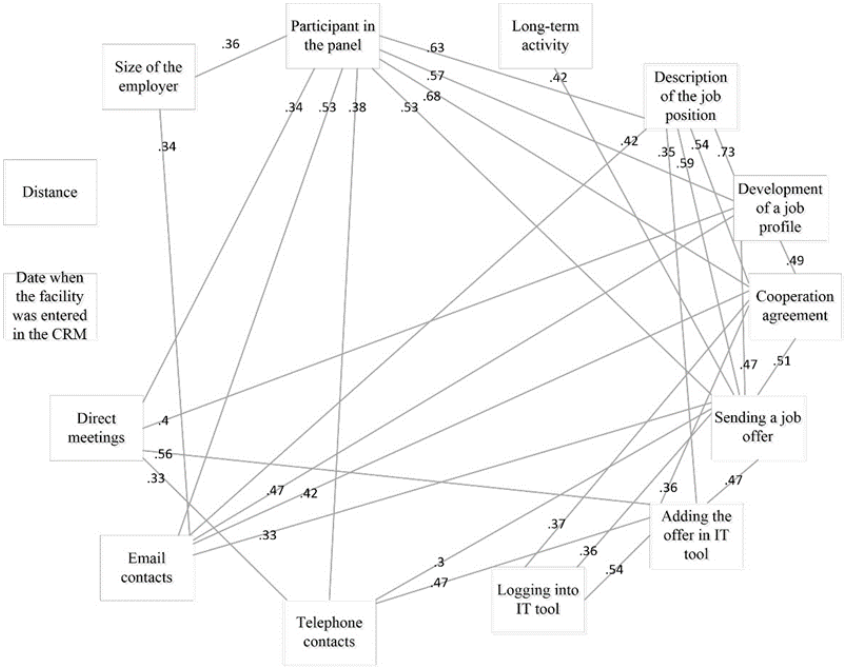

Table 3: Correlations Between Data Describing Entities in the Network and Activities in the Wielkopolska Educational-and-Economic Network

	1.	2.	3.	4.	5.	6.	7.	8.	9.	10.	11.	12.	13.	14.
1. Date when the facility was entered in the CRM	1.00*													
2. The distance between the entity and the network coordinator	0.22*	1.00*												

	1.	2.	3.	4.	5.	6.	7.	8.	9.	10.	11.	12.	13.	14.
3. Size of the entity in the network	-0.21*	-0.14*	1.00*											
4. Participant in the panel	-0.21*	-0.10	0.37*	1.00*										
5. Long-term activity	-0.05	-0.04	-0.02	0.27*	1.00*									
6. Provision of a job description	-0.23*	-0.09	0.26*	0.63*	0.25*	1.00*								
7. Involvement in the development of a competency profile	-0.23*	-0.09	0.29*	0.58*	0.21*	0.74*	1.00*							
8. Sending job /apprenticeship /internship offers	-0.18*	-0.06	0.14*	0.54*	0.43*	0.59*	0.48*	1.00*						
9. Conclusion of a cooperation agreement	-0.21*	-0.07	0.26*	0.69*	0.20*	0.55*	0.50*	0.52*	1.00*					
10. Activity in logging into the IT System	-0.05	-0.04	0.23*	0.27*	0.01	0.29*	0.30*	0.36*	0.37*	1.00*				
11. Adding the offer to the IT System	0.06	-0.02	0.01	0.30*	0.18*	0.36*	0.29*	0.48*	0.37*	0.54*	1.00*			
12. E-mailing activity	-0.26*	-0.15*	0.35*	0.54*	0.14*	0.43*	0.47*	0.34*	0.43*	0.26*	0.20*	1.00*		
13. Phone call activity	-0.18*	-0.09	0.24*	0.38*	0.14*	0.29*	0.27*	0.30*	0.28*	0.12*	0.09	0.48*	1.00*	
14. Activity in direct meetings	-0.16*	-0.11*	0.24*	0.35*	0.06	0.27*	0.41*	0.27*	0.27*	0.22*	0.16*	0.57*	0.37*	1.00*

The correlations considered significant in the inference were those for which $p < 0.05$ which was marked with an asterisk in Table 3. Figure 1 in Attachment 1 only shows only those correlations which present correlation strength higher than or equal to 0.3. In the case of participation in the panels, correlations above 0.3 occur with as many as 7 other activities (from 0.34 to 0.68), with 5 of them showing a correlation higher than 0.5. The lowest correlations linked to the activity participation in the discussion panel occur between direct meetings (0.34) and telephone contacts (0.38). A much higher correlation (0.53) occurs in the context of email contacts. The highest correlation in the context of participation in the panels can be seen in relation to a signed cooperation contract (0.68) and tools supporting defining the demand for competencies such as job description (0.63), development of a job profile (0.68) or sending the job offer (0.53). A similar correlation value between the studied activities can be seen in the item cooperation contract (7 correlations), however, these remain at a slightly lower level. Only 2 correlations of out 7 reached a value above 0.5. Other tools for building relations within the network show fewer connections among one another.

4. Research Findings and Discussion

From the analysis of Total Variance Explained we can conclude that from the point of view of building relationships in the network for the exchange of knowledge of competences, other factors are crucial: involvement in creating job reference descriptions/models, frequency of contacts and independent use of the system allowing for the free addition of job offers, traineeships, internships and the exchange of knowledge of competence needs using an IT system. Sharing knowledge of competence needs in the labour market happens in this case on the side, because the value for employers is to acquire a candidate for a job and not directly transfer knowledge of competence needs in an enterprise in a specific job position. On the basis of Figure 2, it can therefore be concluded that there are 3 islands of significant variables important for strengthening relationships in the network and the exchange of knowledge of competences. The description of key requirements at job positions (Spychała, 2017) can be strengthened by signing a formal agreement between entities and conducting meetings, panels, long-term cooperation and support in the use of an IT system allowing

for the publication of job offers, traineeships and internships. Another important variable in building relationships and contacts may be the size of an entity one cooperates with. Large companies have a more complex structure, but from the level of competence requirements at job positions, their structure is more specialized and not cross-sectional. This makes it possible to precisely describe competence requirements and acquire indispensable knowledge to create a reference model of a job position. This, in turn, may allow young people to see what competences are most often required.

As a result of the studies including Pearson's correlation, a process path was proposed for the purposes of establishing, developing and maintaining long-term relations with big and medium-sized enterprises in the network of entities cooperating in the field of education and business. The path is based on 4 key steps: (1) face-to-face meeting supported by email or phone contact. It is meant to extend an invitation to a discussion panel (2) to strengthen relations in order to (3) sign a cooperation agreement and (4) deepen the cooperation further for the purposes of defining the demand for competencies in enterprises by providing a job description, participating in the development of a competency profile or flow of information on job, apprenticeship or internship offers published on a free IT portal.

Our findings align with the view that the value of external sources and collaborative relationships are critical components of open innovation theory (Stachová et al, 2019). Also Universities play also a strategic role as drivers of regional economic growth (Fluster et al, 2019). We specifically focus on the knowledge network of the strategic relationship between economic organizations and educational entities, recognizing that the creation of such networks can lead to significant benefits for both parties.

Although the results are limited to some extent, e.g. with respect to the regional range of impact of the studied network, it should be noted that the research method can be implemented in any social networks, including educational-and-economic ones. The results of many studies can be compared, providing room for improving methods of shaping and strengthening relations between enterprises and other entities within social structures. In the future, the studies can be extended by the aspect of variability in time of the demand for tools activating entities which cooperate in a network.

Abstract: Currently, organisations must view their intangible assets from a strategic perspective and ensure they can develop intellectual capital to integrate knowledge into their day-to-day management as part of their intangible assets. This strategic perspective leads to using international assignees as knowledge facilitators who can help develop intellectual capital. However, managing knowledge from international assignments to create intellectual capital is often complicated, and the literature pleads for more research on the topic. Therefore, through a systematic literature review, this study aims to overview the state of the art regarding knowledge and intellectual capital management in the context of international assignments to develop a new conceptual model in the field. This study answers the gap in the literature regarding a model that analyses how international assignments influence knowledge management and the creation of intellectual capital in organisations. The main findings suggest that research needs to focus on developing a system to manage knowledge and intellectual capital in the context of international assignments to ensure competitive advantage. The main limitation of this study is the use of only two databases. Further studies should implement the same research procedure using other databases to achieve a broader understanding. In addition, future research needs to focus on developing measurement models of knowledge and IC management for organisations.

Keywords: Knowledge, Knowledge management, Intellectual capital, International assignments, Systematic literature review

1. Introduction

In the current era, intangible resources such as knowledge and intellectual capital (IC) are crucial to creating competitive advantages that secure the success of organisations (Azamat et al., 2023). The increasing attention given to the management of intangible resources such as knowledge and IC is then significant for organisations for different reasons, such as increasing innovation, achieving higher performance and accessing global knowledge, which leads organisations to view knowledge and IC from a strategic perspective (van Criekingen, Bloch and Eklund, 2022; Azamat et al., 2023). IAs are crucial in accessing and acquiring knowledge from different locations (Phil St John Renshaw, Parry and Dickmann, 2020). They are seen as knowledge facilitators despite the need for more research to help identify their organisational value (Reiche, 2011; Renshaw et al., 2020b). However, management practices often do not consider the value of IAs for knowledge and IC management (Crowne, 2009; Awang, Hussain and Malek, 2013).

In the literature, there are few studies establishing a connection between some IC components and some KM processes, namely suggesting that different IC dimensions can impact KM processes differently. Therefore, there needs to be more literature considering the relationship between IC and KM in the context of international assignments, with most studies focusing on just IC or KM. This paper aims to analyse how the literature on knowledge and IC management evolved in the context of international assignments to develop a needed conceptual model in the field. Namely, it aims to answer the following research question: how is knowledge managed in the context of international assignments to help create intellectual capital?

2. Theoretical Background

In this study, IAs can be defined as people who go to work abroad, and different types can be identified in the literature (Fenwick, 2004; Bozkurt and Mohr, 2011). The two main groups of IAs analysed in the literature are expatriates and self-initiated expatriates (SIEs). Expatriates, also denominated as organisational expatriates, are employees sent by their home companies to international posts, following the organisation's path and depending on it (Makkonen, 2015; Farcas and Gonçalves, 2019). SIEs decide to live and work abroad by themselves, being hired as a local in a host country (Cerdin and Selmer, 2014; Andresen, Biemann and Pattie, 2015). Recently, a new type of IAs has been gaining attention, namely inpatriates. These are host or third-country managers transferred into the HQs on a semi-permanent to permanent basis to enhance the globalization of their business activities (Azar, 2012). In general, IAs are seen as knowledge brokers, facilitating knowledge

transfer. In doing so, they play a strategic role for organisations by connecting the home-country company to its subsidiaries (Bozkurt and Mohr, 2011; Azar, 2012). This happens since throughout the entire assignments (from pre-departure until they become repatriates), they can bring essential knowledge regarding the cultural context of potential international target markets they might have been involved (Knocke and Schuster, 2017).

Knowledge management (KM) is crucial from a strategic perspective to sustain competitive advantage for organisations and to help develop IC. In the KM literature, several processes can be identified (Kamoche, 1997; Choi and Johanson, 2012; Wu, Lee and Pham, 2020; Hsu et al., 2021). Since the knowledge involved in these processes can have two forms - tacit and explicit knowledge – it will differently influence how IC is developed (von Krogh, Nonaka and Aben, 2001; Thomas and Gupta, 2022).

In this study, IC is viewed as the knowledge that can be converted into value and englobes the four dimensions, namely human, social, structural and relational capital (Edvinsson and Sullivan, 1996). Human capital (HC) refers to the organisation's members' tacit knowledge, such as competencies and skills (Becker, 1993; Ramaswami, Carter and Dreher, 2016). Structural capital (SC) usually relates to tacit knowledge of the organisation, including mechanisms and structures that support employees in their quest for optimum intellectual performance and overall business performance (Bontis, 1998; Bakhsha, Afrazeh and Esfahanipour, 2018). Social capital refers to the ability of people and organisations involved in networks to secure mutual benefits (Portes, 1998; Ganguly, Talukdar and Chatterjee, 2020). Finally, relational capital (RC) is the relationships between the institution and internal and external entities, including its participation in national and international networks (Secundo et al., 2015; Abu-Rumman, 2018). So, considering the connection between KM and IC, as an example, by efficiently managing tacit knowledge, organisations can develop HC, which, in turn, can lead to SC creation in the form of explicit knowledge.

Since most knowledge derived from international assignments is tacit, it is difficult to codify and transfer it among individuals and throughout the organisation (Crocitto, Sullivan and Carraher, 2005; Glisby and Holden, 2005; Matherly and al Nahyan, 2015). Therefore, organisations must ensure that they have a proper mechanism to manage knowledge from IAs, namely, to transform tacit knowledge into explicit knowledge (Dahou, Hacini and Burgoyne, 2019). Furthermore, organisations must have strategies to manage different types of IAs to transfer the acquired knowledge and, consequently, create IC (Minbaeva and Michailova, 2004; Phil St J. Renshaw, Parry and Dickmann, 2020).

3. Materials and Methods

A literature review helps to gain knowledge on a specific topic of what has been done, the methods used, the key issues and future research needs (Hart, 1998; Denney and Tewksbury, 2013). A systematic literature review was conducted using the PRISMA method, followed by an in-depth literature analysis (Liberati et al., 2009; Page et al., 2021). On February 14, 2022, papers published to date on the Scopus and Web of Science databases were considered for analysis. The search in the databases only includes a limitation to document type, namely articles. No further limitations were included in this phase to achieve a better representative sample.

A first search was conducted using ("knowledge manag*" OR "knowledge shar*" OR "knowledge diff*" OR "knowledge transf*" OR "knowledge creat*" OR "knowledge dissem*" OR "knowledge absor*" OR "knowledge acqui*" OR "tacit knowledge" OR "explicit knowledge") AND ("mobility" OR "job mobility" OR "human mobility" OR "labour mobility" OR "labor mobility" OR "employee mobility" OR "expat*" OR "repat*" OR "assign*"). As a result, a total of 3558 articles were obtained: 1983 articles from the Scopus database and 1575 articles from the Web of Science. The second search was conducted using ("intellectual capital" OR "relational capital" OR "human capital" OR "structural capital" OR "social capital") AND ("mobility" OR "job mobility" OR "human mobility" OR "labour mobility" OR "labor mobility" OR "employee mobility" OR "expat*" OR "repat*" OR "assign*"). Finally, the term "assign*" was used instead of "international assign*" to achieve a broader number of articles that can use the first term to refer to international assignments. As a result, 2354 articles were obtained in Scopus and 2554 in ISI Web of Science (4908 articles in total). Hence, the initial sample was composed of 8466 articles.

After excluding duplicates, 5666 articles were included for the first screening. All abstracts were read. Those that were not aligned with the goal were excluded. Also, the articles with no access and those written in languages other than English, Portuguese, French or Spanish were excluded. Therefore, 105 articles were eligible to be fully read from the Intellectual Capital query and 115 from the Knowledge Management query.

The 220 articles, which comprised the final sample, were then thoroughly read and grouped according to their relevance (see Domingos et al., 2022). Hence, 37 articles were considered irrelevant and excluded. The remaining 183 articles were then analysed using an Excel sheet. This compilation of data made it possible to

create a comprehensive screening of all articles while comparing them to achieve a full systematic review. Figure 1 shows the PRISMA method applied in this paper to screen the articles.

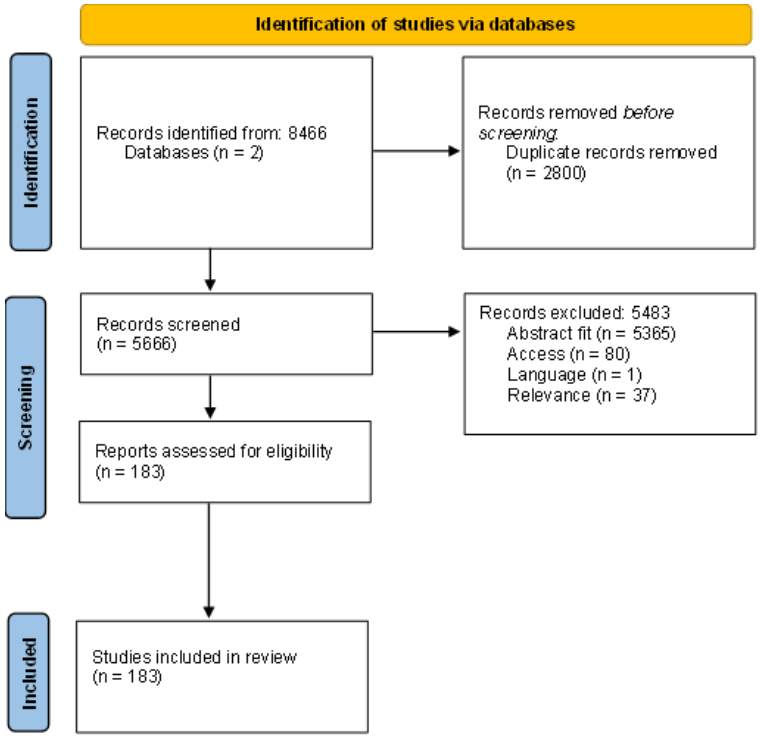

Figure 1: Knowledge, Intellectual Capital, and Mobility PRISMA. Source: Page et al. (2021)

4. Results and Discussion

The analysis of the articles shows a change in careers from people working in organisations that operate at a global level (Andresen et al., 2021). However, the management of IAs imposes several challenges to organisations, namely regarding how they manage their knowledge and IC.

4.1 KM in a Mobility Context

Traditionally, literature has focused on KM as a unidirectional process (from the headquarters (HQs) to the subsidiaries). However, in recent years, seeing it as a bidirectional process gained importance (Sanchez-Vidal, Sanz-Valle and Barba-Aragon, 2018). The sender is usually the IA and the receiver is the host-country national. However, the literature suggests that these parties should play both roles to create a bi-directional knowledge flow (Chang, 2012; Hsu et al., 2021).

The main KM processes referred to in the sample are knowledge (KT), knowledge sharing (KS) and knowledge hiding. Regarding KT, it was found that the process is way smoother when IAs and locals cooperate (Ado, Wanjiru and Su, 2021). Moreover, it was found that KT needs to be managed by considering whether it refers to explicit or tacit knowledge (Ado, Wanjiru and Su, 2021). While some authors suggest that IAs are better transferors of tacit knowledge due to their boundary spanner role, others see them as transferors of explicit knowledge, namely social capital. In the context of KT, increasing attention is given to the reverse knowledge transfer (RKT) process (knowledge from repatriates). However, there is still a lack of mechanisms in organisations to manage RKT (Ali et al., 2021; Amir et al., 2020)

Although KT and KS are commonly used as synonyms, KS is often more used in articles which analyse IAs from a social lens (Boyle, Nicholas and Mitchell, 2016; Heizmann, Fee and Gray, 2018). Concerning the KS process, it should be stressed the effect that cultural intelligence has on it. Cultural intelligence refers to a person's ability to work effectively in culturally diverse work environments (Ali et al., 2019). However, the role played by IAs in the KS process still needs to be clarified, as well as their impact on the type of shared knowledge (Boyle, Nicholas and Mitchell, 2012, 2016; Fan and Harzing, 2017). One crucial aspect to be assessed in the KS process is the direction of the sharing. Two directions are identified: the forward KS (from HQs to subsidiaries) is mainly conducted by expatriates, and repatriates conduct the reverse KS (from subsidiaries to HQs). As identified in the

KT process, less attention is given to the reverse KS (Huang, Chiu and Lu, 2013; Jayasingam, Chong and Abu Bakar, 2021).

Finally, a new process is emerging in the literature on IAs and KM: the one of knowledge hiding. This process refers to more than the absence of knowledge sharing. Instead, it is an intentional effort to conceal or deny knowledge another person requires. Three forms can be identified: (1) Rationalised knowledge hiding - knowledge holder provides a reason why knowledge is not being shared; (2) Evasive hiding - knowledge holder provides misleading, incorrect or partial information and (3) "Playing dumb" hiding - knowledge holder deliberately pretends ignorance or behaves as if unaware to avoid sharing knowledge (Ado et al., 2021; Ali et al., 2021).

4.2 IC in a Mobility Context

Regarding the relationship between IC and international assignments, the most analysed dimension is social capital (e.g., Andresen et al., 2018; Au & Fukuda, 2002; Furusawa & Brewster, 2018, 2019; Yildiz et al., 2019). First, it is mentioned that social capital positively influences IAs since it allows people to access resources embedded in a network (Au and Fukuda, 2002). Moreover, since IAs act as boundary spanners, it was found that social capital helps this role through its bridging and bonding perspectives. The bonding perspective views social capital as a means for establishing close and trustful relationships, while the bridging perspective views social capital as a resource that allows people to bridge ties in networks (Adler and Kwon, 2002; Andresen, Goldmann and Volodina, 2018; Egbe, Adegbite and Yekini, 2018).

The second most analysed dimension is HC (e.g., Andresen et al., 2021; Benson & Pattie, 2008; Breitenmoser et al., 2018; Ewers, 2013). In the analysed articles, HC tends to represent the human resources of an organisation that pursues an international assignment (Andresen et al., 2021). HC is developed through social interactions. Thus, social capital can maximise HC benefits since, i.e. through social networks, it can provide easier access to information and vital resources (Collings, 2014). However, the HC acquired abroad, although a source of competitive advantage, is only sometimes valued by organisations upon repatriation (Benson and Pattie, 2008; Breitenmoser, Bader and Berg, 2018). Such a fact imposes a problem for IC and knowledge management since the organisation's HC is the primary source of knowledge and facilitator of knowledge transfer and sharing (Azar, 2012). Moreover, if people feel that the organisation is not valuing their experience, they can leave it upon repatriation, taking their "new" knowledge with them. In such a case, HC will be lost for the organisation (Shieh, 2014).

The remaining IC dimensions – SC and RC –were less analysed over the years. As a result, most of the articles end up not specifying that they are analysing these dimensions. SC is indirectly referenced in the form of organisational routines and procedures. At the same time, in the assessed articles, RC is grounded on the relationships established between organisations, between the employees and between employees and organisations (e.g., Egbe et al., 2018; Ramaswami et al., 2016).

4.3 KM and IC in a Mobility Context

To answer the research question - how is knowledge managed in the context of international assignments to help create intellectual capital - the literature shows that KM processes boost the development of IC (Ali et al., 2021). However, in both IC and KM queries, there is no analysis of different processes/dimensions and how they can influence each other. With the increased globalisation, IAs act as boundary spanners by mediating the flow of knowledge. IAs are to increase their knowledge by acquiring new skills while abroad. To achieve common ground, it is necessary to consider that an international assignment cycle exists and that multiple aspects of this cycle must be managed according to its different phases. So, organisations should design a system by which IAs can transform tacit into explicit knowledge (e.g., through reports), thus reducing knowledge loss and creating intellectual capital.

Figure 2: Conceptual Base Model

This study aims to help future researchers by offering a base model portrayed in Figure 2 to be further developed as the research moves forward. The main idea behind it is that, in the context of mobility, how knowledge is managed can influence the creation or destruction of intellectual capital.

5. Conclusions

This study is relevant to the field since it aims to analyse KM on a broader way in the context of international assignments. Moreover, by identifying the main processes of KM mentioned in the literature, it helps to clearly define a research path to identify how the management of knowledge can impact the development of IC in the context of international assignments.

Research and practical implications

The main research implication of this study is the development of a base conceptual model. Second, is the identification of a need for studies to interconnect IC and knowledge management in the context of international assignments. Also, this study identified the need for research to differentiate the management of knowledge and IC in this context from traditional human resource management practices.

In terms of practical implications, it was found that it is important for organisations to create a knowledge and IC management team inside the human resource management department, which can develop a proper governance mechanism to retain this knowledge. Moreover, human resource managers must look at IAs as individuals who are different from the rest of the employees due to their knowledge, which can influence the development of IC.

Limitations and future research

This study's main limitation is using only two databases, namely Scopus and ISI Web of Science. Further studies should implement the same research procedure using other databases to achieve a broader understanding. In addition, future research needs to focus on developing measurement models of knowledge and IC management for organisations.

The Dynamics of the Development of a Knowledge Ecosystem

Kristina Grumadaitė and Giedrius Jucevičius
Vytautas Magnus University, Kaunas, Lithuania

kristina.grumadaite@vdu.lt
giedrius.jucevicius@vdu.lt

Abstract: This paper presents and analyses the dynamics of the development of knowledge ecosystem, putting more emphasis on interorganisational context, such as industrial clusters or "geographical concentrations of interconnected companies, specialised suppliers, service providers, companies in related industries and associated institutions (trade / industry associations, universities, educational institutions) that compete but also cooperate" (Porter 2000). This paper contributes to scientific efforts to minimise the gap of research on organisational entities whose development reflects the essence of an ecosystem – a network of interacting actors, which compete and cooperate in order to create and apply new knowledge on the grounds of self-organisation. This paper, following a dynamic approach to the development of knowledge ecosystems, analyses four development stages, the preconditions behind the viability of knowledge ecosystems and their interconnections.

Keywords: Knowledge ecosystem, Development, Dynamics, Viability preconditions

1. Introduction

A knowledge ecosystem in its nature is a self-organising dynamic and adaptive system, in which all the processes of knowledge creation, sharing, using, managing take place on purpose to enhance knowledge (Öberg & Lundberg 2022). Its development accordingly goes through different stages while applying different dynamics modes – for example, Chiles, Meyers and Hench (2004) defined fluctuation dynamics, positive feedback dynamics, recombination dynamics, and stabilisation dynamics. Thus, the research of knowledge ecosystem requires a dynamic and complex approach, while revealing the emerging phenomena during each stage of the system's development. However, the static approach based on the analysis of statistical data about the development of such systems or application of the outsider's view into the development processes still prevail in the scientific literature. Accordingly, it results in the formulation of the following research questions – what are the stages of different dynamics of knowledge ecosystem development? What are the main features and preconditions of the development of knowledge ecosystem?

Thus, this paper adapts the dynamic approach into the development of knowledge ecosystems and *aims* to define and analyse both the dynamics and their preconditions of the development of knowledge ecosystem. It follows the approach that an ecosystem moves through different stages of its development while applying new manifestations with a need to implement particular decisions to make this process as smooth as possible (Grumadaite, Ceicyte, Bernotaite & Brazinskas 2022; Lichtenstein & Plowman 2009; Uhl-Bien & Arena 2018).

The first part of the paper reveals the concept of knowledge ecosystem through the lenses of interactions. The following parts of the paper present the dynamical nuances of different development stages and preconditions to make particular dynamics to happen. These preconditions are based on the empirical research results of industrial clusters in Lithuania those develop their clusters as knowledge ecosystems.

2. Knowledge Ecosystem as a Network of Interactions

Following complexity theory, which analyses how relationships impact the emergence of collective behaviour (Sammut-Bonnici 2015) knowledge ecosystem is a network of various actors implementing different types of interactions based on defined simple rules, values and behavioural standards in order to adapt to the environment, to learn continuously, and to develop trust, identity and responsible behaviour (Anderson 1999; Obolensky 2014). The actors of knowledge ecosystem manage various knowledge processes – they generate and share knowledge by effectively using knowledge generation and sharing tools, they storage knowledge and apply it into decision making processes and professional job-related activities (Zaim, Muhammed & Tarim 2018).

According to Aarikka-Stenroos and Ritala (2017), the ecosystem approach includes competition and evolution, emergence and disruption, stable business exchange and value co-creation. It means that in the case of knowledge ecosystem the main value is knowledge, and multiple actors participate in knowledge co-creation. One should note that knowledge co-creation is impossible without interactions. The types of social interactions by Nisbet (1970) consist of cooperation; conflict; social exchange, related to mutual benefits; coercion and conformity. Conflicts can be seen as a consequence of competition, and social exchange can be manifested in the process of cooperation. Conformity as a form of social interaction, according to Nisbet (1970), is not obedient

behaviour due to authoritarian actions, but behaviour to meet group expectations, for example, to follow certain values and standards of behaviour. Thus, one could conclude that an ecosystem is a network of actors interacting with each other and with the external environment, where because of the absence of control through communication, coordination, obedience to common values and norms of behaviour, competition, cooperation the ecosystem is able to be viable, co-evolving and adapting to external environment.

3. Dynamics Variations of Ecosystem During its Development

Scientific literature emphasises different stages of development of ecosystems, starting from the first initiating event to boost tension to the emergence of a new order based on self-organisation and self-regulation, when the ecosystem returns to stability following defined rules and behavioural norms (Anderson & Russell 2011).

Emergence of non-equilibrium

In general, scientific literature that analyses systems that are based on self-organisation, emphasises the importance of tensions at a starting stage of its development. They state that the greatest changes occur when the system is close to the *edge of chaos* or at the very point of edge of chaos (Boal & Schultz 2004). The first stage is called fluctuation dynamics (Chiles, Meyer & Hench 2004), initiating conditions (Plowman et al. 2007), dis-equilibrium state (Plowman et. al. 2007; Lichtenstein & Plowman 2009), emergence of non-equilibrium state (Jucevičius, Grumadaitė, Jucevičienė & Čeičytė 2019).

Non equilibrium is caused by various factors, that could be defined as *triggers* (Uhl-Bien et al., 2007), which can be planned or unplanned. Often the unplanned changes can be related to the development of external environment, and this development causes the need to acquire, accumulate and apply knowledge while attracting new actors and new resources. For example, the tension may occur because of emergence of a big competitor or many more competitors in a particular sector, merging of other enterprises, or in the opposite- a bankruptcy of an anchor enterprise as it happened in cinema industry in Lithuania. Losing a source of knowledge or seeing someone with a significant amount of knowledge may encourage to develop a new ecosystem with unique accumulated knowledge. In order to make it happen, a response as an initiative for further development of an ecosystem should occur.

Scientific literature reveals different strategic approaches, applied in the stage of non-equilibrium. Grumadaitė and Jucevičius (2022) define strategic approach of experimentation, strategic approach of external agent and strategic approach of ad hoc fellow professionals. Strategic approach of experimentation is based on taking advantage of opportunities without a clear expected outcome; thus, knowledge ecosystem is developing while using mistake-trial method. Strategic approach of the external agent, in the opposite, sees the initiators of development of the ecosystem having a clear expected outcome regarding the ecosystem and accordingly a clear plan regarding the further development of the ecosystem. Finally, the strategic approach of ad hoc fellow professionals emphasises the timely natural gathering of like-minded people and achieving common goals without thinking about formalised forms of cooperation (Ibid.).

One should state that in this stage the communication and cooperation happen only among a group of the main initiators, which communicate and cooperate together. In order to develop the knowledge ecosystem and invite new participants, additional tools are needed because the outsiders and initiators of the ecosystem may have no trust towards each other. Quite often the outsiders may even don't feel any urge to get united because they don't see any danger to come and/or expect to maintain the same direction as nothing happened. Thus, scientific literature emphasises the importance of strengthening non-equilibrium or amplifying actions (Plowman et. al. 2007; Lichtenstein & Plowman 2009).

Strengthening non-equilibrium

Naturally, strengthening non-equilibrium is related to various uncertainties, that are increasing. In the case, when the state of non-equilibrium is created deliberately in order to initiate particular changes, the reactions of all the involved may vary, from intensive discussions and sharing thoughts even with conflictual notes, until a tensed silence. In order to avoid being moved to a higher-level chaos or to return to a previous state with no changes, the following preconditions should be met:

- *Setting simple rules* (Plowman et al. 2007; Uhl-Bien et al. 2007; Palmberg 2009). In the ecosystem there is a variety of interacting actors that mostly are dependent only on local information (Anderson 1999). Thus, simple rules help them to maintain freedom in the actions but to follow common system's rules at the same time (Lichtenstein 2016). These rules reflect the vision, strategy, the best

practices of the system. Authority in the system or system's identity also works as simple rules (Obolensky 2014).

- *Setting main values and principles.* The ecosystem mostly maintains natural-regulation and stabilisation based on self-referencing values and principles that aren't pushed from outside (Chiles et al. 2004). The values could be related to risk taking and tolerating uncertainty; learning; adaptation to new events; cooperation and sharing in order to emphasise the importance of unity and efforts to avoid individualism and competition (Grumadaitė, Jucevičius & Staniulienė 2022).
- *Existing conditions for experimenting and innovating regarding to knowledge processes.* Since non-equilibrium state is related to the highest level of innovation, the conditions for experimentation and fluctuation should be implemented (Lichtenstein & Plowman 2009; Palmberg 2009).
- *Promotion of interactions in the system.* This precondition is related to the statement that the ecosystem is impossible without interactions (Laihonen 2006), thus, interactions inside and with an external environment should be encouraged and promoted in order to share and create knowledge (Lichtenstein & Plowman 2009; Palmberg 2009).
- *Spreading sense of events and vision* (Plowman et al. 2007; Palmberg 2009). Organisational experience reveals that the most active ecosystem's members used to highlight the advantages of working together even in the face of various uncertainties, even bankruptcy. The highlighting of aims to be fulfilled in the ecosystem and clarification of the expectations of ecosystem's members are also applied.

Those preconditions should lead to emergence of community feeling and dependency to the ecosystem, and in other words – movement to the *continuous two-way emergence of a new order* (Jucevičius, Grumadaitė, Jucevičienė & Čeičytė 2019) that is directly related to self-organisation state (Plowman et. al. 2007; Lichtenstein & Plowman 2009).

Continuous two-way emergence of a new order

In this stage, various interactions without centralised control take place, such as:

- Participation in joint learning activities: it also helps to get acquainted and explore the possibilities for future joint activities.
- Communication: representing (knowledge) community in various representative events and creating new contacts, organising joint regular meetings, communicating in informal settings – all that helps to create teams.
- Competition: working on projects with separated research areas or on development of new projects that are not in the area of direct competition.
- Coordination: it is expected that coordination of ecosystem is depending on the ecosystem's members themselves since there are no control outside.
- Cooperation: the ecosystem's members are creating joint activities and projects in order to develop new knowledge and or find new ways of its sharing, storage, etc.
- Compliance: to define simple rules, values and behavioural norms.

The empirical research of nine industrial clusters in Lithuania that formed naturally on a purpose to cooperate and create innovative products, such Cinema cluster, Game industry cluster, Tourism cluster, Machinery cluster, ICT cluster, Wellness cluster, Cluster of medical innovations, Photo electronics cluster and Laser cluster was performed while adapting multiple case research strategy (Yin, 2014) and conducting interviews with industry cluster coordinators – the individuals who see the cluster as a whole. The research was dedicated to the analysis of various factors regarding industrial cluster development dynamics and its preconditions. Starting with the questions about the beginning of the development of knowledge ecosystem, further questions reflected the need to analyse *the cluster viability*, which can be measured by the quantity (increase in the number of members) and quality (activities) in the cluster.

The respondents were asked about admission of new members into an emerging ecosystem, such as How the admission of new members to the cluster looks like? What are the admission criteria (in some cases, clarifying questions are provided, for example, whether a member who is new to the market and unfamiliar to the cluster members can be accepted)?

Later, the focus in the interviews is moved to the area of interactions, such as communication, cooperation, competition. The respondents were asked the following questions: How the process of communication and cooperation is ensured in the cluster? Are there competing companies in the cluster? If so, how is the problem

of competition solved? Are the members of your cluster more likely to act individually? If so, how is this solved? Do cluster enterprises feel like a community of common destiny, where the actions of one person / enterprise affect the whole cluster? What values are dominant in the cluster? How is trust maintained in the cluster? How is the learning process ensured in the cluster?

Research results revealed that in some cases the local development of knowledge ecosystems is limited because of a limited number of actors in a particular sector: "barely few new enterprises over the next twenty years" (Laser cluster). Reasons of such a slow industrial growth, that is related to a creation of unique products could be defined as follows:

- limited number of users: the main users are universities to whom unique products are created;
- the uncertainty of the final result, which implies that industry enterprises are not attractive to venture capital providers;
- a high demand of highly skilled workers who can create start-ups, and it takes time for new professionals to gain knowledge to develop their activities.

However, an increase in the number of enterprises in the industry is not necessarily a prerequisite for ecosystem's growth. On the contrary, some interviews even claimed that the ecosystem had reached the limit of the number of their members. According to the coordinator of Game industry cluster, the industry has a limited number of companies that can enter the developing ecosystem: "We do not see promising members that we can accept. It is not interesting to have people in the list or companies in the list – you need to have them for the activities".

Human resources – a skilled workforce – have a strong influence on the development of both industries and ecosystems. A scarcity of skilled work force was mentioned by the coordinators of both creative industries clusters and Machinery cluster. The coordinator of Tourism cluster highlighted another problem - a problem of keeping trained employees in cluster enterprises, because sometimes these employees simply leave.

Thus, the research revealed the areas of viability of developing knowledge ecosystem those have influence on the dynamics of knowledge ecosystem: *Actions regarding the admission of new members*, *Criteria regarding selection of new members* and *Preconditions behind the active involvement in the ecosystem* (see Figure 1).

As it can be seen in Figure 1, *Using external funding* was of significant importance for the dynamics of development of the ecosystem especially by facilitating the development of R&D infrastructure, joint trainings, participation in public events. However, the main emphasis will be put on the admission of new members and their involvement into the activities of the developing knowledge ecosystem.

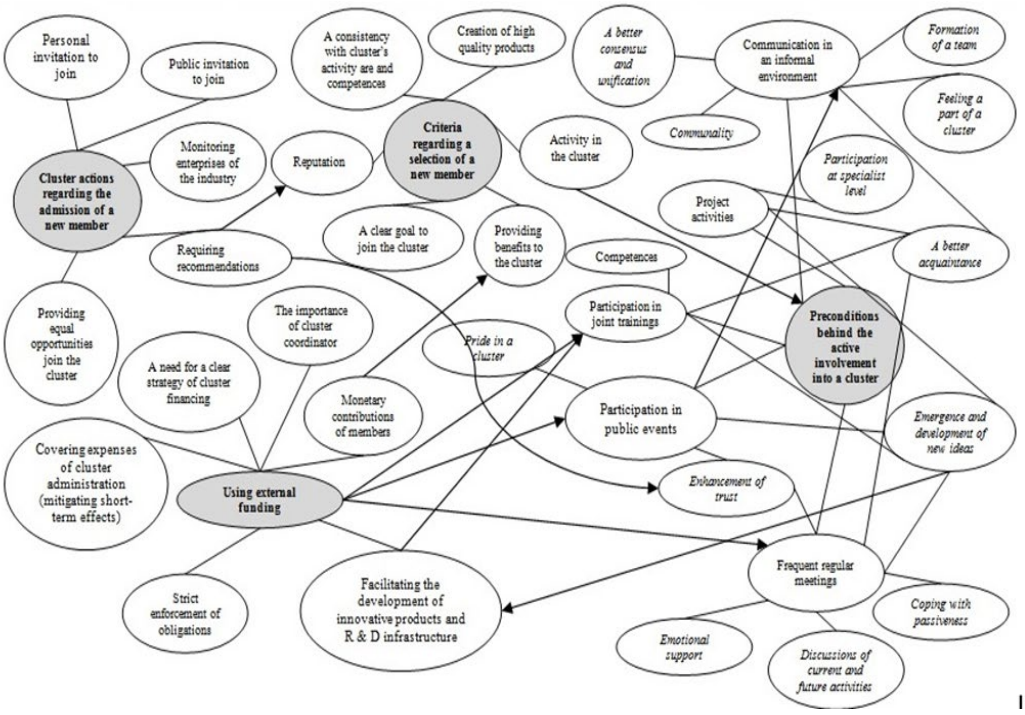

Figure 1: Dynamics and Viability Preconditions of the Knowledge Ecosystem (prepared by the Authors)

Purposeful admission of new members. New members are carefully selected because analysed clusters are oriented towards higher productivity, innovation and access to larger markets, and thus ecosystem's growth is based on quality rather than quantity. The purposeful acceptance of members is highlighted in every single interview. According to the interviews, a potential enterprise should meet the following criteria.

- *To be in accordance with ecosystem's - cluster's activity areas and competencies*. In the case of analysed clusters, a potential enterprise must seek to achieve more than the most of the same industry-based enterprises: "we position ourselves a little higher, that we can, we have bigger goals" (Cluster of medical innovations), especially if the cluster was created to develop innovative products: "Our cluster was created to develop health innovative products and services; if a new member just promotes a healthy lifestyle or is simply a SPA centre, he will be unfit for us" (Wellness Cluster).
- *To develop high-quality products which, for example, meet certain standards* (this is especially important to Machinery cluster, because cluster enterprises would not be allowed to enter international value chain without these standards.
- To have a good *reputation*.
- *To have a clear goal regarding joining the cluster*, in other words, to clearly understand its functions: as the coordinator of Cinema cluster told, "just to be here - there is no such goal".
- *To not limit themselves by getting benefits from a cluster but also provide benefits to the cluster* i.e. complement the cluster with resources and products – "knowledge, people, contacts, products, services", as well monetary investments.
- *To be active in cluster activities:* an enterprise should be focused on cooperation (Cinema cluster).

It is obvious that it is important to know about a particular enterprise as much as possible in order to choose a new member that meets the selection criteria (see Figure 1). As the amount of enterprises that belong to a particular industry is relatively small, enterprises in the industry know about each other quite well, thus one of the naturally occurring processes is a self-sustaining monitoring of the industry through performing activities and providing a personal offer to join the cluster, as in the case of the Cluster of medical innovations: "If we see that there is a company in Lithuania that does a little bit more than others do, or that company meets our ... our common goal ... then we just offer them, they hear our story who we are, what we are about". Similarly, in the case of the ICT cluster, when a cluster enterprise finds out that there is an enterprise that is beneficial to the cluster: "You go, talk to them, and then they get involved". Therefore, the recommendations of cluster enterprises are of great importance to the acceptance of new members, in particular due to the increased trust of that enterprise from the side of remaining members of the cluster. For example, a poorly provided service by a new member may be detrimental to the image of the whole cluster.

However, the most of clusters are open to all actors on the market; if it becomes clear during a conversation with the cluster coordinator that the candidate meets the criteria for the field of cluster's activity, product quality, reputation, providing benefit to cluster and other criteria, he may become a cluster member.

Active involvement in the knowledge ecosystem. In order to make a cluster active and viable, cluster members must engage in cooperation activities. A part of these activities are self-organised meetings between groups of enterprises in order to deal with various business issues. In some cases, an enterprise organises a meeting of all members of the cluster if this enterprise wants to report certain news, for example, to present new service, and the enterprise then "initiates a meeting, and then we all arrive, if we can". Sharing of functions and responsibilities is also being observed in analysed clusters: "some of them are more responsible for marketing, others may be more responsible for development, the third one is more responsible for science and business cooperation"; these functions can be appointed both by cluster members themselves or by a cluster coordinator in order to bring "benefits both to the cluster and to the environment".

Based on the analysis of the interviews, one could distinguish four types of activities that contribute not only to greater involvement in the cluster, but also to better acquaintance with each other, increasing trust and finding new ideas even with limited previous experience of cooperation, as follows:

- frequent regular meetings;
- communication in an informal environment;
- project activities;
- participation in public events;
- participation in joint trainings.

Frequent regular meetings according to cluster coordinators serve as means for a better acquaintance to each other, events, work results; discussions of current and future activities; coping with passiveness; emergence and development of new ideas; enhancement of trust; emotional support (also see Figure 1). In some cases, meetings happen quite naturally when enterprises share some common interests with each other, for example in the case of one of high-tech clusters, "there is constant communication between the labs, the people who work in the labs, and the companies." In Photo electronics cluster some enterprises meet "maybe once a week, and three or four - twice a week." In other clusters, frequent regular meetings are planned by cluster coordinators. Although such meetings can be held flexibly as needed ("we look roughly when we already have some knowledge, news, ideas, many meetings are organised and held regularly at least "six times a year", depending on the field of activity and the need to meet. Sometimes clusters simply follow the practice to organise regular meetings no matter the intensity of news: "even if there is a first impression that there is not much to talk, after meeting it becomes clear that there is something to talk about, new ideas and new thoughts are born, and then something new is born". Cluster coordinators reveal that "we gather and talk about our pains, our troubles, our joys". Such frequent conversations, if they are based on sincerity, also become a means of increasing trust: "we have many beautiful and diverse statistics, how trust is born depending on how many times a week you communicate with that person".

Communication in an informal environment serves as means for a better acquaintance, seeking consensus and unity; formation of a team; development of community feeling. Informal communication includes not only coffee-breaks but also various trips to spend time in an informal environment, for example, in the nature. High technology cluster and Cluster of medical innovations created a tradition to organise annual gatherings (including conferences) of all employees of cluster members-enterprises, even including their family members (see Figure 1). For example, in the case of the tourism cluster, in addition to the aforementioned weekly meetings to share joys and worries, the practice of visiting different companies of the cluster is applied: "we try to make that informal communication as well - we go to some specific companies of our cluster members". Visiting cluster companies by rotation is also a feature of the Wellness cluster - it helps to "feel each other" and "get other results".

Empirical research results revealed that *participating in projects* gives an opportunity to cluster members to get acquainted with each other at specialist level. Based on the interview with the coordinator of ICT cluster, projects help to learn about each other's opportunities and capabilities to take responsibilities, develop new ideas, and discover new markets and new areas for future activities. In addition, participation in public events (including conferences) enhances pride in a cluster and identification with it: "Yes, we are all here together, we did this, look here, this and that has been done". A trip to a particular destination also may become a tool for informal communication: "Through these trips, many different ideas are born, people are talking, gathering together, and there is already a stimulus: we will do something, there is a need to do something". Participation in public events may also act as a means of enhancing trust. A cluster member, who has successfully completed the tasks assigned to him to make new contacts, to bring and share the necessary information and knowledge with other cluster members, to represent the whole cluster, etc., deserves their trust.

Social capital is also developed through participation in joint training online and especially in a defined physical space, where participants of training not only develop their competences but also get acquainted with each other and discover new opportunities (see Figure 1).

Finally, at any time, the ecosystem returns to the state of **stabilisation** that is understood as a natural regulation process, which is understood as continuously following the rules or returning back to rules and values, when there is too much experimentation.

4. Concluding Remarks

This paper emphasises the variety of interactions that occur in the development of knowledge ecosystems – networks of actors that initiate and implement knowledge generation, sharing, storage and adaptation processes. In general, the development of knowledge ecosystems starts with the initiation and strengthening non-equilibrium which leads to a stage of the creation of a new order based on self-organisation and self-regulation.

Empirical research with nine industrial clusters revealed various interconnections between members that are worthy to enter the developing ecosystem and various aspects related to the involvement of the ecosystem's members. This empirical research revealed a context of the development that is emerging itself and still is not the most suitable for the smooth emergence of knowledge ecosystem. For example, there is a scarcity of skilled

work force that is emphasised as one of the most important preconditions for the emergence of an ecosystem. Enterprises that belong to analysed clusters create products, which require much knowledge and creative abilities.

Since gaining independence from Soviet Russia, many Lithuanian industries had created or recreated themselves from the scratch, thus sometimes the industries may be in the development stage. The scarcity of various resources creates a need to attract external funding. External funding contributes not only to softening short-term effects (compensation of administrative expenditures) but, even more - facilitating development of innovative products and R & D infrastructure. On the other hand, the scarcity of cooperation traditions and trust may result in issues of fierce competition, individualism and passiveness in mutual activities. However, the research results shouldn't be adapted only to post-Soviet context because the analysed context in general reflects any development of knowledge ecosystem that needs to start since beginning because of various circumstances. In such a case empirical research results provide practical insights for the active engagement into the development of knowledge ecosystem and what could be interconnections and consequences of various tools, including frequent regular meetings, communication in an informal environment, project activities, participation in public events and participation in joint trainings.

However, a deeper analysis is needed in order to develop a theoretical framework regarding the dynamics of development of knowledge ecosystem. This dynamic could be revealed through knowledge dimensions, such as Socialisation, Externalisation, Combination, and Internalisation, or Nonaka's SECI model (Bratianu 2010), including the mechanisms to overcome competition, individualism and passiveness regarding knowledge sharing. Although cluster coordinators can reveal many facts about the dynamics in the development of knowledge ecosystems, however, the empirical analysis from the perspective of the ecosystem's members is needed to reveal the process dynamics of the development of knowledge ecosystem.

Knowledge Management Practices in Research and Development Strategic Projects Undertaken by Banks

Tadeusz Grzeszczyk and Tomasz Groszkowski
Warsaw University of Technology, Faculty of Management, Poland

tadeusz.grzeszczyk@pw.edu.pl
tomasz.groszkowski.dokt@pw.edu.pl

Abstract: The dynamic development of information technologies that can support the functioning of financial institutions also implies a rapid increase in the number of investments in projects, e.g., related to ICT and AI. In addition to projects concerning current operations in the banking sector, a growing number of research and development projects of strategic importance can be observed. Implementing such projects is an excellent way to improve the banks' competitive position on the market, provide a better response to customers' increasing expectations, improve the quality and increase the security of the financial services offered. The problem addressed in this study is of great significance in the context of seeking new directions to stimulate the development of R&D activities of strategic importance carried out by banks. However, such research has not been run thoroughly enough so far. Therefore, the theoretical, methodological, and practical gaps in this area are clearly visible against the background of the literature review. There is a need to improve knowledge management processes at the level of R&D strategic projects during their planning, implementation, completion, and post-project reviews. Project managers and business practitioners use more or less formalized activities and practices of knowledge management in strategic R&D projects, which are more or less adapted to the specifics of these financial institutions vital for the economy. The paper discusses the practices, procedures, and approaches used in selected big banks in Poland. This preliminary research used reviews of organizational documentation, direct observation, and interviews with people involved in R&D projects. Identification and analysis of these practices can contribute to improving the effectiveness of explicit and tacit knowledge management processes that are of strategic importance in the banking sector.

Keywords: Knowledge management practices, Research and development projects, Strategic bank projects, Knowledge management in projects

1. Introduction

Modern financial institutions and banks are required to effectively manage explicit knowledge in a formalized and documented form, as well as informal, subjective tacit knowledge, which results from personal experiences. The use of appropriate knowledge management practices helps to streamline decision-making processes, improve the quality of customer service and increase operational efficiency. The most important activities supported by these practices include, e.g.: capturing knowledge from various sources, organizing and storing knowledge in an orderly manner, sharing knowledge, ensuring access to knowledge and its transfer, managing the risk of losing critical expert knowledge, supporting knowledge-driven decisions and continuous improving banking organizations in order to ensure an appropriate competitive position in a dynamic banking environment. Knowledge management in banking supports the promotion of learning and innovation, building on the collective intelligence of the organization and gathering knowledge about customers. Apart from that, promotion of learning and innovation development in the banking sector is a subject of considerable interest, as visible thanks to the results of literature research devoted to new trends in knowledge in this sector, new technologies and digital media, as well as problems of adaptation to dynamic changes taking place in the banking sector (Borba *et al.*, 2022).

Constant changes taking place in a turbulent environment are conducive to the increasing use of a project approach in the development of financial software supporting the management of money and financial transactions. Appropriate selection of methodological approaches to project and risk management is one of the critical success factors for large financial software projects (Tae *et al.*, 2020). Among the most important success factors for IT projects in banking are also the right selection of subject matter experts of projects, development environment, project manager skills and good communication (Priambodo *et al.*, 2019). In addition, the literature points to the importance of knowledge as well as human and intellectual capital development, which is necessary for the successful implementation of IT projects and modern management models (Grzeszczyk, 2020). Changes taking place in the environment of financial institutions, therefore, force the use of appropriate approaches and practices to knowledge management in projects. In particular, account should be taken of the high intensity and diversity of knowledge fields, as well as the related need for knowledge and technology intensity (De Borba, 2022). These phenomena affect relations with bank customers, enforce digitization processes and the increasing use of IT supporting the functioning of financial institutions. Such investments take the form of IT projects, the implementation of which significantly modifies the current operations of banks.

In the past, the transfer of technologies developed by scientific and research institutions outside the banking sector was often observed. In recent years, an interesting trend has been noticed - a number of strategic research and development projects is implemented in the banking sector. The implementation of strategic projects is an appropriate way to improve the competitive position of banks, respond more efficiently to the growing expectations of customers, improve the quality and increase the security of the financial services offered. Against the background of the literature review, theoretical, methodological and practical gaps in the improvement of knowledge management processes at the level of R&D strategic projects during their planning, implementation, completion, and post-project reviews are clearly visible. Research related to this has not been carried out sufficiently thoroughly so far, and it is important in the context of searching for new directions to stimulate the development of strategic R&D activities conducted by banks.

Openness to the introduction of innovative solutions and knowledge management play a key role in the planning and implementation of strategic R&D projects undertaken by banks. Proper strategic alignment of information system and innovation can be achieved by implementing innovative solutions supported by organizational learning, knowledge management, developing good cooperation and understanding by the management of the need to introduce innovation initiatives (Yaw Obeng and Mkhize, 2019). Project managers should therefore improve knowledge management activities and practices that foster good communication at various levels of the organization, and the success of strategic IT projects. Thus, it is important to conduct theoretical analyzes and empirical research identifying applied and potentially available practices that may be of interest to project managers and business practitioners in the banking sector. Their identification can contribute to improving the efficiency of knowledge management processes in strategic IT projects and increase the probability of their success. The research results presented in this paper concern the practices, procedures and approaches used in selected large banks in Poland. The following research methods were used during the research: reviews of organizational documentation, direct observation, and interviews with people involved in R&D projects.

2. Knowledge Management in Strategic Banking Projects

Modern advanced economies are usually supported by knowledge management, human capital development and learning processes of financial and non-financial organizations (Clarke and Gholamshahi, 2018). Improving information and knowledge resources through intellectual and mental activity creates the basis for forging key economic resources of modern financial institutions (Ali and Yusof, 2009). Implementation of knowledge-based solutions, development of education and improvement of human capital management have a significant impact on creating favorable conditions for economic growth, as well as improvement of socio-economic well-being analyzed at the micro and macroeconomic levels (Garza-Rodriguez *et al.*, 2020).

Financial institutions are based not only on physical but also on intangible resources, and are knowledge and intellectually intensive (Yao *et al.*, 2019). Expanding knowledge resources, developing human capital and increasing the value of the intellectual capital of the organization provides it with a competitive advantage, and the accumulated resources of data, information, knowledge and experiences create the potential for shaping new values (Dumay, 2016). Projects that involve making temporary efforts and sharing significant amounts of knowledge between individuals and groups participating in these projects can also contribute to the increase in the number of useful knowledge resources, even if they do not have prescribed learning mechanisms, and are usually focused on immediate results (Holzmann, 2013). The importance of long-term and responsible knowledge collection and management is easier to understand when managing strategic projects or programs (sets of projects) that are focused on delivering long-term and strategic benefits.

Management of knowledge in projects is recognized as an increasingly important development factor in many industries. Research is being conducted on analyzing not only knowledge management within projects (temporary organizations), but also between them (Hanisch *et al.*, 2009). Identifying and acquiring knowledge, as well as learning from project experience is a problem increasingly recognized by banks. Previously, the importance of knowledge management was seen mainly in the context of repetitive processes carried out on the basis of traditional organizational structures. The growing importance of issues concerning knowledge management in projects results from the increasing involvement of banks in the implementation of projects. These organizations see more and more clearly turbulent changes in the environment, dynamic technological advances, the growing role of project-based activities and the need to introduce innovations in IT processes and systems supporting knowledge management. Therefore, bank managements clearly notice the growing challenges and competition in the banking sector, the increasing importance of knowledge, intellectual capital and the resulting challenges facing modern financial institutions (Joshi *et al.*, 2010).

Knowledge management is implemented in banks to support the identification, collection, protection, development, maintenance and application of knowledge in the learning processes of individual employees and the entire organization in order to ensure the maximization of knowledge-based sustainable growth of the organization (Mehrotra, 2019). This is done by systematically acquiring, organizing, storing and sharing knowledge, which most often results in streamlining decision-making processes, improving the quality of customer service and increasing operational efficiency. These systematic activities include the effective management of both explicit knowledge (regarding formalized and documented information) and tacit knowledge (related to experts, their subjective experiences, attitudes and observations).

The most important aspects of knowledge management in banking include: knowledge capture, knowledge organization and storage, knowledge sharing and communication in project teams, access to and retrieval of knowledge, knowledge transfer and training, knowledge-based decision-making, risk management and continuous improvement of knowledge resources. Banks strive to acquire valuable and useful knowledge from various sources, and capturing it is of great importance. Potential sources of knowledge include, e.g., contacts with customers, knowledge of field experts employed in banks, results of market research analyzes and expert opinions of consulting companies. Captured knowledge can also come from bank documentation, evaluation reports of projects implemented by banks, summaries of surveys and interviews with employees.

Knowledge capture should be organized and stored in an orderly manner. One way is to use knowledge repositories or databases adapted to storing categorized information that is relatively easy to find and share. Information and knowledge may relate to customers, banking products, regulations, research reports and best practices. In modern banks, systems of communication and knowledge sharing by employees are also being developed in order to facilitate the implementation of scientific knowledge diffusion processes and the introduction of useful innovations. Helpful communication tools include, e.g., employee team meetings, discussion forums, intranet portals, workshops and training programs. Great importance should be paid to improving the culture of knowledge sharing and the collective knowledge of bank employees.

Quick decision-making and efficient customer service are possible if adequate access to knowledge resources and its recovery are ensured. Therefore, mechanisms and tools for searching in often extensive repositories and knowledge bases are useful. The developed tools for accessing knowledge and searching for information include, e.g., systems based on natural language processing and machine learning. Among the important aspects of knowledge management in banks, the transfer of knowledge between key and experienced employees and their young successors should also be mentioned. Therefore, all kinds of courses and trainings are useful, as well as mentoring programs and documenting best practices, e.g. in the form of case studies. Appropriate knowledge transfer can contribute to minimizing the risk of losing critical expert knowledge. The key aspects of knowledge management also include knowledge-based decision-making by providing access to relevant and up-to-date knowledge to assess the risk of financial operations, develop effective strategies and make informed decisions conducive to the sustainable development of the organization. Banks should keep abreast of changes in regulations, industry guidelines and best practices for effective risk management. Implementing effective knowledge management practices help banks disseminate information on these topics and mitigate potential risks.

Continuous development of knowledge management practices enables the improvement of mechanisms for collecting and analyzing knowledge supporting the identification of areas requiring improvement in the implementation of changes. Knowledge of good practices and experience from previous contacts with clients creates a good basis for improving banking processes, products and services. Knowledge management in banking makes it possible to use the collective intelligence of the organization, promote learning and innovation, improve customer experience and create favorable conditions for sustainable growth in a turbulent banking environment, as well as the implementation of strategic knowledge and technological projects.

3. Methodology

The problem addressed in this research is of great significance in the context of seeking new directions to stimulate the development of R&D activities of strategic importance undertaken by banks. The purpose of the conducted study is the initial identification of knowledge management practices in R&D strategic projects in such financial institutions.

The main research was preceded by literature research. The following research methods were used in main study: reviews of organizational documentation, direct observation, and individual interviews with people involved in strategic R&D projects. The scope of considerations was limited to the largest organizations from the

Polish banking sector. This is justified by the fact that, above all, such financial institutions undertake to implement R&D projects on their own. This is a relatively new field of activity in this sector and smaller organizations do not have the appropriate experience and resources required.

The conducted study on knowledge management in R&D projects in organizations from the banking sector was aimed at collecting information on the methods, tools and practices of knowledge management, as well as the reported benefits related to it. The method of individual face-to-face interviews was chosen to collect such data due to the possibility of direct contact with bank employees involved in the processes of planning and implementing strategic R&D projects. The use of this qualitative research method was time-consuming and sometimes difficult to carry out due to the numerous professional duties of the respondents, but it made it possible to conduct in-depth research conducive to a good understanding of the researched problems.

Respondents were asked the following questions related to knowledge management practices in R&D strategic projects undertaken by banks:

- What practices of knowledge management in strategic R&D projects do you know?
- How does the specificity of bank's R&D projects affect knowledge management practices?
- Is there an interest in tacit expert knowledge?
- Are actions taken to record the knowledge of people who may change their place of employment?
- Do you have established procedures or good knowledge management practices (e.g. within the methodological approaches of project management)?
- What is the role of informal information and knowledge exchange?
- Is the state of knowledge constantly monitored or are there periodic evaluations?
- What software tools are used in your work to manage knowledge in R&D projects?
- Is building knowledge bases planned in your department?
- Do you use artificial intelligence methods and data mining to build knowledge bases in your R&D projects?
- Does your department use Electronic Document Management (EDM) solutions?
- Does your department use data warehouse solutions in the knowledge management in R&D projects?

20 potential respondents from several of the largest banks were approached with the proposal to participate in the study. Ultimately, 7 respondents took part in the research. The respondents were people from the management staff of R&D projects related to IT implemented in these banks. Most of the respondents had at least 10 years of experience in the banking sector and more than 5 years in project management. Their education was primarily: finance, management and IT. The study was conducted in March 2023.

The methodology of the research presented in this section has limitations due to the relatively small number of respondents who were available and agreed to participate in the interviews. These studies should therefore be treated as pilot studies carried out before the full-scale research project.

4. Results and Discussion

In general, the respondents were open to knowledge management issues, using appropriate tools and practices, as well as learning about new solutions in this area. Some of them emphasized insufficient knowledge of these issues, in particular of specific tools and technologies supporting knowledge management in projects. The interviewees noted that not everyone involved in the bank's strategic projects was aware of the importance of these issues. Among the main applied knowledge management practices in R&D strategic projects, the following were indicated:

- gathering experience after the completion of projects,
- using tools related to popular methodological approaches, e.g. Agile or Prince2,
- the key role of project managers and the appropriate selection of the scope of competence of individual members of project teams,
- gathering expert knowledge,
- using tools such as Confluence or Jira to manage and share knowledge,
- exchange of knowledge during regular meetings and training workshops,
- creating knowledge bases, documenting experiences from strategic projects, and cooperation between various organizational units of banks.

Respondents were aware of the importance of knowledge management in planning and managing strategic projects implemented by banks. Most of them declared that they used various knowledge management methods and tools in their work. They also pointed out the challenges concerning the application of knowledge management practices related to the constant improvement of the required competences, such as the ability to work in a team or the ability to identify and verify knowledge and good communication. They also pointed out that in knowledge management it is important to care for the quality of processed data, their security and proper use so that they properly support business processes.

Based on the analysis of the answers, three groups of respondents can be distinguished. The first group consists of people who use advanced knowledge management tools and methods in their activities. They are aware of the benefits of using these tools, such as faster and more accurate data analysis and better use of available knowledge. Their answers were more detailed and professional compared to other respondents. They were more focused on the practical application of tools supporting knowledge management and their particular impact on projects related to the implementation of the organization's strategy. They were also more aware of the benefits and opportunities of advanced knowledge management, and more engaged in using these tools in their strategic R&D projects. Respondents from this group also pointed to the use of various knowledge management tools, such as Jira, Confluence, Microsoft Teams or SharePoint. At work, they also took up challenges related to the use of advanced methods of AI and data mining to analyze large data sets and discover new relationships in data. In the knowledge management processes, they also used EDM systems, file sharing systems and a data warehouse. In their opinion, these technologies contributed to facilitating access to information, increasing work efficiency and better use of available knowledge.

The second (largest) group of respondents used less advanced methods of knowledge management. These were people less familiar with the procedures, tools and modern technologies supporting knowledge management. Respondents from this group stated that they had only used basic knowledge management tools so far, such as shared folders, e-mail or teleconferencing. In their work, they did not use AI methods or data mining, and only one of them used EDM or a data warehouse. Despite this, they were aware of the potential benefits of using modern technologies, the practical use of which in their banks was limited. One of the representatives of this group seemed to be aware of the benefits of using advanced methods such as AI and data mining, but had not had the opportunity to use them in his daily work. However, another respondent from this group was not aware of the existence of these methods. One more respondent used knowledge related to experience and training, and another used expert knowledge as part of solving technical problems.

It was also possible to distinguish a third group that answered the questions in a short and somewhat enigmatic way. While this group claimed to have used various tools, its members were unable to provide particular information. They pointed out that the transfer of knowledge is an individual matter and depends on specific people. At the same time, they were aware of factors influencing the quality of knowledge management, such as organizational culture, IT systems or business environment. The responses from this group indicated that knowledge management was, in their opinion, still in its early stages of development. They used tools such as SharePoint, but at the same time indicated that access to knowledge and information was still limited and depended on individual employees who had the necessary knowledge. Respondents from the third group pointed to the lack of formal knowledge exchange systems and the lack of dedicated tools that could facilitate knowledge management practices in projects. In their answers, the respondents also emphasized the importance of organizational culture and a good climate for cooperation and knowledge sharing. This group included answers indicating the lack of implemented solutions for knowledge management and data processing in their strategic R&D projects. In addition, their answers showed incomplete awareness of the benefits of implementing knowledge management tools, such as EDM and data warehouses.

The answers obtained as part of the study indicate the selective use of practices and opportunities resulting from the use of modern technologies in knowledge management in strategic R&D projects. In some cases, this may be due to a lack of awareness or lack of access to the right tools. In other banks, there are restrictions related to the policies of the organization and specifically understood legal regulations. In order to improve the efficiency of knowledge management in projects, it is worth investing in training for employees and the implementation of modern tools and technologies. Efforts should also be made to improve internal communication and develop modern forms of organizational culture based on sharing knowledge and improving cooperation.

The answers of the respondents suggest that in most cases actions were taken to support knowledge management in strategic R&D projects. All respondents used tools supporting team work, although not all of

them used EDM systems or data warehouses. The answers obtained show that the issues of AI and data mining are not yet well known, accepted and used in practice. This is despite the extensive literature on many applications of AI in knowledge management (Pai *et al.*, 2022).

The most frequently mentioned benefits of knowledge management in projects included better coordination and cooperation of teams, better communication, more effective use of knowledge resources, as well as faster decision-making related to project planning and implementation. Respondents also mentioned challenges that were important to them, such as too many documents, the problem with finding and organizing them, and difficulties in keeping knowledge up-to-date.

A group of respondents was identified as less advanced in the use of knowledge management methods, because the answers were 'I don't know' and 'I don't use'. Representatives of other groups were more advanced and aware of the benefits of using different knowledge management methods in strategic R&D projects.

One should also pay attention to some similarities among many respondents' answers. In general, they were aware of the benefits of using tools supporting knowledge management, such as EDM systems or data warehouses, but at the same time some did not use them in their work or used them only in some projects. The approach of the respondents to the exchange of knowledge between employees was also similar. All interlocutors were aware of its importance, but they did not always use dedicated tools to facilitate these exchanges. A common element was also the lack of formalization of processes related to knowledge management and the lack of designated persons or teams responsible for this field. Respondents were aware of the need for knowledge management in strategic R&D projects, but often did not take specific actions in this regard.

Interviews with respondents focused on the initial identification of knowledge management practices in R&D strategic projects undertaken by banks. The possibility of continuing further research on the impact of the use of advanced knowledge management methods and tools on such project outcomes should be considered.

5. Conclusions

Based on the performed study, the following conclusions can be drawn:

- knowledge management tools and methods are quite well known and mostly recognized by respondents, but their use in organizations varies,
- knowledge management tools and methods are considered useful and can bring benefits at work,
- tools and methods of AI and data mining are used only in individual cases,
- EDM systems are used in most organizations and are considered beneficial,
- the use of data warehouses is incidental,
- the main challenges in knowledge management in strategic R&D projects are large data sets and problems with their search and categorization,
- tools and methods of knowledge management in projects can contribute to improving the efficiency of work and the quality of implemented projects,
- appropriate training on knowledge management tools and methods is important so that employees have the necessary skills to use them,
- there is a need for greater use of good practices, tools and methods of knowledge management in strategic R&D projects and organizations. Staff training is necessary to raise awareness in this field and make better use of the relevant tools, practices and methodological approaches.

As a result of the conducted research, the need to broaden the knowledge and experience of bank employees and managers of projects implemented there on the real benefits of applying good and well-thought-out knowledge management practices in strategic R&D projects was identified. It is therefore necessary to develop training programs related to this as appropriately qualified employees can significantly contribute to the implementation of banks' strategic goals and create conditions for their competitiveness. Allocating more funds to employee training may therefore contribute to the growth of banks' long-term strategic potential. In particular, it is important to improve the qualifications of employees in the effective use of new ICT and AI solutions supporting knowledge management in projects. The currently undertaken research is preliminary and needs to be continued among a wider group of respondents from a larger number of banks.

University-Industry Technology Transfer and Coproduction: A Case Study

Fernanda Guimarães, Roberto Carlos dos Santos Pacheco, Mônica Ramos Carneiro and Fernando Alvaro Ostuni Gauthier

Abstract: Universities can promote entrepreneurship and innovation both by training professionals and by offering knowledge resulting from their research. Traditionally, industrial development has benefited from technology transfer (TT) from universities. Although the TT is very known and used, co-ownership and economic exploitation after a TT process remain a challenge to formal University-Industry agreements. In this study we discuss the notion of university-industry coproduction as a means to address formal agreement after TT. The case study is a Brazilian national Program, called CEURS - "Training and Studies for Urban and Regional Sustainability". The main goal of CEURS is to provide practical training to individuals and teams on sustainability matters, focused on how to fulfill the UN's SDG 2030 Agenda locally (i.e., how to empower projects that are already at the community level so that they can become city programs). To do so, CEURS project was led by an academic network, sponsored by national government agencies. The project was developed at the Federal University of Santa Catarina (UFSC) by academics and students of the Graduate Program in Engineering and Knowledge Management, from the research group on Co-production in Digital Commons, in Brazil. CEURS team has developed *CEURS Platform*, a digital education platform, currently in the process of being publicly transferred to be augmented and operated at a national level. In this article, we analyze the institutional technology transfer agreements available to CEURS regarding the need to meet project demands for technology licensing, technology transfer, open innovation, and joint patents. We offer a critical analysis of a current regulatory process in technology transfer in an academic project that combines education, development, and social demand fulfillment. We conclude that a technology transfer licensing agreement can include principles that may fulfill CEURS project needs for nationalization through university-industry co-production. This study contributes to academics, innovation offices, policymakers, and university managers in formulating diligent and fast processes and strategies through technology transfers.

Keywords: University-Company, Technology transfer, Knowledge transfer, Coproduction, Innovation, CEURS Platform

1. Introduction

University-Industry relationship is an engine for the emergence of innovations and new technologies, given that researchers and professionals from different areas interact (Santana and Porto, 2009), benefiting both by complementing knowledge, skills and resources (Santoro and Betts, 2002). Universities learn from the entrepreneurial commercial vocation and companies take advantage of the university structure and qualified labor, thus reducing their research costs (Closs and Ferreira, 2012).

Traditionally, these relationships include Technology Transfer (TT), with legal instruments designed to formalize the university as the licensor and the industry as the licensee of the created technology. In this view, Universities offer to partners knowledge and/or technologies produced by their academics, to be used directly or as components of goods and/or services to the market. Besides promoting economic growth and local/regional competitiveness, universities hope that TT projects can create opportunities not only to support their economic sustainability (royalties), but also to improve their training processes.

When the project involves co-production between the university and industrial partners, factors such as co-ownership and exploitation of results challenge the terms of TT agreements.

In this paper we study the CEURS project - a program funded by federal funds and designed by an academic network to be applied nationwide through a digital education platform. We check specifically for the regulatory mark available to make CEURS a future industry-collaboration, as initially presumed by its authors.

2. Technology Transfer

Technology Transfer (TT) is the process by which organizations or individuals transfer information, knowledge, technology, or innovation to partner individuals or organizations (Parker and Zilberman, 1993; Roessner and Bean, 1991). It can be a highly complex process, as it involves transferring tacit, explicit, and operational knowledge, and not just the technology itself and its supporting mechanisms (Souza, 2010).

In this core, universities with traditional precepts of teaching and research, move towards a third mission, associated with has been called “entrepreneurial universities” (Asheim, Smith and Oughton, 2011; Klofsten et al, 2019; Autio et al, 2014).

In this new vision, universities act towards social and economic development (D'Este and Patel, 2007; Klofsten et al, 2019; Mendoza and Sanchez, 2018; Bercovitz and Feldmann, 2006), committing to the local community and regional and adding value to the environment in which they operate (Khan et al, 2020).

Universities for standing out in qualified human capital (Romero, Ferreira and Fernandes, 2020), in the production, dissemination, implementation of knowledge, innovation (Bercovitz and Feldmann, 2006; Santos, Veloso and Urze, 2021; Khan et al, 2020), have long collaborated with other organizations on technological advances. These collaborations have intensified in recent years due to the development of new technological platforms (Bercovitz and Feldmann, 2006), the need for funding sources and government policies for academic research (Bercovitz and Feldmann, 2006; Romero, Ferreira and Fernandes, 2020).

Thus, TT has been expanded to University Technology Transfer (UTT) referring to the process in which universities transfer and commercialize knowledge resulting from their scientific discoveries and technological innovations to the market (Li and Tang, 2021). Bercovitz and Feldmann (2006) summarize that UTT is the commercialization of university research through transactions between university and company.

Given the importance of these relationships in knowledge production, innovation and sustainable social development, national and local governments have dedicated budgets, incentives, subsidies and infrastructure for innovation. UTT has been one of these instruments (Gonzalez-Pernía, Kuechle and Pena-Legazkue, 2013), where both actors, universities and firms seek competitive advantage (Li and Tang, 2021).

More recently, universities have been demanded by public agencies to not only foster academic multi and interdisciplinary research networks in scientific projects, but also to promote transdisciplinarity by enrolling social players into research, development and innovation projects. This can be seen by current interest in investigating University-Industry (UI) coauthorship (Kohus, Baracskai and Czako, 2020), UI joint patents (Petruzzelli and Murgia, 2020), and UI open innovation (Neves, Costa and Reis, 2021).

The combination between scientific and practical knowledge performed by academic-industry teams changes the traditional roles that universities and firms play in innovation projects.

2.1 UTT and the Brazilian Innovation System

In Brazil, TT is directy addressed by the 1988 Magna Carta. The Federal Constitution provides that the State shall promote and encourage scientific development, research, scientific and technological training and innovation, with a view to the public good, the progress of science, technology and innovation and technological research aimed at solving the Brazilian problems and for the development of the national and regional productive system (Brasil. *Constituição da República Federativa do Brasil de 1988*)

The first regulatory instrument for innovation was the Innovation Law of 2004 (Law No. 10.973 - 2004). This Law offers to the Brazilian State and universities means to foster innovation, research and scientific and technological training, including cooperation and interaction between the public and private sectors and between companies (Brasil. *Lei nº 10.973, de 2 de dezembro de 2004*).

After a decade, the law has evolved into the National Science, Technology and Innovation Code (Law No. 13.243 - 2016), with incentives for scientific development, research, scientific and technological training and innovation. In 2018 this National Code was regulated by the Decree No. 9.283, that established measures to encourage innovation and scientific and technological research in the productive environment, aiming at technological capacity building, achieving technological autonomy, and developing the national and regional productive system (Brasil. *Decreto nº 9.283, de 7 de fevereiro de 2018*).

In 2020, Brazil created its National Innovation Policy (Decree No. 10.534). With the aim of increasing the country's competitiveness and, foremost, improving the population's quality of life, this decree establishes measures to foster research and development, protect intellectual property, encourage collaboration between companies, universities, and research institutions, and other actions to promote innovation (Brasil. *Decreto nº 10.534 de 28 de outubro de 2020*).

In all four regulatory instruments, cooperation projects among universities, companies, and private research and development non-profit entities, have been considered strategic to generate new products, processes and innovative services and the transfer and dissemination of technology.

At the operational level, university-industry projects can be formalized by the following ways: (1) *Technology Licensing* (TL) - an agreement in which the university grants a company the right to use a technology developed in its laboratories in exchange for payment of royalties or other forms of remuneration; (2) *Technology Transfer* (TT) - a process by which a university transfers knowledge and technology to a company, which can involve the creation of spin-offs (companies that emerge from academic research) or strategic partnerships between the university and the company; (3) *Open Innovation Projects* (OI) - collaborative projects between companies and universities, in which both parties contribute knowledge and resources to the development of new technologies or products; (4) *Joint Patents* (JP) - patents resulting from joint research and development projects between universities and companies, in which both parties share the intellectual property and the economic benefits arising from the developed technology.

In the following section we study a recent Brazilian case of technology development fostered by the federal government and that is currently in its phase of choosing one or more of these approaches to go nationally.

3. CEURS Program

CEURS is a portuguese acronym for “Urban and Regional Training and Studies for Sustainability”. This program is funded by Brazilian federal agencies (both National Parliament and Science, Technology and Innovation Ministry) and developed by an academic network to develop courses to empower public officials and civil society organization collaborators in cities on how to localize the Sustainable Development Goals (SDGs) of the 2030 Agenda.

CEURS has been developed at Universidade Federal de Santa Catarina (UFSC), by academics of the Graduate Program in Engineering and Knowledge Management (PPGEGC), from the research group of Digital Commons Coproduction (DCC). In order to achieve CEURS national capacitation goal, the group has developed “CEURS Platform”, a digital education platform designed by DCC members with the support of suppliers, with several technological and pedagogical components to apply Neo-learning methodology (Bresolin, Freire and Pacheco, 2021).

To offer its courses, CEURS Platform has learning objects, content and videos designed under the Neo-learning methodology. These components are accessed through a Virtual Learning Environment (VLE) developed in Moodle. There are also complementary information systems that support CEURS courses learning trajectories. In addition to the "CEURS" brand, the technological components of CEURS Platform have been registered at the National Institute of Industrial Property (INPI). Contents such as the eBook "Introduction to the Municipalization of the 2030 Agenda" (Pacheco and Carneiro, 2020), are also part of the CEURS Platform.

Therefore, in relation to the ownership of the technology presented, the CEURS Platform has copyright for each type of component and is the intellectual property of UFSC. This implies recognizing and explaining the intellectual authors in the technical sheets of books, learning objects, videos and information systems created to compose the Platform. Intellectual property is institutional to UFSC, respecting the respective clauses of use and communication of each contract signed under the CEURS Program.

Since October 2021 CEURS courses have been offered to city employees and social organization collaborators, mainly from Santa Catarina State. Using its national academic network, one of the main goals of CEURS project is to take its courses to the other Brazilian States. In order to do so, CEURS Platform has to be transferred and improved to support thousands of students. This challenge is a typical coproduction project where University intends to invite private partners to adopt and improve its initial technology. In the following section we examine the TT and U-I coproduction options, considering current Brazilian Innovation regulatory mark and its potential impact to CEURS goals.

4. CEURS Platform Licensing as a UTT Process

CEURS Platform is the main technological result of CEURS project. It was developed to not only deliver the current courses offered mainly in Santa Catarina state, but also to foster CEURS regionalization in all other Brazilian states. In order to do so, CEURS Platform has to be expanded with more scalability capacity, on-demand support, with a technological evolution plan to instrumentalize digital training on a national scale.

To provide this evolution, DCC research group and UFSC Innovation Department (SINOVA) are preparing a CEURS Platform licensing process. The goal is to enable the use, operation, development and evolution of the training instrument created for the CEURS, taking the Program incrementally to other Brazilian States.

In the following sections we describe how CEURS program was designed as a multi-institutional program, the regulatory references applied to CEURS Platform licensing, and the licensing term that is currently being developed to fulfill CEURS Program goals.

4.1 CEURS Multi-Institutional Cooperation Agreements

CEURS Program was designed to establish a network of academic and governmental organizations to enable its courses and offer them with technological tools to city halls, city councils, and citizens of Brazilian cities. To this end, UFSC signed a series of agreements with academic and research organizations, understood as disseminators of the CEURS Program and potential leaders of its regionalization projects.

As can be seen in Table 1, CEURS has been funded by the federal government (both Parliament and MCTI), developed by a leading university (UFSC), in cooperation with university partners in other states (currently USP and UTFPR). At UFSC, there is a founding contract with FAPEU that allows the management of scholarships and contracts with third parties, necessary for the completion of services in CEURS.

Table 1: Institutional CEURS Players

Player	Sector	CEURS responsibility
Federal Parliament	Government	Federal deputies offer parliamentary amendments to CEURS, submitted to MCTI with the indication of the beneficiary university.
MCTI	Government	MCTI receives the parliamentary amendments and, through a Decentralized Execution Agreement (TED), transfers the funds to the University to carry out the project.
UFSC	Academy	Leads the research and development process of the CEURS project, including the creation of the CEURS technology, offering courses to Brazilian cities, as well as coproduction and knowledge transfer to partner academic groups.
FAPEU	University Foundation	Manages the CEURS project and the contracts with individual and business suppliers to CEURS technologies
USP	Academy	Coproduction of videos and workshops in CEURS, as well as regionalization of the Program in the State of São Paulo, expanding the model of evolution and application of its courses.
UTFPR	Academy	CEURS regionalization in the state of Paraná, with participation in its evolution and dissemination.
Instituto Stela	R&D institute	Through the UFSC-Stela agreement, it provided infrastructure for the project development during the pandemic and has been carrying out an agreement for the dissemination of the Program with partner organizations.
SEBRAE-SC	Business	Provides infrastructure for CEURS online workshops and has been promoting the program to cities in Santa Catarina.
FECAM	Government	The Federation of Municipalities of Santa Catarina promotes CEURS to city halls, as a reference for training in sustainable urban development.
FAPESC	Government	Santa Catarina State Foundation for Science, Technology and Innovation Support that funds the project of creating educational games in the CEURS Program.

In addition to the relationships between the federal government and universities, CEURS has been supported by partner organizations that have offered technological infrastructure (Instituto Stela), technologies and spaces for course transmission (SEBRAE-SC), and dissemination to municipalities and cities in Santa Catarina (FECAM and SEBRAE-SC).

Recently, in 2022, a research contract was signed with the Support Foundation for Scientific and Technological Research of the State of Santa Catarina - FAPESC, through a competitive research funding process, in which the CEURS Team proposed the development of recreational games for the dissemination of the 2030 Agenda.

In sum, CEURS has been developed based on a series of cooperation agreements. These formal partnerships have been fulfilled for specific purposes through a project and work plans (Portella and Sabença, 2019).

After three years of research, development, communication and application in Santa Catarina State, CEURS project has reached its moment to go national. In the CEURS regionalization UFSC will no longer be solely responsible for the instrumental technology of digital training. It is expected to have the adhesion of the other universities partners, and, particularly regarding CEURS Platform, it is expected that the course services and technology evolution can be provided by a responsible and experienced organization. On the economic level, it is also intended that the transfer of technology generates financial resources to be applied in the evolution of research in the CEURS Program, in its continuity in the national network that is planned to be formed from its regionalization.

4.2 Instrumentalization of CEURS Technology Transfer

At UFSC, the CEURS platform licensing process is subject to the recently approved University's Innovation and Entrepreneurship Policy - UFSC IE-Policy (Universidade Federal de Santa Catarina, 2022). Respecting the national innovation regulatory framework, UFSC IE-Policy encourages innovation and entrepreneurship in the activities of research groups at the University. The IE-Policy provides guidelines for UFSC to offer technological training, promote technological autonomy, and cooperation with the country's innovation systems and from abroad. The Policy recognizes innovation and entrepreneurship as instruments for social inclusion and development of the regional and national productive system.

At CEURS project, these innovation principles will be applied to the CEURS Platform licensing process. A licensing agreement is a formal contract that enables the use and exploitation by a company of a technology produced at the university, without transferring ownership of the technology (Agência Unesp de Inovação, 2020; González-Pernia, Kuechle and Peña- Legazkue, 2013).

In order to make CEURS Platform licensing agreement, the DCC research group contacted Sinova/UFSC to request a *public call* for licensing. A public call is an administrative procedure established by law for selecting the most advantageous proposal for the public administration and guaranteeing compliance with the principles of public administration, especially the principles of impersonality and publicity (Brasil. *Lei nº 13.019, de 31 de julho de 2014*; Portella and Sabença, 2019).

In Table 2 we present the main CEURS Platform licensing regulatory terms presented by DCC research group to Sinova/UFSC, in order to elaborate the public call.

Table 2: CEURS Public Call Instrument

Public Call Element	CEURS expectation
Object	Enabling the use, operation, development, evolution, production, commercial exploitation, provision of services, or obtaining of economic advantage within the scope of CEURS Platform, owned by UFSC.
Target Audience	Public or private organizations with proven competence and history in the conception, development, implementation, and evolution of digital platforms may participate in this selection process.
Objectives	To ensure equal opportunities for organizations interested in promoting the CEURS Program by licensing CEURS Platform. To enable the regionalization of the CEURS Program in Brazil

Public Call Element	CEURS expectation
	To find an organization with technical-scientific capacity to offer and evolve the Platform, in order to meet the emerging demands of the CEURS Program regionalization process.
Legal Basis	Law No. 10.973/2004, which establishes the obligation to publish a summary of technological offers on the official website of the ICT for exclusive contracting situations, guaranteeing the constitutional command of the principle of publicity. As applicable, additionally: Decree No. 9.283/18; Law No. 13.243/2016; Law No. 9.279/1996; Law No. 9.784/1999; Law No. 9.279; Law No. 9.609; and Law No. 14.133/2021.
Licensing Mode	1 - Exclusivity of the license of the CEURS® Platform. 2 - Eventual sublicensing subject to UFSC authorization. 3 - Provision for corrective and evolutionary CEURS Platform maintenance. 4 - Economic compensation (royalties) when licensing under contract. 5 - Costs of maintenance or creation of new intellectual property registrations to be defined in complementary projects. 6 - The term of the license will be 10 (ten) years.
Intellectual Proprietary Rights	1 - Acknowledgement that the UFSC is the exclusive owner of CEURS Platform. 2 - This license does not imply ownership transfer.

As it can be seen in Table 2, CEURS Platform licensing public call has the following principles:

- *Exclusivity*: as CEURS will be taken to different states and CEURS Platform will need to be not only maintained but also improved, a single partnership reduces the complexity of management and governance of the technological offer of the CEURS Program.
- *Previous experience:* the organization partner has to have competence and a proven track record in the conception, development, implementation and evolution of digital platforms (i.e., e-government solutions for a broad target audience).
- *Academic Royalties:* the licensing has to bring economic compensation to the University, when CEURS Platform is used in a digital education project;
- *Sustainable business model:* it is required that the organization partner suggest a business model to foster CEURS that go beyond the current funds from federal Parliament, respecting national and institutional innovation regulation;

The principles of CEURS Platform licensing public aim to bring to CEURS project four ways of formalizing coproduction between university and industry: (1) *Technology Licensing* (TL) - the agreement allows UFSC grant to a company the right to use a technology developed in CEURS project in exchange for royalties; (2) *Technology Transfer* (TT) - CEURS team will transfer knowledge and technology to a company; (3) *Open Innovation Projects* (OI) - the licensing includes complementary projects that can be developed as a joint effort between university and the partner; (4) *Joint Patents* (JP) - these complementary projects are related to intellectual property rights to be discussed case by case.

5. Final Remarks

Technology transfer between university and industry has been an effective instrument to bring academic knowledge and products to market. Nevertheless, the complexity of digital society has demanded not only linear relationships but mainly a coproduction between university and industry. Regarding government, modern innovation systems have demanded new regulatory marks and the alignment between different public levels (federal, regional and municipal) decisions.

Academic research groups can meet the demand for university-industry co-production through innovation projects. However, technology transfer regulatory processes should not only focus on delivering results to the industry but also enable the elaboration and development of joint projects.

The case we have studied in this paper is a current challenge to CEURS research group: the only way they can take their project mission to all Brazilian cities is by multisectorial and multi-institutional coproduction. However, the regulatory mark has to include multiple government levels, academic network and open innovation with private companies has been a challenge. CEURS Platform licensing agreement is one of the UTT instruments that can help the university to take the project to other states. It is also a case to help university innovation policy to include multisectorial and multi-institutional coproduction factors in its regulatory mark.

Acknowledgements

These research has been possible due to the direct and indirect fund offered by CAPES, MCTI, Câmara Federal, UNIEDU, EGC/ UFSC.

Abstract: Knowledge sharing is an important process in knowledge management to foster collaboration. For its effective management, it is often suggested to use the support of adequate technologies. Virtual reality (VR) is a promising technology whose application in business increasingly attracts attention in activities, such as business meetings or training, where participants need to share knowledge in a complex context with communicational, social, and management implications. Due to the immersive capabilities, VR may provide new ways of sharing knowledge. However, due to the novelty of this technology, research is needed to evaluate its potential and drawbacks. This study aims to contribute to further understanding of whether and how the introduction of VR in organizations can favour knowledge sharing and collaboration between employees and to evaluate its potential, challenges, and prospects. It is based on a qualitative exercise of technology assessment based on two approaches: technology monitoring and collection of expert opinions using interviews with experts in organisations specialised in VR. Our analysis shows that VR has the potential to break barriers of time and space that may hinder effective human interactions. It can simplify the sharing of notions, data, and, more generally, knowledge, and allow people to connect and communicate as active protagonists. However, adopting VR may require organisational changes and has some limitations. In addition, appropriate knowledge-sharing models for VR applications still need to be developed. Consequently, our paper argues that although much is possible today with VR, further developments are still needed for this technology to reach complete maturity.

Keywords: Virtual reality, Knowledge sharing, Technology assessment

1. Introduction

Knowledge sharing (KS) is a primary process in Knowledge Management (Edwards, 2016) and key to fostering collaboration and knowledge creation. However, KS can be complicated (Liebowitz and Yan, 2004), and consequently, for effective knowledge sharing, it is often suggested to use the support of adequate technologies (Mueller et al., 2011; Newell et al., 2009). Virtual reality (VR) is a promising technology whose application in business increasingly attracts attention (Wohlgenannt et al., 2020), especially in situations like business meetings, where participants need to share knowledge in a complex context, which has communicational, social, and management implications (Standaert et al., 2021).

Virtual Reality (VR) provides users with a 3-dimensional, 360-degree computer-generated virtual environment (Kandaurova & Lee, 2019). VR can be seen as a knowledge-sharing support system due to the immersive capabilities offered to its users (Cambpell et al., 2019). However, due to the novelty of this technology, which has not yet reached its maturity in business, the application of VR for knowledge sharing still requires research to evaluate its potential and current drawbacks. Therefore, our study aims to understand whether and how the introduction of virtual reality in organizations can favour knowledge sharing and collaboration between employees and to evaluate its potential, challenges, and prospects. It is based on a qualitative exercise of technology assessment (Braun, 1998) based on two approaches: technology monitoring and a collection of expert opinions (Porter, 2011) using interviews of experts working in organizations specializing in VR.

Our study finds, on the one hand, that VR provides benefits as human interactions are supported despite differences in time and space. VR can simplify the data and knowledge sharing, as it allows people to connect and communicate as active protagonists in a virtual space. On the other hand, VR use requires organizational changes and has some limitations. Appropriate knowledge-sharing models for VR applications still need to be developed. Although VR provides new opportunities for KS, further developments are still needed to reach complete maturity in technical and organizational terms to enable successful knowledge sharing in the virtual world.

2. Methodology

This study is based on the technology assessment methodologies described in Porter (2011) and Braun (1998). In particular, it combines two approaches: Technology monitoring and Expert opinion. Technology monitoring consists of a systematic collection, from the specialized literature, of information about the technology and the analysis of its state-of-the-art (i.e., technical features, functioning, main components, and configurations), likely advancements, and future research directions, actual or potential business applications, and its implications for manufacturing and marketing. This process can be divided into steps which, in the case of our study, were defined as follows:

- Set objects and goals of the monitoring (in our case, an analysis of virtual reality, its applications to knowledge-sharing situations in business, its potential pros and cons, and its likely future)
- Select sources of information (mainly scientific journals and books, technical papers, and specialised websites)
- Collect documents and perform a systematic analysis
- Summarise information

The most critical issues are the selection of documents and the analysis of information. In our case, a cross-analysis was performed to seek confirmation between independent sources. The second point was that VR is not often explicitly considered a KS application. Therefore, it was necessary to derive information employing an analysis of its current applications, especially in activities (namely, business meetings and training) where VR can support KS.

The second approach - Expert opinion - is based on the assumption that experts who work in a field can have important elements and new perspectives, especially on the potential and problems of research and on the current applications of technology, information that may be difficult to find in the literature. The method is based on: a) a selection of one or more experts to consult; b) interviews or other methods of collection of information; c) recording, transcription, and data analysis; d) comparisons and synthesis. A problem with this method is that the experts can mix objective data with their personal opinions, so it may be important to contact more experts and conduct a cross-analysis of the collected information. In our case, we selected three technical experts of VR working in three different companies (one in Italy and two in Denmark). Interviews with these experts were conducted based on a set of open questions regarding a) the possible business applications of VR; b) the potential for knowledge sharing in organizations; c) the possible barriers to adoption; d) the impact on humans; and e) the prospects of this technology. Specifically, in the questions, the interviewees were asked to confirm or discuss the main points learned through technology monitoring. The collection of information was conducted in the second half of 2022.

In short, the collection and analysis of data were conducted by adopting the model described in figure 1. First, a technology monitoring was conducted to collect and analyse the available documentary data about the current configurations of the technology, the prospective business applications, the possible trends of market and research, the possible issues and practical problems, etc. This analysis was especially conducted with reference to the application of VR for knowledge sharing, by using the definitions and notions derived from the KM literature. After that, expert opinions were conducted to seek confirmation of what was found in the literature and documentary sources. A set of questions to guide expert interviews were defined, and an analysis of the expert views was conducted.

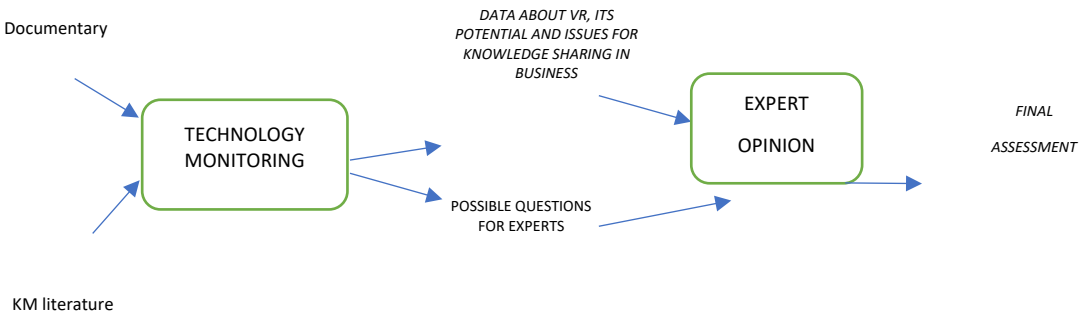

Figure 1: Analytical Framework

Regarding how the analysis was conducted, some further clarifications can be added. The preliminary analysis of the technology by means of the monitoring analysis revealed that VR is a very wide area that includes several applications in different contexts. Being apparent that its use and the specific technical configurations that are implemented can be different and context-dependant, the analysis then focused more specifically on the most promising application areas for business and, especially, those where knowledge sharing processes can be more impacted. As will be illustrated below, the application areas where the use of VR was investigated are internal business training and internal meetings.

In the following sections, we summarise the main findings of Technology monitoring that mainly focused on a description of the technology and its potential for KS (sections 3 and 4), and later of Expert opinion, which primarily focused on business applications, to find confirmation about pros and cons of VR (section 5) as derived from technology monitoring. Section 5 compares the results obtained by the technology monitoring analysis with the information collected from experts.

3. Virtual Reality: State of the art and Prospects

In this section, we describe the state-of-the-art and prospects of VR. We will also frame the notion of VR in the broader picture of the so-called "immersive technologies".

Technologies that allow to extend or create an environment with a high degree of involvement, thanks to a greater sensory isolation, are named immersive virtual reality. This immersive environment is created through interactive interfaces, which reduce the boundary between the physical world and the virtual environment, thus generating a multisensory virtual experience for the user.

This experience can be achieved using different devices, some of which make it possible to extend the physical space by adding virtual elements. Other kinds of technologies transfer the user to another environment with a fully immersive experience that allows forgetting about the physical and material environment in which the user is physically located. Here the concepts of VR and Mixed Reality (MR) emerge. These technologically advanced realities are identified with the all-encompassing term of extended reality (XR) that, according to Fast-Berglund et al. (2018), "refers to all real and virtual combined environments and human-machine interactions generated by computer technology and wearables".

The concepts of AR (Augmented Reality) and AV (Augmented virtuality) are positioned in the middle between the completely real and completely virtual environments. All technologies that "allow the overlay, in real-time, of images, markers or information generated virtually, on images of the real world" are identified under the term AR (Telefónica Fundación, 2011). On the other hand, the term Augmented Virtuality (AV) is less used. According to Valente et al. (2016) it consists "of a virtual world augmented with the mapping of an image or video from the real world in virtual objects".

The two terms combined fall into the broader concept of Mixed Reality (MR), the environment where the physical world and elements of the virtual context are displayed together on a single screen. Therefore, it is appropriate to refer to AR and AV as technologies that offer the opportunity to enhance the real environment with virtual information and elements.

The focus of our study is especially on VR, whose special and distinctive characteristic is that it creates a totally virtual space where the user is completely immersed and that is accessible only through the use of a special headset and, if necessary and possible, other sensorial applications (e.g., gloves) and a high-performance software (Wohlgenannt et al., 2020). Although there is sometimes a variegated use of the adjective “immersive”, in this study we will use the term VR to specifically consider those applications that engage the user in a total or almost total sensorial experience. In these terms, VR represents a more “immersive” technology compared to other categories like AR or AV applications. To perform effective immersive simulations, the headset becomes one of the critical elements of a VR system. A basic version of a technology tool like the head-mounted display (HMD) was already introduced in the 1960s, but several barriers limited its adoption. In recent years, the devices have become more affordable and performant, and VR has been again put at the center of attention. Its market is growing especially in the areas of entertainment and gaming. Still, there are now many other sectors of employment, with a wide variety of applications, for instance, healthcare, education, or tourism (Wohlgenannt et al., 2020).

VR is therefore seen as a medium in which users are involved with their entire body and respond to perceptions of that environment as if they were real. A computer feeds a digital description of an environment, and several visual, tactile, and auditory equipment provide a high level of realism and, consequently, immersion. The

tracking tools used for virtual experience ensure that the displayed images are updated according to the orientation of the head and possibly other body parts with respect to the synthetic environment. The quality of a virtual reality experience, defined as a medium, depends on how the user perceives the virtual world.

In the virtual experience, the user's perception of the digital environment is fundamental. For this reason, sensory displays or VR system output instruments are essential because they stimulate the human senses. These devices feature different characteristics and, in particular, are classified as visual, haptic, and aural displays. The input devices control movements and actions performed by the user and monitor them during the virtual world experience. This allows the participant to be immersed in that environment and to interact with the digital simulations. In addition, user monitoring makes rendering activity possible.

The user can send information to the system both actively and passively. The active method requires physical tools such as keyboards or joysticks that are activated by the user's action; on the other hand, passive inputs include body and position control tasks detected by the monitoring system. There is also the possibility of carrying out a worldwide monitoring where the information of the physical environment mixes with the virtual one, for example, data from meteorological stations.

The performance of the technical system is critical. For the users to perceive that they are totally immersed in a virtual environment, the interaction with their sensorial system must be effective. Telepresence is defined as "the experience of presence in an environment by means of a medium" (Steuer, 1992). As shown in figure 2, to ensure that, the technology must have high performance as regards both the vivid reproduction of the simulated environment and the interactivity of the users with the digital objects.

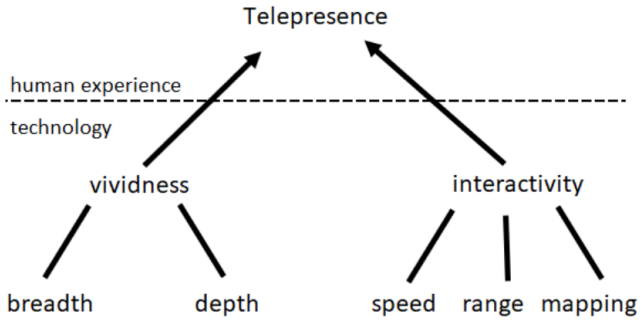

Figure 2: Dimensions of Effective Telepresence (Adapted from Steuer, 1992)

In a VR system, the most relevant tracking device is the position sensor that detects the user's orientation in the digital world through head and hand tracking. In position sensors, three basic parameters are to consider: the speed and accuracy of the detected orientation, the footprint, and the interfering means. Finding systems that ensure optimal conditions in each feature is difficult, so designers must seek compromises based on using the virtual system. Another critical device is the head-mounted display. Although the recent versions of this device are lighter and more comfortable than in the past, these objects are still bulky and have some limitations.

4. Knowledge Sharing and VR Applications

In this section, we summarize the technology monitoring results explicitly focused on using virtual reality for Knowledge sharing. KS is one of the most important processes in knowledge management, and this term is one of the most cited in the literature (Bolisani and Scarso, 2019). In general terms, it can be defined as the activities by which two or more people share a piece of knowledge with or without the support of information technology. Actually, it can involve a combination of different processes: an exchange or transfer of pieces of knowledge and information from someone to someone else, a process by which elements of knowledge become available and easily usable to all interested people in an organization, a process of mutual learning by all parties involved where people learn together and learn from one another, a process of creation and use of a common language and reference so that people can more easily, interact and communicate, etc. Therefore, it is different from a pure “knowledge transfer” (Edwards, 2016), where one person simply provides a piece of knowledge to somebody else, for example, through a document: sharing involves more active participation of both “giver” and “taker” and, actually, the “giver” of knowledge also receives feedback from the “taker” and, in turn, learns from this interaction. In addition, KS necessarily involves human beings and is, therefore, influenced by their attitude to interact, disclose their knowledge, be open to others, change their perspectives, etc. In other words, KS is

substantially a social process and a way for the organization to learn collectively (Cantamessa and Montagna, 2016).

The KM literature has underlined that several factors influence it. The first is a "technical" dimension. Following Nonaka and Tageuchi's (1996) model of knowledge conversion, to effectively share knowledge contents a proper conversion between their formats is needed. Therefore, every single case may require different modalities of conversion. A second important dimension is related to the social context (Asrar-ul-Haq and Anwar, 2016), which is influenced both by the personal attitudes of individuals and by the organizational settings. An important factor is mutual trust between knowledge sharers, which may affect the willingness to share knowledge and also the effectiveness of the process. Culture - i.e., the set of values of individuals in the context where knowledge sharing occurs - can also influence KS and can stimulate or reduce the motivation of individuals. Culture is related to people, but an organization can favour open-mindedness towards different positions and viewpoints, facilitating KS. Finally, the active presence of a "leader" or facilitator of KS can also be an important support.

The KM literature has often studied the technologies that can support KM and KS (Mueller et al., 2011; Newell et al. 2009), and attempts have been made to assess the effectiveness of different technology supports. The literature especially emphasizes two applications where VR can be particularly important in relation to KS: meetings and training. Meetings are a common method used in companies for several purposes and are especially important when there is something to discuss or to decide.

In meetings, people need to share elements of knowledge and, possibly, should actively participate with their contribution to the creation of "collective" knowledge in the group. The objectives of a business meeting can be multiple (Griffin, 2020; Standaert et al., 2021) and include not only exchanging information and making decisions but also communicating sentiments or building relationships, which recalls psychological aspects.

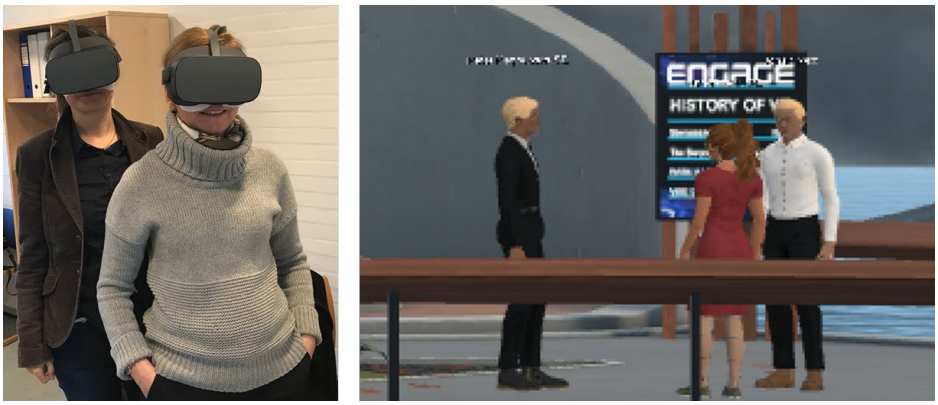

Figure 3: Wearing Head-Mounted Displays (Left) to Meet Colleagues in VR for Knowledge Sharing (Right)

Information and communication technologies can support these more or less effectively. Campbell et al. (2019) discuss that VR functions can reproduce the context where meetings take place with all the sensorial effects so that participants can feel like they are in a face-to-face meeting, but at the same time, the burden of hierarchies and inequalities can be reduced by means of the use of avatars that encourage participants to express their opinions more freely (Fromm, 2020). For example, in a brainstorming meeting, VR could lead to higher and more active participation. In a social event facilitated by VR, participants as avatars walk around freely in the virtual space and share knowledge with others (Figure 3) - which they may feel to be more lively and interactive than video conferences (Kirchner and Nordin Forsberg, 2021).

In training, knowledge must not simply pass from instructors to learners because the latter must be actively involved in the learning process to construct their own knowledge, and the former must take into account the feedback coming from learners and must adapt to their needs; in short, there is a sharing of knowledge. Some studies claim that the use of VR can have several benefits (Xie et al., 2021) and especially, due to high cost or complexity, training in a physical environment would be difficult (Martirosov and Kopeček, 2021) and simulations of real-life cases can be more easily reproduced without risk. This can also result in a better understanding of the specific instructions whose knowledge trainers are sharing with learners with a high realism (Martirosov and Kopeček, 2017). The use of VR environments has some potential benefits. The first is to overcome the lack of qualified instructors: once a virtual environment is set up based on the directions of a skilled instructor, simulations can be run as many times as desired. This is a special form of KS between the instructor (that sets up the VR simulation) and the current and future trainees (that will use it).

The second potential benefit is that a deep immersion of trainees is ensured, and they are therefore not easily distracted. In addition, VR training can lead to a real engagement of trainees even in emotional terms, which is useful, especially in simulated situations where emotions can influence problem-solving and decision-making processes (Martirosov and Kopeček, 2017). Finally, VR allows the creation of contexts where errors are tolerated, producing lower stress levels in trainees. Training can help new employees to feel more included in the workplace and become familiar with their new job and equipment as quickly as possible. Also, by observing the reactions of trainers in the VR environment, instructors can interact with learners in the simulated environment in real-time, and learn more about the training process, its effectiveness, and the problems that may arise.

The analysis of the available studies also made it possible to underline some of the main obstacles of VR for KS. Some are technical. Even though there have been important improvements in technical performance, VR devices still have limitations (Garret et al., 2018) especially because even a minimal imperfection in the VR simulation can reduce its usability and effectiveness and can have negative effects like motion sickness (Jalo et al., 2020). Another point is related to how much the user feels comfortable with this technology (Jalo et al., 2020). Although it may be argued that the young generations, more familiar with digitally simulated gaming, can easily accept this technology, likely, companies willing to use this technology must also provide training courses to employees.

Another key issue is the cost. Despite the decreasing cost, the investments needed for the technology are still significant, especially if many users are involved at the same time. The necessity of highly performant devices and graphic simulations and the related cost can still be a barrier to adoption (Garret et al., 2018)

5. Expert Opinion: Findings and Comparison with the Elements Found in Technology Monitoring

In this section, we summarise the results of the collection and analysis of expert opinions. The main purpose was to find confirmation regarding the points that had emerged in the technology monitoring analysis. We will refer to the three experts as A, B and C for anonymity reasons.

The experts were identified by contacting 3 companies selected through names reported in the "Welp Magazine" repository (see https://welpmagazine.com). For reasons of convenience, companies in Denmark and in Italy, among those most actively engaged in VR research and commercialization (but not merely on videogames), were selected based on their performance in terms of innovation, growth, social impact and management capabilities. After sending invitations to participate in the investigation, those which replied were finally selected, and namely two based in Denmark and one in Italy. In these companies, some key experts were identified and directly contacted for interviews, and namely: for the first company, the current CEO and founder who is an expert in developing "virtual worlds"; for the second company, a sales manager and expert in design, communications, and marketing projects; for the third company, a developer of customized VR solutions and expert in immersive audio and virtual productions. The selected experts have different roles in their companies; therefore they cover various aspects and perspectives on the investigated issues. A semi-structured interview was conducted where respondents were asked to provide information about: their company, its activity and products (to better frame and understand the information they provide); the current use of VR; their opinion about VR and its applications in business; their idea of VR as a tool for knowledge sharing; their opinion about how easy it can be for companies to implement and use of VR, the necessary training, and all the related issues; the current feedbacks and feelings they have regarding their market (i.e., other companies using VR and how they are experimenting and using it); their opinion about the current and future challenges of VR in business, related to technical, management, or market issues; the potential impact on humans; the expectations regarding future demand, and the business applications with more potential.

The interviews were conducted in person (for the Danish experts) or online (for the Italian expert) in the second semester of 2022. The collected answers were then analysed thoroughly by means of a discourse analysis, and the main aspects were compared with the information collected by means of the technology monitoring analysis.

5.1 Benefits of VR for KS

According to the information collected via technology monitoring, it is reported that VR, due to its media richness and synchronous functioning, can help to overcome some barriers that hinder KS. In addition, it can help favor knowledge transfer and an engaging learning experience. The experts confirmed these points at least partially.

The companies where the experts work as technology developers work, have their business in the development of immersive solutions, and VR consulting. However, the consulted experts admit that their organizations are not using VR in their own processes, as it is mainly used as a demonstration prototype for customers. They do confirm that, based on their experience, VR can bring many potential benefits especially due to the ability to provide the user with a realistic and emotional experience. Moreover, VR can reduce costs, time, and space barriers for KS activities requiring face-to-face meetings.

For example, as affirmed by A and B, VR allows recreating scenarios to play role games which is very effective in training, even reproducing dangerous situations, for instance, how to set a fire. This would be expensive and risky if performed physically, but VR, due to the immersive conditions, can effectively replicate decision-making under emotional stress and allow effective learning while avoiding risks. According to C, VR also makes it possible to overcome time barriers by presenting the users something that is not yet existing (for example, simulating interactions in a future situation) or even reducing some social challenges (e.g.: virtual experience can be proposed even to people with physical disabilities). In substance, VR can even extend the opportunities for KS in organizations.

5.2 Business Applications

The experts also confirm that VR's characteristics apply to different use cases and business fields. This is in line with recent reports affirming that thanks to the big investments by major companies, VR is finding more and more space (Wohlgenannt et al., 2020).

More specifically, regarding business meetings, the interviewed experts confirm that, more than other existing technologies, VR is effective in covering certain moments of human interactions, so it can be used for some parts of the collaboration process. An interesting point is made by expert A, who noticed that this can still be a conservative view - substantially, a mere transposition of traditional meetings to the virtual world. In other words, the real novelty of VR may emerge when new perspectives or modalities of KS will be implemented with the support of this technology.

Regarding training, according to expert A, there are a number of indicators that show that the use of immersive technologies has a high added value in learning. In fact, all experts confirm what was found in the technology monitoring analysis: immediate and lasting learning is favoured thanks to the learning-by-doing simulated method in an immersive environment, where users become protagonists of the actions, enabling them to familiarise themselves and improve their procedures and tasks. Training is, therefore, an elective field of introduction to VR, especially as regards learning about how to use products, production sites, and for safety instructions. In short, the interviews lead to expectations that VR will continue to significantly impact these business activities.

5.3 Limits and Problems

As analysed in the technology monitoring, there are some challenges to fully introducing VR in business. First, it was underlined that the companies could be held back by the economic expenditure required to purchase the devices. In addition, there may be costs associated with introducing VR related to required organizational changes. Firstly, virtual technologies must be adapted to internal systems. Although he considered VR to be an intuitive technology, Expert C admits that teaching employees how to use the technology properly may be necessary. Also, the complexity of headsets and the problem of motion sickness may not encourage their use. However, the experts pointed out that motion sickness is due to the insufficient quality of some headsets available in the market at a low cost. Probably, this problem will be reduced by improvements in performance.

The interviews also confirmed that some risks of digital technologies - e.g., privacy - are amplified in the virtual context; for example, the issue of fake news and false perceptions is amplified. Moreover, the experts also admitted that immersive technologies might affect users' emotions and psyches. This is still an unexplored area.

According to the experts, predicting what negative aspects can be improved and what limitations will not be easily overcome is difficult. However, there is a lot of research being carried out, and as was declared by experts A and B, over time, many problems with information technologies that were thought to be unresolvable have been overcome later, so the same can happen in the case of VR.

5.4 Future Expectations of Business Impact

The experts affirmed that the spread of VR can significantly impact how we work; and increased requests of working from home have already changed how we interact in business and normal life. This has further increased

the demand for collaborative virtual environments. Although, even for the experts, it is difficult to predict if and when the current limits of VR will be overcome, they all agree that the areas with the greatest potential for development and success are those of collaborative meetings and training.

6. Conclusion

Figure 4 summarises the analysis results and the main points regarding the potential benefits and current limits of VR, especially regarding knowledge sharing. The figure includes the points derived from the technology monitoring and later confirmed through expert interviews.

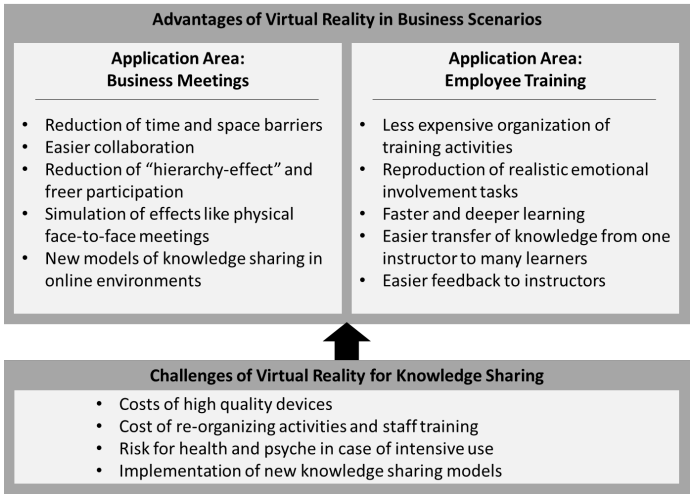

Figure 4: Advantages and Challenges of VR use for Knowledge Sharing in Business Activities

A general comment can be made on the real novelty of VR especially compared to other online communication tools. An important characteristic of VR is its capability to reproduce a context where participants can be involved emotionally and with all their senses. In other words, it is the closest possible reproduction of a real-life experience but in a simulated environment.

For this reason, knowledge sharing can be supported in entirely new ways compared to traditional technologies used in both meetings and training - such as, e.g., video conferencing. As is well known, knowledge sharing using human interactions can require, to be effective, a "total involvement" or sharers. Therefore, VR can be a really new approach.

It must, however, be noted that the technology still has some limitations, especially as regards its cost (at least, for high-quality devices), the organization of the activities (that can imply the adoption of new models for knowledge sharing), and the familiarity of use by the staff (which may be laggard to adopt the innovation). For this, there is still work to be done regarding technological advancements and managerial modifications. There is also an interesting implication for KM research: VR and immersive technologies can show new ways and processes of knowledge sharing and can need new interpretative models to understand how these processes can take place.

This study has some limitations. First, the approach used to collect and analyze data, although it was based on popular methods of technology assessment, is qualitative. Second, the selection of experts was subjective. A larger sample can be used, and other techniques (for example, a Delphi analysis) may be used. In any case, it is believed that the study still provides a preliminary picture of an important issue and can provide inspiration for further research.

Onboarding and Knowledge Sharing: Cases From the Netherlands and Norway

Hanne Haave[2], Pascale Peters[1, 2], Yasmina Khadir-Poggi[1] and Tone Vold[2]
[1]Nyenrode Business University, The Netherlands
[2]Inland Norway University of Applied Sciences, Norway

hanne.haave@inn.no
tone.vold@inn.no

Abstract: Whereas some organizations struggled and had to let staff due to the COVID-19 pandemic, others had to expand to keep their business running. In this case, new employees had to be onboarded remotely due to the governmental restrictions regarding physical appearance in the workplace. The newcomers needed interactions to learn about organizational rules and regulations (compliance) and develop personal mastery (Clarification). To adopt and internalize the organizational norms and values (culture) and to become part of the work community (connection) interactions with leaders and co-workers are important. In this paper, we focus on the onboarding process of newcomers during the COVID-19-pandemic and what we can learn from this after the COVID-19 pandemic. By building on Bauer's 6C framework for onboarding (compliance, clarification, culture, connection, confidence and checkback), we analyse the data from two countries: the Netherlands and Norway. Two main themes are elaborated from the study: uncertainty regarding the work to be done and sensemaking of the introductory courses and follow-ups. We discuss possible implications for a post-Covid onboarding processes. Our findings show that the newcomers experience uncertainty with little or no personal contact. At the same time, they claim that the e-learning is supporting their learning process and their introduction to the organization. The perception of information varies and some of the newcomers' experience solitude and the responsibility of actively seeking information is placed with them, whilst others perceive the team designated for their onboarding sufficient to becoming a full member of the organization.

Keywords: Onboarding, Knowledge sharing, Telework, Sensemaking, Uncertainty

1. Introduction

The onboarding of new staff is important to reduce the time they need to be fully operative, as this can reduce costs of unproductive time for the organization (Filstad, 2016). During the COVID-19 pandemic, most organizations had to send their workforce to a home office and any newcomers had to be onboarded without any opportunities to meet a future colleague. All introductions and trainings were online (with exception of going onsite to collect working equipment such as a laptop for example) (Haave, Kaloudis and Vold, 2023). The rest of the onboarding had to remain digital and online. The opportunities for socializing the organization could have provided through formal and informal practices and programs, were inexistent (Klein and Polin, 2012; Klein, Polin and Leigh Sutton, 2015), perhaps coming at the expense of a successful onboarding process and reducing newcomers intention to stay (Feldman, 1981; Taskin and Bridoux, 2010a, 2010b). An unsuccessful onboarding process may be very costly for organizations. Since the end of the pandemic, in a time called now the "New Normal" (Bergum, Peters and Vold, 2023), most organizations agreed with their employee to continue with the practice of working from home for few days a week.

Due to the absence of homeworkers from the office, opportunities for face-to-face interactions with new colleagues may be reduced. In this paper, we will look at the results from onboarding processes from two countries; The Netherlands and Norway. Our research question is thus:

What are the consequences of less face-to-face interaction during an onboarding process?

Based on the study of the evidence collected from these two countries, it can be said that the times of digital onboarding are more than likely to have an impact on onboarding processes within the "new normal". For example, what may be offered digitally in an onboarding process, and what is important to maintain in a face-to-face interaction in order to secure a successful onboarding?

In the following paragraphs, the first section introduces the theoretical background concerning the two themes of uncertainty and sensemaking. Second, we describe the data collection process and results from the study. The paper closes on a discussion and way forward.

2. Theoretical Foundation

Onboarding is about bringing newcomers to a state where they are able to do the work that they were hired to do using formal and informal practices and programs (Klein and Polin, 2012). It is about bringing an "outsider"

to participate with efficiency in the organization (Feldman, 1976, 1981). Hence, the onboarding process require knowledge sharing where the organization and designated members share their knowledge with the newcomers in order to make them participants in the organization.

Russo, Morandin and Manca (2023) claim that "the objectives of the onboarding process, regardless of its format, revolve around the reduction of initial uncertainty and time for productivity" (Russo, Morandin and Manca, 2023, p. 207). They further state that during the COVID-19 pandemic, there was a risk of social isolation leading to a slower learning process, and that trust became an issue (Russo, Morandin and Manca, 2023).

Socializing is about acquiring "asset of appropriate role behaviours", develop "work skills and abilities", and adjusting "to the work group's norms an values" (Feldman, 1981, p. 309). Feldman (1981) proposes a three-phase process; "anticipatory socialization" – the learning before the newcomer joins the organization, "encounter" – engages with the organization and get a clearer picture of values, skills, and attitudes, and "change and acquisition" – where the newcomers learn to master their work and adjust to their roles and adjust to the norms and values (Feldman, 1981). In this last phase, it is important to master the tasks and, through this, gain self-confidence and "attain consistently positive performance levels" (Feldman, 1981, p. 310). The outcome is "general satisfaction," "internal work motivation," and "job involvement" (Feldman, 1981, p. 311). This is also tied to performance evaluation. With positive evaluations, it is possible to enhance the performance and the opposite: negative evaluations may lead to loss of self-confidence. Also, newcomers contact other staff members to interpret experiences and to learn the different codes of conduct. General satisfaction encompasses role definition, handling role conflicts within the work groups and obtaining work life balance. Internal work motivation is connected to experiencing personal growth and a sense of meaningful work (Feldman, 1981). The social interaction (working in teams) support task mastery and thus job involvement (Feldman, 1981). Although onboarding is about newcomers, organizational socialization may embrace other members of the organization too (Haaland, 2019). Van Maanen and Schein (1979) claim that the newcomers will try to reduce their uncertainty and Berger's uncertainty reduction theory (1986) suggests that newcomers will use different channels and both peers and superiors to reduce uncertainty. Within this theory, sensemaking and seeking information are two important dimensions. Sensemaking is a key in newcomers' adjustment as it is about how they construct meaning from their work day (Weick, 1995; Weick and Sutcliffe, 2015). Klein and Heuser (2008) developed the Inform Welcome Guide (IWG) framework based on academics' and practitioners' reviews. Inform is about providing the newcomer with all necessary information needed prior to the entrance in the organization. This includes communication, resources, and training prior to entering the organization. Upon entering, the welcome includes meeting other members of the organization and here the social capital may be developed (Klein and Polin, 2012). In the "Guide"-part, one may be assigned a "buddy" or a mentor. Klein, Polin, and Sutton (2015) also touch upon self-determination theory (Ryan and Deci, 2017), mentioning the dispute about triggering intrinsic motivation when newcomers maximize the outcome of the training programs. Below, an overview of the IWG- framework is presented (Figure 1).

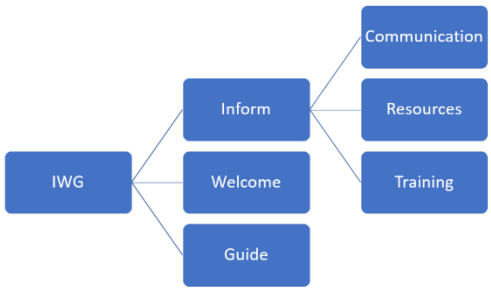

Figure 1: The IWG Framework

According to Bauer and Green (1998), managers also have an impact on newcomers' information seeking. If managers supported and clarified behaviours, the information seeking would be of less importance to the newcomer. Bauer (Preppio, 2022) developed a checklist for onboarding consisting of 6 C'; Compliance, Clarity, Culture, Connection, Confidence and Checkback, see table 1 below:

Table 1: Bauer's 6 C's

Compliance	Clarity	Culture	Connection	Confidence	Checkback
How the organization adapt for the newcomer to understand organizational knowledge regarding rules and routines	How the organization facilitate for the newcomer getting a clear idea about expectations and understanding of the job tasks	How the organization contribute towards the newcomer adapting to the organizational culture	How the organization facilitate for building the necessary connections and network in the organization	How the organization contribute towards the newcomers' personal mastery	How the organization keep track of the onboarding and feedback on the different facilitations – how they are adapted and how they work

In the 6 C model, there is a focus not only on understanding the job and environment but also on securing the "confidence" of the newcomer and making sure that the different initiatives in the onboarding process really work or whether they need to be adjusted (Preppio, 2022). In our case studies we have mainly utilized the first four of these C's.

3. Method of Inquiry

In this paper, we present the results from two different research studies: the "Millennials study" performed in the Netherlands and the "Onboarding under the pandemic-study" from Norway. Both studies aim to reveal how the participants experienced the onboarding process during the COVID-19 pandemic and had a qualitative approach, using semi-structured interviews. In the Dutch study, 14 informants were interviewed, all working in different organisations and recruited among the researchers' network (Table 2). The interviews were carried out both physically and online. In the Norwegian Onboarding-study, a total of six persons, all working in the same organisation were interviewed about their experiences with onboarding under the COVID-19 pandemic. The interviews were carried out digitally in November 2021.

Table 2: Overview of respondents

	Study from The Netherlands	Study from Norway
Informants	Interviewees nr. 1-14	Informants 1-6
Selection criteria	Ages 25-41 From different organisations Both employees and managers	Ages 25-41 Newly hired during 2021 In one organisation. Employees

The themes for the studies in both countries were to investigate how the newcomers perceived being onboarded without being able to meet physically at work, and about how they experienced support in their onboarding process from their "buddy"/supervisor/manager. Our particular foci have been on experiencing uncertainty and sensemaking.

The data analysis started by reading through the transcribed texts and coding the interviews by highlighting sentences with relevance to issues and themes that are central to the research question. In the process, both empirical and theoretical categories were developed. Furthermore, we discussed our findings up against the theoretical perspectives presented above.

4. Findings

As previously stated, we focussed on "uncertainty and sensemaking," as these were amongst the most common features in the data material in both countries. In the study from The Netherlands one of the respondents claim that "The clarity about the roles was not sufficient, due to little guidance. The best seems to be having a regular one-to-one meeting with the manager." (Interviewee 1Ne) In the Norwegian study two respondents claimed : "Most of the newcomers experienced that they "felt thrown into the work" with little support and had to take action themselves to work it out." (Interviewee 1No) and "The supervisor that were appointed to me was new to the organization and was not able to answer some of my questions. Hence, I contacted our manager instead" (Interviewee 2No).

Here, we see an example of unclear roles, what Bauer would call "Clarity/Clarification" (Bauer, 2010; Preppio, 2022). In the Dutch study, the informant turned to the manager. This may be an example of confusion that needs to be sorted out and where the newcomer/respondent turned to another than the designated mentor/buddy just like described in Feldman (1981) and Bauer and Green (1998). The Norwegian informants also displays uncertainty but has a slightly different approach as the informant shows independence regarding figuring things out by him/herself. It is possible that this is a display of the self-determination theory (Ryan and Deci, 2017). The informants also have to make sense of whatever is possible to work out (Weick, 1995). In the case where the closest supervisor/"buddy" lacks the necessary information, the next level (up) is approached in order to obtain the needed input.

Study from The Netherlands	**Study from Norway**
Many reports on partly passive information, partly interactive via e-learning videos "You receive an email with the pieces that are relevant to read." (Interviewee 1)	Information via e-learning videos about the organization. Since all were in the same organization, most report a positive learning experience about the organizations.

The above mentioned forms of information can be seen as a part of the "Welcome" in the "IWG" framework (Klein and Heuser, 2008). Again, it is about making sense of the information given, mostly to get an insight into the structure and culture of the organization. Learning about the organization via e-learning initiatives seems in both countries to work well.

Study from The Netherlands	**Study from Norway**
Though they often are being introduced to relevant contacts by having an appointment, but then the newcomer finds themselves responsible for follow up. This can be difficult when not knowing many colleagues. …"sometimes I didn't really have a clue who to contact…" (Interviewee 2)	Statement 1: One of the informants was followed up by colleagues with the same profession. (Interviewee 3) Statement 2: "I did not want to trouble the same person all the time, so I found others to ask my questions." (Interviewee 2)

This "connection" (Bauer, 2010) shows a difference in the organizations' approaches to follow up on their newcomers. The Dutch study shows what potentially may be a very unsecure position for the newcomers as they are responsible for making contacts in the organisation. In the Norwegian study, this seems be resolved in as shown in Statement 1, as there was a team that followed up the newcomer. In Statement 2, there again was uncertainty and a wish not to "tire out" one designated person and that the uncertainty reduction theory applies (Van Maanen and Schein, 1979; Berger, 1986).

5. Conclusion

In the data from the two studies there seems to be minor differences in approaches to handling uncertainty and sensemaking. The findings show that the digital information about the organization may contribute positively towards being a part of the "Compliance" (in the 6 C's) or "Welcome" in the IWG framework. "Clarity" regarding job understanding and expectancies require more than a video course, it requires either a "buddy", a manager, or the newcomer must be encouraged to find the information themselves. Obtaining the "Clarity" through asking the presented network, may also aid both building the "Culture" as well as support the "Connections" – the networking. Regarding "Inform", some of the communication would benefit from being personal, but may also be conducted via technology.

Our investigations show that introductory courses and some of the basic training can be offered digitally. Depending on the nature of the job, some job training that for example provide a deeper understanding should be conducted in a face-to-face setting for clarity and sensemaking regarding job content and enabling the newcomer to perform.

Stabilizing uncertainty and supporting sensemaking will for newcomers in most organizations contribute to the onboarding process being successful such that it will bring the newcomers to a level of being compliant with their work situation and thus be contributing in the organization rather than being a cost.

5.1 Further Research

This paper look into the evidence collected from two countries. The data requires more studying to see if there are other differences/similarities that may contribute towards reducing insecurity and enhancing sensemaking for newcomers to become full members of their new organization. For example, will differences in age groups in the material impact on insecurity/sensemaking issues? And are there any differences in how organizations facilitate their onboarding programmes.

c.deraffaele@mdx.ac.uk

Abstract: Knowledge Management Systems enhance innovation, increase operational efficiency, and improve decision-making in business organisations. The administrative and resource overheads required to implement and maintain such systems, however, inherently exclude the smallest of firms from reaping these benefits. This paper aims to identify, evaluate, and summarize the distribution of research on knowledge management and supporting systems across business size classifications with a particular focus on micro-enterprises. It also seeks to establish if existing knowledge management models, practices, and systems have invested due consideration in their design to cater for the limited resources typically found in the micro-enterprise. It contributes new insight into the applicability of knowledge management systems to micro-enterprises and stimulates a possible re-think of how such systems can cater for the specific constraints of this prolific business type. This taxonomy provides a thorough analysis of 168 research papers from a total of 10511 papers published in reputable conference proceedings since 2012. It focuses on key knowledge management themes covered, including the size of the enterprise, the adoption challenges, the potential benefits, the technologies used, and the aspects of the knowledge management cycle that are being employed. Furthermore, it draws on this analysis to highlight the appropriateness of existing knowledge management systems to the distinctive risk and opportunity characteristics of the micro-enterprise.

Keywords: Knowledge Management, Micro-enterprise, Small and medium business, KM Cycle, KM Adoption Challenges, Taxonomy

1. Introduction

Since Karl Wiig's keynote address 'Management of Knowledge' in 1986, a steady flow of milestone implementations on knowledge management (KM) in the industry have been studied and recorded. KM brings particular benefits to enterprises by registering a lowered incidence of repeated mistakes, enhanced personal knowledge base, improved organisational competence and a saving in operating costs and expenses (Cheng and Kuan Yew, 2015). These benefits are attained through the adoption of a cyclic approach that manages knowledge from the point of its creation, dissemination, throughout its application, and eventual destruction. The motivators for KM system (KMS) adoption are diverse, and "in an economy where the only certainty is uncertainty, the one sure source of lasting competitive advantage is knowledge"(Nonaka, 2007). Strengthening the collective expertise of staff and partners contributes to increased success in the marketplace (Fred *et al.*, 2016). KM "continues to be a critical strategy for an organization to achieve a sustainable competitive advantage, and consequently survive in today's knowledge-based economy" (Halawi, Mccarthy and Aronson, 2017). A reduction in project timings, an improvement in the quality of products, and a higher level of customer satisfaction have all been attributed to effective KM, particularly when used for guiding the firm's actions in these areas (Rhem, 2018). Recent studies established that micro-enterprises largely employ personalization strategies that depend heavily on the tacit recollection of memories and experiences rather than explicit knowledge (Alvarez, Cilleruelo and Zamanillo, 2016; Sadat, 2018). Despite their ability to rapidly adapt to market changes, the limited resources available to the micro-enterprise constrain this size of firm from leveraging the benefits and strategically applying a KMS to their often-incongruent IT systems. The "existing KM tools seem too difficult to use for micro-companies due to their lack of available time and resources" (Camille, Huret and Segonds, 2017), a position reaffirmed by Michna, Kmieciak and Brzostek, (2018) who state that given their particular characteristics of "limited human, financial and material resources and a lack of time for creativity development" a different approach in terms of tools and resources to those appropriate to large organisations is necessary. KM literature often assumes the micro-enterprise to be sufficiently similar to a 'start-up' or 'small to medium-sized enterprise' (SME). This has led to the general perception that the micro-enterprise is sufficiently catered for in this domain. Although a start-up may, particularly in its early existence, classify as a micro-enterprise, its primary survival objective is to secure the largest market share in the shortest possible time. SMEs have similar objectives but use significantly more resources to satisfy market demands. The micro-enterprise is different, it typically serves a niche market without necessarily warranting an increase in resources for its survival (Gherhes *et al.*, 2016). However, the

enduring resource limitations that characterize the micro-enterprise present unique challenges to its adoption of KM.

This taxonomy paper aims to identify, evaluate, and summarize the distribution of research on KM and KMS across business size classifications with a particular focus on that specific to, or in its absence, relates closely to micro-enterprise. It also seeks to establish if any existing KM models, systems, and practices, have catered for the limited resources of the micro-enterprise. It contributes new insight into the applicability of KMS to micro-enterprises and stimulates a possible re-think of how KMS can cater for the specific constraints of this prolific business type. The next sections present the methodology used, the findings and a discussion of the results to further research.

2. Methodology

This research investigates whether the micro-enterprise needs a different approach to KM by seeking evidence of 'organizational size' factors as pivotal to the realization of KM utility, i.e., it questions whether due consideration needs to be applied to the size of an organisation when designing, implementing, and operating a KM system to realize maximum benefit. This research takes a bottom-up approach and is divided into two main phases. The first is a preliminary selection based on search criteria applied to the advanced search facilities of selected databases. It results in a set of shortlisted peer-reviewed academic papers that form the basis for this study. The second phase conducts a content analysis on the shortlisted papers, and through a series of structured queries addresses the research question and yields the taxonomic hierarchy. A taxonomy needs to be concise, robust, comprehensive, extendible, and explanatory (Bailey, 1994). In a recent review of 33 taxonomy articles used in Information Systems Research, Lösser et al. (2020) observed that most taxonomies that took an ad hoc approach lacked these essential aspects. In search for a more structured form, Nickerson proposes an iterative seven-step method (Nickerson, Varshney and Muntermann, 2013). Therefore, to ensure that this taxonomy is explicit, transferrable and reproducible, an adaptation of the Nickerson et al. (2013) seven-stage approach is used.

For this first phase, the IEEE Xplore and ACM databases have been purposefully selected to ensure that the output yields empirical primary research data about KM that is rooted within the field of information systems and computer science. This selection avoids the inevitable influences from the predominant 'business management' perspective of KM which can misrepresent the intended focus and results. The "Full-Text Collection" of the ACM database is being used to limit results to articles that are sponsored or published by the ACM rather than the 'ACM Guide to Computing Literature' since this would dilute the scope through the inclusion of other third-party publishers. The data collected from this phase is intentionally constrained by date range, initially excluding papers that had been published before the establishment of the term 'Micro-enterprise' by the European Union (EU) in May 2003 and further still to papers published within the last 10 years. This further constrained date range allows the use of the term to have become well understood and applied within its new EU context.

A sequence of three exclusion filters, illustrated in Figure 1, are applied to the databases to ensure the relevance and intended scope of the resulting papers. This phase will produce the set of shortlisted papers on which the second phase is conducted. The first filter looks for the presence of the phrase "Knowledge Management" or any variant key phrases such as KM, KMS, or Knowledge Acquisition, within the abstract part of the paper. This initial filter serves to exclude papers where KM is not the main topic of discussion. The second filter searches for the presence of the word "business" or any variant key phrases or words such as Firm, Company and Organisation, within the abstract part of the paper. This second filter serves to exclude papers that do not discuss KM within the context of business activity. The third filter searches for the presence of the word "size" or any variant key phrases such as SME, Small or Micro, that indicate the size of the business is a relevant point of discussion. This third filter serves to exclude papers that disregard business size as a factor that impacts KM.

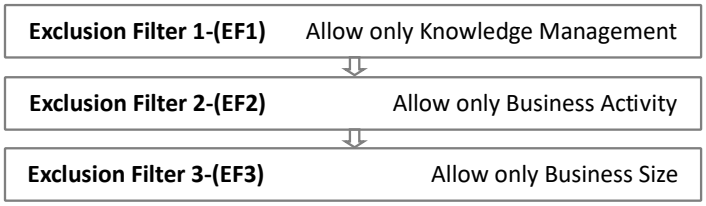

Figure 1: DB Exclusion Filters of Phase 1

The second phase consists of three stages, a preliminary manual screening stage for establishing paper eligibility, a series of close-ended questions that address the research question, and a concluding set of open-ended questions that serve to complement the data collected from the close-ended questions toward constructing the taxonomy. This three-stage process is represented in Figure 2.

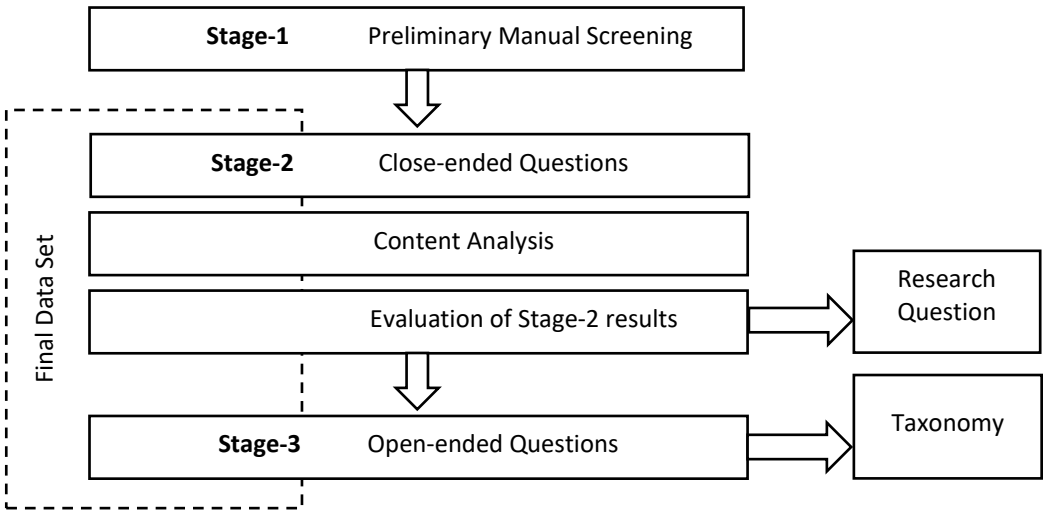

Figure 2: The Three Stages of Phase 2 - Showing the flow of Investigative Analysis, Addressing the Research Question, and Building the Taxonomy

3. Findings

The Phase-1 preliminary paper selection process is conducted against the ACM and IEEE Xplore databases. Table 1 details the resulting values from the application of each of the exclusion filters illustrated in Figure 1. The search criteria used, and respective variants of the principal keywords and phrases applied are also detailed for the purpose of replicability. A total of 168 papers were shortlisted for the Phase-2 analysis.

Table 1: Phase 1– Preliminary Paper Selection as of 12th Nov 2022

Search Criteria	IEEE Xplore	ACM	Total Papers
EF1- Abstract:("knowledge management" OR "Management of knowledge" OR "Knowledge transfer" OR "Knowledge acquisition" OR "Knowledge capture" OR "Knowledge distribution" OR "Knowledge dissemination" OR "Knowledge share" OR "Knowledge sharing" OR "Knowledge application" OR "Knowledge retrieval" OR "Knowledge use" OR "Knowledge creation" OR "Knowledge Usage")	9284	1227	10511
AND			
EF2- Abstract:(business OR firm OR organization OR organisation OR company OR enterprise)	3564	278	3931
AND			
EF3- Abstract:(size OR smb OR sme OR medium OR small OR "Very small" OR micro)	278	52	330
AND			
since 2003	247	52	299
AND			
since 2012	131	37	168

3.1 Stage 1 – Manual Eligibility Screening

This next phase begins with a manual screening process that assesses whether the key phrases, words, and their respective variants were filtered correctly by the databases' advanced search facilities. Furthermore, the

evaluation seeks to confirm that the context within which the key phrases and words are used is relevant to the study and to address the research question. The series of close-ended Assessment Criteria Questions (ACQs) used to manually screen the papers are detailed in Table 2.

Table 2: Phase 2 - Stage 1 ACQs for the Manual Paper Screening Process

ACQ#	Manual Paper Screening Criteria	Yes	No	Set
1.0	Is the paper unique within this dataset? (NO for Duplicate)	166	2	168
1.1	From 1.0 is EF1 met? (the phrase 'Knowledge Management' or variants)	166	0	166
1.2	From 1.1 is the paper's primary discussion on KM?	132	34	166
1.3	From 1.2 is EF2 met? (the word 'Business' or variants)	132	0	132
1.4	From 1.3 is the paper's primary discussion on Business Activity?	112	20	132
1.5	From 1.4 is EF3 met? (word 'Size' or variants)	112	0	112
1.6	From 1.5 is 'size' used within the context of business size?	81	31	112
1.7	From 1.6 does the paper present primary research? 'NO' represents literature review, systematic review, or taxonomy	72	9	81
1.8	Exclude paper from further review if the value of 1.0 to 1.7 = 'NO'	N/A	96	N/A

Of the initial 168 papers that were eligible for Phase 1, the manual screening process found 96 papers to have failed the screening criteria and were therefore excluded from further processing. 2 papers were found to be duplicated and 34 papers did not tackle KM as the primary focus of the research (ACQ# 1.2). A further 20 papers failed to meet ACQ# 1.4 which requires the paper to discuss the application of KM within the context of business organizations. Of these, 31 papers were found to have used the term 'size' as a measure for aspects other than to describe the size of a business entity (ACQ# 1.6). A final 9 papers were excluded since they analyze secondary research (ACQ# 1.7) and would include data that is duplicated from other papers that already form part of this study. In summary, a total of 72 papers passed the manual screening process and formed the final data set.

3.2 Stage 2 – Does the Micro-Enterprise Need a Different Approach to KM?

This stage seeks to answer the research question by performing an in-depth analysis of the 72 shortlisted papers. The first series of questions (Series 2.1) seeks evidence supporting the existence of research on KM that specifically caters for a particular size of an organisation. Each paper is assessed against the close-ended ACQs detailed in Table 3. The results are not mutually exclusive and therefore if a single paper meets the criteria for mentioning large and small enterprises it is added to each row accordingly.

Table 3: Series 2.1 - Close-Ended ACQs to Determine the Sizes of Organisations Being Discussed

ACQ#	Series 2.1 - What research on KM exists that considers organisational size?	Yes	No	Set
2.1.1	Does the paper mention Large Enterprises?	32	40	72
2.1.2	Does the paper mention Small or Medium Sized Businesses?	66	6	72
2.1.3	Does the paper mention Very Small or Micro-enterprise?	9	63	72
2.1.3.1	From 2.1.3 does the paper mention Very Small or Micro-enterprise exclusively?	0	9	9
2.1.3.2	From 2.1.3 is Micro-enterprise a key focus of the paper?	7	2	9
2.1.3.3	From 2.1.3.2 does the paper suggest a different KM approach for Micro Ent.?	4	3	7
2.1.4	Does the paper mention more than one size of enterprise?	30	42	72
2.1.4.1	From 2.1.4 does the paper consider firm size to be a key factor influencing KM use?	9	21	30
2.1.5	Does the paper discuss issues that challenge SMEs or Micro Ent. when using KMS?	20	52	72

As a result of this series of criteria assessments, 32 papers mention Large Enterprises, 66 mention Small or Medium sized and 9 mention Micro-enterprise (ACQ# 2.1.1 to 2.1.3). 30 papers mention more than one size of

organization and will be assessed further since they have the potential to discuss firm size as a key factor in KMS utility. Of these 30, only 9 discuss firm size within their study. Of the 9 papers that mention micro-enterprises, none mention it exclusively, implying that all the papers in this set have some correlation to at least two firm sizes. 2 of these papers Rumanti *et al.*, (2016) and, Rahim, Mahmood and Masrom, (2016) make an insignificant mention to micro-enterprise choosing to focus on the larger firm sizes, however, 7 papers make a notable contribution toward organisational size being a key factor of KM utility. Torres-Blasido *et al.*, (2019), validate a production model within a manufacturing micro-enterprise that seeks to increase productivity by encouraging its staff to share knowledge through the process of socialization. Pham and Nguyen, (2017), explore the impact of KM on business performance and provides evidence that "there is a difference in understanding and applying KM across three categories of firm size: medium, small and very small enterprises." Hall and De Raffaele, (2013), discuss the increased threat of corporate amnesia to the micro-enterprise due to its size and the dissemination of the entire organization's tacit knowledge among the few staff members. Hartono *et al.*, (2017), conduct a qualitative study that compares KM strategy to various organization sizes. The paper finds that a codification-based KM strategy benefits the larger firms whereas a personalization strategy benefits the smaller firms. The findings on micro-enterprise are largely inconclusive and "more follow-up studies" are required (Hartono *et al.*, 2016)(Mahmod, Rosnan and Hazman-Fitri, 2013). Whilst mostly informal, Knowledge Sharing is at its highest level in the smallest of firms and proportionately less in firms of increasing size (Riaz, Buriro and Mahboob, 2019). Holistically, Hartono *et al.*, (2016), determine that, unlike large and medium-sized firms, smaller firms suffice with a simple KM system without the need to pursue a level of KM maturity. Their study recognizes that research "often treat firms as a single monolithic group" and disregards firm size to be a moderating factor in KMS'. Mahmod, Rosnan and Hazman-Fitri, (2013), claim that "most of the studies conducted have not considered the differences of company size as well as specific features of SME that could affect KM" and "is largely disregarded by SMEs". Of these 7 papers, Pham and Nguyen, (2017), Hall and De Raffaele, (2013), Hartono *et al.*, (2017), and Hartono *et al.*, (2016) suggest that a different approach to KM for the micro-enterprise is necessary.

The second series of questions (Series 2.2) evaluates each paper on the KM models and cycles studied. Table 4 summarizes the findings and shows that 67 of the 72 papers discuss at least one stage of the KM cycle, and 57 of these include Knowledge Sharing amongst other stages. Despite only 20 of the 72 papers referencing an established KM model, there exists a fair distribution of papers that discuss each of the main KM cycle stages. However, the discussion on knowledge sharing has a significantly higher presence across the papers than in other stages of the KM cycle.

Table 4: Series 2.2 - KM Models and Cycles Used

ACQ#	Series 2.2 – What KM Models and Cycles are being used or proposed	Yes	No	Set
2.2.1	Does the paper reference an established KM model? (Wiig, Zack, Bukowitz, McElroy, Dalkir, Nonaka, SECI, ICAS, Boisot, Choo, I-Sense, von Krogh and Roos etc.)	20	52	72
2.2.2	Does the paper discuss specific KM-Cycle stages?	67	5	72
2.2.2.1	From 2.2.2 does the paper discuss K-Capture / Collection?	34	33	67
2.2.2.2	From 2.2.2 does the paper discuss K-Creation / Innovation?	45	22	67
2.2.2.3	From 2.2.2 does the paper discuss K-Dissemination / Distribution / Sharing?	57	10	67
2.2.2.4	From 2.2.2 does the paper discuss K-Application / Retrieval / Usage?	24	43	67

The third series of questions (Series 2.3) seeks to establish the implementation/adoption challenges of KM for Micro, Small and Medium-sized enterprises (MSME). Table 5 summarizes the findings.

Table 5: Series 2.3 - The State of Research on KM Implementation for MSME

ACQ#	Series 2.3 - What are the implementation challenges of KM for MSME?	Yes	No	Set
2.3.1	Does the paper argue firm size to be a key factor affecting KMS implementation?	25	47	72
2.3.2	Does the paper argue firm size to be a key factor affecting KMS's usable features and functions?	10	62	72
2.3.3	Does the paper identify implementation challenges?	21	51	72

This series of ACQs found 25 papers that support business size to be a determining factor affecting the use of KM. Mansfield et al.'s (2021) paper identifies the "lack of resources", the "paucity of data governance policies" and opposition toward "accepting new practices and knowledge" as the main factors in smaller enterprises that determine the use of KM. Sadler & Evans (2016) supports this by stating that although "KM is now easier to implement and manage" it should "not be underestimated as 'easy to implement'" and proceeds to explain that "it requires change from all levels of management and a shift in culture" to be of potential value. This implies that the smallest of firms would find it easier to change organizational culture and have fewer strata of management to contend with. Despite Alvarez et al. (2019) focus on KM in a factory production line, their paper recognizes that a key challenge of SMEs is "low human productivity" which they attribute to the prioritization of production numbers over a "practice of knowledge management within their production chain". This is evidence that SMEs involved in a production line setting either negate the benefits of KM or may not justify its implementation. Hartono et al. (2017) found recent studies suggesting that the "size of the organization may be considered as a key moderating variable" in the implementation of KM. The paper explains that there exists "a statistically significant relationship between the level of implementation of KMS and a construction firm's performance", and that a "codification-dominant KMS" is more attuned to the requirements of the larger firm. The paper also found that the statistics relating to the smaller firms were inconclusive and required further study. Only 10 papers presented evidence that firm size determines the usable features and functions of KMS. Key amongst these was Wiratmadja et al. (2014) who identify "six areas of SME technical competence that became a crucial source of knowledge in its business processes". Although they are specific to the firm being studied, the identification of key technical competencies and key business activities would determine the applicable KMS features and functions that would feasibly yield the desired benefits. Implementation challenges were identified by 21 of the 72 papers reviewed. Mahmod, Rosnan and Hazman-Fitri, (2013) argue "organizational policy, a knowledge-friendly culture, an information system culture and training" are essential prerequisites for KM implementation. Risman, (2012) consider the lack of motivation to be among the key challenges, and Torres-Blasido *et al.*, (2019) perceive cultural change as being the largest challenge. From the Stage 2 analysis, too few papers make any substantial contribution toward KM for the micro-enterprise, clearly indicating that the amount of research in this area from a computer science perspective is in very short supply. Although this analysis cannot be considered conclusive for addressing the research question due to the limited number of qualifying papers, there is, however, clear evidence that indicates the need for further research to determine this with certainty.

3.3 Stage 3 – The Taxonomy

Through a series of open-ended questions, this third stage builds on the data gathered from the previous two stages, results in a reflective analysis of the findings, and forms the structure of the taxonomy. Four specific focus areas were extracted from the set of 72 papers, these are Adoption Challenges, Perceived Benefits, and Suggested Technologies.

The taxonomic elements in bold print detailed in Figure 3 represent those extracted from the subset of 7 papers (ACQ# 2.1.3.2) and therefore exclusively represent the Micro-enterprise.

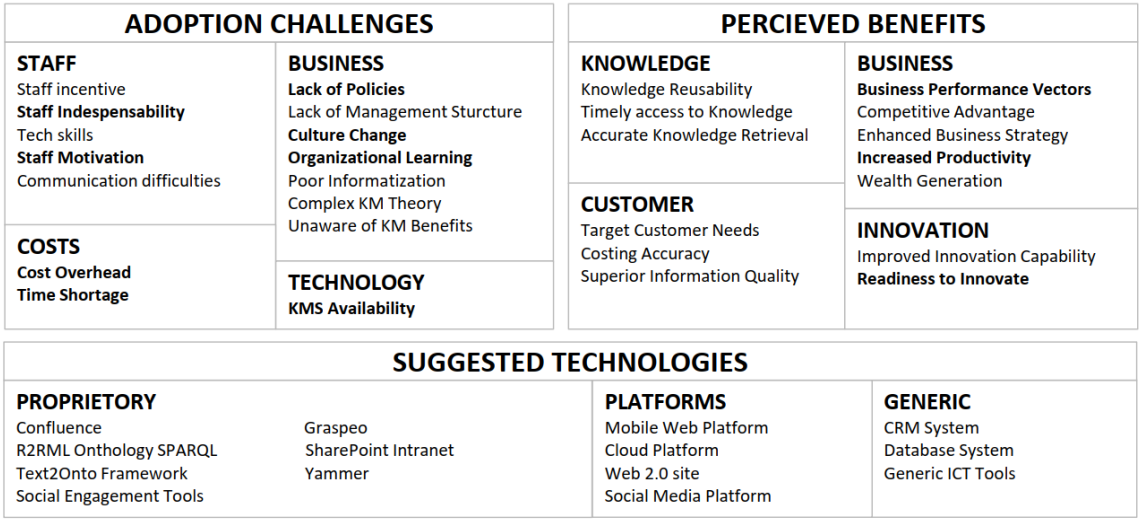

Figure 3: The Taxonomy

The phenomenon of Staff Indispensability is found to be accentuated in micro-enterprise. Staff members feel that they personally own certain knowledge and refuse to share it with others out of fear of losing the value they contribute toward the firm. A constant need to keep staff motivated to capture and share knowledge is also noted together with a lack of organizational policies in the micro-enterprise. This allows for processes to be applied out of convenience rather than need. Furthermore, the need for cultural change toward organizational learning is paramount to successfully realizing the benefits of a KMS. The lack of KMS availability for micro-enterprise, together with the overhead costs resulting from licensing, skills training and administrative time required is also recorded in the taxonomy.

4. Conclusion

This paper summarizes the distribution of recent studies on KM and KMS across the European Union's MSME business size classifications. This endeavour is supported by a rigorously structured and formal approach within the research area and outlines the analysis of the literature represented. It exposes the existence of a gross imbalance in KM research through a resulting emphasis on knowledge sharing and dissemination over other KM stages. The resulting taxonomy contributes new insight into the applicability of current KM research to MSMEs. Furthermore, it establishes that there is insufficient consideration for micro-enterprise in existing KM models, designs, systems, and practices, and provokes a re-think on how KMS can specifically cater for this business size.

rawaa.hammemi@gmail.com
ka.bouzguenda@gmail.com

Abstract: Knowledge creation (KC) is viewed as one of the important practices in knowledge management (KM) process. It is argued that the success of the firm is measured, to a great extent, by its level of innovation. In fact, an innovation-oriented perspective contributes to sustainability. Moreover, innovation is usually developed through new knowledge and creative ideas. That's why; it is relevant to examine the relationship between KC, creativity, and innovation. The first objective of the present paper is to study three direct relationships: The first relation is between KC and innovation (managerial, marketing). The second direct relation is between knowledge creation and creativity. The Third direct relation is between creativity and innovation. The second objective is to analyze the relationship between KC and innovation through the mediation of creativity. Finally, we will compare the results and identify the strongest and significant links useful for practice. The focus is on non-technological innovation because the majority of studies dealt with technological innovation. Added to that, managerial and marketing innovation is supposed to procure an advantage for emergent economies in a post-revolutionary and Covid context. The quantitative approach is adopted upon which 83 valid questionnaires are analyzed using the SEM with Pls3 to test the relationships between the variables. The results show that KC has a positive and significant effect on the two considered types of innovation. In addition, since KC dynamics allow organizations to develop and generate new ideas favorable to innovation, it has a positive effect on creativity. The test of mediation proves that creativity intervenes in the relation between KC, operationalized by the SECI model, and innovation. Based on these results, we may conclude that the relationship between KC and innovation becomes the strongest with the mediation of creativity. Certainly, these results have several implications both on the theoretical and empirical sides.

Ke words: Knowledge creation, Creativity, Marketing innovation, Managerial innovation, PLS

1. Introduction

In reference to knowledge-based view (KBV), knowledge is considered as a resource that is a source of competitive advantage (Costa et al, 2016; Davenport et al, 1998). Even though KM is often recapped in a non-exhaustive list of practices, the importance of the creation's phase, as a foremost and critical practice, has been largely emphasized in assuring the success of KM initiatives (Grimsdottir et al, 2018; Ermine, 2003). In fact, organizations focusing on innovation must be able to inspire and create new knowledge that can be translated into innovative output.

Furthermore and due to the changes that have marked the environment, among the most recent ones is the propagation of Covid19 that has dominated the whole World, organizations were confronted with an obligatory change in their managerial modes and their marketing approaches; we may evoke the appearance of the phenomenon of the delivery service and the online sale that did not frequently exist before. Companies must, therefore, manage themselves internally and develop new knowledge that aligns with the new needs and challenges. Despite the importance such new innovations' needs, the majority of research has been dealing with technological innovation mainly process and product innovation (Ferreira, 2018).

Referring to previous work, some researchers have identified the relationship between KM and innovation (Sankowska, 2013, Wang et al, 2012) by considering KM as a holistic variable (Ode, 2020). Moreover, the effect of creativity has been often overlooked (Sigala et al, 2015). Yet the latter constitutes an antecedent and a determinant of successful innovation.

The present study suggests overcoming this gap by examining the relationship between KC and managerial and marketing innovation while highlighting the mediating role of creativity. Such inquiry is realized, in a first part, on the theoretical side by mobilizing some hypothesis. In a second part, an empirical study is engaged to test the relevant links between the variables, discuss the results, and infer the implications useful for practice.

2. Theoretical Background

In this section, we present the concepts related to the study and establish their link to research question.

2.1 Knowledge Creation as an Important Step of KM Process

By recurring to KM practices, it is argued that the firm may benefit from a build-up in its competencies which may contribute to the development of its competitive advantage (Rahimli, 2012). In fact, literature review reveals that KM process is usually initiated by the KC phase (Miller, (1999); Bose, (2004); Lee et al, (2005); Torabi et al, (2017); Antunes et al, (2020). It follows that the success of the KM process is, a great extent, attributed to the effectiveness and dynamics of KC. Knowledge created "is sometimes more important than the existing knowledge" (Tajpour et al, 2022).

The present study is based on the KC theory founded by Nonaka and colleagues (1995) which is one of the best known in knowledge-based theories (Nguyen et al, 2016). This theory focuses on the conversion of the two dimensions of knowledge, namely tacit and explicit, yielding to four modes of KC:

- - Socialization from tacit to tacit: the conversion is achieved through shared experiences and know-how and realized through observation, imitation, and practice (Nguyen et al, 2016).
- - Externalization from tacit to explicit: this step is about formalizing tacit knowledge into supports in order to make it more understandable, accessible, and useful.
- - Combination from explicit to explicit: this conversion corresponds to the social interaction between the members of the organization on the shared explicit knowledge. This step refers to the activities of synthesizing, sorting, and collecting explicit knowledge (Schulze et al, 2008). These activities allow for a new combination in a way to create new knowledge (Nguyen et al, 2016).
- - Internalization: from explicit to tacit: the new knowledge resulting from the new combination is applied through its implementation. Learning by doing is the appropriate tool during this stage of KC (Nonaka et al, 2000).

As a result of the social interaction during the KC process and the transition from one mode of conversion to another, new interpretations and ideas are developed. In this regard, Chang et al (2014), confirm that the KC process is directly related to creativity.

2.2 Creativity as a Dynamic of new Ideas' Generation

Creativity is one of the factors that facilitate the path to innovation (Ferraira, 2018) and a vital necessity for organizations (Botega, et al, 2020). More specifically, creativity is viewed as the ability to create useful and new ideas (Amabile, 1997) that are appropriate to the context in which they are applied (Howard et al, 2008). These characteristics related to ideas constitute a pillar that guarantees a high level of creativity (Amabile, 1988; Sternberg, 2005). Moreover, it is, in essence, a cognitive activity that allows for the development of new ideas (Fadaee et al, 2014). It is aimed at the development, selection, and enhancement of creative ideas (Rietzschel et al., 2018). If these ideas are evaluated and valued, they are ready to be applied and translated into innovation.

2.3 Innovation Typologies as Opportunities for Organizational Development

According to Shumpeter (1934), innovation includes all innovations related to products, processes, markets or organizational modes. The OECD defines innovation as "the implementation of a new or significantly improved product (good or service) or process, a new marketing method or a new organizational method in business practices, workplace organization or external relations" (OECD, 2005, pp. 46-47). Based on this definition, the notion of innovation may take several forms: - Product/service, process, marketing, and managerial. Such forms are classified as technological innovations (the first two types) and non-technological innovations.

Since the majority of studies has focused on technological innovation (Lam, 2005; Damanpour et al, 2012; Apanasovich et al, 2016), we will pay attention to non-technological innovation as they constitute potential sources of opportunities for organizational development especially for the developing countries.

2.3.1 Managerial innovation and new forms of organizations

The Oslo's Manual defines organizational innovation as "the implementation of a new organizational method in business practices, workplace organization or external relations." (OECD, 2005, p.51). It is based on the creation of new modes of organization and management that can improve firm's performance (Besbes et al, 2013; p.163). It "is a new administrative system, new managerial practices, or new techniques that can create value for the organization that adopts them." (Damanpour et al, 2012, p. 424). Given the fact that it affects all functions of the organization (Le Roy et al, 2013), the development of NFOs would have not taken place

without the engagement in managerial innovation due to its incidence on performance as preconized by Hamel (2009).

2.3.2 Marketing innovation

It deals with any "introduction of new marketing methods that involve significant changes in product design, product placement, and product promotion or pricing (OECD, 2005, p.49). It reflects any changes in marketing tools and techniques which would lead to the increase in sales volumes while continuously satisfying customer needs or conquering new markets (Kalkan et al, 2014). According to Chen (2006), the success of the organization depends on innovation as it provides some opportunities to collect information from customers, understand their needs as well as to conquer new markets globally. Indeed, the proliferation of e-commerce and online business witnesses the value-added of new marketing methods.

The specification of the conceptual framework of the study leads to two main deductions: On the one hand, the terms “new “ and “newness” seem to be the common denominator of KC, creativity, and innovation. On the other hand, the latter are grounded both in the RBV and the evolutionist view as paradigms of apprehending and explaining organizational phenomenon related to the capacity to face challenges and environmental changes.

3. Hypothesis Development and Conceptual Model

In this section, we will develop the conceptual model and the underlying hypotheses dealing with the nature of the links between KC, creativity, and innovation.

3.1 Effect of KC on Innovation

KC is the principal core of innovation (Nisula et al, 2022). It is considered as the output of a cooperative and collaborative effort instead of a new work from a unique entity (Krishnan et al, 2021). Collaborative dimension represent the capacity of an organization to create, integrate and transform knowledge and idea into innovation (Shen et al, 2021). It is argued that KM process and innovation start mainly from KC (Grimsdottir et al, 2018) which is considered as a core activity to innovation path (Nonaka et al, 1995; Wang et al, 2012 and Xue, 2017). In fact, created knowledge may be used to enhance management and marketing policies.

3.1.1 Effect of KC on managerial innovation

Given that the effective functioning of an organization depends first of all on its working strategy and its mode of management, it is then important to give more attention to these administrative procedures, to make adjustments in a permanent way, and to create new specific strategies that align with the internal and external needs.

On the theoretical side, authors demonstrate that KC is a cornerstone of management (Nonaka, et al, 1995, and Lam, 2005). On the empirical side, a study conducted in the Vietnamese context confirms that the SECI model influences innovation initiatives (Nguyen et al, 2016).

Based on the above, we propose the following hypothesis:

Hypothesis 1: KC practices (SECI) have a positive effect on Managerial innovation.

3.1.2 Effect of KC on marketing innovation

The focus is on the marketing factors that enable the organization to improve its market position. Thus, creating new knowledge allows the organization to develop new ways to promote the level of sales and increase its revenues. Also, the launching of new product needs knowledge related to the place of distribution and the way in which the product is commercialized. The creation of a packaging and distinguishable design requires so much knowledge to have a distinctive image compared to the competitors.

In other words, it is the process of SECI that guarantees the incorporation of such new knowledge (Popadiuk, 2006; Nguyen et al, 2016).

On the basis of the above, we hypothesize the following:

Hypothesis 2: KC practices have a positive effect on marketing innovation.

3.2 Effect of KC on Creativity

In an environment characterized by continuous change, creativity is the appropriate response for any organization aiming at succeeding (Egan, 2005). As knowledge mobilization (transfer and conversion) is the basis of KC practices, the development of new ideas is achieved through social interactions and the conversion of knowledge from one mode to another. Then, KC practices are closely related to creativity (Chang, 2014 Rhimi et al, 2011) and may serve as a facilitator for creativity (Bladé et al, 2018). Empirically, the study of Lee et al (2003) provides evidence of the positive and significant relationship between KC and creativity.

Based on this reasoning, we propose the following hypothesis:

Hypothesis 3: KC practices (SECI) have a positive effect on creativity

3.3 Effect of Creativity on Innovation

If creativity is simply the ability to create and develop new ideas that meet needs (Amabile, 1996), innovation refers to the application of effective implementation of these ideas (Péres-Luño et al, 2011; Rietzschel et al, 2018). As all novelty starts mainly from new knowledge, the SECI nurtures the innovation process through which knowledge emerges, develops, and is shared and translated into new market practices and/or management methods.

Based on the above, we make the following hypothesis:

Hypothesis 4: Creativity has a positive effect on managerial innovation.

Hypothesis 5: Creativity has a positive effect on marketing innovation.

3.3.1 Mediating role of creativity on the relation between KC and innovation

The starting point is that creativity is the basis of all types of innovation (Sarooghi et al, 2015) and it is founded on knowledge. The latter facilitates the generation of new ideas that are susceptible to be translated into innovation (Borghini, 2005). It follows that the relation between innovation and creativity is etymologically grounded; what is needed is the implementation of creative ideas, for them to be innovation. Moreover, empirically studies showed that creativity has a mediating effect on the relationship between market orientation and new product performance and between the encouragement of risk-taking and new product performance (Sethi et al, 2009). The research of Chang et al (2014) assesses the intermediary role of creativity between KC and the performance of new products. The present study takes another angle by treating creativity as a mediating variable between KC and innovation as proposed in the following hypotheses:

Hypothesis 6: Creativity has a mediating effect on the relationship between KC and Marketing innovation.

Hypothesis 7: Creativity has a mediating effect on the relationship between KC and Managerial innovation.

Based on the theoretical argumentation, the issue related to the extent to which the SECI model influences non-technological innovation through creativity becomes more relevant than ever before as illustrated in the figure 1. Such relevance needs to be validated empirically.

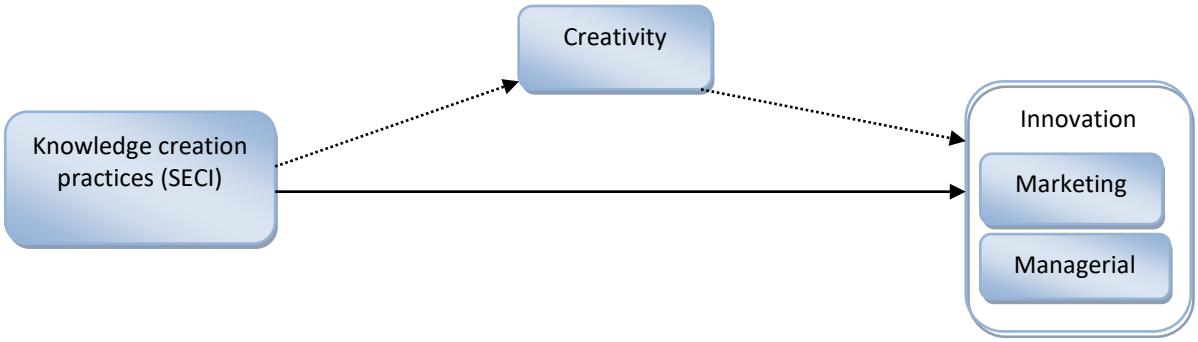

Figure 1: Conceptual Model of the Study

4. Methodology of Research and Results

In this section, we present the methodology of the empirical study and the results obtained.

4.1 Methodology of Research

A quantitative study through a survey is conducted. The sample concerns 83 to Tunisian companies operating in the agri-food sector and certified ISO 9001 which requires the implementation of KM practices. In this context, Gardeazabal et al (2023) argued that Knowledge is an important factor for agri-food systems. Table 1 presents the variables and the sources of scales used.

Table 1: Measurement of Variables

Variables	Nature	Reference
KC (SECI)	Independent	Lee et al (2003)
Creativity	Mediator	Lee et al (2003)
MkgInnov	Dependent	OCDE (2005)
ManagInnov	Dependent	OCDE (2005)

4.2 Descriptive Analysis

In this section we present a detailed description of our sample.

4.2.1 Distribution of the sample by geographical area

Our sample is composed of 83 companies geographically distributed as shown in Table 2 below.

Table 2: Distribution of the Sample by Geographical Area

Zone	%
Tunis	37%
Coastal	41%
South	22%

Representing a fertile agricultural zone, the Coastal zone was the primary source of data collection with 41% of the total sample.

4.2.2 Distribution of the sample by company size

Based on table3 below, we notice that the majority of the companies surveyed have a medium size.

Table 3: Distribution of the Sample by Company Size

Size	%
Medium	55%
Large	30%
Small	50%

4.2.3 Distribution according to the respondents' profile

The distribution of the respondents' profile is based on the criteria of gender and age (see Table 4).

Table 4: Distribution by Gender of Respondent

Gender	%
Male	55%
Female	45%

The majority of respondents are men 55%. Women represent 45% of the total population (see Table 5).

Table 5: Distribution of the Sample According to the age of the Respondent

Age	[25-35]	[36-45]	[46-55]	>55
percentage	15%	42%	35%	8%

Based on this classification, we note that the majority of respondents are young, as they are between 36 and 45 years old.

We note that more than half of the respondents are young. 57% of them are between 25 and 45 years old.

4.3 Exploratory Factor Analysis (EFA)

The results of EFA show that all variables have a determinant different at 0, and at 1 and a KMO value between 0.6 and 0.7 (Table 6). Hence, principal component analysis can be applied.

Table 6: Results of the Exploratory Factor Analysis

Variable	*Determinant*	KMO	Proper value	Explained variance
Socialisation	0,366	0,732	2,271	56,78%
Externalisation	0,378	0,655	2,117	52,93%
Combination	0,151	0,764	2,88	57,775%
Internalisation	0,433	0,665	1,969	65,61%
MkgInnov	0,177	0,884	2,602	65,043%
ManagInnov	0,195	0,746	2,686	67,16%
Creativity	0,02	0,771	3,850	77%

4.4 Results of Research

The reliability and validity of the constructs are verified before testing the hypotheses.

4.4.1 Validity and reliability results

Table 7 indicates that the constructs have high levels of reliability with values between 0.817 and 0.927 as recommended by Hair et al. (2014). All constructs have satisfactory average variance extracted indices that exceed the threshold recommended by Fornell et Larcker (1981) and Bagozzi et al. (1988).

Table 7: Results of Reliability and Validity Tests

Constructs	Reliability composite	AVE	Alpha de Cronbach
Socialisation	0,841	0,570	0,749
Externalisation	0,817	0,529	0,701
Combination	0,870	0,576	0,812
Internalisation	0,850	0,655	0,737
MkgInnov	0,881	0,650	0,819
ManagInnov	0,890	0,670	0,836
Creativity	0,927	0,762	0,895

4.4.2 Hypothesis testing

Our research model is composed of 5 direct relationships and 2 indirect relationships.

The alleged effects tested using SEM with PLS, yield to the following results as exhibited in table 8. The analysis confirms the positive and significant effects between all the variables supporting the hypotheses proposed. There is evidence on the effect of SECI on creativity and managerial and marketing innovation in the studied firms.

Table 8: Results of Direct Relations

H	Relation	Path coefficient	t-Student	P value	Decision
H.1	KC => ManagInnov	0,413	3,590	0,000	Accepted
H.2	KC =>MkgInnov	0,463	3,369	0,001	Accepted
H.3	KC => Creativity	0,860	20,502	0,000	Accepted

H	Relation	Path coefficient	t-Student	P value	Decision
H.4	Creativity => MkgInnov	0,346	2,482	0,013	Accepted
H.5	Creativity => ManagInnov	0,474	4,118	0,000	Accepted

As for the mediating effect of creativity, table 9 shows that the latter intervenes positively in the relationship between KC and both types of innovation. The mediation was tested by Sobel test.

Table 9: Results of Mediation Relations

H	Relation	t-Student	p-value	Z	p-value	Decision
H.6	KC=> Creativity => MkgInnov	2,383	0,017	2,4710168	0,006	Accepted
H.7	KC => Creativity => ManagInnov	3,749	0,000	4,0406889	0,000	Accepted

5. Discussion of the Results and Conclusion

Three main paths of relationships addressed in the present study are grounded not only theoretically but also empirically. These paths witness the existence of some dynamics favorable to KC, creativity, and innovation in the studied context.

5.1 Discussion of the Results

The first path deals with the effect of KC on innovation and creativity which is statistically significant and positive. Such effect may be explained by the following reasons.

- Social interactions seem to be useful, to a great extent, to identify problems and stimulate the creativity and innovation process (socialization). As a matter of fact, in order to find solutions, new opinions emerge as a result of discussions (exteriorization) and changes in behavior are likely to happen (combination and interiorization) as asserted by Le Roy et al (2013).
- In reference to RBV, training policy strengthening the competencies and skills of participants facilitates the delegation of decision making. The emergence of new structures and methods would add value to all functions and shape internal and external relations (Rajapathirana et al, 2018).
- Recently, the proliferation of social networks and the digital transformation are having a strong influence on business models and organizational behavior.

The results corroborate those of Lee et al (2003), Pezzillo Iacono et al. (2012), Hira et al. (2019), and Barua (2018); a fact that show a certain steadiness in the effect of KC on innovation.

The second path confirms the link between creativity and innovation which is conditioned by the capacity to transform new ideas into practical new managerial modes and marketing techniques perceived as valuable by all stakeholders. Studied firms have been able to develop a certain level of congruence between creative ideas generated and changes in organizational functioning and marketing strategy. Creativity provides, thus, the novelty of ideas in reference to the market and not in reference to what exists within the organization. This result aligns with that of Sarooghi et al (2015) yet diverges from the study of Stupa et al (2017) conducted in the Indonesian context. We may advance the contingent nature of the effect of creativity on innovation.

The third path examined concerns the mediating effect of creativity on the relation between KC and innovation. The results that KC practices have more direct effect on MkgInnov and ManagInnov with β indices respectively (β=0.463; β=0.413) than with creativity mediation (β=0.297; β=0.408). This partial effect may be explained by the relative dynamic of KC, creativity, and innovation characterized by a certain level of timidity and ineffectiveness in exploiting available resources and knowledge created. It seems that studied firms fail to either stimulate the detection of useful new ideas or develop new organizational modes and marketing methods that are appropriate to the context. KC is deemed important but insufficient to innovation performance.

Anyway, the findings may be traced to the premises of the institutional theory which emphasizes the weight of some pressures on the adoption of new managerial and marketing techniques becoming “fashion fads” more than “innovative practices”. It seems that coercive and mimetic pressures have been exerted on the studied firms leading to a fictive innovation resulting from the imitation of successful practices of big companies.

Such observation is relevant since Tunisian firms have been engaged in quality certification following coercive and mimetic pressures from government and external partners. As a matter of fact, the number of firms certified ISO 9001 keeps falling down since the revolution in 2011 and along with the propagation of COVID-19. Consequently, the changes in managerial and marketing methods are “superficial” and did not undergo real changes in paradigms and practices. Or, practices related to "benchmarking" may constitute a source of false innovation (Demil & al, 1998) and what DiMaggio et al (2012) calls "mimetic isomorphism". Besides, the relative innovation stems from the lack of creativity (Li et al, 2018) and the absence of favorable conditions to KC. For that, studied firms have a long way to go in order to conceive “new structures” approving the effective conversion modes of KC and targeting creative ideas.

5.2 Conclusion

Even though the question related to the performance of innovation is not new, one may assert that the majority of research has studied innovation from a global perspective by considering it as a holistic variable with the exception of the work of Nguyen et al (2016). Moreover, no research work has taken into consideration the mediating role of creativity in the relationship between KC and different types of innovation.

The idea is that creativity and the development of new ideas are generated from the activities carried out during the implementation of KC practices (SECI) (Lee et al, 2003; Riaz et al, 2019 and Barua, 2018).

The literature argues that creativity is a level that stimulates innovation (Parmentier et al, 2015) and that it is developed from knowledge (Lee et al, 2003). So it can be considered as a mediator between KC and innovation. This is our theoretical contribution.

At the managerial level, the results proved the role played by KC on non-technological innovation. Tunisian organizations need to give more attention to KC practices and take seriously the process of SECI by aiming the generation of ideas leading to value-added innovation. Some deficiencies are observed knowing that Tunisian firms have been losing their competitiveness in the international market and many contracts have been canceled. Despite the pressures of the institutional framework, managers must be creative in order to avoid different types of isomorphism.

This research can be enriched by conducting a qualitative study to detect best practices in KM and to analyze the meaning of innovation according to managers' perceptions. As KC practices are not well practiced, it seems important to study the facilitator of KC such as the use of social media.

To improve our research, it’s able to study the role of human resource practices to enhance KC practices. Also, the analysis of the cultural dimension may be deepened as it constitutes an important framework that can provide some answers since the Tunisian culture is characterized by haziness (Zghal, 1994).

Abstract: The challenging global environmental, economic, and societal transformations urge Norwegian industry to capitalize on all value creation from the manufacturing processes. For many companies, this implies taking manufacturing back to Norway. However, high labour costs do not allow Norway to compete in the global market, and therefore industry needs to take advantage of state-of-the-art technologies. Norwegian society is experiencing a steep learning curve: the acquisition of new knowledge and skills for engineers and managers in companies, while simultaneously transforming and aligning educational programs in universities with Industry 4.0 and Industry 5.0. This research presents a knowledge management perspective of the Industry 5.0 competence platform from the viewpoint of Manulab, a research and innovation lab specializing in Industry 4.0 technologies for the small-scale production of customized products. Located at the Norwegian University of Science and Technology in Ålesund, Manulab collaborates closely with regional industries, including marine, maritime, furniture, and food production, as well as suppliers to these sectors. While Industry 4.0 concepts developed in Manulab have significant potential for value creation, companies and stakeholders have yet to fully capitalize on them. To address this issue, the research adopts Nonaka and Takeuchi's organizational knowledge creation model and applies it to the competence building processes in Manulab, investigating the contribution from different knowledge workers to each phase. The term "knowledge workers" refers to individuals with specialized knowledge and expertise who create value for their organization. The study shows that involving additional knowledge workers in various phases of the Manulab competence building process is crucial for successful implementation of research projects in industry. Furthermore, this human-centric approach can assist companies in transitioning to the Industry 5.0 paradigm. The research is a collaborative effort among researchers, students, and employees holding various positions within industrial companies

Keywords: Knowledge management, Industry 5.0, industry-university, Research laboratory

1. Introduction. A new Vision for Norwegian Industry

The tremendous global environmental, economic, political changes have pushed everyone into looking beyond the conventional emphasis on technology and economic-driven growth that characterizes the current production and consumption-based economic model. Instead, the global community now promotes a more transformative approach that prioritizes human progress and well-being. This approach is a new paradigm Industry 5.0 (i5.0)(Renda *et al.*, 2022). It entails reducing and shifting consumption towards sustainable, circular, and regenerative economic value creation, and promoting equitable prosperity. Industry 5.0 does not merely represent a technological advancement but rather builds upon the Industry 4.0 (i4.0) approach to provide a regenerative purpose and direction for industrial production (Huang *et al.*, 2022). This shift focuses on creating value for people, the planet, and prosperity, rather than solely benefiting shareholders through value extraction.

But what knowledge and skills are needed for the transition to Industry 5.0?

Researchers at the Norwegian University of Science and Technology have used industry-university projects conducted in a research and innovation laboratory to find an answer to this question. The laboratory, known as Manulab, is equipped with Industry 4.0 technology and has been a valuable arena for exploring and using knowledge about Industry 4.0 technology in research, education, and industry. Some of the industrial cases conducted in Manulab have revealed the challenges of implementing Industry 4.0 technology in companies. This led the researchers to question how companies can benefit more from Industry 4.0-advantages and become ready for Industry 5.0. Since the knowledge and its application in organizations were central for the study, the researchers took Nonaka and Takeuchi's organizational knowledge creation model and applied it to the competence-building processes in industry-university projects in Manulab (Nonaka and Takeuchi, 1995). Furthermore, the researchers investigated how different knowledge workers contributed to competence building processes within i4.0 and i5.0.

"Knowledge workers" refers to individuals who possess specialized knowledge and expertise that they use to create value for their organization (Drucker, 2011). These workers are involved in knowledge creation, dissemination, and application, and are critical for organizations that rely on knowledge-intensive processes. Nonaka and Takeuchi argue that knowledge workers are not just passive recipients of information, but active participants in the knowledge creation process, constantly synthesizing and transforming information to generate new knowledge. They also emphasize the importance of socialization and interaction among knowledge workers, as knowledge is often created through dialogue and collaboration.

This study unveils the vital roles of specific knowledge workers in the distinct phases of the competence building process within i4.0 and i5.0. The application of these findings does not only enhance the adoption of Manulab i4.0 concepts by industry but also facilitates companies in transitioning to the new Industry 5.0 paradigm. The results are of significant interest to researchers and companies worldwide who are engaged in innovation projects within i4.0 and i5.0.

This article covers the following topics: an introduction to the Manulab i4.0 concept, a brief overview of Nonaka and Takeuchi's organizational knowledge creation model, a detailed description of the Manulab-industry competence building process, and the findings and conclusions.

2. Manulab i4.0

The Norwegian University of Science and Technology, campus Aalesund, opened the Manufacturing laboratory, (Manulab), in 2020 (Kleppe *et al.*, 2022). The lab was developed as a collaborative effort between the campus and local industries, with a prominent presence from the marine and maritime sectors such as shipbuilding and aquaculture (Madappilly and Mork, 2021). Additionally, the district boasts a strong representation by the furniture industry.

Despite broad variation in types of products, the industrial companies had shared manufacturing goals which became a foundation for the design of the Manulab, as shown in Figure 1 . To respond quicky to evolving customer needs, companies had to transform their manufacturing approach from producing big batches of a narrow range of products to producing a wider range of products at lower volumes. Furthermore, Norwegian companies recognized the importance of transitioning from manual or semi-automated to fully automated production to decrease production costs and remain competitive in the global market. Keeping these industrial goals in mind, the Manulab was created as a small-scale factory that used Industry 4.0-technology - Manulab-i4.0 concept. The concept involves both creating and developing technological products, as well as designing and assessing adaptable and automated manufacturing processes for these products. The Manulab equipment includes 3d-printers, laser-cutters, collaborative, mobile and industrial robots that communicate with each other through sensors, cameras and IoT technology. The equipment incorporates simulation software, machine learning, virtual reality, and artificial intelligence to enhance the functioning of Manulab (Kleppe and Bjelland, 2022).

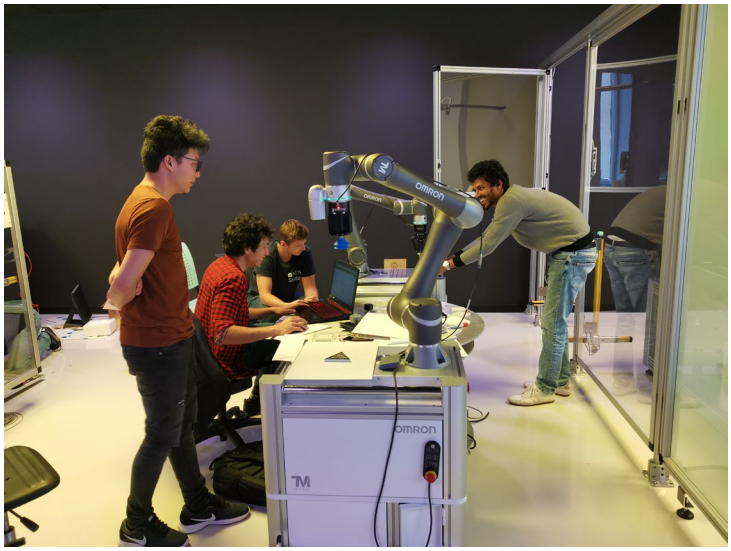

Figure 1: Students Working on the Industrial Case in Manulab Using Industry 4.0 Technology

From the day it opened, Manulab has been actively used for research, education, and industrial innovation projects. These activities intersect in the laboratory. For example, industrial cases can be elaborated in engineering courses. In addition to PhD students doing research, there are bachelor and master students, who are working as research assistants on research and innovation projects. Thereby, Manulab has emerged as a potent platform for building competencies by fostering collaboration among students, researchers, and industrial companies. However, not all industrial cases have yielded successful outcomes, as some of the industry 4.0 concepts developed in Manulab have encountered obstacles for their implementation in the industry. To tackle these challenges, the four authors of this article used a knowledge management approach to analyze industry-university cases in Manulab. All four authors are researchers, three of them are associated with the university while one is the head of research and development in an industrial company. The researchers employed the Nonaka and Takeuchi's organizational knowledge creation model on competence building process in Manulab, a brief introduction to which is given below.

3. Five-Phase Model of Organizational Knowledge Creation Process

According to this model, knowledge creation is a spiralling process of interaction between tacit and explicit knowledge, that goes through five phases as shown in the upper segment of Figure 2 (Nonaka and Takeuchi, 1995).

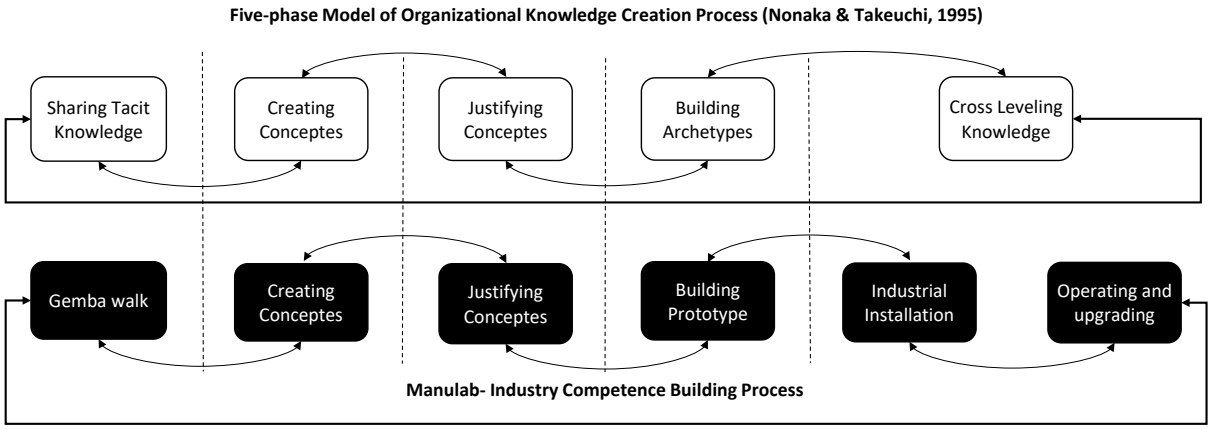

Figure 2: Nonaka and Takeuchi's Organizational Knowledge Creation Process and the Manulab-Industry Competence Building Process, Showing the Interrelations Between Their Phases

Nonaka and Takeuchi's organizational knowledge creation model describes five phases, which are:

Sharing tacit knowledge: This phase involves the sharing of tacit knowledge between individuals through interaction, observation, and communication. Tacit knowledge is difficult to articulate and is based on subjective experiences and insights.

Creating concepts: In this phase, individuals combine their tacit knowledge to create new concepts and ideas. This process involves a combination of intuition, insight, and creativity, and can lead to the development of new products, services, or processes.

Justifying concepts: In this phase, the new concepts and ideas are tested and refined to ensure their validity and usefulness. This process involves testing the concepts against existing knowledge and experience and adjusting, as necessary.

Building archetypes: In this phase, the validated concepts are used to create archetypes or models that represent the underlying principles and ideas. These archetypes can be used to guide future actions and decisions, and to communicate the knowledge to others.

Cross-leveling knowledge: In this final phase, the knowledge and insights gained through the previous four phases are shared and integrated throughout the organization. This involves creating a culture of knowledge sharing and collaboration and ensuring that the knowledge is accessible and useful to everyone in the organization, regardless of their level or position. By doing so, the organization can create a shared understanding and language around the knowledge, which can lead to ongoing innovation and improvement.

4. Manulab - Industry Competence Building Process

Guided by Nonaka and Takeuchi's model, the researchers set the phases of the competence building process in the Manulab industry projects, as illustrated in Figure 2. The process of competence building in Manulab follows the same pattern as the organizational knowledge creation process proposed by Nonaka and Takeuchi, with the exception that the Manulab process encompasses six distinct phases. The final two phases of the Manulab process, namely "industrial installation" and "operating and upgrading," are equivalent to a single phase of cross-leveling of knowledge in Nonaka and Takeuchi's model. The phases in the Manulab-industry competence building process are as follows.

The first phase is a Gemba-walk, which corresponds to the sharing of tacit knowledge in Nonaka and Takeuchi's model. This is the phase of socialization between a company and the Manulab team. The Manulab team typically consists of three to four researchers and two to three students, all from different fields of study. These are people with knowledge within information communication technology, mechanical engineering, automation, and manufacturing design. From the industrial side, it is usually engineers that work with product design and production in the company. If the company and Manulab team do not already know each other, the collaboration starts with several Gemba-walk-visits to the factory and to the Manulab. Gemba is a Japanese term that translates to "the actual place" or "the real place". The term is often used in the context of the Toyota Production System and lean management (Womack, Jones and Roos, 2007). It refers to the place where value is created and where problems can be identified and solved by observing and engaging with the work being done. The Manulab team has had several Gemba-walks at places where industrial work is done, such as a factory floor or construction site. The industry has had Gemba-walks in the laboratory workspace to observe and engage with the Manulab team working on production cases. Gemba-walks help to build relationships, promote understanding of each other's working methods, values, and clarify the expectations for the collaboration. The Gemba walks also help to find several industrial challenges that can be solved in the Manulab workplace. Once the specific challenging case has been selected, the company and the Manulab team initiate the project to tackle the challenge. This typically involves developing and testing an Industry 4.0 production robot cell, as well as modifying the product design to suit automated flexible production.

The next phases in the Manulab-Industry competence building process are 'creating' and 'justifying the concept' and 'building the prototype'. These phases are intricately linked, with continual iteration between modifying the concept and building a prototype. Prototype building goes through many virtual and physical interactions between product- and production design concepts, before arriving at a version that is approved by the company for industrialization.

The next phase is 'industrial installation' when the technology solution is implemented in the industrial company facility. Installation of the solution in an existing manufacturing process can often take time and interrupts production activity. Industrial installation is usually the responsibility of the system integrator, another partner in the Manulab-industry competence building process. System integrator is a supplier of the industrial version of a technological prototype. In this phase, the system integrator's role also includes training operators that will use the system.

The last phase is 'operating and upgrading'. Operators and engineers in an industrial company run the system, while the system integrator's responsibility involves servicing and upgrading the delivered system.

5. Research Method

Researchers conducted a series of four workshops with four industrial companies to gain insights into how knowledge workers contribute to competence building processes within Manulab i4.0 and i5.0 projects. A separate workshop was organized for each company. The purpose of using workshops as a research method is to generate dependable and accurate information concerning forward-thinking procedures, such as organizational change and design, in order to obtain reliable and valid data about the specific field under investigation (Ørngreen and Levinsen, 2017). In each workshop, there were between two and three people from the industry. The participants were middle management with engineering backgrounds, with the exception of one CEO. In each workshop, there were also two to four researchers who had dual roles as discussion partners and researchers.

The workshops began with presentations of industrial cases and demonstrations of technology prototypes in Manulab. Next, the researchers explained these cases from the perspectives of Nonaka and Takeuchi's knowledge creation process and the Manulab-industry competence building process, drawing upon Figure 2 to

illustrate the parallels between these processes. This approach facilitated in-depth discussions about the involvement of knowledge workers in the Manulab i4.0 and i5.0 projects.

Each workshop lasted for approximately one-hour during which researchers took detailed notes to capture the key points. Following the workshops, the researchers analyzed the collected data and later presented the findings to the workshop participants for final discussion and approval. The findings will be presented in the following section.

6. Findings and Discussions

6.1 Partners' Involvement in Distinct Phases of Manulab-Industry Competence Building Process

Figure 3 visualizes how industry, Manulab and the system integrator are involved in distinct phases of the competence building process.

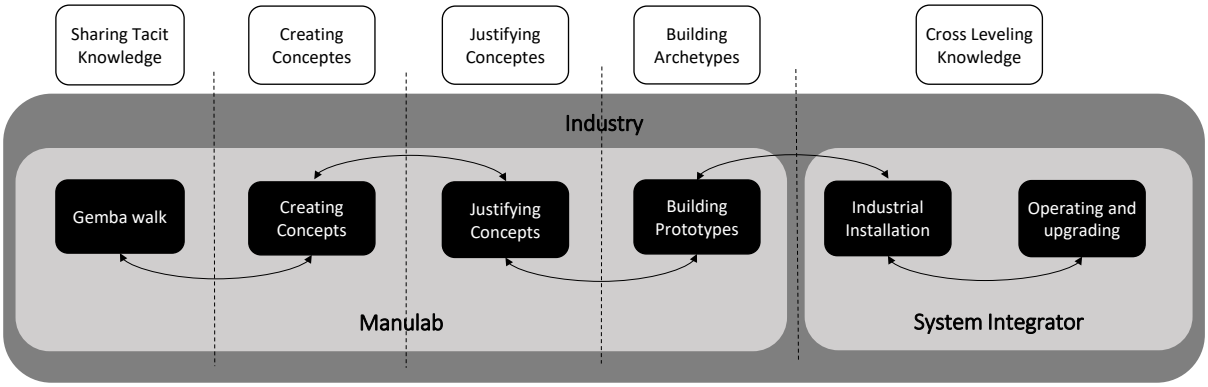

Figure 3: Involvement of Partners in Manulab i4.0- Competence Building Process and Corresponding Nonaka and Takeuchi's Organizational Knowledge Creation Process

As Figure 3 shows, the only partner that participates in the entire process is industry. The Manulab team collaborates with industry in the first four phases of the process, which involve the exchange of tacit knowledge, conceptualization, justification, and prototyping. When it comes to installation of the industrial system in a company's facility, a system integrator is typically brought in to take over. The system integrator utilizes their own concepts, often based on prior experience from other projects, to develop and install the technological solution, providing a warranty for the operating system and training for operators. Together with the system integrator, industry is cross-leveling knowledge by learning from the installation, operating and upgrading of the system. Meanwhile, the Manulab team is not involved in these last phases of the competence building process as it is today in the Manulab i4.0 concept.

While the system integrator's expertise is invaluable in the installation phase, they do not typically contribute to the Gemba, concept creation, concept justification, and prototyping phases. By involving the system integrator in the earlier phases, it is possible to create a shared Manulab-industry-system integrator concept, leading to a higher quality industrial solution.

The involvement of Manulab in the installation phase would benefit the collaborative competence building process. For instance, testing the industrial version of the technological solution in the Manulab facility can reduce the risk of new system errors that often arise during the initial stages of system usage.

Manulab can also assist in operating and upgrading systems by enabling the design and testing of enhanced systems in the laboratory before deploying them in the industrial company's facilities.

The participation of all three partners, industry, system integrator and Manulab in all phases would allow cross-leveling of knowledge by lifting the level of competence across and inside all three organizations. It would also, in accordance with Nonaka and Takechi's model, trigger a new spiral of knowledge building in organizations, which means the adjustment of organizational knowledge building strategies based on 'lessons learned' from each collaborative project.

6.2 Involvement of Specific Knowledge Workers in Different Phases of the Manulab-Industry Competence Building Process

Analyzing the Manulab competence building process from the knowledge management perspective not only highlighted the need for the participation of all three organizations along the whole competence building process, but also emphasized the importance of involving specific knowledge workers from these organizations.

Table 1 shows the knowledge workers and their involvement in the Manulab-industry competence building phases in the current Manulab i4.0 concept and how the researchers and industrial partners see knowledge workers' involvement in the Manulab i5.0 concept. The plus-symbol in Table 1 shows the need to involve knowledge workers. The higher degree of need for involvement is shown with two plus symbols.

Regarding the Manulab team, the knowledge workers, comprising of students and researchers, possess the necessary skills for both the i4.0 and i5.0 concepts. However, it is crucial to include them in the final two phases of the Manulab i5.0 competence building process.

For the system integrator, engineers are the knowledge workers needed for i5.0. However, it is necessary to involve them in the first four phases of the process.

Engineers from the industrial company have been actively involved in all phases of competence building for the Manulab i4.0 concept, and this level of full involvement will remain relevant for i5.0.

Table 1: Knowledge Workers Involvement in Manulab i4.0 and Manulab i5.0

Organizations	Knowledge workers	Ind.	Gemba walk	Creating concepts	Justifying Concepts	Building Prototype	Industrial Installation	Operating Upgrading
Manulab	Students & Researchers	4.0	++	++	++	++		
		5.0	++	++	++	++	+	+
System integrator	Engineers	4.0					++	++
		5.0	+	+	++	+	++	++
Industrial company	Operators	4.0					+	++
		5.0	+	+	+	+	+	++
	Engineers	4.0	+	+	+	+	+	+
		5.0	+	+	+	+	+	+
	Decision makers	4.0					++	
		5.0	+	+	++	+	++	+
	Sales Managers	4.0						
		5.0	+	+	+	+		+

Compared to Industry 4.0, Industry 5.0 has a broader approach to value creation by promoting sustainability, human-centricity, and resilience in manufacturing (as stated by the EU). As the industry moves towards the integration of smart technologies and the cognitive skills and critical thinking of employees, it becomes increasingly crucial to involve knowledge workers such as operators, sales managers, and decision makers from the industrial company in the process.

Manufacturing operators should be involved in all phases of knowledge creation. In the context of human-centric automation in Industry 5.0, operators' knowledge and skills are essential for manufacturing processes and procedures. It is also crucial to introduce operators to new products and manufacturing technologies early on. Their input is valuable for concept creation, prototyping, and installation. Since operators are the ones who use the technological solution in the operation phase, their knowledge is essential for upgrading the solution.

The decision maker should participate in all the Manulab i5.0 knowledge process phases. The experience so far in the Manulab, is that the decision maker enters the process too late. The consequence is that the valuable early phases, like the Gemba walk, creating the concept, concept justification and prototyping, are not

receiving the required attention, and neither will the project be properly funded. It is a common challenge in industrial companies that automation has too much focus on eliminating operators and less on value creation. By involving decision makers early on, the potential for industrial performance, sustainability, and value creation for society can be maximized. Decision makers can provide valuable insights into business objectives, investment decisions, and strategic planning that can inform and enhance the Manulab-industry collaboration. As such, their participation is crucial for the success of the competence building process and the realization of the Industry 5.0 paradigm.

In Industry 5.0, there is an increased emphasis on meeting customer needs through continuous improvement and upgrading of the manufacturing system to enhance the overall customer experience and make the supply chain more resilient (Renda *et al.*, 2022). As such, the role of the sales manager as a representative of the "voice of the customer" is crucial in the Manulab-industry competence building process. Sales managers should participate in the introductory phases to ensure customer preferences, wishes, and experiences are considered.

Overall, the involvement of certain knowledge workers in specific phases of the process is essential for the successful utilization of Manulab projects within the Industry 4.0 concept and can support Manulab's transition to Industry 5.0. The next section presents how the researchers used their findings to plan the Manulab-industry competence building process within the Manulab i5.0 concept.

6.3 Manulab i.5.0 – Concept: Proposing Competence Building, Learning Contexts and Tools in the Knowledge Creation Process

Based on the findings, the researchers designed the Manulab-industry competence building process to support the Industry 5.0 paradigm.

The first phase is a Gemba walk. The knowledge workers from the industrial company, the system integrator and university's Manulab meet for socialization sessions and to experience each other's learning and innovation contexts. The Manulab team arranges a Gemba walk in the Manulab with the knowledge workers who need to be involved in Manulab i5.0, that is, researchers and students from Manulab, industrial engineers from the system integrator and the industrial company, operators, decision makers and the sales manager from the industrial company. Design tools, rapid prototyping, collaborative and mobile robotics, should be demonstrated at this point. The knowledge workers can explore the design of products, jigs, fixtures, and grippers and combine it with automatic manufacturing both in simulators and in the physical Manulab factory. The industrial company should arrange a corresponding workshop with the design department and manufacturing department in their factory to explain how they work. The customers' experiences can be presented by customers if possible. The industrial company may use digital market research or IOT (Internet of Things) technology to collect and present data from customer experience and product and services performance. The operator's knowledge is important to build in the human centric approach for manufacturing systems, and therefore it is important to study the operators' work in the factory. The decision maker should participate in the Gemba walk to understand the opportunities of innovative technology. The decision maker has knowledge about the industrial company's value chain strategy and approach to sustainability. The decision maker is also the enabler of financial and human resources. Drawing a parallel between the Gemba phase and Nonaka and Takeuchi's initial phase of tacit knowledge sharing, there are several methods for exchanging tacit knowledge, including direct observation, narration accompanied by direct observation, imitation, experimentation, comparison, and joint execution (Nonaka and Takeuchi, 2019).

Concept creation phase – here the aim is to enable tacit knowledge, and use this to develop product, process, and business concepts. It is important that the creating concept phase also includes 'high flying' ideas and thoughts. The concept creation phase must evaluate whether we have the needed knowledge and skills onboard. Do we use the right methodology to externalize tacit knowledge? Do we use creative language and metaphors? Are we able to understand tacit knowledge to its full potential? If certain knowledge is not included in the second phase, it will be absent in the concept creation phase and will not be integrated into the prototype at a later phase. Innovative product and service concepts, and automatic manufacturing concepts should be made, and combined with customer experiences. Operators' role and how to use human knowledge in combination with artificial intelligence should be elaborated in several scenarios. Manulab's facilities and features, such as design and prototyping equipment, should be effectively utilized for this purpose.

Justifying the concept phase is where the concept is tested and elaborated relating to the industrial company's short term and long-term business strategy, human centric automation, sustainability performance and value

for society. The sustainability view should be elaborated and highlighted within the design, manufacturing, transport, and use and recycling of products and services. If the justification of concept does not meet the industrial companies' business advancement and strategy, there should be a low threshold for creation of a new or modified concept. Concept can include pay-back time, return on investment, costs, and profit margins. The industrial company could invite customers, suppliers, and authorities to contribute to the justification of the concept.

Building a prototype phase is where the justified concept is built into a prototype of the product and an automatic manufacturing line. This means that the concept is combined with the industrial companies' existing concepts, products, components, and manufacturing facilities. It can be useful to use CAD and CAM System for visualization and simulation of the product and the manufacturing processes. However, building of physical product prototypes and real life set up of a manufacturing line will give more insights for verification and validation.

The industrial Installation phase refers to installing the automatic manufacturing line in the industrial company's factory. The industrial installation can be related to a completely new automatic manufacturing line or an upgrading of an existing manufacturing line. The industrial installation phase can be costly and critical for the industrial company since in many cases, it is done in parallel with daily operations. The engineers from the system integrator are responsible for this phase. Their knowledge, skills, experience, and access to technological resources are vital for the performance of the industrial installation process. High complexity of the product, components and manufacturing equipment can lead to delays in manufacturing, because substantial numbers of failures must be fixed 'on the line.' This can be avoided if Manulab supports the industrial installation work, by making proof of concept and even delivering the needed products and services for a period, to the customer.

The operating and upgrading phase are the normal industrial operations where the industrial company is responsible. However, in a dynamic business world customers will continuously ask for new variants of the products and services. The price of the products and components will normally decrease by 2% to 4% every year, and this puts pressure on the industrial company to find more efficient manufacturing methods. This is done as an iterative development process aiming to lower the cost of the product and components. It is also likely that both the system integrator and Manulab can take an active role and contribute with ideas and concepts if they create a lifelong partnership with the industrial company.

The knowledge and skills required for development of Industry 5.0 concepts are intertwined among the three partners and represent a common knowledge foundation. This knowledge foundation is vital for the industrial company's performance.

Following Nonaka and Takeuchi's KM model, organizational knowledge creation is a spiral process, with each new project building on the knowledge gained from previous collaborations. Long-term collaboration, lasting a minimum of three to four years, would enhance the partners' competences and equip them to meet future industry demands. To achieve this, the three partners will establish procedures and routines for their work, with the socialization process at the foundation of all knowledge creation and application. Care, trust, and commitment are the key factors that will enable the partners to create and apply new knowledge effectively.

7. Conclusion

The research findings propose a long-term cooperation between the industrial company, the system integrator and the Manulab team. Decision makers, sales managers and manufacturing operators should participate throughout the knowledge creation process, and their participation is considered crucial for human centric automation, sustainability in product and processes, and value creation for business and society. The Manulab i.5.0 concept also bridges university and industry collaboration with students participating as knowledge workers. This is regarded as beneficial for knowledge diffusion and societal development.

The findings show that Nonaka' s five phase model can support the Manulab i.4.0 concept for a transition towards the Manulab i.5.0 concept. Involving both industry, system integrator and Manulab with all the relevant knowledge workers, throughout the Manulab-industry competence building process is likely to support enabling tacit knowledge, and more innovative product concepts, production concepts and business models. A more dedicated concept creation phase and justification of concept phase can connect and adapt products, services, and manufacturing concepts more to the industrial company's short-term and long-term business strategy.

However, the Manulab i.5.0 concept must be validated with case studies. Future research should concentrate on elaborate real-life industrial cases, collecting and analyzing qualitative and quantitative data.

marcela-purificacao@sesisc.org.br

Abstract: This work presents a new framework for studying the emotional and physical conditions of workers in Virtual Reality (VR) environments. The framework collects data from simulated virtual environments and helps develop adaptable models for different contexts. It introduces an architecture based on immersion in virtual reality (IVR), focusing on sensory perception, natural actions, narrative engagement, and social features. The author proposes categories to assess the impact of each concept on IVR applications, supported by an artificial intelligence module for data analysis and feedback. The framework also enables the collection of physiological parameters using VR glasses with storage and processing capacity. This facilitates control, performance, and integration with IoT contexts. The primary objective is to identify behavioral patterns for decision-making and employee emotional health management.

Keywords: Knowledge management, Artificial intelligence, Emotional intelligence,Virtual reality,Information management, IoT technology

1. Introduction

The discipline of knowledge management has gained prominence worldwide in recent years. Focused on the business area, it addresses technical concepts about the processes that govern the creation, dissemination, and use of knowledge to meet organizational objectives (Zyngier, S. (2011)). In principle, most organizations face numerous challenges, which limit the efficiency of a knowledge management system, to name a few:

- Not using a significant amount of structured data.
- High complexity of analysis and organization of these data.
- The lack of technological systems capable of extracting and distributing useful information from unstructured content.

Thus, emerging technologies, such as *artificial intelligence*, play an important role in the protection and management of information, breaking down the obstacles that prevent the use of knowledge originating internally in organizations (An, X. and Wang, W. (2010); Albena, A, and Elissaveta, G. (2006).

The human factor is the fundamental slabon in the knowledge management chain and in recent years companies have highly valued their emotional health. Computational emotional intelligence (Sherer, K. R. (2005)) will be useful in all areas of human collaboration with AI, including entertainment, medicine, social work, education, and more. Modern intelligent agents, however, are below the human level in their ability to decide how to behave socially appropriately in a given situation involving others, how to respond to human emotions, or how to guide the climate of interaction with a partner. In order to bridge this gap between natural intelligence and AI, many attempts have been made in recent decades (de Melo, C. M. et al, 2013) to develop a universal approach. Still, a general model of human-compatible socially emotional behavior is needed to guide the design of intelligent agents. Currently, there are two main approaches used in the development of such models. One of them – statistical – relies primarily on deep learning in popular neural network models (e.g., Balan, O. (2019)) and requires large volumes of data annotated for training that are not normally available for high-level real-life moral and ethical decision-making. Therefore, this approach is primarily used for the recognition and expression of emotions (e.g., Reed, R. et al(2019)), rather than for the implementation of emotional intelligence itself.

The use of a virtual reality (VR) test may be a future solution to accurately and sensitively measure emotion regulation in experimental behavioral paradigms with social situations. Virtual reality tasks allow the simulation of naturalistic, multimodal, and complex cognitive challenges that are like real-life situations, maintaining a controlled environment and minimizing confounding variables (Nurn-berger et al., 2011).

VR simulations create a digital psychological sense of being immersed in a synthetic computer-generated virtual world as if it were a real-life place. This evokes a feeling of "being there," or as Witmer and Singer (1998) have defined it, a "sense of presence." As such, these unique immersive characteristics can increase students' affective arousal and boost their cognitive processing (Guan, Wang, Chen, Jin & Hwang, 2021; Parong & Mayer, 2021). Building on VR as a highly emotional and cognitively stimulating learning environment. With the increasing accessibility and representational fidelity of IVR technology, the number of researchers investigating the educational possibilities of IVR technology is increasing dramatically (From, J. et al (2020); Dubovi, I.,(2022)). Armourgun, A. et al (2019) analyze the effect of the cognitive load of train travelers in real-life situations by taking the VR model. Freeman, D. et al, (2019) conduct a review on the potential of VR technology for mental health. Yen, H. E and Chiu, H.-L. (2019) explore the effectiveness of VR exercises in improving cognition in older adults and improving depressive outcomes through a systematic review, meta-analysis, subgroup analysis, and meta-regression. Tawil, N. et al (2021) explore solutions for assessing psychological well-being and mental health in response to interiors presented in virtual reality. Despite the increased interest of researchers in the development of the study of mental health, there are still solutions that can be optimized and challenges to be solved.

Even the knowledge of the authors of this study was not found in the literature, a proposal that considers a management system that allows knowing all levels of detail of the structure of an organization in the area of emotional health or emotional intelligence. The purpose of this work is to create a framework that helps companies identify and manage information associated with emotional health using the integration of virtual reality immersion technologies and artificial intelligence.

2. Methodology

We discuss a new methodology to create a framework that assists in the management of information about the user subjected to a process of emotional analysis. The study was segmented into four areas based on the literature (Won, M et al (2023); Dede(2009)). Figure 1 represents the integration of the active and passive modules that make up the method infrastructure. The following are described as their functions.

The external *social feature* is classified as an active function in relation to the execution models of the proposed framework. The authors highlight a different function to the methods presented in other works (Won, M et al (2023)). Considering the function as a source of acquisition and knowledge management of our method. In this process, three important characteristics were highlighted:

- *Building an emotional questionnaire* is the basic pillar in emotional assessment through questions validated by protocols, instruments, and solid organizations in the area of emotional health studies (Watson, D. et al(1988)). These questionnaires are selected by health professionals for the purpose strongly related to the objectives of using our solution, an example, to help detect possible cases of depression and stress.
- The *Development of interaction environments* aims to construct virtual reality (VR) environments. These environments are created using the concepts discussed in the previous process. Each question of the questionnaire is associated with a virtual location, allowing for the identification and evaluation of emotions.
- *VR/IoT information collection planning*, the data collection process involves gathering information from the questionnaire and capturing all interactions within the virtual reality environment. Additionally, hardware devices are utilized to collect external data, including heartbeats, that are not directly part of the VR environment.

Narrative has two processes:

- *Gamification the* initial step aims to enhance the overall execution of subsequent processes by creating a more enjoyable and engaging experience. Its purpose is to motivate users to participate in all tests and interactions presented in the VR environment and questionnaires, ensuring a smoother and more seamless engagement.
- The *Elaboration of scripts* is aligned with *Gamification* to create a user-friendly VR environment that enhances the overall experience. Regarding the Sensory/Actional/Inner social feature, once the previous steps have been executed, information from the internal VR and physiological environment is collected using IoT devices.

- *VR/IoT information collection*, enables the system to collect the data through the questionnaire carried out in the virtual environment (Tawil, N. et al (2021)) and through the integration of hardware devices are obtained the associated physiological parameters HVR (Morales, J. M. et al (2020)).

The *AI Model* analyzes the collected data and performs various functions during this stage. These functions include data processing to prepare and format the data according to the required standard for the next phase. Additionally, the data is classified based on a pre-trained pattern using machine learning (ML) techniques. Finally, the data is specifically studied to identify any divergent or unique results that may need to be communicated to the registered models within the AI Model. This phase emphasizes the continuous updating of information and transforms the system into an evolving model of knowledge.

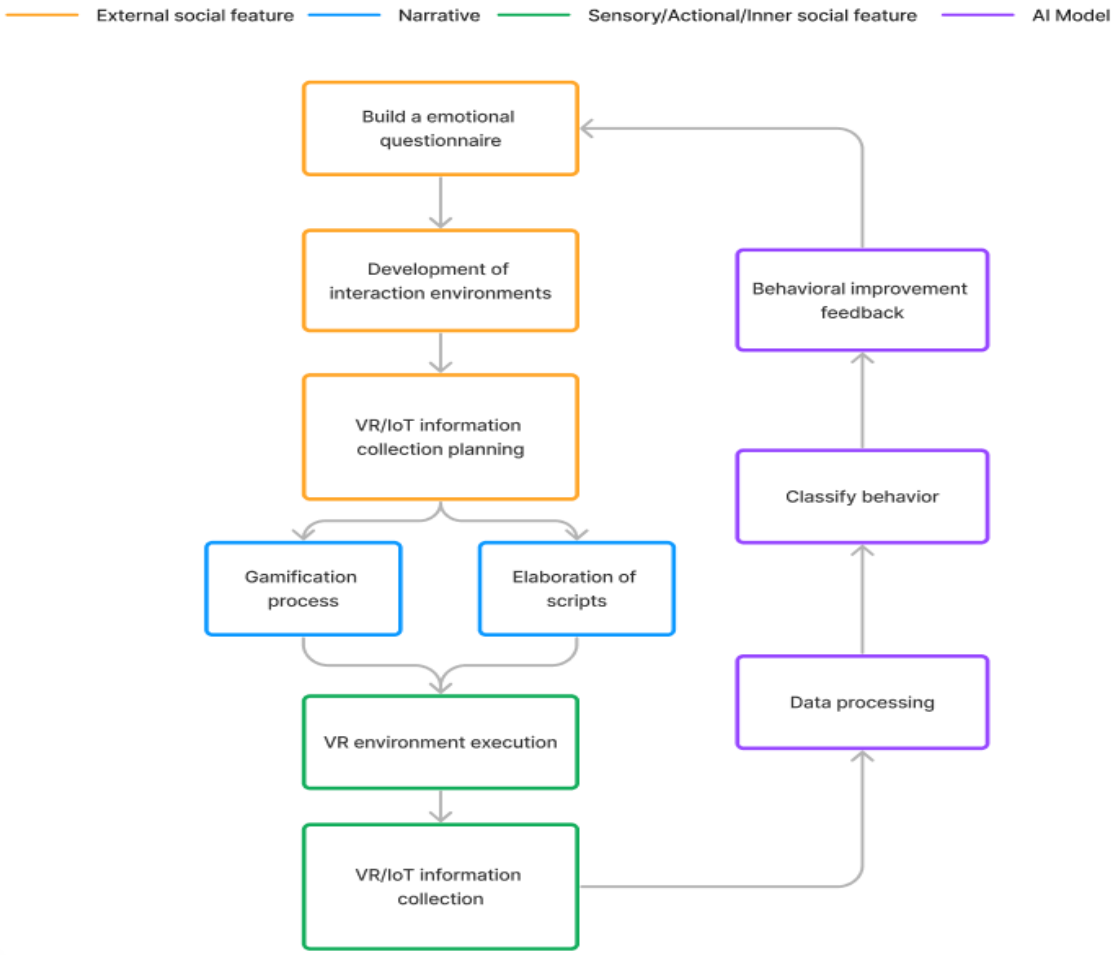

Figure 1: Operational Functions of the Information Technology Model

The *External social feature* consists of three processes, starting with the creation of an emotional questionnaire. This involves using validated emotional assessment questions from reputable instruments and organizations specializing in emotional health studies. Healthcare professionals carefully select these questionnaires to support our solution's objectives, such as detecting potential cases of depression.

The *development of interaction environments* aims to create immersive virtual reality (VR) environments that align with the selected questions from the previous process. For example, if there are ten questions in a questionnaire aimed at assessing depression, an environment is constructed for each question with the specific objective of capturing the essence required by the instrument. This ensures that the VR environments effectively meet the intended purpose.

VR/IoT information collection planning collects the data related to the questionnaire being applied as well as all the interactions with the applied virtual reality environment. In addition, hardware is used to collect data external to the VR environment, such as heart rate.

The narrative has two processes, *Gamification* is the first of them, with the purpose of making the execution of all other processes lighter and more fun as far as possible, motivating the user to perform all the tests and interactions proposed in the VR environment and with the questionnaires in a more fluid way. It follows the process of *Elaboration of scripts*, which aligned with Gamification produces a user-friendly VR environment to be observed.

Sensory/Actional/Inner social feature, with the execution of the previous processes we run the VR environment and collect all information from the internal VR and external IoT environment. The data is processed in the *AI Model*, where we process the data collected in the previous steps and classify the information according to the instruments adopted.

Our framework operates cyclically, meaning that if the results are not deemed acceptable in the initial cycle, we continue to iterate until the solution becomes suitable and aligned with the health instrument being utilized, as well as the aspects of virtual reality (VR) and the Internet of Things (IoT) in the interactive process. This iterative approach allows for continuous improvement and ensures that the framework evolves to meet the desired standards and objectives.

3. Results

Our work aims to achieve a comprehensive framework that facilitates the identification of emotions through the use of standardized emotional health tools. Figure 2 visually depicts the relationship between the operational model and the user. Each component of the framework serves two primary functions: enabling immersive experiences within a virtual reality (VR) environment and gathering physiological parameters through the Internet of Things (IoT). The results of our efforts culminate in a well-defined structure that enhances emotion identification processes.

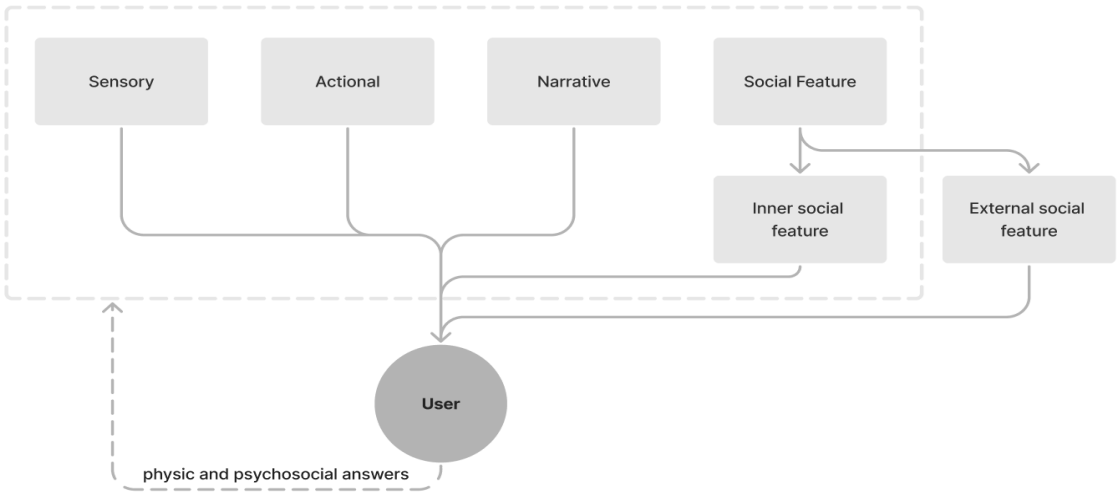

Figure 2: Diagram of the Interaction Between the *Framework and the User*

Immersion in the VR environment

During the immersion process, we begin by utilizing standard questionnaire models recommended by the literature. The user's responses to each scenario are then compared to predefined outcomes facilitated by the AI Model. The Sensory, Actional, and Narrative blocks collaborate with the Inner Social Feature, forming part of the Social Feature layer. This allows for periodic updates to the Social Feature, emphasizing its dynamic nature as the system evolves. The External Social Feature serves as a temporary validation mechanism for the generated information, emphasizing the model's robustness as a fundamental aspect. Consequently, it acquires sufficient data to directly engage with the user and enhance their social well-being.

IoT Technology

In Figure 3, an IoT technology was *designed,* being an extension of the *framework* to monitor the physiological parameters of *HVR.* As the figure shows, the data travels in one direction and is integrated into the overall system solution. The architecture helps to perform measurements through sensors that are connected to a processor to determine the values associated with stress and relaxation before an activity and finally the data is transferred

to a platform that will archive and analyze the data. The correlation of physiological and psychosocial data helps in the identification of the emotional state with greater precision.

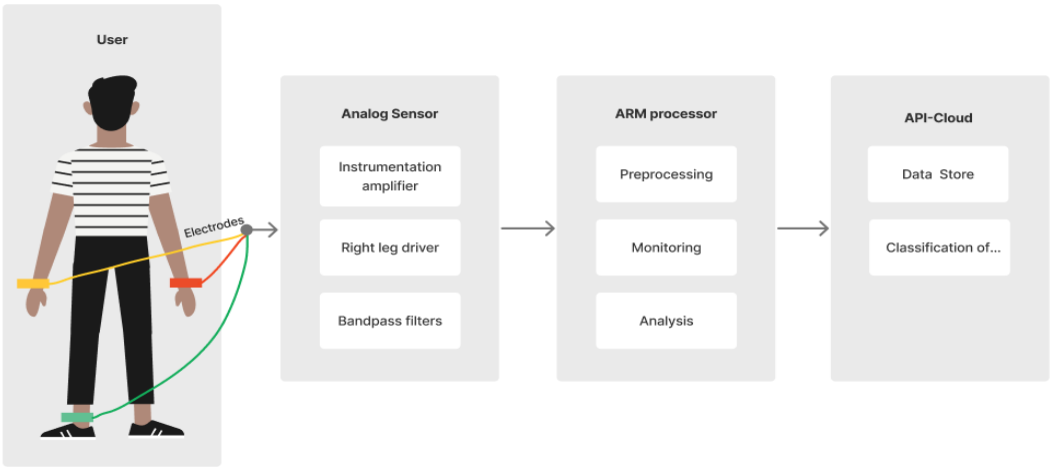

Figure 3: Representation of the IoT Diagram in the Collection of Physiological Parameters

The techniques employed synergistically contribute to the development of a comprehensive solution that encompasses a multidisciplinary evaluation of employees. A manager in a company or industry requires insights into the emotional well-being of their workforce to facilitate effective administrative supervision. Hence, our framework provides a means to acquire knowledge about various emotional aspects of employees, thereby enabling informed decision-making.

4. Conclusion

Our study introduces an innovative and comprehensive framework designed to develop virtual reality environments that assess emotional health characteristics. By combining advanced technologies, including medical instruments and IoT equipment, our framework offers a diverse range of tools to evaluate both external and internal aspects of emotional well-being.

The utilization of interactive virtual environments provides several advantages over traditional methods of assessing emotional health. Through immersive experiences, patients can engage with scenarios that elicit specific emotions, replicating situations relevant to their emotional challenges. This exposure allows patients to confront and address difficult circumstances within safe and controlled settings, offering a unique therapeutic approach for emotional disorders.

The integration of IoT equipment with virtual environments brings further benefits by enabling real-time monitoring of physical and emotional data. Wearable sensors, for instance, can track a patient's heart rate and brain activity during therapy sessions, granting healthcare professionals a comprehensive understanding of the patient's emotional state.

Moreover, our framework can be tailored to individual patients, accommodating their specific needs. Virtual environments can be customized to align with their emotional requirements, providing a personalized therapeutic experience that promotes more effective treatment.

Furthermore, our solution can contribute to the development of knowledge regarding the mental health aspects of employees in industries or companies. This empowers managers with insights to make informed decisions aimed at preserving and preventing issues related to the emotional well-being of their workforce.

Abstract: Covid-19 has emerged with inevitable changes in societies around the world. Organizations face difficulties in both pandemic and post-pandemic situations, engaging people towards producing knowledge to remain competitive. Knowledge is deemed to be a crucial asset for organizations. Quality knowledge contribution among employees can provide a competitive advantage by enabling them to serve their clients in a more advanced and well-organized manner. Despite this, research on knowledge management activities in service organizations in South Asia, specifically in Bangladesh, is limited. This study is motivated to explore the post-pandemic scenario of a developing country based on the service sector. The study aims to understand the relationship between gamification and employee knowledge contribution with a diverse group response highlighting gender aspects in the context of Bangladesh. The study employs a quantitative method, gathering data from various service sector employees through a questionnaire survey. This study develops a research model relating organizational gamification activities (rewardability and competition) and quality knowledge contribution. The results confirm the impact of rewardability and competition on employee quality knowledge contribution, with the multi-group analysis based on gender showing disparities between male and female responses. Male responses found a significant relationship between gamification and quality knowledge contribution with both activities. In contrast, female responses are insignificant considering competition regarding quality knowledge contribution. The study result produces a unique context related to Bangladesh's service sector as the first initiative to the best of our knowledge. The study recommends modifications in service organizations to foster an environment that promotes quality knowledge contribution in day-to-day transactions. It will also enhance issues related to women's empowerment and the quest for new approaches the organization may rethink to remain competitive. Therefore, the study's findings can provide research pleas to the policymakers, academics, and practitioners and will explore diversity in similar economies related to the service sector.

Keywords: Gamification, Knowledge, SEM, Bangladesh

1. Introduction

The pandemic of COVID-19 has altered the manner in which businesses operate, introducing new opportunities and challenges. The pandemic has compelled many companies to modify their business models to survive. With an increased emphasis on innovation and competitiveness, the quality of employee knowledge contributions can assist organizations in generating new ideas, products, and services by leveraging their existing knowledge. By exchanging knowledge and expertise across departments, businesses can accelerate innovation processes and maintain a competitive advantage (Ram et al, 2021).

The post-COVID-19 environment is also linked to the fourth industrial revolution, characterized by rapid technological change, and requires organizations to adapt rapidly to remain relevant. This can result in a more agile and adaptable organization responding more effectively to shifting market conditions (Zieba et al, 2022). According to Riar et al. (2022) collaboration is essential as organizations increasingly rely on cross-functional teams to generate innovation and solve complex problems. Effective knowledge management systems can facilitate collaboration by dismantling silos and enabling employees to share their knowledge and expertise across departments and geographies (Chiu and Lin, 2022). Therefore, by encouraging employees to contribute their knowledge and expertise, organizations can better identify opportunities and develop new products and services to satisfy customers' evolving needs (Nguyen et al, 2022).

Prior research (e.g., Jalili 2020; Deterding et al. 2011; Davenport & Prusak 1998; O'Dell & Grayson 1998) also identified several reasons why employees might not be interested in making quality knowledge contributions,

such as a lack of motivation, engagement, or recognition for their efforts, fear of job loss or competition, or a lack of understanding of the benefits of knowledge sharing for the organization. To surmount these obstacles, organizations are increasingly employing gamification, applying game design principles to non-game contexts to increase engagement and motivation (Deterding et al, 2011). Gamification can be an effective instrument for promoting quality knowledge contributions in organizations, as it provides incentives and rewards for employees who make quality knowledge contributions, along with healthy competition (Hamari et al, 2014).

However, the relationship between gamification and employee quality knowledge contribution is crucial for today's businesses, particularly in the service sector. Service demand is changing, and organizations face a competitive challenge in developing new ideas to meet these demands. Given this context, it would be intriguing to investigate the Bangladesh service industry, as the country's economy is growing in tandem with the shift in consumer preferences.

2. Literature Review and Hypothesis Development

2.1 Quality of Knowledge Contribution

In recent years, organizations have substantially improved how they manage knowledge to help their businesses, but organizations still need to encourage employees to contribute more knowledge (Riar et al, 2022; Suh and Wagner, 2017). Gamification motivates and engages employees directly about their knowledge contribution. Organizations rely on their employees to provide data that can be used to develop in areas where they are deficient and to maintain success in areas where they excel (Bizzi, 2023). Knowledge contribution encompasses a wide range of activities, starting with contributing new ideas, refining old ideas, creating documents, assisting colleagues, and even teamwork (Suh and Wagner, 2017). Knowledge quality is regarded as a greater asset when making decisions than knowledge quantity. Knowledge quality is determined by the extent to which the knowledge is utilized and how it contributes to the organization's growth (Suh and Wagner, 2017). Suh and Wagner also discovered that gamification in the form of reward and competition encourages employees to acquire and contribute more knowledge to the organization (Lier and Breuer, 2020). Therefore, it is expected that the greater the use of gamification techniques in a business, the higher the quality of the knowledge contributed by its employees.

2.2 Gamification

Diverse industries have extensively implemented gamification to increase employee engagement. Gamification is used extensively in businesses to motivate employees because it makes many activities more enjoyable. Nevertheless, gamification needs to be more frequently understood. Gamification does not involve transforming a business or website into a game (Bizzi, 2023). According to Harris and O'Gorman (2014), gamification is "the presence or addition of game-like qualities to anything that is not traditionally considered a game." Gamification is not a game but an activity that employs game design principles (Riar et al, 2022). Gamification is a crucial concept that businesses should be familiar with. According to Harris and O'Gorman (2014), gamification is no longer merely a trendy business term. It has helped companies improve employee engagement, consumer loyalty, and revenue. The advantages of gamification are immense. Riar et al (2022) note that these include making monotonous tasks entertaining, making hard work pleasurable, increasing concentration on the job, enhancing employee contribution, assisting in maintaining motivation and satisfaction, and, most importantly, making employees more active in knowledge contribution. However, because gamification has been misconstrued, many strategies have failed to achieve their objectives. In late 2012, Gartner published a report predicting that, by 2014, the inadequate design would render 80 percent of gamified business strategies obsolete (Harris and O'Gorman 2014). Furthermore, critics have asserted that the increased visibility of employees' activities will create problems, resulting in unproductive employees and harming the organization's reputation (Suh and Wagner, 2017). Therefore, businesses must employ gamification with caution. Gamification implementations are as diverse as the businesses they serve and the business requirements they address (Harris and O'Gorman, 2014). This research paper examines the various approaches of gamification (e.g., rewardabilty, competition) to the service industry to explore the quality knowledge contribution of the employees.

2.2.1 Rewardability

Many gamification approaches focus on the reward system, where employees are given a material or non-material reward after accomplishing a particular task. Suh and Wagner provide one such example of rewardability: contribution of knowledge rewards the employees with points, and after reaching a certain

milestone, they are even given badges or trophies; they can also compete in challenges or set their own goals, which would reward more points (Riar et al., 2022; Suh and Wagner, 2017). Humans love positive feedback, and getting rewarded would encourage them to repeat even the most tedious tasks (Caton and Greenhill, 2014). Social media applications have already jumped in, and their reward systems which are more commonly found in the gaming world has kept more and more user enticed in their applications (Suh and Wagner, 2017). Gamification is tied closely to the reward system. Most computer games challenge players to complex tasks with rewards and penalties; therefore, even after repeated failures, the player stays engaged in the game (Caton and Greenhill, 2014). The quicker the feedback in terms of reward is given, the more focused the user stays on the activity, and this response has improved the hedonic value of performing required activities by quite a lot (Suh and Wagner, 2017). However, ensuring that the rewardability structure is sustainable and that the employees are not only doing the task to achieve rewards is important. Therefore, the study finds:

H1. The rewardabilty practice will increase the willingness of employees' quality knowledge contribution

2.2.2 Competition

Competition adds a new spark to gamification. Like the excitement of jumping to the top of the leaderboard in a game, competition makes employees' jobs more enjoyable. It incentivizes them to work harder to be ahead of their colleagues. Humans always have an innate desire to compete and be recognized for their achievements (Caton and Greenhill, 2014). Competition is, therefore, perfect for satisfying that desire as it helps them to compare their performances with everyone else, keeping them more motivated as they can challenge each other to achieve the best score in any given activity (Riar et al., 2022; Suh and Wagner, 2017). The effect of the competition is seen more in male employees, who are more motivated to stand out from the crowd (Lier and Breuer, 2020). The competition also helps people feel in control and allows them to introduce their ideas while working with others (Suh and Wagner, 2017). Gamification use has been proven beneficial in all workplace settings (Lier and Breuer, 2020). The friendly competition among employees has been successful because it induces teamwork at the end of the day and motivates employees to work positively on the project (Lier and Breuer, 2020). Despite all the positives of competition, this gamification approach must be carefully used. Employee motivation may be negatively affected as the pressure of competition may decrease creativity and limit the employees into a bubble, leading to less creation of new ideas (Suh and Wagner, 2017).

Thus, this study hypothesizes:

H2. The competition will increase the willingness of employees' quality knowledge contributions.

The impact of gender on the connection between gamification and quality knowledge generation is also a topic of debate. Males and females share some social and biological features used to classify gender. According to Hasan et al. (2022) and Kanter (1997), gender diversity in management practice is a demographic issue that is generally recognized. For instance, Hasan and Islam (2022); Eagly and Carli (2003) suggested that male staff members have knowledge sharpness and the ability to logically and analytically reason more than female staff members. On the other hand, female workers are preferable to male workers when establishing connections and maintaining positive relationships. More significantly, men and women behave differently in various social and cultural contexts. Therefore, this study also attempts to observe whether the male and female groups respond differently while considering gamification elements in their quality knowledge contribution.

3. Methodology

As the population of interest, this study concentrates on employees of service organizations, particularly those working in banks, telecom companies, hospitals, etc. This selection is based on the fact that these respondents are the largest contributors to the service sector in Bangladesh and are suitable for the study. Data were collected from respondents at various service organizations using a structured questionnaire. The questionnaire contained a measurement scale for rewardability, competition, and contribution of high-quality knowledge. The survey items were adapted from previous studies by Tang and Zhang (2019); Adornes, and Muniz (2019); Zeng, Tang and Wang (2017); Suh and Wagner (2017), with all items evaluated for internal consistency using Cronbach's alpha on a five-point Likert-type scale. PLS-based SEM was also used in this study. In this investigation, WarpPLS 8.0 was used to analyze the SEM. This study also introduces income and age as control variables to address the diverse thoughts. Questions regarding age and income are resented numbers with intervals.

4. Result

4.1 Sample Characteristics

A total of 170 samples were collected from various service organizations in Bangladesh, with 75 samples being male and 95 being female. The participants were from different age groups, with 28.2% belonging to the age group of 15-25 years, 39.4% falling in the age bracket of 26-35 years, 24.1% belonging to the age group of 36-45 years, and the remaining 8.2% of participants were aged above 46 years. In terms of income, 21.2% of the participants earned between 21000-30000, 23.5% earned between 31000-40000, 21.2% earned between 41000-50000, and the remaining 34.1% earned a salary of 50000 or above per month.

4.2 Validation and Measurement Model

This study confirms both convergent and discriminant validity. The factor loading presented in Table 1 shows adequate convergent validity since the loading range from 0.541 to 0.861, as approved by Hasan et al. (2022). In SEM analysis, latent variables are reliable if their Cronbach alpha is above 0.50. This analysis shows an acceptable range on Cronbach's alpha (0.563–0.592) and composite reliability (0.786–0.781). All variance inflation factors (VIF values) in Table 1 are less than 5, indicating no multicollinearity.

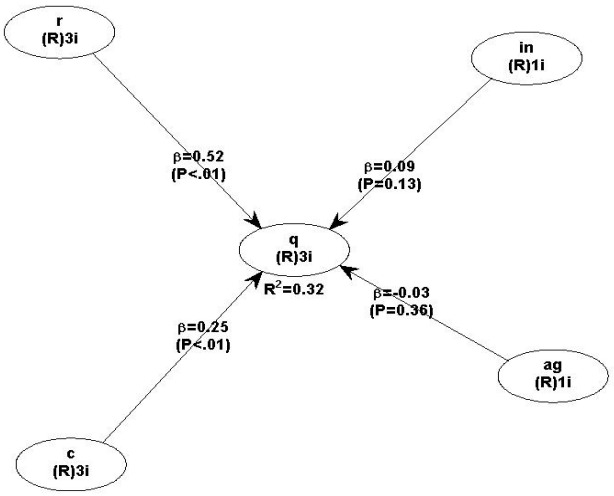

Table 1: Convergent and Discriminant Validity Measures

Latent Variable Items	Loadings	R-squared	Adjusted R-squared	Composite reliability	Cronbach's alpha	Average variances extracted	Full collinearity VIFs
Rewardabilty							
R1	0.800	0.320	0.311	0.774	0.563	0.539	1.313
R2	0.809						
R3	0.569						
Competition							
C1	0.742			0.786	0.592	0.550	1.054
C2	0.752						
C3	0.732						
Quality Knowledge Contribution							
Q1	0.861			0.781	0.576	0.551	1.348
Q2	0.541						
Q3	0.786						

The measurement model of the study also confirms the Discriminant validity as all square roots of average variances extracted in Table 2 are accepted, as Hasan et al. (2021) suggested.

Table 2: Correlations and Square Roots of AVES

	Rewardabilty	Competition	Quality Knowledge Contribution
Rewardabilty	0.734		
Competition	-0.053	0.742	
Quality Knowledge Contribution	0.469	0.17	0.742

Notes: r= Rewardability, c= Competition, q= Quality knowledge contribution, in= Income, ag= Age

Figure 1: Estimated Parameters in the Structural Equation

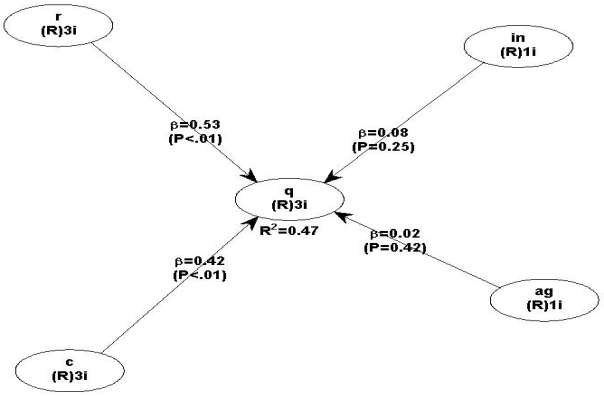

Figure 2: Estimated Parameters in the Structural Equation Model Based on Male Response

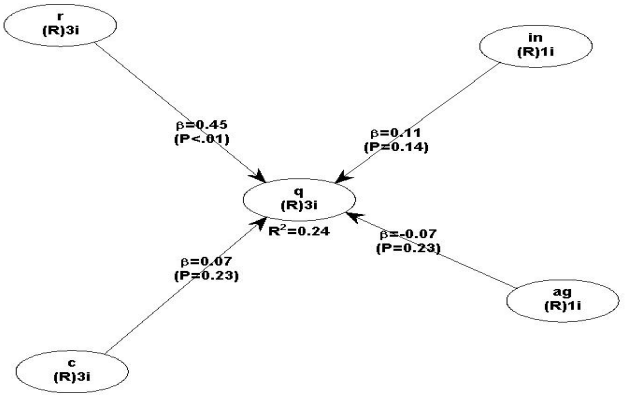

Figure 3: Estimated Parameters in the Structural Equation Model Based on Female Responses

The software utilized in this study measures three fit indices that are significant in variance-based Structural Equation Modeling (SEM) analysis, including average path coefficient (APC), average R-squared (ARS), and average inflation factor of variance (VIF) (Hasan and Islam 2022; Kock, 2011). The values obtained for the three indices are as follows: APC = 0.222, P = 0.011; ARS = 0.321, P < 0.001; and AVIF = 1.039. The results indicate a

good model fit with the data (statistically significant APC and ARS) and low overall collinearity (AVIF < 5) (for other indices, see Table 3).

Table 3: Model fit and Quality Indices

Measurement	Result	Remarks
Average path coefficient (APC)	0.222	P=0.011
Average R-squared (ARS)	0.321	P<0.001
Average adjusted R-squared (AARS)	0.305	P<0.001
Average block VIF (AVIF)	1.039	acceptable if <= 5, ideally <= 3.3
Average full collinearity VIF (AFVIF)	1.306	acceptable if <= 5, ideally <= 3.3
Tenenhaus GoF (GoF)	0.484	small >= 0.1, medium >= 0.25, large >= 0.36
Sympson's paradox ratio (SPR)	0.750	acceptable if >= 0.7, ideally = 1
R-squared contribution ratio (RSCR)	0.992	acceptable if >= 0.9, ideally = 1
Statistical suppression ratio (SSR)	0.750	acceptable if >= 0.7
Nonlinear bivariate causality direction ratio (NLBCDR)	0.875	acceptable if >= 0.7

The SEM analysis results are presented in Figures 1, 2, and 3, respectively, which depict a positive and significant relationship between rewardablity and quality knowledge contribution ($\beta = 0.52$, $P < 0.001$). Thus, we confirm Hypothesis 1, indicating that rewardablity confirms service organizations' quality knowledge contribution (QKC). The competition also impacted QKC positively (confirming Hypothesis 2, $\beta = 0.25$, $P < 0.001$). On the other hand, the study result shows some contrasting results while performing multi-group analysis where both the hypothesis for the male group was found significant with a better projection of H1 ($\beta = 0.53$, $P<0.001$) and H2 ($\beta =0.42$, $P <0.001$), respectively. Where female found H1 ($\beta = 0.45$, $P<0.001$) significant and H2 ($\beta = 0.07$, $P = 0.230$) found insignificant. Additionally, the effect of control variables, including Income ($P > 0.13$), age ($P > 0.36$) all-inclusive, male (Income ($P > 0.25$, age $P > 0.42$), female (Income $P > 0.14$, age $P > 0.23$) were also explained. The summary of the findings is also presented in Table 4.

Table 4: Path Coefficient and Significances

Path	Beta (*p*-value)	Supported or Not
H1: Rewardabilty → Quality Knowledge Contribution	0.52(<0.001)	Yes
H2: Competition → Quality Knowledge Contribution	0.25(<0.001)	Yes
Male Reflection		
H1: Rewardabilty → Quality Knowledge Contribution	0.53(<0.001)	Yes
H2: Competition → Quality Knowledge Contribution	0.42(<0.001)	Yes
Female reflection		
H1: Rewardabilty → Quality Knowledge Contribution	0.45(<0.001)	Yes
H2: Competition → Quality Knowledge Contribution	0.07(0.230)	No

5. Discussion

Gamification creates an environment that may make the work environment more pleasurable and vibrant for employees. Service organizations deem to be innovative for the customer preferences where quality knowledge contribution is fundamental to innovate new services for the customers. Therefore, gaining a competitive advantage and providing innovative service is challenging for organizations where engaging employees in contributing knowledge is a prerequisite. Different studies make various implications and highlight that the gamification approach attracts and engages employees in their work. The current study also finds these facts and wants to share the contemporary practices on post covid-19 to help the service organizations to develop their policies and strategies further to remain competitive in the market.

This study finds some interesting facts with its results exploring gamification in the Bangladesh context. This study explores rewardability and competition as gamification to assure quality knowledge contribution among service organization employees. The result of the study found that both rewardability and competition were related to the quality knowledge contribution behavior of the employees working in various organizations in Bangladesh. The result of the study also complies the prior studies of Riar et al. (2022), Jalili (2020), Suh and Wagner (2017), and Harris and O'Gorman (2014), where gamification is found to be an exciting concept of work which make the organization's monotonous tasks entertaining, making hard work pleasurable, increasing concentration on the job, enhancing employee contribution, assisting in maintaining motivation and satisfaction, and, most importantly, making employees more active in knowledge contribution.

Nevertheless, the study shares different results when comparing gender responses regarding gamification to quality knowledge contribution. Concentrating male group rewards and competition initiating gamification to sharing their knowledge was found significant, whereas, in the female group, it founds that females recognizing completion is a challenging issue in the Bangladesh context and makes insignificant relation to contributing their knowledge. According to Bizzi (2023), rewadabilty opens the opportunity for the employees to be appreciated for their jobs while gaining different points and recognition, which makes the monotonous or boring jobs interesting one where both groups agree to have this gamification mode in their jobs where competition makes different implication from the male and female perspectives. According to Caton and Greenhill (2014), competition sets the leaderboard in a game that excels the competition among colleagues to work harder and wants to be ahead of others. However, it will satisfy the individual's innate desire but create pressure in the jobs to reach this desire. In their study, Lier and Breuer (2020) found that male employees are more motivated to stand out from the crowd. The study results also comply with this fact for males, whereas females are not interested in this pressure game over their regular jobs in day-to-day transactions. Considering this finding, the service sector of Bangladesh is believed to be in quality knowledge contribution to their organizations through gamification. However, they are supposed to be certain of females' empowerment in policy and strategy-making to make the organization even more productive. The study result also could not find the impact of the control variables to share the diverse responses.

5.1 Implications and Future Research Suggestions

The significance of this research can be observed in several ways. Firstly, there need to be more studies on quality knowledge contribution in service organizations in Bangladesh, and this empirical research contributes to the advancement of theoretical knowledge on the subject. Secondly, this study stands out as the first initiative to our knowledge addressing gamification in the Bangladeshi context presenting service sector. The study tests a theoretical model and hypothesizes the relationship between gamification (rewardability and competition) and quality knowledge contribution. The results of this study also provide practical implications for the service organizations in Bangladesh, emphasizing the need to initiate gamification to enhance employee knowledge contribution to remain competitive in the market. Furthermore, Bangladeshi policymakers, academics, and industry experts can use this study's findings and future research to design a workplace practice or strategy that promotes viable quality knowledge contributions for service organizations.

In addition, the present study has identified various opportunities to conduct further research. It will examine the underlying causes for female participation in gamification to assure quality knowledge contribution in the current organizational setting in Bangladesh. Therefore, addressing the study's drawbacks, it would be beneficial to explore how other factors such as engagement, bullying, leadership, and workplace environment may be influential in exploring the knowledge contribution among the service sector employees in Bangladesh.

6. Conclusion

The present research has shed light on various literal constructs to emphasize the significance of quality knowledge contribution in service organizations in Bangladesh. Relating gamification with knowledge exercise is regarded as a crucial resource to enhance organizational performance and remain competitive in the market. Although the competition was found insignificant in knowledge contribution from the female group, it may not suffice to discourage the quality knowledge contribution in organizations. Therefore, to establish a successful practice in service organizations in Bangladesh, it is imperative to consider the overall impact of gamification to maximize its potential impact on employee quality knowledge contribution.

The present study has several limitations worth mentioning. Firstly, the sample size and sampling method employed may not be sufficient to confirm the generalizability of the findings. Secondly, the challenge of obtaining responses also poses limitations to the study. Lastly, it was not feasible to cover all service

organizations in Bangladesh. However, it is worth noting that this methodology is commonly utilized in empirical research (Hasan et al, 2022). Given these limitations, we recommend that future research endeavours consider other factors contributing to quality knowledge exploration in Bangladesh's service and manufacturing organizations.

The Role of Marketing Knowledge Sharing in Building Organizational Immunity

Tareq Hashem
Marketing Department, Isra University, Amman, Jordan

tareq.hashem@iu.edu.jo

Abstract: This study aimed to assess the impact of sharing marketing knowledge on attaining organizational immunity in Jordanian industrial corporations using a quantitative methodology. Marketing managers from Jordan's 53 industrial corporations made up the study's population. 40 questionnaires were found to be valid for analysis. The following outcomes have been obtained: The sharing of marketing knowledge influences building organizational immunity in Jordanian industrial corporations. The benefit of marketing knowledge sharing on obtaining organizational immunity in Jordanian industrial corporations is linked to marketing managers' academic qualifications. The following are the researcher's recommendations: Creating unique procedures for assessing economic data relating to the company's operations to foresee any future marketing changes. In addition to focusing on educating marketing department employees in the art of gathering information about the external environment regularly, to confront and face any marketing changes that may arise in the surrounding environment.

Keywords: Organizational immunity, Marketing knowledge sharing, Marketing knowledge, Organizational learning, Organizational memory

1. Introduction

Organizations in the twenty-first century face significant quantity and quality challenges, including rapid changes in information and communication technology, global market openness and liberalization, the growing role of the knowledge economy, increased competition, merger movement, and joint ventures between organizations. These difficulties need companies, in general, to adapt to them with a clear vision that allows them to forecast the future, locate and embrace opportunities, and identify and avoid dangers and hazards. From these prospects, the notion of focusing on the knowledge resource of intangible knowledge assets evolved in the late twentieth century as a strategic resource that should be accorded the attention it deserves, no less than its interest in tangible assets(Hoegl et al., 2003).

It is well recognized that information plays a vital role in society, and knowledgeable people are the most valuable assets in businesses. Knowledge management in organizations is connected with several benefits that may help the firm retain its competitive position in today's marketplaces. Information sharing and production are two critical components of knowledge management that play a significant role in generating corporate value. Organizations must successfully develop the knowledge and skills of their personnel in order to attain an adequate degree of knowledge creation and innovation. This approach aims to emphasize the vital role that information exchange plays in a company (Hung et al., 2011).

The company's immune system is comparable to the human body's immune system, indicating the body's capacity to sustain it efficiently. Although its origins and early writings date back to the mid-1990s, this is a crucial problem in today's corporate climate and is rarely discussed theoretically (Ivanov, 2013).

To begin, it is vital to distinguish between an organization's immunity and its immune system. Organizational immunity exists at all times and can be represented in the organization by its people, systems, culture, procedures, policies, and programs that automatically show their impact in emergency incidents in the form of reaction, and organization immunity may be present there; this frequently occurs in developing countries where management is not a study area. Especially crucial, and vice versa, when departments understand the relevance of the immune system and aim to grow it based on scientific rather than arbitrary situations (Neilson et al., 2004). The random act of the immune system's presence makes the work of its immune system a system of action and reaction, which is the worst logic in administrative sciences today, so it is necessary to distinguish between the characteristics of the immune system and then a gap in the characteristics of the immune regulatory system in order to integrate the picture and reach a measure that is concerned with measuring the availability of The components of the system on the one hand and the nature of the work of the system on the other (Smith and Chris, 2013).

The significance of this study stems from the subject of the study, which is a new addition - according to the researcher's knowledge - in the field of knowledge and its participation in the field of industry and its application

in the field of improving the level of organizational immunity in industrial public shareholding companies. Furthermore, this research focuses on one of Jordan's most important economic sectors, the industrial sector.

The researcher believes there is a need to conduct a contemporary study that clarifies this significant concept and tests the degree to which it impacts knowledge sharing because there needs to be more clarity about the application of organizational immunity in industrial public shareholding companies. In light of this, the primary objective of the research was to respond to the following questions:

- What is the extent of Marketing knowledge sharing application in Jordanian industrial corporations?
- What is the level of organizational immunity in Jordanian industrial corporations?
- How does knowledge sharing affect organizational immunity in Jordanian industrial corporations?

The researcher highlighted the importance of Marketing Knowledge Sharing and Organizational Immunity in this study. As well as describing the study's population and sample size. in addition to the primary findings of the analysis and the study's recommendations.

2. Literature Review

2.1 Marketing Knowledge Sharing

Today, knowledge management is a crucial factor in progress and transformation. It's evidence of a dramatic improvement in the efficiency of several establishments. Knowledge management has been shown to have several positive effects on organizations, including higher levels of efficiency and effectiveness, better performance, higher levels of production, and more innovative thinking (Al Duwailah & Hashem, 2019).
Marketing knowledge is defined as market knowledge that is required via knowledge collecting, information transmission, interpretation, and storage in an organization's memory (Hanvanich et al. ,2003)
November (2008) outlined seven sorts of marketing expertise that businesses should be aware of:

1. Consumer knowledge;
2. Product knowledge
3. Competitors' knowledge
4. Understanding of the marketing services offered
5. Knowledge of the company's processes and systems
6. Knowledge of the current themes of interest to the organization.
7. Knowledge of the people with whom the company interacts, both within and outside.

Knowledge sharing describes the sharing of employees' ideas, knowledge, skills, abilities, and competencies with colleagues and group members. This requires a shared culture to entertain employees by providing access to relevant knowledge and using that knowledge to address problems and increase efficiency (Hoegl et al., 2003).

Lin (2007) defines knowledge sharing as "a culture of social interaction, which involves the exchange of employee knowledge, experience and skills through the entire department or organization."

Knowledge sharing refers to providing employees with information, ideas, know-how, and other assistance to perform a specific job or task (Wang et al., 2014; Hashem, 2016)).

Knowledge sharing can happen at the individual level between two employees where they can share their skills, knowledge, and experience to solve different problems and help each other to perform different tasks more quickly and effectively. It can also occur among group members where the knowledge, skills and abilities of one group member can help other group members to perform well to increase the efficiency and overall output of the group (Niqresh et al., 2021). At the organizational level, knowledge sharing is about collecting, arranging, transforming, reusing that knowledge and making it available to others in the organization. Any organization can successfully promote a culture of knowledge sharing by including knowledge sharing in its strategic formation. However, it can also be promoted through encouragement by changing the attitude and motivation that top management provides to its employees for knowledge sharing (Connelly and Kevin Kelloway, 2003; Hashem and Suleiman, 2019).

In their study, Paulin and Suneson (2012) proposed the idea that sharing knowledge increases the rate of customer satisfaction. This means that an organization whose members share their knowledge and experience is usually able to meet its obligations to its customers. This increases the rate of customer satisfaction because it takes less time to provide a service or product.

On the other hand, Paulin and Suneson (2012) said that knowledge sharing has many positive strategic effects on the organization because it helps to identify the basic and important knowledge, experiences, and skills of the organization that must be properly utilized and managed. Organizations can gain access to both explicit and tacit knowledge and cut losses through knowledge exchange.

On the other hand, knowledge sharing is strategically important because it is an effective way to make scarce expertise available to the whole organization through forums, training courses, presentations, research papers, etc..

2.2 Organizational Immunity

Organizational immunity is a company's ability to protect and defend itself, either by preventing or overcoming weaknesses and threats or by removing and avoiding them by preventing their growth or stopping their effects (Simmons, 2013).

Models of systemic immunity vary depending on the researchers, their intellectual mindset, and their practical objectives. Leadership, integration, flexibility, participation, a problem-solving culture, empathy, energy distribution, and learning are the requirements for organizational immunity. According to Simmons (2013), it includes oversight and oversight committees, legal compliance, risk management systems, incentives, and rewards.

Huang (2013) said that it depends on organizational learning, memory, and knowledge, while Brown (1997) said that regulatory genes represent it. DeGeus (1997) returned to its roots, which can be seen in the organizational structure, information flow, power-sharing culture, the right to make decisions, and incentive and reward systems. Due to the differences and similarities in the above, our research was able to identify the dimensions of organizational immunity that came up more often than others because there was some agreement on them:

- Organizational learning:

It simulates the function of thymus cells (T) in the human immune system, which plays a crucial role in protecting humans from viruses, and organizational learning refers to the increased awareness of organizational problems and then recognizing and treating them, which is positively reflected on the performance of the institution and its outputs (Abdul Majeed, 2016). Organizational learning consists of (individual learning, group learning, and learning from others, i.e., competing organizations, and self-learning, i.e. within the organization (Smith and Chris, 2013; Neilson et al., 2004).

- Memory Regulatory:

It mimics the human immune system's Bone Marrow (B) memory cells. These cells can remember human diseases and produce appropriate antibodies to attack them. Organizational memory involves recalling the organization's prior archived knowledge through intelligently stored information and using it in decision-making Current and future building sustainable competitive advantages (Park and Bunn, 2003).
Organizational memory is similar to the human mind, where the organization recalls its past experiences in dealing effectively with current situations and planning for the future in light of previous knowledge (Croasdell, 2001). Intentionally generated by organizational culture, business environment, organizational structure, and external memory, including information about competitors, industry financial reports, and government records

- Regulatory genes:

It mimics the human genes deoxyribonucleic acid (DNA) essential for life. Organizational genes reflect the company's specific fingerprint that makes it different from others, enabling it to adapt aggressively to competition. An organization's DNA is defined by its core values, beliefs, culture, and personality that shape its identity, determine its destiny, and are reflected in its performance and activities in a way that limits or increases its capabilities and effectiveness (Ivanov, 2013).

Organizational DNA consists of the natural genetic imprint that belongs to a specific organization as natural defenses such as competitive position and market share, and the acquired genetic imprint resulting from the organization's disposal of environmental risks after which it recovered, such as immune cells resulting from exposure of a part of the body to environmental influence and was able to recover and became immune from this danger; organizational memory of previous treatments and stored solutions; organizational vaccine where outsourcing is used to deal with threats and risks; Benchmarking when using alternatives that have proven successful with the strongest competitors (Hovivyan, 2006)

According to the above literature review, the following hypotheses are presented:

- There is a high level of applying knowledge sharing in Jordanian industrial corporations
- Jordanian industrial corporations are attempting to improve their organizational immunity.
- The sharing of marketing knowledge influences building organizational immunity in Jordanian industrial corporations.
- Due to marketing managers' academic qualifications, there is a statistical difference in the effect of marketing knowledge sharing on obtaining organizational immunity in Jordanian industrial corporations.

3. Research Methodology

This study relies on the descriptive analytical approach by reviewing the theoretical literature related to the study variables, applying the study tool to collect data, and reaching results that contribute to presenting a set of recommendations.

4. Study Population and Sample

The study population consists of marketing managers in the 53 Jordanian industrial corporations. 40 questionnaires were found to be valid for analysis., representing 75.5 % of the sample size.

5. Data Collection Methods

The study relies on two types of data: primary and secondary data.

The secondary data is represented by previous theoretical and field studies, books and research related to the subject under study.

As for the primary data, it is represented in developing a questionnaire to measure the variables and their dimensions and to study the hypotheses.

6. Demographic Results

Frequency and percentage were calculated for the study sample. Following results (Table 1) are found:.

Table 1: **Descriptive Statistics of Demographics**

		f	%
Gender			
	Female	38	95%
	Male	2	5%
Age			
	Less than 30	12	30%
	40-31	20	50%
	50-41	8	20%
	50+	-	-
Qualifications			
	High school	1	2.5%
	Diploma	1	2.5%
	BA	31	77.5%
	High studies	7	17.5%
Experience			
	Less than 3 years	6	15.0%
	3-5 years	10	25.0%
	6-10 years	10	25.0%
	11-15 years	10	25.0%

		f	%
	16+	4	10.0%

We can see that 95% of the sample is male, and 5% is female. This suggests that Jordanian public shareholding industrial businesses are interested in recruiting guys to the role of marketing manager owing to the substantial loads needed by this job, which are consistent with male talents. 30% of the sample is between the ages of (30-40), and 20% is between the ages of (41-50). This demonstrates employers' desire to hire young people for the post of a marketing manager.

We can see that 5% of the sample has a diploma or less, 77.5% has a bachelor's degree, and 17.5% has a graduate degree. This demonstrates the high academic qualifications of the study sample concerning the tasks and work of the marketing manager position, as well as the public shareholding companies' awareness of the importance of the university degree in enhancing the capabilities of the marketing manager's incumbent to carry out his duties. We also notice that 15% of the sample has less than 3 years of experience, 25% have experience between (3-5), 25% have experience between (6-10) years, 25% have experienced between (11) -15) years and the remainder have more than 15 years of experience. This means that 65% of the sample has less than 10 years of experience. This might be owing to its members' young average age.

7. Reliability and Validity of the Scale

Many marketing arbitrators were given the questionnaire to complete, providing feedback on the scale's apparent validity.

The questionnaire was subjected to a Cronbach's alpha test, and the overall result of was 0.906, which is good because it is higher than the generally recognized value of 0.60. Malhotra (2004)

8. Hypotheses Testing

- There is a high level of applying knowledge sharing in Jordanian industrial corporations (see Table 2)

Table 2: H1 Test

One-Sample Statistics				
	N	Mean	Std. Deviation	Std. Error Mean
MKS	40	3.9225	.70219	.11103

One-Sample Test						
	Test Value = 3					
	t	df	Sig. (2-tailed)	Mean Difference	95% Confidence Interval of the Difference	
					Lower	Upper
MKS	8.309	39	.000	.92250	.6979	1.1471

Using a one-sample T-test, we find that the result of (t = 8.309) is statistically significant at the 0.05 level, indicating that there is a high level of applying knowledge sharing in Jordanian industrial corporations.

- There is a high level of organizational immunity in Jordanian industrial corporations (see Table 3)

Table 3: H2 Test

One-Sample Statistics				
	N	Mean	Std. Deviation	Std. Error Mean
Immunity	40	3.4050	.84821	.13411

One-Sample Test					
	Test Value = 3				
	t	df	Sig. (2-tailed)	Mean Difference	95% Confidence Interval of the Difference

					Lower	Upper
Immunity	3.020	39	.004	.40500	.1337	.6763

Using a one-sample T-test, we find that the result of (t = 8.309) is statistically significant at the 0.05 level, indicating that Jordanian industrial corporations are attempting to improve their organizational immunity.

- The sharing of marketing knowledge influences building organizational immunity in Jordanian industrial corporations.

Table 4: H3 Test

Model	R	R Square	F	Sig.
1	.686[a]	.471	33.865	.000

Coefficients						
		Unstandardized Coefficients		Standardized Coefficients		
Model		B	Std. Error	Beta	t	Sig.
1	(Constant)	.152	.568		.269	.790
	MKS	.829	.142	.686	5.819	.000

Linear Regression was used to evaluate the hypothesis. Table (4) indicates that the value of F is statistically significant at the (0.01) level . This means that the hypothesis was correct, and that The sharing of marketing knowledge influences building organizational immunity in Jordanian industrial corporations. A correlation value of R=0.686 is considered high.

- There is no statistical difference in the effect of marketing knowledge sharing on obtaining organizational immunity in Jordanian industrial corporations due to marketing managers' academic qualifications.

Table 5: H4 Test

Tests of Between-Subjects Effects					
Source	Type III Sum of Squares	df	Mean Square	F	Sig.
Corrected Model	21.226[a]	19	1.117	3.270	.006
Intercept	1.920	1	1.920	5.620	.028
academic qualifications	1.677	1	1.677	4.908	.039
MKS	14.880	18	.827	2.420	.029
Error	6.833	20	.342		
Total	491.820	40			
Corrected Total	28.059	39			

ANCOVA test is used to test above hypothesis. it is found that F value= 2.42 is significant at 0.05 . that means There is statistical difference in the effect of marketing knowledge sharing on obtaining organizational immunity in Jordanian industrial corporations due to marketing managers' academic qualifications

9. Results and Recommendations:

The purpose of this study was to assess the impact of sharing marketing knowledge on attaining organizational immunity in Jordanian industrial corporations by using a quantitative methodology. Marketing managers from Jordan's 53 industrial corporations made up the study's population. 40 questionnaires were found to be valid for analysis.

The following outcomes have been obtained: There is a high level of applying knowledge sharing in Jordanian industrial corporations This result is consistent with the study of (Connelly and Kevin Kelloway, 2003; Hashem and Suleiman, 2019; Pauline and Sunesson ,2012). Whereas, Jordanian industrial corporations are attempting to improve their organizational immunity. This result is consistent with the study of (Simmons ,2013; Huang ,2013; DeGeus,1997) .

Also, the sharing of marketing knowledge influences building organizational immunity in Jordanian industrial corporations. As well as, there is a statistical difference in the effect of marketing knowledge sharing on obtaining organizational immunity in Jordanian industrial corporations due to marketing managers' academic qualifications.

In light of the results thus far, the researcher suggests:

- The importance of creating unique procedures for assessing economic data relating to the company's operations in order to foresee any future marketing changes that may occur.
- The importance of creating specialized tools for monitoring business-related economic data in order to foresee potential marketing shifts.
- The need to tailor marketing research to the specific demands of a business to ascertain its place in the market and determine its relative strengths and weaknesses to adapt to a changing business climate.
- To cope with and adapt to any changes that may occur in the external environment, it is essential to teach marketing department employees in the art of gathering information about the external environment on a regular basis.
- To monitor potential shifts in client preferences, it's important to provide real-time reports to their profile database.
- In order to manage and deal with fluctuations in sales quantities, the marketing department must be eager to collect information and data about its goods on an ongoing basis.
- We are expanding the research's scope by analyzing its implications in other fields.
- Focusing on educating marketing department employees in the art of gathering information about the external environment on a regular basis, in order to confront and face any marketing changes that may arise in the surrounding environment.

10. Conclusion

In the twenty-first century, organizations face significant quantity and quality challenges, such as the rapid evolution of information and communication technology, the opening and liberalization of global markets, the expanding role of the knowledge economy, increased levels of competition, the movement towards mergers, and the formation of joint ventures between organizations.

Because of these challenges, businesses, in general, have to find a way to adapt to them by developing a clear vision that enables them to see into the future, find and seize opportunities, and recognize and steer clear of any risks and hazards. As a result of these possibilities, in the latter half of the twentieth century, the concept of concentrating on the knowledge resource of intangible knowledge assets emerged as a strategic resource that ought to be afforded the attention it deserves, no less than its interest in physical assets. This idea was developed as a strategic resource that should be accorded the attention it deserves.

Knowledge creation and dissemination are two essential aspects of knowledge management, and businesses should effectively develop their employees' knowledge and capabilities. The method highlights the critical role that the exchange of information plays in an organization. According to this research, marketing knowledge sharing is crucial for boosting organizational immunity.

Abstract: This paper presents the case study of the CLARK (*Captured Lessons applied for the Reuse of Knowledge*) project which is an evolution of the Lessons Learned (LL) portal at the European Space Agency (ESA). The SCARLET research activity has been a key for-runner to this project on an academic research level. It has provided us with important insights into the architecture of the system design. A knowledge graph (KG) has been developed to (re)search (for) knowledge from different angles through the established relationships by combining and structuring data from many sources. Additionally, a chatbot is trained to provide a conversational intelligence experience on top of the data provided by the different Knowledge Management (KM) activities at ESA. Hence, CLARK project enables to retrieve, search, or provide knowledge for the employees across ESA through different interfaces connected to the core systems. In this paper, we also report some findings from the initial testing which indicate very promising results in terms of user engagement and usability of CLARK system and the overall approach. The paper also discusses current and future challenges.

Keywords: Conversational intelligence, Chatbot, Knowledge graphs, Natural language querying, Space, Knowledge re-use

1. Introduction

This paper is a case study of the European Space Agency development project to create a major evolution of the existing Lessons Learned capabilities currently in use at the Agency through their existing SharePoint-based webtool. Through considering the application of knowledge graphs and chatbot technologies to achieve this major “next step” in better addressing user needs, it has been possible to realise a radical shift in capabilities offered to users. This adoption of multiple novel technologies has in turn provided a higher level of relevance to user needs and hence benefit regarding user themselves. As a result it is suggested that these capabilities can now be more broadly applied and be available as Knowledge Management activities start to yield real solutions to everyday problems in a way that users want these to be offered and presented. In placing the user front and centre to the proposed solution, CLARK - Captured Lessons Applied for the Reuse of Knowledge, a diverse range of user interface options are being developed to provide knowledge through image and text-based interfaces, including providing interactions between CLARK and the user in a human like, conversational way, through the conversational agent (commonly known as a Chat Bot).

This project is a follow up on the research project SCARLET - Space Conversational Agent for Retrieving

Lessons learned and Expert Training - performed by the team of Strathclyde University led by Massimiliano Vasile (Mihaylov et al. 2022). The research has been done as a joint undertaking with the European Space Agency by Strathclyde University from a perspective “which technologies can be used to create a conversational agent” and “how to prove this technology imparts a higher quality of lesson capture and dissemination”. A minimum viable product has also been built by Strathclyde using static data and tested successfully. The CLARK project uses the experience from the Strathclyde University SCARLET research team to build a production system that collects and processes data continuously, robust enough for ESA engineers.

As to be expected from a large organization like the European Space Agency, particularly one that works on very complex problems and technological solutions, there is a lot of new techniques being generated and knowledge being acquired. Project teams working in the many different Directorates (of which ESA has eleven) focussing on different aspects of space missions are all working hard to get the (large) space programs aims realised (together with the space industry), operationalized and maintained.

For nearly two decades, ESA has had procedures in place to gather Lessons, captured and learned at the Space program level. For the last six years a centralized Lessons Learned (web-based) portal has been implemented that further helps ESA implement its process and to capture the important knowledge in a centralized system and in a common way. The lessons learned portal is the flagship of the knowledge management activities undertaken by ESA to safeguard its internal knowledge. The next step, and the main subject of this paper, is the implementation of CLARK on top of the centralized Lessons Learned repository. The main objective of CLARK is to directly address the identified use cases and user needs in order to allow the ESA workforce to access knowledge through different interfaces and through different approaches.

The technical setup of the CLARK system was configured in such a way to allow it to suit different types of situations users are looking for Knowledge. The simple search, for example, for a user who knows exactly what they are looking for and can find it with just a few keywords. The

Knowledge Graph is provided for the user who is visually inclined and knows how to navigate a number of data streams through their interrelationships (as presented in a knowledge graph). In turn, the chatbot being provided for the users that prefer to "interact" with the system, entering or extracting knowledge in an assisted manner, this particularly applies to the case where the user has an idea what he or she is looking for, but not how to look for it and wants a more "open" search environment.

For the end result of the CLARK project four components had to be developed.

- A data platform capability where data from different sources is held centrally and continuously updated from each source. The sources provide primarily structured data (content). At this point there are 9 sources that provide data to the CLARK data platform. The Lessons Learned portal being the primary source of configured information.
- A Knowledge Graph platform. In the Knowledge Graph platform different relations between the data (given in the graph as unique named nodes) are created and displayed to the user. Examples of a node and their relationships is a person and lessons, technology and a project and so on. This gives the user a possibility to browse through large, interconnected datasets through a completely visual interface where the node relations determine the outcome of the term being searched.
- A chatbot platform. The chatbot interface that is fed by the data platform and the Knowledge Graph platform, provides a conversational assistant to the user for both knowledge capture and retrieval. The chatbot also has a learning loop which allows it to learn from the interactions with ESA workforce. Additionally, the chatbot also has the capability to improve the quality of the capture a new lesson from a user, such as by identifying terms and acronyms not understood (i.e., not available) in the CLARK system.
- User Interfaces. For the user to use these new capabilities, two interfaces (offering the same capabilities) are built, a web interface (for desktop use) and a mobile app interface (for mobile device use). The key here is for the interfaces to be as simple and intuitive as possible, so the user does not have to focus on understanding what the interface does, but rather focussing on which capabilities she / he wants to start utilizing . In addition the user interfaces allow for a simple customisation by the user, to have the interface provide lessons matching the user interests, zas these lessons become available in the lessons learned portal.

2. Related Work

The fields of knowledge management and information processing historically have attracted a lot of attention from the scientific community; therefore, complete discussion of all the work which can be attributed to the success of this work is out of scope. However, there are several subfields which are considered more relevant in this context. Knowledge graph related research is one of these fields; in fact, knowledge graphs (also referred to as semantic networks) have been widely adopted in various domains. National Aeronautics and Space Administration (NASA) has also adopted KG technology for its Science Mission Directorate domains (Timmer et al. 2023); moreover, they have previously adopted it for scientific knowledge storage and organization (Zhang et al. 2020).

One of the most important recent developments in natural language processing (NLP) was the introduction of BERT transformer architecture (Devlin et al. 2018) and its successor RoBERTa (Liu et al. 2019). Transfer learning paradigm enables simplified reuse or adoption of previously pretrained models for different tasks or domains. Hence, these models are often applicable as parts of modern NLP systems, providing contextual embeddings with more relevance for particular domains. Several models exist for space related domains, namely SciBERT

(Beltagy et al. 2019), AstroBERT (Grèzes et al., 2021), SpaceBERT, SpaceRoBERTa and SpaceSciBERT (Berquand et al. 2021). In the context of CLARK project, they might be helpful to improve detection of named entities or concepts, as well as improve support for domain specific language or terminology.

Question answering (QA) is another influential topic; the most recent and well-known applications emerge from large generative language models (LLM), such as GPT-4 (OpenAI 2023), LaMDA (Thoppilan et al. 2022), LlaMA 2 (Touvron et al. 2023), combined with careful prompt engineering. This approach was first verified by creators of GPT-3 model showing that providing several examples can vastly improve generated output quality (Brown et al. 2020). However, although widely developed, such systems still struggle to provide precise answers. To overcome this issue, techniques like prompt chains or direct integration with external data sources or knowledge bases directly is generally considered. (Diefenbach et al. 2017) provide an extensive survey of traditional approaches for QA over knowledge bases; they show that a huge number of issues in question analysis, query construction, disambiguation and general natural language processing could be required to be solved to achieve high quality results.

Finally, natural language querying enables formulating queries in natural language which is more appropriate for human users. This is one of the core problems addressed by CLARK (and particularly chatbot) development. (Affolter et al. 2019) identified four types of NL database interfaces, particularly, keyword-based, pattern-based, parsing-based, grammar-based. Moreover, one can observe emerging trends of neural translation-based systems based on deep-learning approaches. Sequence-to-sequence (seq2seq) architecture, which was introduced for machine translation tasks, is also applicable for SQL-like query language generation (Zhong et al. 2017). (Bazaga et al. 2021) introduce Polyglotter translation approach based on Seq2Seq architecture which can be applied to generate queries for almost any database due to graph abstraction which is used to represent query candidates (in their work, MySQL and Neo4J are used as case studies).

3. The CLARK Approach

3.1 It all Starts with the Data

The primary target of the whole system is to let people learn from the experience(s) of their colleagues within ESA. For this target to be met, and the technology to be enabled, different types of data are required. Such data enables the user to perform contextual search for answers to his questions together with supporting objects or entities. In the context of CLARK, two categories of data are considered. The first category are primarily the lessons from the ESA Lessons Learned portal, associated with relevant documents. These lesson objects also contain information based on experience from all types of people (roles and functions) within the large projects. The second category of data is relevant to provide context in search, such as project list, technology tree and product tree. These all help the system to categorize the results and the user to put the input in perspective.

There are nine different sets of data sources in total which have been imported into the data platform. Some of them provide unstructured (e.g., text content) or partially structured data, hence they are processed using more advanced search technologies (such as Apache SOLR). Additionally, it is enriched with additional metadata to create cohesion between different data sources. As each source has its own schema for enrichment, this step can be performed automatically, resulting in structure within the unstructured data. Additionally, to enable change management (different metadata, change of sources, etc.) data is initially stored in data lake.

3.2 Knowledge Graphs

Knowledge graph (KG) technology enables organizing data as a set of entities and relations between them, thus forming a semantic network, which can be further traversed to mine more complex relationships (including complete hierarchies represented by *isPartOf* or *isParentOf* relations), filter them or visualize in a hierarchical way which is very convenient for such type of data. This inspired us to build a KG-based system based on two core components: a graph database (Neo4J) which stores all the relations and nodes, and a graph visualization component to render to representation of these nodes and their relationships. The core data comes from the data platform (described in Section 3.1), where it is further refined, preprocessed and a set of nodes are formed, together with their interrelations.

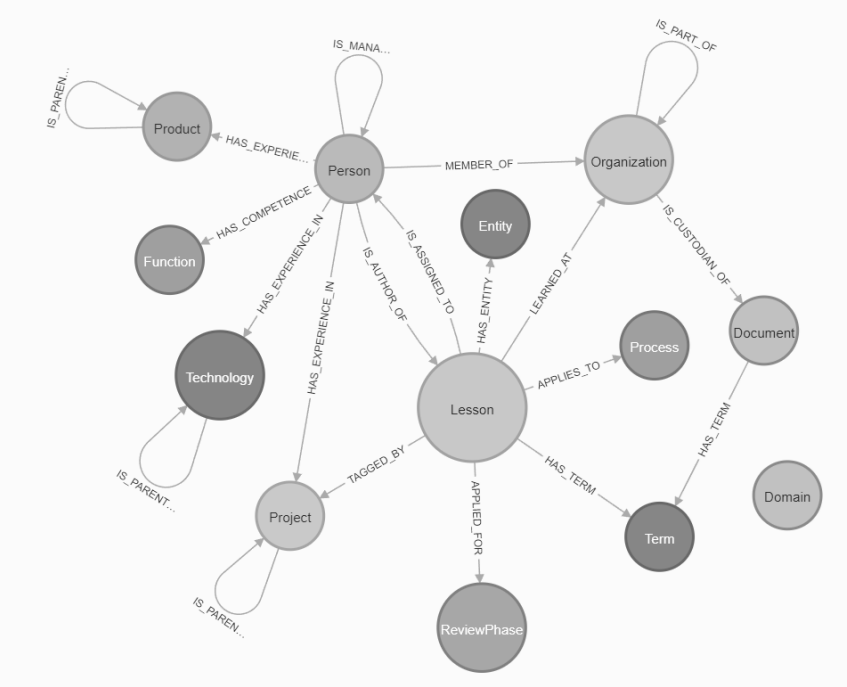

Figure 1: Knowledge Graph Structure

The KG system provides an interactive search tool for the users. This gives the user a possibility to browse through large datasets in a completely visual interface where the relations determine the outcome. Additionally, knowledge graph enables advanced search capabilities which can be employed by the chatbot to generate consistent and domain-focused answers to the system users, such as answering questions *Who is the author of this lesson?* or *List me lessons associated with project Sentinel*.

3.3 Conversational Intelligence with CLARK Chatbot

Arguably, the main and the most complex objective of CLARK project was to create a chatbot that can provide the user with the knowledge he or she is looking for through a conversation. Moreover, this is a domain-specific chatbot which should be capable to provide precise answers as available in the underlying KG database, which makes it more complex compared to recent trend of generative deep learning based chatbot technology (such as GPT) that tend to sometimes provide incorrect answers or even perform so-called “hallucinations”. Therefore, it also addresses several specific challenges as discussed further.

To communicate with the user and successfully assist him, CLARK chatbot implements a certain number of scenarios. They define how the user is expected to interact with the system. Currently, the following scenarios are implemented:

- List objects which can be searched: "Show me employees available in the database”, “Provide me the list of available technologies”
- Find number of objects in the database: "How many lessons learned are available in the database?”
- Find one or more objects by related term: "Show me information about Peter Peterson”, “Give me information related to Sentinel“
- Find objects that are related to other objects by some relation: “Show me people who worked in project Lunar Lander“, “Show me documents containing term flow control”
- Find property of some object: "Find me upper-level products for product Sensors", “Who is the supervisor of Peter Peterson?”
- Help on lessons learned similarity: “What is the similarity between lessons LL-0641 and LL-0650?”
- Submit new lessons learned: “I want to submit new lesson learned”
- Create specific recommendations to the user: “Could you give me some recommendations?”
- Add keywords and narrative to the lesson learned through the chatbot interface in the portal
- Provide help, sample queries and assistance to the user about the use of the chatbot: “How can I discover objects associated with a specific entity?”, “Show me how to search for properties of a specific object”

Additionally, it can provide recommendations for the user:

- Based on common terms from lessons in the previous user learning experience and lessons in the database
- Recommendations related to the working domain of the user
- Based by work of colleagues in the department of the user
- Based on similarity to a particular lesson

Recommendations are created using a specialized interactive menu-like scenario: the user is asked to select a recommendation type and, if required, provide additional input. The chatbot outputs several lessons learned according to the selected criteria. This scenario is illustrated in Figure 2.

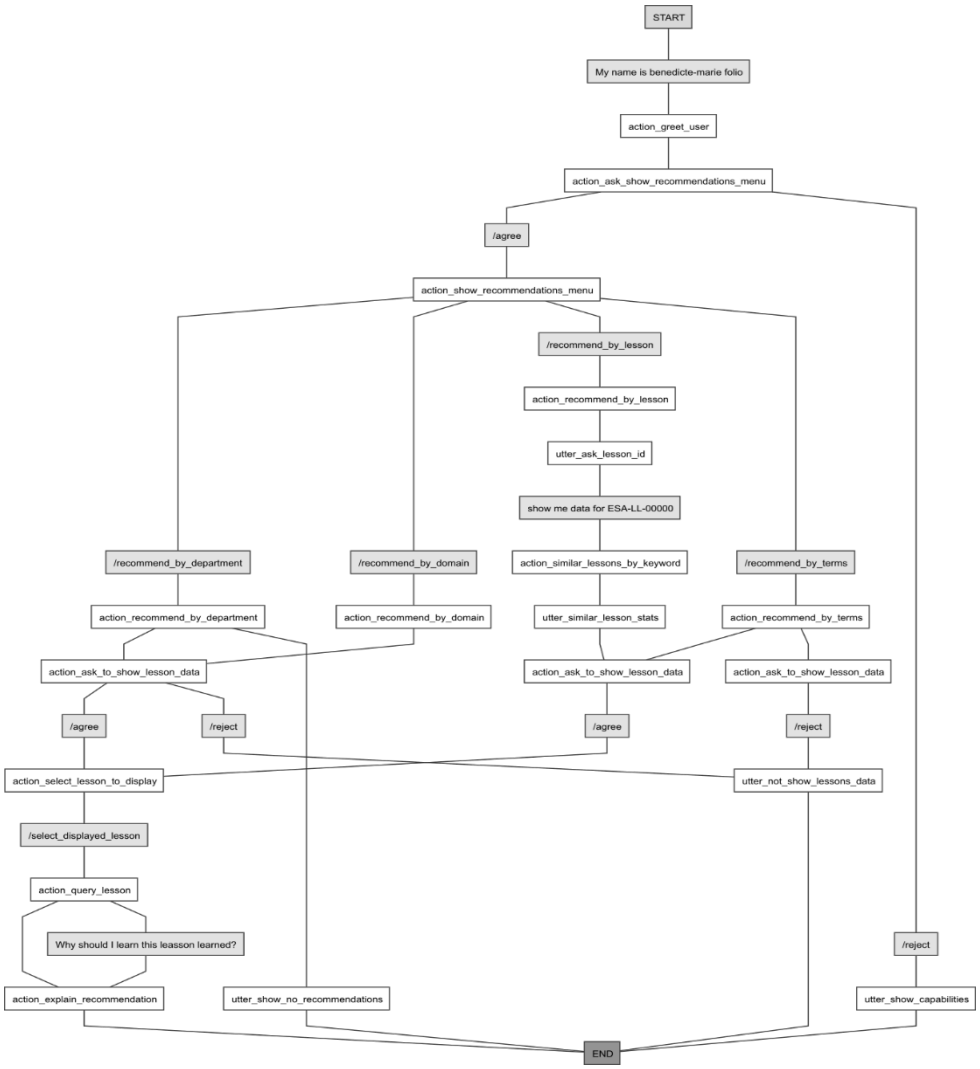

Figure 2: Recommendations Scenario

The final implementation is based on RASA framework which provides its own deep learning-based technology (DIET classifier) for training chatbot models and mapping them with specific knowledge-based actions. Moreover, it is also capable of integrating recent developments in language models, such as transformer models (BERT, RoBERTa) or generative GPT-like models, to provide their contextual embeddings as inputs. However, our experimental testing indicated that application of BERT or GPT-2 did not result in significant performance increase, hence, final model is based on RASA default DIET classifier with advanced processing pipeline setup.

3.4 The Complete View

For the user to use these new capabilities, two interfaces are built. From the usability perspective, interfaces should be as intuitive as possible, so the user does not have to focus on understanding what the interface does, but rather which capabilities are now available and can be used immediately.

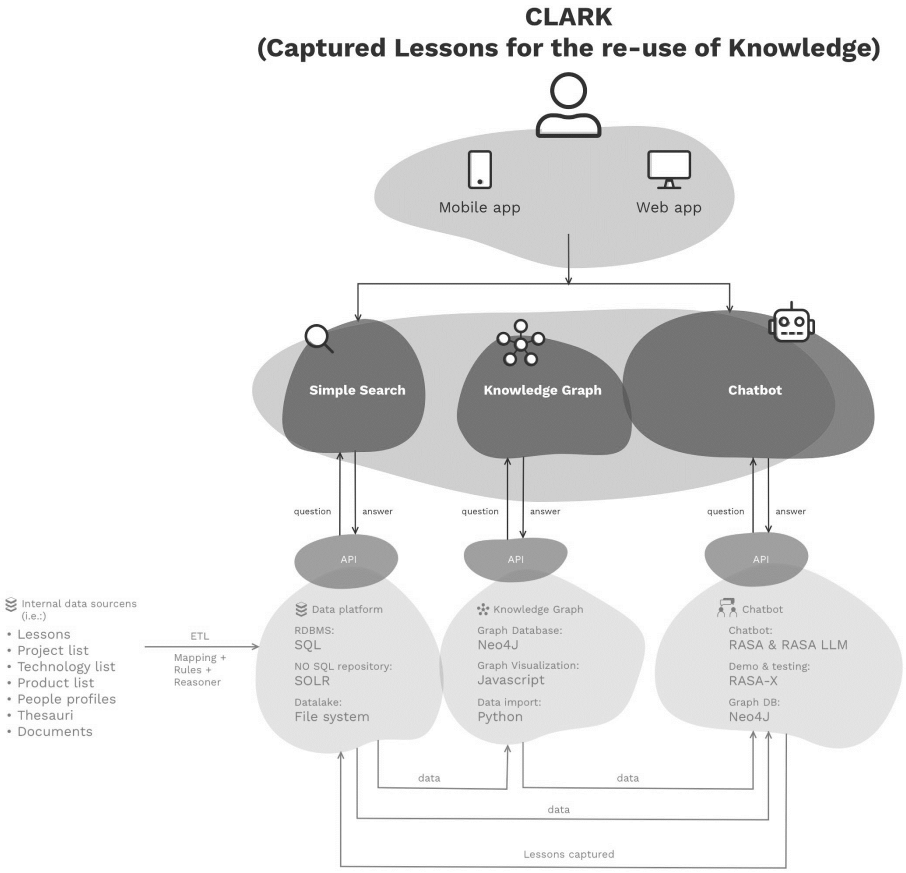

Figure 3: CLARK Architecture

Creating an elaborate system like CLARK does not mean the intended users will automatically start using the system. For the adoption of the CLARK system a webapp and mobile app (both compliant with ESA requirements) have been built. The webapp will by incorporated in the Lessons Learned portal and a mobile app will work only on ESA issued phones to comply to strict ESA security requirements. Both interfaces offer the user the chance to search for knowledge through the three possibilities.

4. Experimental Evaluation

To test the initial system, we ran an internal experimental evaluation at ESA. Eight users were selected to perform initial testing of the chatbot. They were provided with the documentation, including implemented scenarios, sample intents (questions for the chatbot). RASA-X, a visual frontend for conversation-driven development provided by RASA NLU framework, was used for interactive testing. We note that RASA-X does not represent the final user experience and should be viewed only as a temporary means for testing the overall approach; this is different actual usability testing performed for the CLARK webapp and mobile app.

The users were asked to provide their feedback in a free form. In this summary, we omitted feedback which was related to technical limitations which are to be solved after final integration of all components, minor technical inconsistencies (missing text, errors in text display, etc.) or out of scope functionality (mostly user interface related). While we consider them as less relevant at the initial stage, we admit that it could affect their first impression**.** Nevertheless, all these results proved to be beneficial for both the teams of chatbot and webapp/mobile development, as they clearly indicated the expectations from the end users and helped to solve some of them at initial stages of development.

Below we provide a summarized evaluation obtained from the feedback of the testers.

- *User feedback*. The main factors that users observed were related to the inconsistency of the output messages.

- *Conversation*. The overall chat experience seemed to be too formal or constrained for some of the users ("*the conversation had the feeling of being a set of commands input by the user..*"). This is not surprising since this is a chatbot focused on information retrieval, rather than communication; yet it provides hints for the future iterations. However, some of the users emphasized the intuitiveness but emphasized the limited feedback, especially when the chatbot failed to recognize intent and to continue scenario (*"unclear where you were at any on time and what process you were in..", "abrupt endings…"*). Clearly, this not only helped us to solve some unintended issues but provided clearer guidelines to handle such situations as fallback scenarios in the future.
- *Usability*. The feedback in this group is mostly related to the scenario. The key factors that users lacked were loss in conversation, absence of integrated chatbot help and user guidance, confirmation whether the chatbot understood their intents correctly, and inability to reset the chat.
- *Visualization*. This input is more relevant to the mobile app group, as it provided some expectancies for the user interface (bold field names, selection of black/white background, presence of reset section button), content layout or general output of the results.

Some important findings were observed after analyzing the obtained results:

- The feedback from the users who, according to their feedback, seemed to be familiar with the LL portal was more positive. This is not surprising as familiarity with the data present in the portal helped them to understand chatbot capabilities and formulate their requests to the chatbot more clearly.
- The actual expectations of the users were quite different – some of them were satisfied with the overall experience (although they had some comments) while the others seemed to have some skepticism about it. Such satisfiability distribution is not surprising at the initial stages, as it is expected to improve chatbot performance and usability in later iterations.
- From the system engineering viewpoint, the variability of user feedback clearly identified to need for multiple iterations of requirements re-elicitation and refinement, as well as application of agile development while developing conversational intelligence-based systems.

5. Current Challenges and Future Work

The initial testing has already provided us with valuable feedback from the users. However, there are multiple challenges or guidelines to be addressed in the future developments:

- *Integration of large language models (LLM).* LLMs, as the most recent developments in NLP, provide numerous application capabilities in solving various tasks. Despite their widely recognized issues, they can provide quite satisfactory solutions to various problems. In CLARK context, they could be applied as enhancements for multiple tasks, such as correcting mistypes or grammatical errors, improving general text quality, paraphrasing, summarizing text, extracting keywords or named entities, answering answers directly from LL text, and even generating structured representations such as visual diagrams or mind maps from text.
- *Longer chatbot memory context window*. This would enable more natural communication between user and chatbot. For instance, the chatbot could be able to extract various facts and store them in memory, while making use of them if asked. However, it might impose challenges related to advanced natural language processing and dialog management, such as co-reference resolution ("*it*" – which fact would it refer to?), word-sense disambiguation among others.
- *Better and more personalized recommendations for the user*. The user could get more personalized LL recommendations based on his preferences. This might be enabled by setting these preferences directly or by using integrated user feedback mechanisms (such as asking if the user liked this lesson, etc.). This requires the ability to set, store and manage these preferences. Moreover, lesson similarity and matching techniques could be improved as well, using novel semantic matching techniques.
- *(Semi) automated knowledge graph construction*. The knowledge graph could be automatically enriched with entities or relations extracted for LL text; this is also addressed in recent developments in the field of knowledge graph completion.
- *Dynamic alignment to changes in the underlying knowledge graph*. The chatbot should be capable of detecting new node types, entities or relationships. We note that the current implementation is already KG metadata-aware, yet, it still has some limitations, mostly due to restrictions or internal elements which must be excluded during search.

- *More advanced fallback implementation scenarios*. The proper implementation of fallback scenario, albeit seeming to be very simplistic, might not be trivial. Practical realizations may require handling different situations, such as: the text entered by the user, is garbage and should be skipped from further processing; the chatbot does not recognize any relevant entities or intents; handling and incomplete list various undefined exceptions.

6. Conclusion

The complete CLARK system is now in beta and will rapidly advance to production level. There are still a number of hurdles that need to be cleared as part of the planned integrated tests later in the year. An ESA team of testers with different backgrounds have used all three capabilities in their "stand-alone" form with positive and constructive feedback. The next step is to deliver the knowledge graph and Chatbot capabilities integrated in a single user interface and connect all platforms with the final "live" data (production).

The test results up until now are promising which are in line with the initial outcomes of the Strathclyde research that this technological solution (combining knowledge graph and chatbot in a single interface) is a unique and novel means to address user needs for quality knowledge capture and retrieval.. Some rapid progress has been made of the past months to realise this new capability and it should be acknowledged that none of the CLARK components existed 15 months ago when the project first started. Having said that, directly building upon the work of Strathclyde, and with the combination of the skills and capabilities of the knowledge graph and chatbots teams, the development project has been able to make great steps and a production version will be delivered within the next three months and deployed on the ESA corporate infrastructure as a standard capability.

The CLARK development is already creating a wave of interest within the Agency which is undergoing an internal transformation, and it is hoped that others (and other technology developments) can use this new exciting technology to achieve other significant advancements in lessons learned and any other application that might benefit from this capability..

Finally, it can be stated that CLARK basis is robust enough for further development, by extending it with additional entities (or nodes in KG), relations between them, concerning the chatbot – implementing new actions and scenarios. This can be in the form of additional sources and data, creating more context and scenarios. Moreover, as stated in the future work, there are numerous ways to improve it, making it even more accessible and personalized for the end user.

Threshold Concept for Promoting Business Transformation

Yayoi Hirose
Toyo University, Japan

yayoi.hirose@iniad.org

Abstract: This qualitative study highlights the importance of considering the threshold concept for promoting the business transformation of large-sized enterprises. The wide range of business literature and experts has debated how traditional large-sized companies can transform conventional approaches and mindset to be competitive. For example, many global enterprises now focus on digital transformation (DX), aiming to disrupt their conventional routines and adopt new DX knowledge and approaches. The literature on leadership identifies how a business leader should behave for their staff to transform their conventional approach, including promoting crisis awareness, setting up a clear strategy vision, and creating a DX department. However, without considering how to transform employees' conventional way of thinking at the individual level, a leader's action will be a unilateral announcement, and the company cannot promote company-wide transformation. In order to get a clue for promoting the recent DX of large-sized traditional companies, this study is based on the past successful cases of two Japanese large-sized conservative companies that completed company-wide transformation and improved corporate business performance from financial haemorrhage in just a few years. The study suggests that, in order to promote corporate transformation, company leaders need to consider how their staff members and middle-managers overcome the threshold concept to learn transformative business knowledge at the individual level, instead of simply promoting crisis awareness and presenting a company goal. The study reveals the usefulness of the threshold concept for understanding transformative business knowledge, as it offers the ability to imagine a successful business scene by disrupting the conventional cognitive frame and adopting new values and approaches. The two cases suggest that by imagining a successful business scene, the employees were able to understand their concrete goal, learn transformative business knowledge, make huge efforts to attain their concrete goal, and ultimately improve their business performance. After overcoming the threshold concept, the employees, through a team effort, actively created their own business knowledge for transformation. This study thus suggests that business leaders who aim to promote DX in traditional companies should consider how company staff and middle-managers will be able to overcome the threshold concept for understanding transformative business knowledge.

Keywords: Threshold concept, Leadership, Business transformation, Business knowledge

1. Introduction

Nowadays, many global enterprises aim to implement transformational projects. For example, they focus on how to implement DX systems, as DX is necessary for many enterprises to survive severe global competition (Rogers, 2016; Wade, 2019). They expect DX to transform and deepen their relationship with their stakeholders – such as customers, suppliers, and employees – by leveraging advanced digital technologies, including artificial intelligence and robotics, for their competitive advantage (Wade et al., 2019). In order to promote DX, it is necessary to transform employees' mindsets from a conventional approach, disrupting their conventional way of thinking and creating new business (Rogers, 2016; Wade, 2019). This study aims to discuss the usefulness of threshold concept to transform employees' mindsets from a conventional way of thinking.

In many global companies, the CEO has taken the leadership role in implementing a transformational system. As for DX, the CEO announces a clear strategy vision, which includes the message of why DX is necessary, organizes the DX department, and assigns the chief digital officer (CDO). The DX department is required to frequently communicate with business departments under the CDO's initiative to implement the DX system to transform their conventional operations and practices and launch a new business (Rogers, 2016; Wade et al., 2019). The leadership literature claims that a business leader who aims to transform a conventional organization should enable his/her staff and middle-managers to understand the necessity of disrupting the conventional approach and present them with a new business direction (Heifetz et al., 2009; Rogers, 2016).

However, companies that implement transformative business knowledge – including how to conduct a new strategic vision and make profit through the new projects – have not necessarily successfully transformed their organizations. This means that a business leader needs to consider another factor in order to transform the company. This study emphasizes the overcoming of the threshold concept as a successful factor to understand transformative business knowledge. In order to transform a company, organizational people need to disrupt their conventional ways of thinking and implement a new approach. However, as large-sized firms struggle with bureaucratic structures that sap initiative, they tend to maintain a conventional way of thinking; it is hard for them to understand new transformative business knowledge (Hamel & Zanini, 2018). This study discusses two key questions. First, what are threshold concepts to understand transformative business knowledge?

Second, how can an organizational leader generate new business knowledge by collaborating with various stakeholders through an understanding of the threshold concept?

2. Literature Review

2.1 Leadership for Transformation

Past literature on leadership describes how a business leader should promote transformation. Heifetz et al. (2009) emphasizes that an executive leader should present the threat by continuing conventional business and evaluating challenges for adapting to a new environment. Kotter (1996) identifies the importance of promoting staff's crisis awareness, organizing collaborative teams for transformation, presenting a strategic vision, and encouraging staff initiative. The DX literature claims the importance of clarifying a strategic vision and organizing a new division for transformation (Rogers, 2016; Wade, 2019). Mintzberg (2004) stresses that a leader should first reflect on him/herself and frequently communicate with his/ her front-line staff to take effective action for transformation.

Although this literature on leadership for transformation focuses on how a business leader ought to be and what a business leader should do (Heifetz, 2009; Hughes, 2016; Kotter, 1996; McKnight, 2013; Mitzberg, 2004; Rogers, 2016; Wade, 2019), it does not discuss how employees can transform their way of thinking or how they understand transformative business knowledge to the degree of actualizing the knowledge from an employee perspective. The leadership literature identifies the importance of communication with staff (Mintzberg, 2004), but it does not discuss what a business leader should consider in their communication with staff members to promote their understanding.

2.2 The Threshold Concept

The threshold concept was more developed in the field of school education rather than business solution (Barradell, 2013; Meyer & Land, 2003, 2005, 2006). Past discussion on threshold concepts focuses on how learners understand more complex knowledge that is not accessible to a novice, such as using a statistical lens to understand statistics (Beitelmal, et. al., 2022; Luoma, 2006; Meyer & Land, 2005). The discussion mainly addresses students learning technical, mathematical, and business material rather than learning organizational knowledge generated in a different culture (Bajada &Taylor, 2016; Chrispin, 2016; Hoatly, 2016).

The literature emphasizes that threshold concepts have five characteristics. They are gateway functions that prove troublesome for the learner to integrate with what they already know but, once learned, they are both transformative and irreversible. 'Transformative' refers to a complete and radical change in a learner's understanding, interpretation, and view of a phenomenon, topic, and/or practice (Meyer & Land, 2003; Meyer & Land, 2005). Threshold concepts completely alter the learner's view of the world and their way of thinking and behaving (Meyer & Land, 2005; Trafford, 2008). They change a learner's internal mental structures with respect to the way they perceive and interact with external reality (Yip & Raelin, 2011).

The concept is also irreversible. Once a learner has deeply embedded knowledge into their mindset, it is hard to unlearn because the conceptual framework used to interpret experiences has been reconfigured as a result of a novel integration of new thinking that applies to many phenomena (Davies & Mangan 2007; Meyer & Land, 2005). A threshold concept is also integrative in that it makes sense of and combines past knowledge through a different logic so that a learner can relate factors that have been previously hidden or separated (Meyer & Land, 2005). In this way, a threshold concept can enable learners to grasp and re-interpret the implications of previously tacit assumptions. Davies and Mangan (2007) argue that a threshold concept integrates past dimensions in complex ways by transforming conventional perception so that a learner cannot unlearn. When applying it to transformative business knowledge, it is important for employees to understand the threshold concept, as they are required to deal with tacit assumptions that they have already obtained.

Another characteristic of a threshold concept is that it acts as a gateway. It can be a portal or a step progression that enables a person to understand more complex knowledge that is inaccessible to a novice (Luoma, 2006; Meyer & Land, 2005). For example, Beitelmal, et. al (2022) argues that when a learner aims to understand statistics, he needs to have a statistical lens rather than a mathematical one; otherwise, the statistical concepts will not make sense. When an organizational leader aims to promote a transformational project, he/she needs to consider the gateway function, because they are novices in the field of transformation.

Finally, a threshold concept is troublesome because learners are being offered knowledge but cannot intuitively understand what it means in experience; it feels uncomfortable because it contradicts what they are

familiar with and, at the initial stage, there is no sense of how to relate it to what they do know well (Meyer & Land, 2005; Perkins, 2006). Basically, it looks unfamiliar and alien, generating feelings of anxiety or tension as learners wrestle with the complexity of how to integrate it with knowledge that has worked well for them up until now (Cousins, 2006; McCormick, 2008; Perkins, 1999; Yip & Raelin, 2011). While the previous four points refer to cognitive dimensions, this difficulty is most connected to the emotional dimension of learning. Lucas and Mladenovic (2007) discuss how to make students understand new knowledge in pedagogical practice. They stress that a teacher needs to address the fundamental principles or assumptions for students to transform their conventional framework (Lucasa & Mladenovic, 2007). Students' preconceptions of new knowledge can be a barrier; for example, they tend to avoid understanding statistics because they think they cannot understand mathematics. Therefore, they first feel it to be troublesome before they even reach the gateway for understanding statistical knowledge (Lucas & Mladenovic, 2007). When learners think the concept is troublesome, they present emotions such as fear, concern for rejection, anxiety, tension, resentment, and worry (Lucas & Mladenovic, 2007).

For organizational people, it is troublesome to transform their worldviews by challenging prior knowledge and information, as their organizational cultural context affects the recognition of business knowledge (Carlile, 2004). Nahavandi (2016) claims that a mindset that recognizes and accepts many cultures can be a threshold concept for management and leadership. He identifies the significance of self-assessment, reflection, and experience regarding global diversity to understand their own culture and the diversity of other cultures. However, although recognition of cultural diversity can be an important factor in understanding global management, organizational people will not intend to transform their mindsets to learn a new approach, as it is uncomfortable for the staff who have followed conservative norms and rules, and they do not recognize its necessity and value for improving their organizational performance (Hirose, 2022; Khoja & Maranville, 2010; Todorova & Durisin, 2007). Thus, it is necessary to explore another threshold concept to understand transformative business knowledge.

For employees who have been involved with conventional values and approaches for a long time, understanding the threshold concept can be effective for understanding transformative business knowledge. This is because, in order to promote organizational transformation, the learners (i.e., the employees) need to disrupt their conventional knowledge, completely transform their way of thinking, and create their own new business knowledge that integrates with the knowledge that has worked well for them up until now (Kotter, 1996; Heifetsz, 2009; Wade, 2019). Thus, a business leader needs to provide a gateway function for transformative business knowledge from an employee's perspective.

3. Case Study

This study discusses the threshold concept for Japanese business people to understand transformative business knowledge. In order to promote the recent DX, analysis on the past transformation projects can be helpful because transformation of employees' mindset is one of the most important factors for any types of transformation projects. It examines two traditional companies, Hitachi, Ltd. and Japan Air Lines (JAL), which showed a heavy deficit starting with the Lehman Shock in 2008. Hitachi, Ltd. recorded the largest deficit of Japanese manufacturing companies in 2009, and JAL filed for bankruptcy protection in January 2010. The business leaders of both companies implemented transformation projects and successfully turned business around within a short period (Inamori, 2015; Kawamura, 2015; Koitabashi, 2014). Table 1 summarized the two cases.

Table 1: Transformation of the two Cases

	Number of employees before the transformation	**Year of foundation**	**Circumstances**	**Goal of the transformation project (in terms of employees' mindset)**
Japan Air Line	Around 47,600	1951	Filed for bankruptcy protection in January 2010	Impress the importance of making a profit and customer first principle
Hitachi	Around 330,000	1920	Recorded the largest deficit of Japanese manufacturing companies in 2009	Impress the importance of making a profit for each small unit of business.

The reason this study examines Japanese traditional companies is because the norms and routines of Japanese companies are completely opposite of the direction in which transformation projects develop. Generally, Japanese traditional companies are based on conservative values, and their cultural values do not require clear goal setting which the leadership literature requires (Davis & Ikeno, 2002; Hirose, 2022). Historically, Japanese companies have struggled with disrupting conventional bureaucratic culture in order to be competitive. Business experts refer to *big company disease*: bureaucratic structures do not consider their customers and are unable to create new ideas because they have conventional and fixed ways of thinking (Tateishi, 2008). As Japanese traditional companies have been based on a bureaucratic seniority system, it takes a long time to make a decision, resulting in missed business opportunities (Kawamura, 2015; Parkinson, 1962, Tateishi, 2008; Yutani, 2008).

Although many Japanese business journals and books have criticized Japanese bureaucratic systems, including those of JAL and Hitachi, Ltd., it is hard for organizational people in Japanese companies to understand transformative business knowledge (Kaneko, 2017; Kawamura, 2015; Ogasawara, 2016). Both Hitachi, Ltd. and JAL are said to be successful cases of overcoming big company disease and implementing transformational business knowledge (Kaneko, 2017; Kawamura, 2015). There are various books and documents regarding how Hitachi, Ltd. and JAL successfully transformed, including statements by the CEOs at the time, middle managers, and staff members (Inamori, 2013; Kaneko, 2017; Kawamura, 2015; Shinko, 2020)

Many global enterprises are still struggling with transforming their conventional business thinking. Business departments resist transforming their conventional operations and practices. For example, in many companies, only one or two departments implement a DX system on a trial basis now, and the CEO cannot decide to launch a new DX business at the level of the entire company. Under these circumstances, the companies need an approach that enables the promotion of a transformational project. Such an approach requires organizational people to understand transformative business knowledge.

4. Findings

The cases of Hitachi, Ltd. and JAL suggest that the threshold concept for understanding transformational business knowledge can be the ability to imagine a successful business scene by disrupting the conventional cognitive frame and adopting new values and approaches. Organizational people tend to take actions based on their cognitive frames, which have been collectively generated in their organizations (Kaplan, 2008; Witt, 1998). As a result, in long-established organizations, many employees who have simply followed the conventional approach tend to focus on working based on conventional values (Tateishi, 2008). This is because following conventional norms and operations have made their business successful and their evaluations high. For example, the ex-CEO of JAL, Mr. Inamori (2015, p. 114), described the organizational situation when he became CEO in 2010: 'JAL staff did not recognize that JAL went bankruptcy as the airline continued regular operation even after JAL filed for bankruptcy protection'.

The ex-CEO of Hitachi Ltd., Mr. Kawamura (2015, pp. 89–90), referenced the difficulty of transforming employees' business when their business performance was going well: 'Even if I explain, "Because overseas companies become competitive, we will not be able to compete with them," the employees claim "we should not withdraw from this business because our business go well"'. He suggested that employees had difficulty in imagining the threat of a well-performing mature business being surpassed by new entrants. He stated that this is the most difficult issue when he aims to transform a company (Kawamura, 2015).

Past literature on leadership claims the importance of presenting the threat in continuing conventional business and evaluating challenging spirits for adapting to a new environment (Kotter, 1996; Wade, 2016). However, the two cases suggest that a leader unilaterally promoting crisis awareness does not necessarily mean that the employees can clearly imagine the urgent situation. Kaplan (2008) argues for the process of transforming cognitive frames through collective actions. However, organizational people who are used to conventional frames have a hard time understanding why it is necessary. They cannot understand why they need to disrupt their present approach. If they think they can still be successful using their conventional approach rather than a new one, they will not be able to disrupt the present business approach because they do not understand why they need to disrupt it and because it is stressful for business people to negate a successful way of thinking that had worked up to that point (Heifetz et al., 2009)

Marton et al. (2000) distinguish learning knowledge related to context from surface learning, where external knowledge is simply acquired and memorized, and the capacity to repeat what is known to others. In order to learn knowledge generated from a different value, learners need to understand the meaning of that

knowledge in relation to their context, change their perspective of the world, and, as a result, change or transform the self (Marton et al., 2000). Thus, it is important to argue for the threshold concept, which considers how learners change their view of the world and their way of thinking (Meyer & Land, 2005; Trafford, 2008). Considering this situation, Mr. Inamori (2013) raised the awareness of employees by continuously and directly talking to them about deeply recognizing that JAL went into bankruptcy, reflecting on the reason, and addressing the reform.

The ability to imagine a successful business scene includes entrepreneurial imaginings about the business to be conducted and how to conduct it (Witt, 1998). For example, Mr. Kawamura stated:

> *When I became a president of Hitachi company, I required the business unit leaders to set a benchmark, their competitors and present counteracts to their competitors. That is, they were required to explain their plan regarding how to increase their sales, such as the amount of increase in facility investment. Previously, the only executive management team members explain the company performance. So it was like a somebody's else's problem at that time. After I became a president, they were required to present their future successful business scene based on their concrete business data. Since then, they had a different look in their eyes and some business unit leader asked staff members to check the price of even small equipment. (Kawamura, 2016, pp. 52–53)*

Mr. Inamori also claimed the importance of a concrete goal (Inamori, 2013; Shinko, 2020)

> *Since we belonged to private company, we were required to make decision based on concrete data on our business performance. However, our staff rarely presented concrete data and they just presented very rough figure on our business a few months ago. Furthermore, it was not clear who own responsibility for what business. (Inamori, 2013, pp. 114).*

He also required the employees and middle-managers to have a sense of ownership over their business, set a concrete goal, and make efforts to achieve the goal, no matter how the business environment changed (Inamori, 2013).

These successful cases suggest how organizational members should have a concrete image about their business performance. For successful business, organizational staff need to collectively share entrepreneurial business concepts rather than conventional business procedures and routines (Witt, 1998). Inamori (2012) claimed that JAL needed to change from bureaucratic norms and values to customer-first values and Amoeba management. Inamori created the Amoeba management system, in which small financially independent branches take responsibility for making their business profit. By implementing Amoeba management, the staff clearly imagined their goals and what they should improve in order to successfully achieve this goal (Shinko, 2020).

Through the reforms, JAL's middle managers' eyes sparkled and generated a sense of unity among the staff: 'We should have learned how we should act as a leader for customer-first and profit-oriented business much earlier to prevent JAL's bankruptcy. I would like to transfer this knowledge to my staff' (Inamori, 2013, p. 115).

The two cases illustrate how, when a leader focuses on carefully transferring the transformation's successful business image, the staff will be able to understand the image and take the transformative actions that the leader expects. For example, JAL middle managers collectively and actively created JAL's norms and business approach based on the successful image and shared them among all staff members (Inamori, 2013). The reason that new business knowledge was created was that most of the middle managers clearly understood their goal, so they were able to collectively create an approach for how to achieve this goal. As a result, JAL transformed into a customer-first company and in 2012 recorded a 17% profit ratio, which is miraculously high in the airline industry. Hitachi, Ltd. also achieved a record net profit in 23 years.

Table 2 summarizes the threshold concept for the transformative business knowledge of Hitachi, Ltd. and JAL and the business knowledge for transformation collectively created by employees and middle managers when the companies recovered from huge deficits.

Table 2: Threshold Concept and New Business Knowledge in Japanese Cases

	Transformative business knowledge	**Threshold concept: The ability to imagine a successful business scene**	**New business knowledge collectively created by the middle managers and staff members**
Hitachi, Ltd.	How to conduct a new strategic vision and make profit through the new transformative projects to reach the goal	Understand the goal, a concrete figure of profit at the business unit level	Report on business performance based on the new strategic discipline by each business unit
JAL	How to conduct a new strategic vision and make profit through the new transformative projects to reach the goal	Understand the goal, (1) a concrete figure of profit at the level of small independent branches and (2) customer-first service, which is highly evaluated	The 'JAL philosophy' regarding customer engagement and business strategy

5. Discussion, Conclusion, and Limitation

While past literature on leadership tends to emphasize what actions aa business leader should take, this study presents the importance of considering employees' and middle managers' perspectives in corporate-wide transformative projects. By analysing the two cases of the past transformation project, this study presents the effectiveness of adopting threshold concept for transforming employees' mindset.

The findings show that employees who have belonged to traditional organizations have a hard time understanding transformative business knowledge, as they are used to bureaucratic organizational rules and norms. The threshold concept for business transformation can be the ability to imagine their successful business scene through transformation. By understanding the threshold concept, they become able to collaborate with colleagues who similarly overcame the challenge and thus generate transformative business knowledge that supports their business transformation.

This study highlights the importance of considering the threshold concept in the context of past discussions on business leadership, which emphasize the steps and actions a business leader should take from the viewpoint of a C-level leader. While the past discussions on threshold concept mainly focus on school education, this study contribute to extend the discussion to practical business projects. In order to promote transformation, a business leader needs to consider the individual level of employees and middle managers in overcoming the impediment to understanding transformative business knowledge.

When business leaders aim to promote DX, they need to define a successful business scene more clearly. In the two cases of this study, where the purposes were to recover from the huge deficit, the successful business scene was easy to be imagined for employees based on a concrete profit figure. However, the DX goal can be more conceptual and not simply to achieve short-term profit, as DX strategy is related to company-wide long-term platform strategy (Rogers, 2016). This is the limitation of this study. Thus, further research is expected to clarifying threshold concept for employees' understanding of DX strategy

Use of Knowledge Management Strategies to Prevent Knowledge Loss in a Government Agency

Ike Hlongwane[1] and Kamogelo Molekwa[2]

Abstract: There is increasing evidence that tacit knowledge is "the important strategic resource that assists in accomplishing a task (Woo, 2004)." According to Haughton (2021), Knowledge is a valuable asset, and managing that knowledge is now recognised as a significant contributor to organizations in the current business climate'. When people with expertise leave a job, the organization often loses critical tacit knowledge because the person did not pass it on to others. This knowledge gap can be costly and time-consuming or impossible to replace (Leonard, 2014). However, government institutions and agencies are known to be not good when it comes to knowledge management (KM) implementation and thus often suffer knowledge loss when employees/people with expertise leave a job, retire, or pass away. A qualitative study was conducted in one of the government agencies which has recently embarked on KM initiatives to find out what their strategies and challenges are in preventing knowledge loss. The study used the Knowledge Management Capability Assessment Tool (KM CAT) theory to assess KM initiatives in the agency. The data was collected by purposefully interviewing senior officials/managers in the agency's KM directorate. Despite the results of the study revealing that there are several challenges experienced by the agency in its endeavour to implement an effective and efficient KM process and strategy to help stem the tight against loss of knowledge, there are signs of good improvement. However, the agency needs to be resolute in its adoption of a systematic approach to KM to ensure the full utilisation of the organisation's knowledge base, coupled with the potential of individual skills, competencies, thoughts, innovations, and ideas to create a more efficient and effective organisation.

Keywords: Knowledge management, Tacit and explicit knowledge, Loss of knowledge, Government agency, Knowledge sharing, Knowledge retention

1. Introduction

There is increasing evidence that tacit knowledge is an important strategic resource that assists in accomplishing a task (Woo, Clayton, Johnson, Flores & Ellis, 2004). According to Haughton (2021), knowledge is a valuable asset, and managing that knowledge is now recognized as a significant contributor to organisations in the current business climate. When people with expertise leave a job, the organisation often loses critical tacit knowledge because the person did not pass it on to others. This knowledge gap can be costly and time-consuming or impossible to replace (Leonard & Swap, 2014).

Knowledge is recognised as the most significant asset for those companies that focus on capabilities and intangible resources as tools to compete in the marketplace; however, it is not managed easily (Whelan & Carcary, 2011). The management of knowledge is becoming more important now as most organisational, economic, and social activities are knowledge driven (Muslim, Indra, Lystiardi & Anggiani, 2021). Furthermore, using knowledge resources effectively gives organisations the ability to be innovative, quickly respond to customer demands, and support operational activities (Daghfous, Belkhodja & Angell, 2013). This shows that organisations are realising that knowledge is becoming the most important asset they can leverage to achieve a competitive advantage. Massingham and Massingham (2014) state that companies in the United States invest in knowledge management by spending $73 billion annually on software related to the concept alone; however, they also lose approximately $31.5 billion a year by failing to share knowledge.

As a developing country, South Africa is witnessing fast population growth, which drives up the travel demand. Many of the country's citizens continue to rely on public transport to get to work, school, healthcare, recreation, and tourism sites. To manage an innovative rapid rail transport system in the country, an agency was formed as a public-private partnership (PPP) project to provide a more affordable and accessible transport system to alleviate traffic congestion, while also providing a reliable and quick mode of public transport. In the intervening process, a wealth of skills and technical knowledge, particularly in the management of the protracted design and construction review process and the legal and environmental compliance processes, are organically produced. Therefore, if this tacit knowledge residing in the minds of the organisation's employees is not captured and preserved, it could be easily lost when an employee exits the organisation at the end of the project.

Government institutions and agencies are known to be not good when it comes to knowledge management (KM) implementation and thus often suffer knowledge loss when employees/people with expertise leave a job,

retire, or pass away. A qualitative study was conducted with the objective of providing an overview of the knowledge management processes in one of the government agencies. This would help determine if there are any gaps in the implementation of KM in the organisation. Furthermore, the other objectives of the study were to examine the strategies used to capture tacit knowledge in the agency and the difficulties encountered in the knowledge capturing process, and to suggest effective strategies to prevent tacit knowledge loss in the agency.

The study used the Knowledge Management Capability Assessment Tool (KM CAT) theory to assess KM initiatives in the agency to provide an overview of the KM implementation process in the agency, examine the strategies and difficulties encountered, and suggest effective strategies to deal with the challenges encountered in the agency's KM processes

The data were collected by purposefully interviewing senior officials/managers involved in the agency's KM directorate. A thematic approach was used to analyse the data to obtain the results.

2. An Overview of the Current KM Strategy at the Government Agency

The agency's KM strategy (2016) was firmly established by the South African transport Act, Act 5 of 2006. Section 5 (e) and (f) of the Act requires the agency to establish and operate information and management systems for transport projects in Gauteng province, and liaise and exchange information with institutions, authorities, or professional bodies regarding rail matters in South Africa or in other countries. The agency as part of the Gauteng province is required to support and contribute to the implementation of the Gauteng 25-year Integrated Transport Master Plan (ITMP25). Given the mandate of the agency and public transport development imperatives for the province a KM strategy is critical for the organisation. There have been tremendous efforts put in place on the electronic document control and management particularly during the development phase of the transport projects in Gauteng province.

KM enjoys strategic leadership support in the organisation. KM communication initiatives need to be cognisant of this strength and leverage on the support for maximum benefit. Harvesting knowledge from employees and consultants is critical for the preservation of knowledge and corporate memory, this may be the most difficult yet critical of interventions for the successful implementation of the strategy.

However, the SWOT analysis conducted by the agency in 2015 identified several gaps in the agency that the needed to be addressed by the KM strategy implemented in 2016 which included:

- Loss of institutional memory
- Knowledge not captured during the crucial project stages
- Loss of skills due to retirement or resignation
- Lack of knowledge transfer
- KM not embedded in
- business processes
- Lack of KM resources

The vision for the agency's KM Strategy is to develop agency as a learning organisation with the ability to share and disseminate information to relevant stakeholders. The strategy can be achieved through active participation in the knowledge economy by prioritising; preservation of existing knowledge, sharing of existing knowledge and gathering of external knowledge or information to create new knowledge.

3. Problem Statement

Organisations are increasingly concerned about loss of knowledge due to unprecedented employee turnover. Noting the positive spin-off of KM trends, Lamont (2021) asserts that "at a time in which few organizations have been able to conduct business as usual, knowledge management solutions have sustained momentum and even accelerated their growth. Increased use of collaboration, cloud technology, AI, language processing solutions, and graph databases has all contributed to a robust environment for knowledge management". This shows that the harmful effects of knowledge loss from employee turnover can easily spill into other areas of the business.

In their position paper (2018), Knowledge Management South Africa claims that KM is still a black box in South Africa, understood only by KM practitioners and not valued as a corporate value-add. This is despite the inclusion of KM as a requirement in ISO 9001: 2015, clause 7.1.6, which is a step change towards formalising the discipline in organisations in South Africa. The concern raised by the Knowledge Management South African Position Paper (2018) is that KM in business is often concealed within other disciplines such as research and development, strategy, IT, and human capital (resources).

According to the agency's annual report (2021), the agency experienced a turnover rate of 2%. Although it has been consistently below the industry average norm of 10% in this financial year, this loss of talent equates to a loss of knowledge that could be difficult and costly to replace. This is because the agency operates in an industry where scarce and specialised skills are in great demand and it faces a high risk of knowledge loss which could significantly affect the agency's ability to carry out its mandate.

Through the agency's strategic workforce planning, the agency endeavours to continue to attract, engage, develop, and retain the best calibre talent needed to deliver on the agency's strategic outcomes (Annual Report, 2021). However, it is unclear whether the agency is doing enough to prevent knowledge loss. The risk of knowledge loss can significantly affect the agency's ability to carry out its mandate. This study, therefore, sought to investigate KM practices at one of the government agencies in South Africa to provide new insights into how KM is implemented in public institutions in developing countries. The assessment of challenges experienced by KM officials will be identified for proper remedial action to enable the agency to achieve a competitive edge.

4. Study Objectives

- To provide an overview of the KM implementation process in the government agency
- To examine the strategies used to capture knowledge in the in the government agency
- To examine the challenges encountered in the knowledge capture process in the government agency
- To suggest effective strategies to deal with the challenges encountered in the agency's KM processes

5. Knowledge Management Capability Assessment Tool (KM CAT)

To assess knowledge management maturity in the organisation, the study used the Knowledge Management Capability Assessment Tool (KM CAT). The KM CAT is best suited for reviewing procedures, recognising intellectual assets in an organisation, and developing KM solutions that enhance organisational performance such as improved efficiency, increased productivity, and knowledge retention (Kapofu (2014).

According to APQC (2022) the KM-CAT helps an organisation assess its capabilities and maturity in knowledge management (KM) and focus its KM investments to produce the highest return on value. This assessment maps the current "as-is" state of KM and the knowledge flow processes within an organization to:

- measure the current maturity of the enablers and infrastructures employed,
- evaluate the status of knowledge flow processes and supporting approaches,
- set an objective for the improvement of business processes through the flow of knowledge,
- guide the evolution of organizational change, and
- compare or benchmark with similar efforts of other internal units or external organizations.

The KM CAT is divided into four major sections and each section is also subdivided into subcategories assess as follows:

- Strategy (objectives, business case, and budgets)
- People (resources, governance structure and roles, change management, and communication)
- Process (knowledge flow process, KM approaches, and measurement)
- Content and Information Technology (content management and IT processes and tools)

The focus of the current study was limited to the KM process category. However, the objectives stretch across the subcategories of the four major sections mentioned above. Although this seems like the adaptation of the KM CAT, the results of this study provided a clear sense of strengths, gaps, and opportunities for improvement, as well as appropriate steps to enhance the KM process and strategies in the agency.

6. Literature Review

Knowledge is a key component providing organizations a competitive advantage in the current business environment (Fong & Kwok, 2009; Lin, Lai & Yang, 2016). Arsenijević, Trivan, Podbregar and Šprajc (2017) assert that knowledge is now a key source of wealth for many organisations.

There are various ways of categorising knowledge that exists in an organisation, namely explicit knowledge and tacit knowledge.

Explicit knowledge is tacit knowledge that is codified, documented, and shared, making it readily available to either a single person or a group of people at a minimal cost (Jasimuddin & Zhang, 2014). Some examples of

explicit knowledge are policy manuals, technical documentation, and reference guides (Terzieva & Morabito, 2016).

Tacit knowledge, also known as implicit knowledge, is present in the individual but cannot be expressed easily by the individual in either spoken or written form (Turner, Zimmerman & Allen, 2012).

According to Davenport and Prusak (1998), KM is defined as the process of developing, documenting, and applying knowledge to improve the performance of an institution. However, KM is also seen as an essential process for enterprises to determine where they are going and for organisational survival in the long run, given that knowledge creation is the core competency of any organisation (Leonard-Barton, 1995). The aforementioned definition provided the setting for the paper to discuss the various strategies that can be used to capture tacit knowledge in order to prevent knowledge loss in the organisation.

7. Knowledge Management Processes

Knowledge management is defined as a "process that enables an organisation to improve its performance by enabling learning and innovation whilst solving its problems, acknowledging, and resolving gaps in organisations, and recognising knowledge (comprising people and information) as an organisational asset which has to be managed through enabling policies and institutional tools." (Mavodza & Ngulube, 2012:2).

However, there is no single commonly accepted definition of KM in the literature, consequently, there are various models that can be followed to transform knowledge into a valuable strategic asset for the organisation. The Wiig model consists of four dimensions, namely completeness, connectedness, congruency, and perspective and purpose. The Meyer and Zack model (1996) proposes the following stages for refining knowledge: acquisition, refinement, storage and retrieval, distribution, and presentation or use. The Bukowitz and Williams model (2000) consists of six stages that support the strategy of the organisation. According to the Nonaka and Takeuchi model (1995), knowledge creation is a continuous process that follows four methods in terms of how knowledge is converted. These methods are socialisation, externalisation, combination, and internalisation. The McElroy (1999) model posits that organisational knowledge is held both subjectively in the minds of individuals and groups to produce knowledge and that four high-level processes must be followed, which are individual and group learning, knowledge claim formulation, information acquisition, and knowledge validation.

8. Barriers to Successful KM Implementation

When carrying out KM activities, several barriers or bottlenecks could be encountered. According to Wiig (1995:9), these include knowledge not being managed as a valuable asset; insufficient knowledge at point-of-action; and missed learning opportunities such as situations in which the feedback is not always given by those who performed earlier work, as this eliminates chances for knowledge workers to learn about the implications of their actions. Wiig (1995:12) also argues that "different entities (knowledge workers, departments) possess part of the knowledge required to perform the whole task", which may lead to unnecessary "divided knowledge".

In addition, Trivedi (2007) believes that effective KM can be or is hampered by, among other things, failure to document intellectual capital; the culture of not sharing knowledge in the organisation; obsolete information, which leads to overload if not removed; and rapid changes in technology that pose serious problems, especially in its adaptability and application in KM manipulation processes.

9. Knowledge Management Strategies

Knowledge loss is the result of a more mobile workforce, employees nearing retirement, employee turnover, and disability (Bratianu, 2018; Massingham, 2018). Collective knowledge resides in the minds of the organisation's employees, customers, and vendors. Tacit knowledge is often shared through face-to-face interactions, such as community of practice, storytelling, mentorship, or on-the-job training, which allow individuals to learn through direct observation and experience. Explicit knowledge is knowledge that can be easily documented and shared, such as facts, procedures, and processes. It is often shared through written documents, presentations, and formal training programmes. On the other hand, implicit knowledge is knowledge that is embedded in the practices, processes, and culture of an organisation. It is often difficult to identify and capture, but it can be shared through shared experiences, traditions, and cultural practices.

10. Methodology

To address the main research question, this qualitative study used a case study research design because a case study enabled the researcher to conduct an in-depth study of the KM process in the agency. The case study research design enabled the researcher to explain the complex situations where important factors could be lost or not described completely enough in a generalised method. This study used semi-structured interviews to gain an understanding of how the loss of knowledge (tacit) affected this South African government agency, rather than acquiring a more superficial overview.

The researcher purposefully selected senior management involved in the agency's KM directorate. The interview guide was prepared to help the researcher to comprehensively cover identified topics relevant to the study objectives. Each participant was allocated one and a half hours for the interview.

The interviews were conducted using the Microsoft Teams app, which is a virtual platform the researcher deemed fit to use due to the COVID-19 pandemic. The interviews were recorded with the consent of the participants.

Owing to the semi-structured nature of the interviews, participants were encouraged to elaborate on the subject and provide as much information as they could. Apart from the interviews, internal documents of the agency such as the KM policy and strategy plan were used to achieve data triangulation to enrich the data collected.

The collected data were analysed using ATLAS.ti version 9 according to a thematic approach, in which the data were aligned to the study themes, and a coding procedure was followed.

11. Profile of the Participants

The study initially targeted 10 senior managers in the KM directorate who are actively involved in the agency's KM projects and processes. These included the executive manager of KM, five KM specialist, a senior records officer, a registry officer, a senior manager for reputation, and a senior manager in stakeholder relations. Owing to the COVID-19 pandemic, four employees were unavailable because of ill health and death.

In the end, six senior managers in the KM directorate with the relevant knowledge and experience in KM programmes and processes of the agency were interviewed.

12. Discussion of the Findings

- Overview of the knowledge management implementation process

The study results revealed attempts have been made to develop a KM process that is anchored on four pillars of the KM life cycle, namely knowledge creation, acquisition, storage, sharing and application, and a high level of knowledge culture among employees which is a necessary condition for the development of an effective KM programme in the agency. To expand the potential capability of the current KM system to produce knowledge that can be used for productivity enhancement, a coherent and practical framework for how KM processes should be carried out or managed in the organisation, must be developed.

- Strategies used to capture knowledge in the in the agency

Most participants noted the use of technology to support knowledge initiatives in the agency such as knowledge portals, podcasts, intranet, LinkedIn, case studies, project wikis, corporate blogs, fact sheets, presentation repositories, exit interviews, taxonomies, and more. However, some participants shared that there was a pressing need to find or create new ways of capturing and preserving knowledge amid increasing staff turnover and shrinking budgets. Therefore, the availability of funding for IT infrastructure will encourage employees to use a variety of techniques to share lessons learnt, insights, and experiences to mitigate organisational knowledge loss.

- Challenges in the knowledge capture process

The study revealed that due to budgets cuts, the existing technologies are not sufficient to provide support for processes of acquisition, preservation, and dissemination of knowledge. A lack of trust, rewards and incentives, and little collaboration among employees hampers the organisation's knowledge capture and sharing efforts. Top management needs to intervene decisively, as this situation can result in high employee turnover rates, which can lead to knowledge loss if individuals with decision-making authority continue to exit the organisation.

13. Conclusion

This study showed that despite KM implementation being a black box in South African public and private sectors, there are islands of good practice in the implementation of KM in some government agencies in South Africa. Despite the current challenges experienced by the agency in its endeavour to implement an effective and efficient KM process and strategy to help stem the tight against loss of knowledge, there are signs of good improvement. However, the agency needs to be resolute in its adoption of a systematic approach to KM to ensure the full utilisation of the organisation's knowledge base, coupled with the potential of individual skills, competencies, thoughts, innovations, and ideas to create a more efficient and effective organisation.

Abstract: "Moneyball" (Lewis, 2003) is one of the most influential non-fictional books of the 21st century. It is a story of how a financially constrained baseball team, the Oakland Athletics, managed to turn around its fortunes and become competitive by exploiting an inefficient labor market with an extensive use of data analytics. Moneyball has had a great influence on how professional sports teams conduct their operations these days, it has spread from professional sports to several other realms, and its hypothesis has been a subject of academic studies. In the areas of business and economics, Moneyball has become a profound slogan for a firm's data-driven revolution and the resulting new ways of conducting business. However, Michael Lewis, the author of Moneyball, accordingly thinks that the core message of Moneyball has been misinterpreted or misused to some extent (Dubner, 2022). It seems that adopting such a context-specific framework to other realms is neither easy nor simple, as the business logics and extra-organizational contingencies are different. The objective of this study is to better understand how Moneyball has been applied and discussed within academic research literature. This is done by systematically reviewing the Moneyball related literature that has been published in academic journals from 2003 to 2022. For both academic and managerial audiences, this study points out that sustained competitive advantage does not sprout from knowledge resources that are commonly available in the market. This study also serves as a reminder that a contemporary business and management buzzwords, such as Moneyball, Big Data, and Artificial Intelligence, may become elusive and misleading and the related research evidence scattered, if the academic research community cannot find ways to agree upon the definitions of the key concepts.

Keywords: Moneyball, Data analytics, Data-driven culture, Performance management, Literature review

1. Introduction

Moneyball offers a data-driven perspective to firms that may achieve competitive advantage. Firms that follow Moneyball philosophy are typically capable of identifying better data sources than their rivals and/or applying superior methods and models to analyze the data that is commonly available. Moneyball involves identification of new data or new ways of approaching the existing data, development of new insights based on data and rigorous analytics, and ultimately data-driven decision making (Hakes and Sauer, 2006). Moneyball is similar to business analytics that is defined as the extensive use of data acquired from diverse internal and external sources, statistical and quantitative analysis techniques, explanatory and predictive analytics models, and fact-based management to drive decisions and actions to proper stakeholders (Davenport & Harris, 2017; Soltanpoor & Sellis, 2016). However, the difference is that in the original Moneyball case example, competitive advantage was based on commonly available data and the first mover advantage: the Oakland Athletics was able to outperform their rivals by being the first one to identify baseball labor market inefficiencies through baseball match data and back then novel data analytics approaches. The market inefficiencies were caused by the rival teams' misjudgment of some employee attributes and performance statistics that were believed to translate as team performance. For example, batting average and stolen bases were widely seen as among the most important statistics to assess players, but the Oakland Athletics were able to gain competitive advantage by looking at other statistics, such as on-base percentage (OBP, see Lewis, 2003).

In broader business management context, Moneyball can be defined as an extensive use of data-analytics to capitalize new business opportunities and to invent new ways of conducting business. Conversely, the increased use of data-analytics is not Moneyball if it does not lead to the capitalization of new business opportunities or new ways of conducting business. Neither is a new way of doing business Moneyball if it does not involve extensive use of data-analytics. Building on the knowledge-based view of the firm (KBV, see Grant, 1996; Spender, 1996), the benefits gained from the use of commonly available data in competitive markets are mainly short-term information benefits that are quite easily imitated by the rival firms. Commonly available data as such possesses almost zero intrinsic value, but when it is approached in an original way, analyzed rigorously, and its hidden insights are used in decision making, a firm may achieve competitive advantage. KBV posits that knowledge embedded in people is the firm's most important strategic resource, and the firm's task is to combine and coordinate knowledge to create value and sustained competitive advantage (Grant, 1996; Spender, 1996). In the original Moneyball case example the use of commonly available data was not the key to

the Oakland Athletics' competitive advantage, but it was rather the people and knowledge on how to use the data in a way that was never done before: 1) the new General Manager, a context expert, had the vision and courage to make drastic changes to how employee performance was evaluated, 2) the data analytics expert (hired by the new General Manager) had the suitable knowledge to view the baseball data in a new way that produced information on undervalued employee performance statistics, and 3) the data-analytics knowledge and methods that were adopted from other realms proved to work well in the professional sports context. When these three different types of knowledge were combined, refined, and applied, it disrupted the Major League Baseball's labor market.

Moneyball hypothesis has been a subject of several academic studies, such as econometric evaluations (Hakes and Sauer, 2006; 2007). However, according to the author of the original Moneyball book, Michael Lewis, most of the Moneyball applications fail at their attempts to adopt the Moneyball philosophy to new realms, as they try "to make some boring business much more entertaining to yourself than it actually is." (Dubner, 2022) The objective of this study is to review the academic Moneyball literature to understand whether and to what extent the original idea of Moneyball has been correctly applied. By doing that, we show the merits of the extensive use of data-analytics in transforming how business and operations are conducted and discuss why firms need also other knowledge-related resources than data to gain sustained competitive advantage.

2. Methodology

Literature for this study were searched on January 30th, 2023, from citation and abstract databases Scopus and Web of Science Core Collection. A single keyword "moneyball" was used and the search was targeted to document titles, abstracts, and keywords, and limited to journal articles. The search in Scopus yielded 57 document results while the search in Web of Science returned 65 document results – altogether 122 results. The citations and abstracts were then exported to a reference management service RefWorks. In RefWorks, the 122 returned documents were checked for duplicates, which reduced the number of potentially relevant documents to 88.

In the next step, the full texts of the 88 remaining documents were searched and downloaded. Full texts of 8 documents were not found, which reduced the number of potentially relevant documents to 80. Full texts of the remaining documents revealed that 19 documents were not academic journal articles, which reduced the document count to 61. Finally, out of 61 remaining documents, 24 were successful interpretations of the Moneyball philosophy, while 37 were lacking some aspects of Moneyball. We will discuss both categories in the results section.

3. Results

We analyzed 61 academic journal articles that were based, to a varying extent, on the Moneyball philosophy. Our objective was to find out whether the various academic Moneyball studies were really about Moneyball or something else. To determine whether a study was regarded as a successful interpretation of Moneyball, we utilized the following qualification criteria:

- In the original baseball context: Moneyball is a combination of extensive use of data analytics and exploitation of an inefficient labor market.
- In a broader management context: Moneyball refers to an extensive use of data-analytics to capitalize new business opportunities and to invent new ways to conduct business.

By utilizing these definitions as qualification criteria, we identified 24 "Moneyball studies" and 37 "non-Moneyball studies". In the next sub-sections, we will describe our findings regarding these categories.

3.1 Moneyball Studies

Our analysis suggests that there were 24 such studies within the reviewed literature, which have successfully adapted or adopted the Moneyball philosophy. These studies fall into three subsets regarding their contexts: professional baseball (the original context), other sports, and non-sport realms.

3.1.1 Baseball context

Plethora of other Moneyball studies have been conducted in its original context, the MLB's inefficient labor market. In one of the most influential academic Moneyball studies, Hakes and Sauer (2006) focus on a case of mispricing in the MLB labor market: the hitters' (baseball player position) salaries in the change of the millennium did not accurately reflect how different batting skills contributed to winning games, which allowed

one team, the Oakland Athletics, to gain sustained competitive advantage over their rivals. The competitive advantage evaporated many years later, as the other teams were able to close this knowledge gap. The same authors published another study a year later where they conducted a more refined analysis which suggested that this pricing anomaly existed well before the MLB's "Moneyball period" and that the post-Moneyball market correction persisted (Hakes and Sauer, 2007).

Deli (2013) addresses the limitations of the earlier Moneyball studies and demonstrates how a methodological choice may improve understanding of the relative importance of the key predictors of baseball team performance. Brown et al. (2017) provides updated evidence that the post-Moneyball correction has persisted: the study demonstrates this persistence by showing that the OBP salary premium has risen for the class of baseball players known as "free agents" (i.e., players whose contracts have expired). With the expiration of their contracts, free agents are, in theory, involved in actively marketing their services to all MLB teams. Also, Congdon-Hohman and Lanning (2018) assess whether a broad range of production indicators (i.e., aggregate or rate statistics) translate into better salaries in the MLB's free agency market and find that the Moneyball's production indicators have accurately predicted the salaries in the 2000s. Conversely, Gin (2018) shows that the increasing reliance on the lower-paid baseball players has not translated as salary increase for the lower paid players. Interestingly, the analysis shows that the salary share for lower-paid players has even decreased in the Moneyball era. Holmes et al. (2018) builds upon Hakes and Sauer (2006; 2007), refines their earlier models, and finds new insights based on cleaner dataset: they find that the labor market for hitters/batters in baseball was efficient both before and after the appearance of Moneyball, thus providing new type of evidence. Pinheiro and Szymanski (2022) arrive to the same conclusion about the efficient labor market for batters before and after the publication of Moneyball.

Moreover, Duquette et al. (2019) seeks to test the analytics underlying Moneyball by modelling MLB teams' regular-season won-loss records over a long period (45 full seasons) and confirm the hypothesis of the significance of the previously overlooked predictors of team performance. They also find that some of these aspects are still undervalued by MLB teams in terms of the player-payrolls. With a slightly different focus, Caporale and Collier (2013) approach the Moneyball subject through the efficiency of the player draft in professional sports by evaluating a key implication of the Moneyball hypothesis, the superiority of college baseball players over high school players, which does not receive empirical backing. Finally, Abisaid and Cassidy (2017) investigate whether journalists have adopted sabermetrics, the use of advanced baseball statistics for making player projections and objectively measuring player performance, in their reporting of MLB stories since the print and theatrical release of Moneyball. They conclude that despite the increase of Moneyball statistics reporting, the traditional baseball statistics still dominate the reporting.

3.1.2 Other sports

Moneyball has been adopted in other sports contexts, and association football is clearly the second most popular context for Moneyball studies. For instance, Gerrard (2007) evaluates the transferability of Moneyball philosophy to professional association football context and finds that there are technological, conceptual, and cultural barriers that make in rather difficult. Weimar and Wicker (2017) study whether certain association football players' skills are undervalued, and they find that the labor market undervalues the player's running distance. However, McHale and Relton (2018) find in their study that the amount of running is not positively related to team success. Gavião et al. (2020) develops a Moneyball model that is applied to evaluate the efficiency of association football player market, whereas Aydemir et al. (2021) provides a generic framework for estimating player performance and performing player-fit-to-criteria assessment, under different objectives, for left and right backs (association football player positions) from competitions worldwide. In addition, Zaytseva and Shaposhnikov (2022) conclude that there is a Moneyball effect in professional association football: defensive actions contribute positively to the team's winning probability, but they are undervalued by the player market. Lastly, McHale and Holmes (2023) utilize advanced player rating systems to develop models for estimating the transfer fees of professional associate football players.

Stewart et al. (2007) apply Moneyball approach to study elite Australian Football. They use regression models to identify and quantify the relationship between important player statistics and match outcomes, suggesting that the Moneyball approach can be adopted to other team sport contexts, too. Millington and Millington (2015) argue that Moneyball is part of a highly important trend in sports: the utilization and impact of Big Data. Lastly, Plant and Stowe (2019) study horse racing and find an undervalued predictor of a racehorse's late racing development and a measure that is valued by the auction market but predicts only early racing development (not career earnings).

3.1.3 Non-sport realms

Based on the reviewed literature, researchers have struggled to successfully adopt Moneyball to other realms than professional sports. There are, though, three instances where it seems to have worked. First, McHugh (2009) analyzes the applicability of the Moneyball book in management education. The study concludes that Moneyball is a useful complementary resource "to a traditional textbook when addressing topics such as organizational change and innovation, leadership, recruiting and selection, performance management, employee development, and negotiations" (McHugh, 2009, p. 219). Second, Mauboussin (2012) arguments for the applicability of Moneyball in various other realms but highlights that using the right statistics is prerequisite to compete and identifying and exploiting them before rivals do will be the key to seizing competitive advantage. Third, from the medicine industry's point of view, Gayvert et al. (2016) proposes a model for clinical trials that goes beyond the drug-likeness methods that consider only the chemical properties of a molecule by including previously overlooked features related to the properties of the drug's target.

3.2 Non-Moneyball Studies

37 of the reviewed articles did not qualify as successful applications of the Moneyball philosophy. These studies can be assigned to the following categories based on what they lacked: lack of data-analytics insight, and lack of new ways of conducting business.

3.2.1 Lack of data-analytics insight

As stated earlier in this study, Moneyball involves extensive use of data-analytics. However, it seems that a large proportion of the extant research that claims to be Moneyball has overlooked the role of extensive use of data-analytics. From the viewpoint of non-Moneyball studies in the sports context, Mason and Foster (2007) discuss the potential of applying Moneyball in a professional ice hockey league (National Hockey League). They highlight several issues that my hinder a widespread adoption of the Moneyball practices, but do not go as far as demonstrating how Moneyball would change the business operations of the National Hockey League teams. Moreover, Hughes et al. (2012) lists skill requirements for association football players, including seven different playing positions, but does not describe the data related to these "KPIs" and whether they statistically matter for team performance outcomes. Regan (2012) analyzes how different payroll efficiency strategies affect the baseball teams' average game attendance but does not explain how extensive use of data analytics is linked to payroll efficiency. Elitzur (2018) analyzes the temporary and longer-term competitive advantage gained from establishing an analytics department within a baseball club, thus oversimplifying the Moneyball philosophy just as the existence of analytics department in a baseball club. Cassilo and Sanderson (2017) finds that media reports about analytics as the opposite of the conventional operational practices in the National Football League (American football) but does not explain how the National Football League teams could benefit from using data analytics. Wang and Cotton (2018) examine how strategic and support teams' experience is related to MLB team performance, and highlights the roles of social capital and human resource management. However, the study does not fully grasp the original idea of Moneyball. Kovalchik and Reid (2019) present a framework for sports-academia collaboration but does not present evidence of how it actually works. Roach (2022) study the impact of organizational decision-makers' career concerns on their spending in the baseball player market and find that underperforming expectations decreases spending on signing bonuses. The role of an extensive use of data analytics is, however, very small.

In non-sports contexts, Wolfe et al. (2006) suggest that data has become a cornerstone of effective human capital management and therefore this should reflect also as changing competence requirements for human resource professionals. However, they do not show evidence of how extensive use of data-analytics improves the human resource operations. Wolfe et al. (2007) investigate the applicability of Moneyball in other realms outside baseball and conclude that the analytics-based performance assessment approaches might not be useful in those organizations with relatively low interdependence, but some of the Moneyball lessons, for instance, managing radical organizational change can be generalizable in broader context. In addition, Cullen (2009) takes 8 lessons learned from Moneyball to propose improvements for correctional agencies' operations. However, the study makes a comparison between Moneyball and evidence-based management, which are two quite different things. Antoun's (2011) essay on the shifting forms of competition and changing political and cultural economies explains why poor teams and cities need to figure out something new to stay competitive. However, the connection to Moneyball philosophy is quite minimal. Evans (2011) suggests that Moneyball can and should be adopted in the healthcare sector to decrease the money spent on hospital readmissions, but the study does not provide any empirical backing for this idea. Kelly's (2011; 2013) anthropology studies refer to Moneyball but only as a generic metaphor for change. Cohan (2012) suggests

that science would benefit from utilization of advanced analytics methods, but there is no evidence of how these ideas work in practice.

Vito and Vito (2013) study the views of police managers on the applicability of Moneyball in policing. The findings suggest that statistical analyses are a promising lever to steer operations, to challenge the status quo, and to enable doing more with less. However, the elaboration on the use of data-analytics remains rather anecdotal. Butterworth (2014) tells a story about Nate Silver, who was able to predict the outcome of the 2012 US presidential election. Butterworth's essay describes Nate Silver's background, which involves some baseball analyst experience, but otherwise the study has nothing to do with Moneyball. Furthermore, Coe and Best (2014) proposes a model for the American Dental Association membership renewal but does not really show how the model improves the membership renewal in practice. Kaiser and Pratt (2016) uses data-analytics to show that pre-PhD publication activity predicts the researcher's career publication activity. However, the novelty of this finding is questionable, as publication productivity is a commonly utilized criterion in academic recruiting.

Valerdi (2017) applies Moneyball to software project context and elaborates how it might help software teams to operate more efficiently and effectively through untapping their hidden value. However, the discussion remains on a rather hypothetical level. Norton et al. (2018) assess the extent of the marginal future payments for hospital payments but refers to Moneyball only in the introduction. Harewood (2019) tries to adopt the Moneyball philosophy to healthcare context, but the study focuses on basic data-analytics and established performance measures. Houck (2019) uses Moneyball metaphor to lay foundations to improve the performance of public forensic service providers but gives no empirical evidence. Howard and Mayes (2020) relate the employee credentials to their performance, with Moneyball mentioned only as a keyword. Szymanski (2020) connects dots between alchemy and sport analytics as they are both characterized by opacity and secrecy: evidence of success is limited according to the scientific criteria. Liu (2021) illustrates how social limits prevent mispriced human resources from being arbitraged away sooner, with implications for engaging cognitive diversity that go beyond sports. Mori et al. (2022) finds similarities between the sport and pharmaceutical industry: quantitative modelling could be useful for a broad set of stakeholders in the drug development technology ecosystem.

3.2.2 Lack of new ways of conducting business

Some of the non-Moneyball studies seemed to lack the insight of new ways of conducting business or operations. For instance, Tingling et al. (2011) study the National Hockey League player draft and find that earlier choice leads to better outcomes, but the effect becomes insignificant after the first 100 selections. However, this is common knowledge in the National Hockey League and based on talent scarcity. Bonomo et al. (2014) provides evidence that algorithms can be used to optimize management of a fantasy football team. Kringstad and Olsen (2016) study the effect of budgeted revenues to sporting outcomes, which is not a new way to analyze the input-output paradigm in professional sports. Kryscynski et al. (2018) study the individual level analytical abilities of HR professionals to their job performance, which is not related to Moneyball philosophy. Soland (2014) connect dots between Moneyball and predictive analytics in education — schools' use of early warning systems to predict student dropouts. While this is an important research topic, its connection to Moneyball is rather vague. Ehrlich et al. (2021) mentions Moneyball but does not provide any definition or base its analysis on the Moneyball philosophy. Finally, Simmons (2022) recaps the influence of Moneyball on the rise of sports analytics on the input–output (pay-performance) relationship.

4. Discussion and Conclusion

The objective of this study was to review the academic Moneyball literature to understand whether and to what extent the original idea of Moneyball has been correctly applied. We find that Hakes and Sauer (2006¸2007) have had a great influence on the Moneyball studies conducted in the original baseball context. Some of the follow-up studies (e.g., Brown et al., 2017) confirm the inefficient labor market of the MLB and thus are aligned with Hakes and Sauer's findings, while some other studies that utilize refined models and more (detailed) data show evidence of an efficient labor market (e.g., Holmes et al., 2018). Therefore, the research output is far from conclusive on the Moneyball's mispricing hypothesis, which could be partially explained by Deli's (2013) suggestion of the effect of the methodological choices on the research output. Those studies that point out to the post-Moneyball correction of the Major League Baseball labor market (e.g., Hakes and Sauer, 2007; Brown et al., 2017) receive backing from the KBV (e.g., Grant, 1996; Spender, 1996): when the key resources are commonly available (baseball match data) or easily transferred between firms

(baseball data analyst leaves the organization and is employed by a rival), a firm cannot gain a sustained competitive advantage with those resources. In order to attain sustained competitive advantage, a firm should be dynamic in its data analytics by utilizing new and better data sources, combining new and existing data, renewing the data analytics skills and methods (e.g., machine learning), and developing new "research questions" to set objectives for data analytics.

Regarding the successful Moneyball adoptions in other sports contexts, it seems that association football (soccer) has been the most fertile soil for the Moneyball philosophy (e.g., McHale and Holmes, 2023). However, "flow team sports" such as association football are quite challenging contexts for Moneyball, as they are characterized with high interdependence between players, and it is difficult to isolate a single player's effect on team performance. In non-sports contexts, we find that successful adoption of such a context-specific philosophy has been rare.

From the non-Moneyball findings, we can conclude that Moneyball as a concept has been used liberally. In some instances, it means just the existence of analytics department in organization (Elitzur, 2018), figuring out something new (Antoun, 2011), or just a metaphor to describe the increased opportunities related to data utilization (e.g., Vito and Vito, 2013). Some studies argue that Moneyball could be a good option to change how things are done in some contexts (e.g., Valerdi, 2017) but they do not provide evidence on how the extensive use of data-analytics provides benefits in practice.

All in all, those studies that have stayed true to the original idea of the Moneyball philosophy have been done in the baseball context or other sports context. At the other end of the spectrum, there are studies that have used Moneyball only as a metaphor without contributing to the Moneyball literature.

Identification of Knowledge Workers and Analysis of Methods for Managing their Competencies in Baltic Sea Region Enterprises

Michał Igielski
Gdynia Maritime University, Poland

m.igielski@wznj.umg.edu.pl

Abstract: This article is a continuation of the 2017 research process on the identification of key employees in the companies participating in the research process. Now the main objective of the research is to identify knowledge workers and analyze the methods of managing the competencies of this group of employees in the studied companies. Of course, at the outset, the author attempted to identify knowledge workers and described their main competencies . In the following part of the article, the author tried to evaluate the measures taken by companies to optimally manage and use this capital to build a competitive advantage. These objectives determined the further course and nature of the research - the author used the following set of research methods: an analysis of the literature on the subject, a comparison of defined concepts and an interview with executives of the surveyed companies. The survey was conducted in 2021 in 100 randomly selected large companies based in the Baltic Sea Region (BSR) - a total of 261 people participated in the study. As literature analysis and empirical studies show, the degree of utilization of knowledge workers' potential is at different levels - there is a distance between developing countries and the richest and most developed countries. This is all the more surprising because company executives are aware of the importance of this capital to the future of their organizations. They also know what barriers they would have to overcome to better manage it. Therefore, according to the author of the article, it is necessary to remove all barriers that prevent the optimal use of the potential of this group of employees. For the organization, this will mean greater efficiency, greater innovation and flexibility in adapting to change. And for employees, intelligently organized work will be easier, more useful, more satisfying and meet a wider range of needs.

Keywords: Knowledge workers, Key competence, Human capital management

1. Introduction

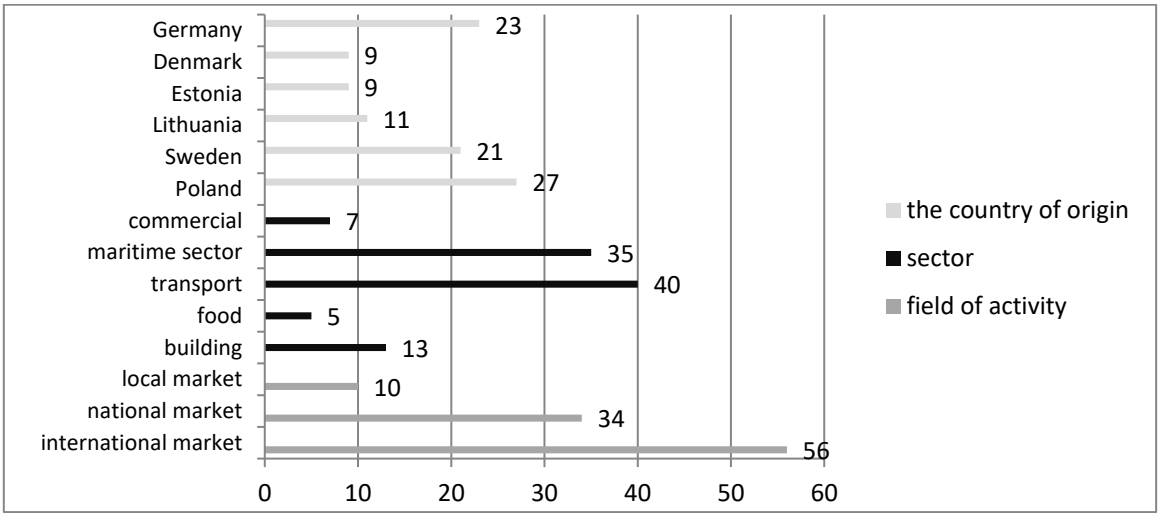
One of the most important metatrends accompanying the evolution of our civilization is the continuous increase in the overall mass of information in human society. It is the result of a feedback loop between our cognitive activity and our ability to influence reality. Wider knowledge increases the scope of our ability to shape reality. How does this affect economic processes? We are seeing the development of the concept of the personnel function towards the study of the growing role of knowledge at work, knowledge management and intellectual capital. Organizational managers are realizing that in such economic conditions, the proper use of the competencies of identified knowledge workers will increase the chance of success in the market.

Changes and accompanying turbulence in the modern economy have led companies to modify the rules of building competitive advantage on the market. This resulted in the necessity to introduce changes in the approach to management. The era in which we live is completely different from the previous ones. Now, the main form of economic activity (social activity too) is the creation and transfer of information and services. All this, combined with new management models and a higher pace of work and life, makes it necessary for entrepreneurs to focus on competences that are important for the type of work. Flexibility, mobility and adaptability to changing conditions are becoming increasingly important. Nowadays, many enterprises need developed interpersonal skills and practical competences.

This means that globalisation, technological innovations and the rapid growth of knowledge and information have forced changes in the structure of employment and a change in the approach to competences that are needed to perform a specific job. In today's world without knowledge we will not build an optimal model of competition and we will not be able to manage the enterprise. It is human capital that has become the most valuable resource in an enterprise. It is the only capital that can obtain, collect and select the necessary information. It has the knowledge that we use to make decisions and solve problems at every level of management.

The purpose of the article is to identify knowledge workers and analyze the methods of managing the competencies of this group of employees in the surveyed companies. In addition, the author presented basic issues in the context of knowledge workers, their competencies and methods of managing them - based on the analysis of the literature and the research process.

2. Method and Description of the Research



This survey is a continuation of the 2018 survey on the identification of key employees in companies. Now the main objective of the research is to identify knowledge workers and analyze the methods of managing the competencies of this group of employees in the studied companies. The author used 3 research methods: analysis of the literature on the subject - systematization of the language of terms; comparison - the author wanted to indicate characteristic features and defined terms; structured interview with senior managers in the surveyed entities.

The survey was conducted in 2021 in 100 randomly selected large enterprises with the seat in the BSR) - a total of 261 people took part in the survey. At the stage of planning the research process, the author intended to apply a targeted and random selection of the sample on the basis of information on enterprises in this sector contained in statistical data for the BSR. Unfortunately, the author did not have such large resources and he adopted the principle of selection on the basis of his own declaration of participation (questions were sent to 250 entities whether they are interested in participating in such an undertaking). Unfortunately, the research sample does not have the characteristics of the whole group for this region - the presented research results are not a complete set. It is the basis for extending the research process to the whole BSR in the future - for the time being it is a pilot study.

The author used the method of individual interview. A paper questionnaire was a research tool. The selection for the sample was purposeful on the basis of the following criteria: the status of a large company, having its registered office in the BSR, having a Human Resources (HR) department. The HR department was to help the author to obtain information about employees who can meet the criteria of belonging to the group of "knowledge employees".

Why did the author choose the method of individual interview? He believes that it is the managers who have the greatest knowledge of the nature of the work of their employees in each position. The basic technique of researching the methods of managing the competences of key employees may be an interview. Other techniques provide partial data that are less reliable.

The respondents were managers due to their daily contact with employees. Calculations and statistical analyses of empirical material, which was collected in the research process, were made using the Statistica statistical program and Microsoft Excel spreadsheet. The author used the following structure indicators and descriptive statistics: average, median, standard deviation, quartile range, measures of Spearman's rank correlation. They allowed to determine which of the surveyed phenomena are the most important in the opinion of respondents and what the diversity of their opinions looked like. They were also used to measure the interdependence between particular features of the variables.

Source: Own study.

Figure 1: Characteristics of Companies That Participated in the Research Process

The author could not find companies from other BSR countries, i.e. Russia, Finland and Latvia, to participate in the research (Russia was not considered from the beginning). Unfortunately, none of the companies from these

countries wanted to participate in the research. Therefore, the larger group of companies is from Poland, Germany and Sweden. As we can also see, more than half of the companies operate on the international market, in the transport and maritime sectors.

3. The Essence of Knowledge Workers

However, before we begin to discuss and consider increasing the productivity of today's knowledge workers, it is important to define what productivity and knowledge workers themselves actually are. It was P. Drucker who first described the knowledge worker in a meaningful way in his 1959 book Landmarks of Tomorrow, and in 1969 he posited that the productivity of knowledge work would be the great management challenge of this century, just as the productivity of manual labor was the great management challenge of the previous century. Continuing his reflections, in 1997 he went even further in, paying special attention to knowledge workers themselves by claiming that the productivity of knowledge and knowledge workers will not be the only source of competitive advantage in the global economy. Obviously, it will be a decisive factor, at least for most industries in developed countries. Therefore, the question arises: why is knowledge worker productivity such a significant challenge and who are knowledge workers?

A knowledge-based economy must create new organizations, hitherto unheard of, in which the essential ingredient for success is the worker. The new enterprise models are the people with personalized knowledge who make optimal use of other resources. They occupy a central place in their organization, they constitute its competitive advantage - they are its driving force.

Knowledge itself is a body of knowledge acquired through learning, a body of information in some field, knowledge of something or awareness of something (Dubisz 2003). From the point of view of a modern enterprise, knowledge is an economic good that can be privately owned and, as a commodity, can be traded on the market. In this case, knowledge is treated as an asset of the enterprise (Lobesko 2004). But looking from a human perspective, it is a key internal capital of each of us, each employee.

Returning to employees, however, the focus on people with high professional potential increased significantly as early as the late 1990s in the United States, where the talent search began to notice and focus on additional employee attributes, which included, first and foremost: distinctive abilities in a particular field - called specific; elevated intellectual potential; originality; openness to ambiguity; risk-taking; commitment to work; internal discipline; diligence.

Thus, if we associate a category of workers with knowledge, we are already dealing with a group of so-called knowledge workers, who, according to T. H. Devenport (2007), have a high degree of specialized education or experience, and the work they do requires the creation, distribution and use of knowledge. They earn their living by thinking, their working tool is the mind, and any effort involved in their profession is intellectual, not physical.

In a similar vein about knowledge workers is expressed by F. Horibe (1999), who believes that it is a worker who uses his mind in creating new value, through innovative ideas, analysis, evaluation, synthesis and design. This is confirmed by the theory of C. Winslow and W. Bramer (1994), which states that a knowledge worker interprets and uses information to create and deliver new value and validate information. On the other hand, M. Morawski (2009) in the layered management model presented categorizes employees according to their importance and value to the company, listing the following categories of knowledge workers: key employee, knowledge process manager, mature specialist, promising talent. Equally interestingly, knowledge workers are characterized by A.K. Koźminski (2004), stating that they are people with: personal intellectual capital (experiences, thoughts, intellectual prowess), personal social capital (acquaintances, contacts, social position), documented qualifications and achievements, and a stable financial situation (an indicator of independence and the value of their services).

Knowledge workers can be found in almost all organizations in developed economies, regardless of the type of business. It is difficult to determine exactly what percentage of the total workforce is made up of knowledge workers, as we do not have a one-size-fits-all definition at the global level - this issue will be discussed further in the next subsection. Arguably, the majority of knowledge workers can be located in organizations engaged in new or advanced technologies, among those in the professions of doctors of certain specialties, scientists, engineers, among professions requiring creativity, non-standard thinking and innovation, as well as among those in certain managerial positions.

The main dilemma, however, remains how to define workers who are not knowledge workers. This issue raises a lot of controversy, because since the productivity of knowledge workers is to constitute the competitive advantage of enterprises in the modern economy, it is necessary to correctly identify the specific characteristics of both the object of their work (knowledge work) and a certain set of characteristics and personal predispositions of knowledge workers as a group. On this basis, it is only possible to develop and implement measures - to create the right work environment - that will bring out the potential in this group of workers and make their knowledge as productive as possible.

Of course, in the era of the new economy, most professions require a certain level of knowledge - but this was also the case at the time when F. W. Taylor implemented the principles of scientific organization of work. External conditions at the turn of the century have changed due to unprecedented economic, technological and social development. Therefore, the minimum level of knowledge necessary to perform any work has increased. Revolutions in technology, telecommunications, automation, productivity impose a certain minimum level of knowledge and the ability to apply it, whether for direct production workers (e.g., automation of production), service workers (knowledge of customer needs, product offerings, etc.) or farmers (mechanization and computerization of farming). However, they do not become knowledge workers by doing so. To be a knowledge worker, one must (i) do knowledge work and (i) have certain specific competencies.

However, it is the productivity of knowledge workers that poses one of the greatest challenges for organizations in the 21st century. The most valuable resource of 20th-century enterprises was production equipment. The most valuable resource of 21st-century institutions, business or not, will be knowledge workers and their productivity (Ducker 2009).

T. H. Davenport (2005), in keeping with the trend of considering knowledge work and the productivity of knowledge workers, created a classification of workers based on the quantity, quality, application and creation of knowledge that accompanies the operations performed by each group of workers. The classification he presented reflects very well what Drucker advocated and brings us closer to a consensus on differentiating workers by the share of knowledge in their work. In short, the idea is that certain types of work require more knowledge, experience, expertise, autonomy, independent, out-of-the-box thinking than others.

On the other hand, today most tasks require at least a minimum level of thinking and knowledge, but not all of the same type and scale. It is important for employers to recognize these differences and act accordingly.

On the one hand, it is important to raise the productivity of those groups of employees who are the most numerous in the organization (such measures most often in practice boil down to the traditional management of industrial era employees - cyclical evaluation and planning of employee development and structure management). On the other hand, if companies want to compete in the global market, they need to attract and adequately motivate employees who, through the use of their knowledge, determine the lasting market success of the company - and these are knowledge workers.

4. Identifying Knowledge Workers in Theory and in Practice

It is already known that the productivity of knowledge workers is a challenge, but how the very distinction between a knowledge worker and a manual worker *vel an industrial era worker*, remains unresolved. Neither managers, workers nor professors at universities have reached consensus on defining these differences clearly, and it is often the case that the existence of such a division is questioned at all. It seems that the main challenge in the coming decade will be to identify knowledge workers themselves, classify them internally, define their tasks and the quality of their performance, and only then, work on their productivity. However, in the literature on the subject, among recognized research authorities, the author has encountered rather harsh criticism of the introduction of the above division.

However, disregarding the different opinions on the subject, the author for the purpose of this article, after synthesizing the definitions of knowledge workers proposed by other researchers, has made a kind of summary and believes that:

- the main purpose of their work is to create, distribute and apply knowledge (taking into account manual operations, which require highly sophisticated and theoretical knowledge);
- thinking occupies most of the time they spend on their work;
- the results of their work are mainly ideas and knowledge, which most often contribute to the work of others;
- the basis of their work performance is knowledge, expertise, experience, education;

- the problems they solve and the opportunities they seize are most often new, unprecedented, non-routine;
- they seek, process and produce information or data from which they are able to draw meaning and take necessary actions based on it;
- their work requires innovation, creativity, problem-solving skills, systemic thinking, high concentration and focus.

To sum up, a necessary but not sufficient condition for a person to be referred to as a knowledge worker is the performance of knowledge work. People with the above-mentioned knowledge worker competencies, but who do not perform knowledge work, will not be referred to as knowledge workers. However, the main dilemma still remains how to find employees who are or are not knowledge workers. This issue raises a lot of controversy, because if they are to be included in this group and constitute a competitive advantage for companies in the modern economy, it is necessary to correctly identify the specific characteristics of both the object of their work (knowledge work) and a certain set of their personal characteristics and predispositions as a group.

In the author's opinion, this is not so simple and of course. Usually, the simplest measures that are available in measuring the number of knowledge workers go to the "first fire":

- ISCED-97 classification - the number of economically active people with full tertiary education.
- ISCO-88 classification - the number of economically active people in an occupation that requires a significant body of knowledge at the tertiary level.
- HRST measure - the number of economically active people with higher education occupying positions that require a significant body of knowledge at a higher level.

Of course, we can assume that higher education is one of the characteristics that I can distinguish a knowledge worker from other workers. But are we sure? On the one hand, it seems that a knowledge worker must, not at all, have an extensive body of theoretical knowledge that will help him understand the essence of the work he is doing and allow him to gain knowledge of how to do it well - methods. At the same time, he must also possess the ability to use such already acquired knowledge in business practice to carry out the tasks assigned to him independently. Of course, such knowledge in the 21st century is acquired primarily during higher education, as evidenced by programs prepared by universities around the world, along with competence matrices that have been in force for almost two decades.

However, on the other hand, the empirical experience of each person who has or has had contact with the higher education system causes them to treat these measures with great caution and distance. The reason for this situation can be attributed to the significant growth of this group of workers (people with full higher education) in the labor market over the second decade of the 21st century. The trump card in the labor market in the form of higher education is slowly becoming a requirement in most of the jobs that are arriving. These booming industries are reporting demand for new professions and are looking for specific specialists to work through, thus greatly expanding educational offerings. In addition, there has been a need to retrain or diversify the competencies already held by a large number of those already working, which also increases the demand for studies.

Besides, can we not be surprised by the fact that the previously described criteria determining the membership of a given employee in the group of knowledge workers, often among many researchers of the subject (not only about the author of the work), did not include this determinant. We can find many more such uncertainties, but some assumptions must be made to make at least an attempt to determine the size of this group of employees in the population under study.

Therefore, the identification of knowledge workers turned out, for the author of the article, to be one of the major challenges during the conducted research, which is described in detail in Chapter 5 of this article.

The first objective of the study was to identify knowledge workers in the surveyed entities - of course, the beginning was the most difficult, as the concept of knowledge worker did not function in any of the surveyed entities (100 large companies in the Baltic Sea Region). Fortunately, having previous experience in this area (the author of the study conducted similar research in 2013-2015) and the characteristics of this group of employees established for the needs of other countries, the author created criteria and conditions affecting the membership of a given employee in the group of knowledge workers, which worked well.

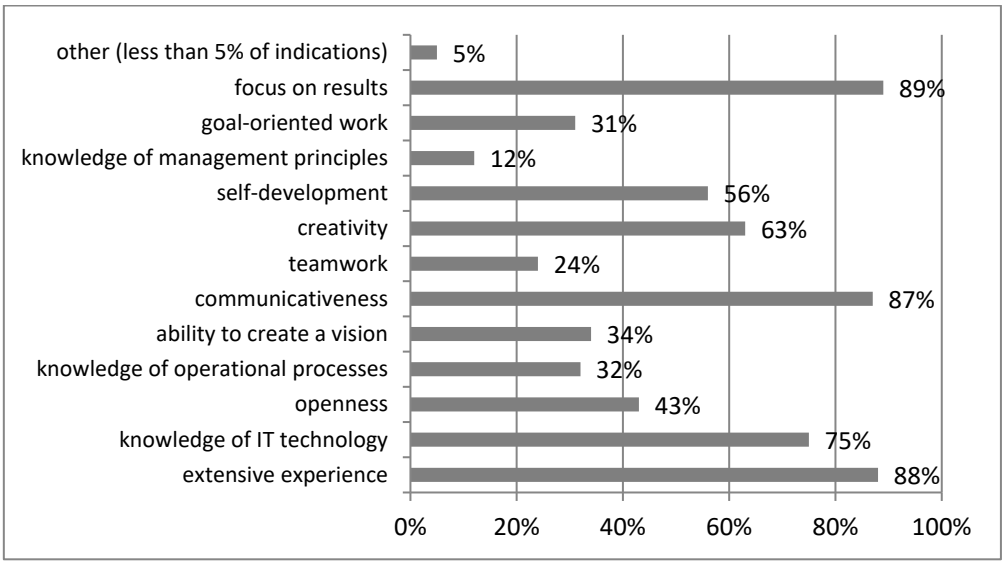


Table 1: Kryteria i warunki przynależności do grupy pracowników wiedzy

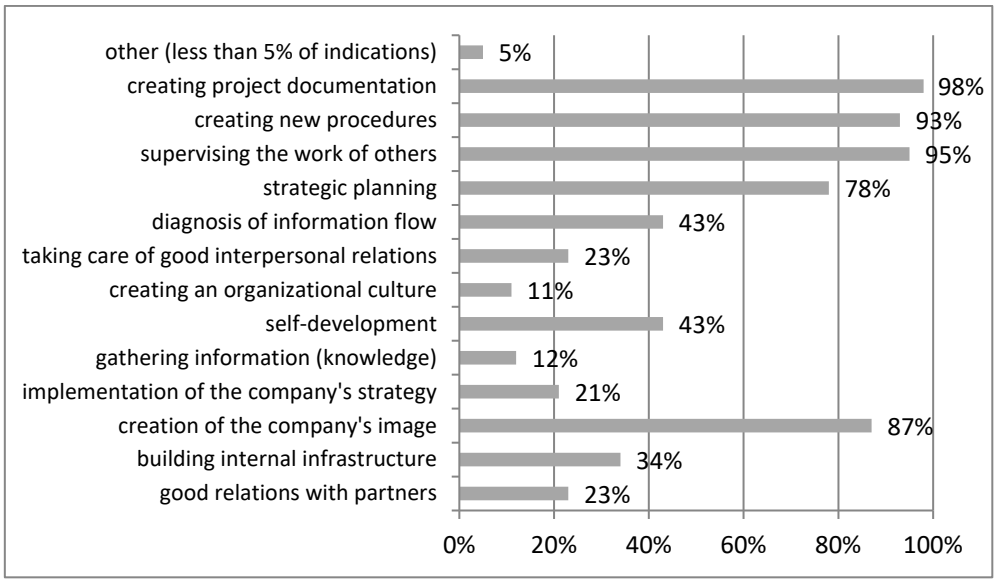
	Criterion/condition
1.	Expertise
2.	Creativity in daily work
3.	Courage to implement innovative solutions
4.	Independence and responsibility in action
5.	Expanding and developing existing knowledge
6.	Combining technical and managerial skills
7.	High professional culture
8.	Ability to properly organize work
9.	Dedication to the work performed
10.	Ability to work with others
11.	Possessing the confidence of co-workers
12.	Sharing knowledge with others

Source: Own study.

5. Analysis and Interpretation of Research Results

The entire research process was inspired by the words of.H. Davenport (2005), who put forward some time ago, a rather bold thesis that one of the strategic goals of a company nowadays is to provide a high level of satisfaction to its best employees - this was certainly confirmed in the research process conducted among companies in the new economic conditions. With the above statements in mind and in order to start the research process at all, it was necessary to identify knowledge workers. Therefore, in the first step of the first stage of the research, since the functioning of the concept of knowledge worker was not found in any of the companies selected for the study, the author planned to obtain the opinion of a group of respondents on the qualities which, in their opinion, a knowledge worker should have (Figure 2.).



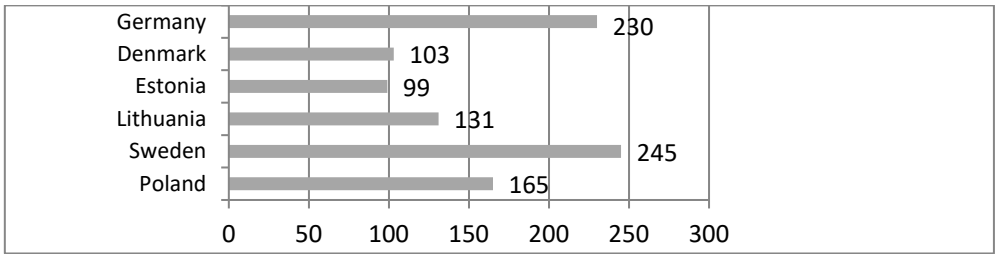
Source: Own study.

Figure 2: Features of Knowledge Workers Identified by Respondents (Managers)

As it can be seen, managers, when defining the qualities of a knowledge worker, attach particular importance to their experience, achieved results or specific competencies (in this case, IT), which may prove the thesis that they expect results from their employees above all - this is the main barrier to creating a vision for managing their competencies and knowledge. Interestingly, respondents placed great emphasis on leadership qualities,

which included, first and foremost, systems thinking, a shared vision, a friendly attitude toward others (even altruism), courageous commitment, or knowledge of the business.

Equally interesting opinions of the respondents appeared when they were asked what tasks they set for the people they would include in the group of knowledge workers (Figure 3.) - of course, the condition for fulfilling these tasks, is to have, first of all, the appropriate qualities identified earlier.



Source: Own study.

Figure 3: Tasks set for Knowledge Workers in the Opinion of Each Manager

In this case, the respondents focused primarily, once again, on day-to-day work (preparation of documents or procedures), although, in the author's opinion, issues related to the use of knowledge, i.e.: its collection, processing and use, should prevail. This is undoubtedly the result of the lack of identification and in general the presence of the concept of a knowledge worker in the surveyed companies - it seems that the management is not aware of the potential of such people and their impact on the overall functioning of the company (at this point it was known that the level of difficulty in achieving the set research objectives increased significantly).

Reassuming. thanks to the analysis of the above data and on the basis of the experience of the research process in previous years, it was possible to identify knowledge workers (Figure 4) in all the companies participating in the study - in 973 employees.

Source: Own study.

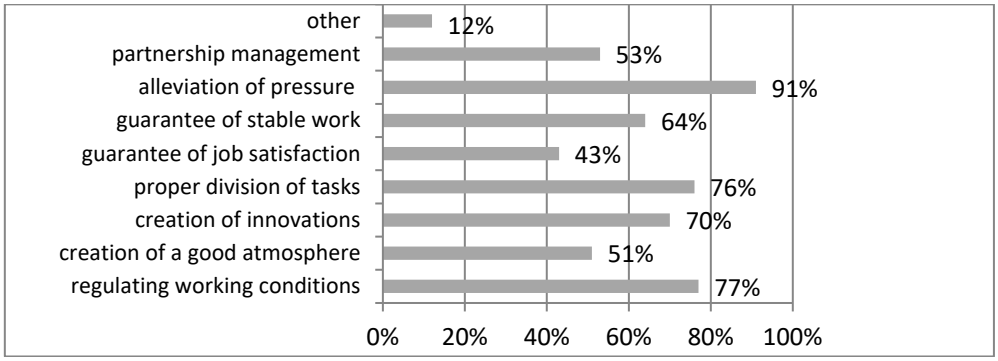
Figure 4: Number of Identified Knowledge Workers by Country of Origin of Enterprise

Analyzing the above data, it may seem strange to us that the number of identified knowledge workers was distributed almost evenly across all the surveyed companies - in proportion to their number from a given country (Scandinavian countries minimally lead the way). This is probably a result of the fact that in no enterprise such a concept was functioning, and the process of identifying them, created and implemented for this purpose, may have been imperfect - it was perhaps too unified a picture. In summary, however, it can be assumed that the first stage of the research process has been completed - the established sub-goals have been achieved - the author moved on to the next stage of the research.

In the next part, in accordance with the research plan, respondents were asked about their opinions on the conditions that the companies created for knowledge workers. Respondents were given a rating scale from 1 to 5 - where one was very poor conditions and 5 was very good. The answers given nevertheless add up to a fairly positive picture of this area in the surveyed entities - the main mistakes most often made by companies are: lack of agreement to act independently, lack of experienced among managers (this causes lack of recognition among employees), excessive bureaucracy or lack of expected training, These are the biggest problems and at the same time challenges faced by the managements of the surveyed entities. It is difficult to talk about building relationships with knowledge workers in the case of poor evaluation of the working conditions created for them.

Table 2: Assessment of the Conditions Created for Knowledge Workers and Identification of the Biggest Problems of Managing Them

Evaluation of the created working conditions				
very weak	weak	medium	good	very good
11%	19%	20%	33%	17%
Mistakes made by enterprises in the process of managing knowledge workers				
lack of acceptance of self-reliance				88%
little experience of managers				78%
excessive bureaucracy				77%
lack of expected training				76%
poor relations between manager and subordinate				67%
favoritism of individual employees				65%
lack of opportunities for promotion				64%
poorly constructed evaluation system				61%
one-sided communication				59%
too much control				56%
authoritarian management style				54%
too many ritualistic activities				52%
low level of remuneration				49%



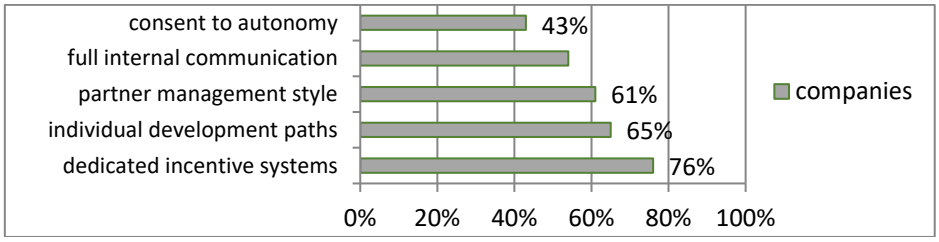
Source: Own study.

At this point, it should be noted that, on the one hand, the respondents are aware of the challenges they face due to the new determinants of the economy - this was shown by their opinions on knowledge workers and "competencies of the future" and the role I these people to play in the process of building a competitive advantage for their companies in the market. They also understand that their companies will become organizations of the digital age, producing physical products and providing innovative services based on data analytics - there will be a radical transformation in the way they operate and the dynamics of the processes in the market will also increase. They also know that data and information are central to the coming changes, and they have a long and difficult road ahead of them leading to advanced analytical capabilities.

5.1 Tools and Principles of Cooperation with Knowledge Workers in the Enterprise

Unfortunately, the problems / barriers or challenges are quite numerous - this confirms the need to set directions for improvement and implement corrective actions. This shows not only a gap in the research and scientific treatment of the problem, but also a gap in business practice. Therefore, decisive steps should be taken to eliminate the barriers that have arisen, which contribute to the escalation of further dysfunctions and will help (initially at least to a small extent) to better manage knowledge workers. In the next stage of the research, it was possible to observe and, importantly, identify, from the opinions of respondents, new areas / directions of activities implemented in the surveyed companies in the field of knowledge worker management strategies: the creation of systems to prevent psychosocial risks at work, strengthening of already existing and implementation of new tools, improvement of the quality of relations and working conditions.

This is the result of the understanding of the needs of employees by the responsible boards, conversations with managers, as in the next step of this stage of the research, the respondents themselves indicated the need for specific actions and changes in management systems, in line with the above-mentioned areas, which would affect the effectiveness and efficiency of work (Figure 5).



Source: Own study.

Figure 5: Changes Needed to be Made in Knowledge Worker Management Strategy

All of the above plans must, of course, be translated into concrete actions that will gradually modify the management systems already in place. Interestingly, at this stage of the research, based on the analysis of all the data, we can see the analogy with the earlier theoretical argument about contemporary working conditions resulting from the economic changes taking place and the specific characteristics of knowledge workers, who do not attach as much importance to a permanent place of employment, and put their independence first. The most important thing, however, is that employees, together with their managers, at least in the companies surveyed, are aware of this.

Summarizing all the above considerations, while moving on to the essentials of changes in personnel policies in the context of knowledge worker management, it was possible to identify in the surveyed companies, the initial directions of activities aimed at achieving the highest possible productivity of this group of employees and creating optimal conditions conducive to the effective use of their potential and competencies (Figure 6).

Source: Own study.

Figure 6: Measures for Knowledge Workers in Surveyed Companies

An equally important condition that an organization must meet to enable knowledge workers to act as innovators is the issue of building employee commitment. When planning to fully utilize the potential of this group of employees, it is necessary to cause them to be sincerely interested and preoccupied with their work and willing to take on additional activities that go beyond their formal duties. However, it is often possible, as the research has shown, to encounter barriers that hinder the optimal use of the potential of knowledge workers (and not only this group of employees) for the development of the enterprise: haphazard recruitment of team members, the lack of specialists on the market, the lack of mechanisms developed by companies to function in the new economic conditions, the lack of awareness of the role of intellectual capital in the knowledge economy.

Of course, when analyzing the data, we can come across measures to effectively manage this group of employees - according to the author, they can be directed to 4 main areas - acquisition of new knowledge, use of knowledge by the largest possible group of employees, knowledge management, encouraging employees to continuously acquire new knowledge.

Below, in Table 3, the author has matched, in his opinion, the main actions taken by the surveyed companies to optimally utilize the potential of knowledge workers and assigned them to the 4 areas plotted earlier.

Table 3: Actions Taken to Optimally Utilize the Potential of Knowledge Workers

Areas	Actions seeking to realize the potential of knowledge workers
Area No. 1	Clarifying the role of management
	Determining the influence of strategic goals on each employee's work
	Careful listening
	Eliminating ventures that do not benefit the company
	Encouraging the creation of new ideas
	No punishment for mistakes - only he who does nothing is not wrong
	Promoting attitudes related to admitting mistakes
Area No. 2	Informing employees about organizational conditions
	Consent to corporate actions
	Joint decision-making / consultation on changes
	Preferowanie pracy zespołowej Preferring teamwork
Area No. 3	Delegating decision-making authority to knowledge workers
	Changing the role of managers: coordinator, coach (helps strengthen commitment), leader/authority (represents the interests of their employees), mentor (reminds them of the organization's mission)
Area No. 4	Training that takes into account the strategic goals of the company
	Training that takes into account employee development goals
	Zachęcanie do uczenia się nieformalnego Encouraging informal learning
	Rewarding learning outcomes

Source: Own study

This means that in the new economic reality created by globalization, technological advances or the rise of intellectual capital, at the dawn of a 5.0 society, there will be changes in the perception of employees in every workplace. In every industry - in the factory and in the law firm. Knowledge workers will need new competencies in the face of the dominance of digital tools. They will expect completely different treatment and support from their employer. Daily experiences with Artificial Intelligence, Internet of Things, robotics and automation will imprint on them and evoke unprecedented feelings and needs, and HR departments around the world must be prepared for this.

In addition, the above measures are all the more important because knowledge worker productivity is one of the biggest challenges facing organizations in the 21st century. However, before even discussing and considering how to increase knowledge worker productivity, it is important to define what productivity is and how we distinguish between the productivity of industrial era workers and knowledge workers. Therefore, it seems that this will be another very important research problem that the author plans to address in the near future.

6. In Conclusion

In summary, no matter what method or strategy an organization chooses to support (or even build) its business goals through optimal management of knowledge workers, it must base this sphere of activity on specific rules:

- All people employed in the company, not just knowledge workers, must be treated as an asset of the organization - not a cost or resource.
- The organization must have a concrete and flexible business model, from which the applicable personnel strategy is derived.
- Organizational culture is the basis for managing knowledge workers - primarily a system of values and norms, as well as people's attitudes and behavior.
- Combining the goals of the employer with the interests of knowledge workers.
- Breaking down the responsibility for managing all human capital to several centers in the organization: starting with the top management and ending with each manager.

- The top management in an organization must realize that the expertise of the people they employ largely determines its competitiveness - they must trust them and motivate them properly.
- Properly define the tasks for the HR Department, which should include helping to solve social problems in the organization. Managers of these departments should have at their disposal HR solutions and tools that are easy to apply and tailored to the specifics and needs of the company.
- In building and managing teams of employees, techniques should be used that will enable, on the one hand, proper organization of work and effective problem-solving, and on the other hand, take into account the interests of the company and its employees.

Changes in the Labor Market in the era of the COVID-19 Pandemic: Occupations Desired by Employers in the Polish Labor Market

Waldemar Jędrzejczyk
Czestochowa University of Technology, Poland

waldemar.jedrzejczyk@pcz.pl

Abstract: The contemporary business environment is very dynamic. Only two years ago, the factor that determined changes in organizations the most was the technological progress – mass digitization of processes combined with progressive automation and robotization. Currently, the situation has changed a lot. Today's economy has to cope with another crisis caused by the COVID-19 pandemic and exacerbated by Russia's military aggression against Ukraine. The pandemic caused worldwide social and economic disruption, including the deepest global recession since the Great Depression. The pandemic also brought changes to the labor market and work environment. The most visible impact of the COVID-19 pandemic on the work environment was the spread of remote work. In this article, the main subject of consideration will be the issues of occupations in the context of the COVID-19 pandemic. The main objective is to assess the overall impact of the COVID-19 pandemic on the labor market. The analysis covered 2019-2023 and was based on secondary and primary research. The unemployment rate and the Occupational Barometer were analyzed. In-depth interviews with employment agents and career advisors were conducted. The conducted analyses and research showed that the changes in the labor market caused by the COVID-19 pandemic were temporary. The most significant changes occurred during the first year of the pandemic. Today, after the cessation of the epidemic threat and the revocation of the pandemic, the situation in the labor market has returned to normal - to the pre-pandemic state. The only change in the labor market that has not returned to the pre-pandemic state is the number of people working remotely.

Keywords: COVID-19 pandemic, Labor market, Remote work, Occupations, Poland

1. Introduction

On March 11, 2020, the World Health Organization (WHO) declared a COVID-19 pandemic caused by the SARS-COV-2 virus – as a consequence of the rapid increase in the number of people infected with the virus, which first appeared in Wuhan, China. Due to the spread of the pandemic, most countries, including Poland, introduced various types of restrictions to prevent the spread of the coronavirus at the turn of the first and second quarter of 2020, i.e., ordering people to stay indoors, closing schools and workplaces, banning mass events and public gatherings, restricting movement and crossing borders, or using public transportation. In many countries, the state of epidemic emergency was introduced first, and then the state of epidemic. After three years, on May 5, 2023, the WHO declared the COVID-19 pandemic revoked.

The coronavirus pandemic has affected the economic climate worldwide. Global GDP in 2020 fell by 4.3% compared to 2019. The pandemic has also brought significant changes to the labor market - the demand for occupations and competencies changed, and forms of work organization evolved. Changes in the labor market were not identical for all entities, both at the macro and micro levels. The pandemic had a varying impact on different countries and regions of the world, both in terms of the object of change and the period of change. The same applies to industries and professions. For some, the impact was favorable, while for others, it was neutral or unfavorable.

The main purpose of the article is to assess the overall impact of the COVID-19 pandemic on the labor market. According to the definition, the labor market is a type of economic market that consists of, on the one hand, job seekers and their offers and, on the other hand, entrepreneurs who create new jobs and need a workforce. Within the main objective, the following research questions were posed to elucidate the research problem:

- Has the COVID-19 pandemic caused an increase in the level of unemployment?
- Has the COVID-19 pandemic affected the demand for occupations in the labor market?
- Has the COVID-19 pandemic caused significant changes in work organization?

With regard to the main objective and the posed research questions, the primary hypothesis was formulated: The changes in the labor market caused by the COVID-19 pandemic were temporary and were not perpetuated after the cessation of the epidemic threat and the revocation of the pandemic.

Against the background of global changes in the labor market, detailed analyses in terms of the most important indicators of the labor market, i.e., unemployment rate, number of job offers, employment conditions, and scarce occupations, were carried out for Poland, a country ranked 69th in the world in terms of administrative area, and 9th in Europe.

2. Work Changes Caused by the COVID-19 Pandemic

The most visible impact of the COVID-19 pandemic on labor was the spread of remote work (Marcus, 2023). The threat posed by the coronavirus and the introduction of the lockdown forced the market to shift some of the work activity of employees from workplaces to their homes (*Impact of Pandemic …*). In Poland, according to the Central Statistical Office, in the fourth quarter of 2020, the number of people usually doing their work at home was 1,609,000 (which accounted for 9.7% of all working people). It constituted a significant increase – the number of people working remotely increased by 128% compared to the end of 2019, before the pandemic. The trend was intensifying, and during the so-called "Third Wave of the Pandemic" in March 2021, 14.2% of the employed were already working remotely (GUS, 2020, p. 10).

Another visible effect of the pandemic was a change in expectations regarding the competencies employees should possess. Employers began to pay more attention to competencies related to the use of new technologies, as well as time management, organizational skills, and resilience to stress, which is closely connected with the spread of remote work.

The pandemic has made employers and employees realize the importance of flexibility and responding quickly to change. It is also vital to have the ability to make decisions in uncertain conditions and adapt to new realities. As a result, companies are more likely to hire people characterized by so-called learning agility, i.e., the ability to learn quickly and adapt to change.

3. State action to Protect Jobs

The crisis caused by the COVID-19 pandemic detrimentally affected the labor market, which has contributed to a decline in people's living standards and created socioeconomic problems (Hupkau et al., 2023). To counteract these adverse developments, governments in many countries have undertaken a series of countermeasures (Köhler et al., 2023). The Polish government introduced the first package of support for businesses and employees, known as the Anti-Crisis Shield, as early as April 1, 2020. Within the framework of the Anti-Crisis Shield, an assistance program was launched targeting businesses affected by the pandemic. Its purpose was to protect the labor market and provide companies with liquidity during a period of severe economic disruption. Support granted to employers aimed at maintaining jobs and consisted of (*Life and Work …*, 2020, pp. 194-195):

- Subsidizing micro, small, and medium-sized entrepreneurs for part of the cost of employee salaries and social security contributions;
- Subsidizing entrepreneurs who are natural persons not employing workers to conduct business activities;
- Granting low-interest loans to micro-entrepreneurs;
- Subsidizing salaries with funds from the Guaranteed Employee Benefits Fund during the period of economic downtime or reduced working hours imposed by employers.

In addition, small businesses could receive support through an exemption from Social Security contributions for three months. Medium-sized companies were able to apply for more funds from the Export Insurance Policy Committee for insuring trade turnover at home and abroad. Large enterprises could obtain state support by, among other things, being subject to more flexible labor market regulations.

4. Working During the Pandemic

With the economy grinding to a halt, many employers have suspended hiring processes and cut back on hiring people in order to survive the challenging times. They dismissed a significant portion of their staff, leaving employees without jobs and income (Nunes et al., 2023). It affected the service sector in particular. Industries such as tourism, hospitality management, catering, hairdressing, culture, and entertainment suffered the most. Customer service departments in companies also showed a downward trend. Many employers reduced working hours for their employees.

The Covid-19 pandemic and the resulting lockdown have led to significant changes in the perception of performing work. Employers and employees alike had to adapt to the new conditions in a rapid manner. Initially, the lockdown caused panic and complete paralysis of most industries in the market. However, when the public realized that the shutdown of the economy would last over a dozen days, it became necessary to develop new solutions that would enable the continuity of the work of individual entities. As a result, a significant part of the professional activity was transferred from the company to the home. It was a milestone in working conditions,

as under regular conditions, the application of remote work on such a scale would certainly not have happened sooner than in a few or a dozen years (*Impact of Pandemic …*).

The epidemiological crisis has fundamentally changed the organizational reality. In many industries, remote work has become a requirement and the only option. It posed a significant organizational challenge, especially for those companies that had never had experience with this form of work organization. The pandemic, therefore, caused remote work to become widespread in organizations (Marcus, 2023). This form of work was a safe choice for many companies and provided them with an opportunity to maintain work continuity. In this circumstance, the ability to work remotely, good work organization, and soft skills were becoming vital qualities of employees.

Remote work should rely on cooperation between supervisors and employees and a sense of responsibility for the work performed. The pandemic has forced employees and employers to adapt to a new way of working. To this end, new technologies and information techniques have been used, enabling the digitization of all forms of work. The manner of communicating at work, including the mode of meetings between employees or meetings with the employer, has changed. These have become possible through the use of video and teleconferencing (Stanciu et al., 2023).

The pandemic has intensified the demand for IT professionals and specialists in finance and economics-related occupations. Demand for blue-collar workers in positions such as warehouseman and courier has also increased. It is related to the shift of sales to the Internet and the development of e-commerce platforms and services for delivering products directly to the customer's home.

The ability to work in home office mode should occur in accordance with the following rules (*Working remotely …*):

- Adequate management support – especially a results-focused approach that requires precise identification of tasks and main goals and proper monitoring of work performance without excessive reporting.
- Provision of work tools (including laptops and apps), platforms for communication with management and colleagues, and the necessary training.
- Explicit rules and transparent expectations regarding telework performance, its hours, the method of reporting, and the contact ability and availability of employees.
- Allowing employees time flexibility so that they can perform their work at the most convenient time for them, balancing their home responsibilities and at the same time remaining in contact during the company's working hours.
- Mutual trust, which determines the effectiveness of remote work.

After an initial period of complete stagnation, organizations gradually began to initiate recruitment processes. However, they offered much less favorable employment conditions in comparison with the pre-pandemic period. It was caused mainly by the desire to reduce labor costs. The number of provided non-wage benefits declined, such as subsidies for learning foreign languages, private medical care, or sports cards. Instead, companies offered in-house training, which generates lower costs.

The COVID-19 pandemic has undoubtedly brought changes in the way work is organized and in demand for particular job positions. However, it did not lead to the collapse of the labor market but only to its transformation. The pandemic showed that companies, regardless of size, have become efficient organizations, quickly adapting to the new reality.

5. Research Method

The main purpose of the article is to assess the overall impact of the COVID-19 pandemic on the labor market. With regard to the main objective, three research questions were posed:

- Has the COVID-19 pandemic caused an increase in the level of unemployment?
- Has the COVID-19 pandemic affected the demand for occupations in the labor market?
- Has the COVID-19 pandemic caused significant changes in work organization?

The primary hypothesis was formulated: The changes in the labor market caused by the COVID-19 pandemic were temporary and were not perpetuated after the cessation of the epidemic threat and the revocation of the pandemic. The trends of changes in the labor market were analyzed in two dimensions: macroeconomic and microeconomic. The phenomenon was considered on the scale of a single country – Poland, in 2019-2022.

In the macroeconomic dimension, the unemployment rate and the Occupational Barometer were analyzed. The unemployment rate is one of the primary macroeconomic indicators. It is a statistical quantity that describes the severity of unemployment in a given population. It is most often defined as the ratio of the number of unemployed people to the economically active population. The fundamental premise for selecting this indicator, which characterizes the state of the labor market, was its unified nature. This feature makes it possible to conduct comparative analyses between regions, countries, and industries. Furthermore, the level of unemployment determines the level of economic growth and translates into the living standards of the population.

The "Occupational Barometer," on the other hand, is a one-year forecast of the state of occupations. The barometer divides professions into three groups: deficit, balanced, and surplus, and the results apply to districts, voivodeships, and the country as a whole. It is a qualitative study based on so-called expert panels. Participants in the study, recruited from among employees of labor offices and other institutions statutory involved in the labor market, as well as companies that operate in the HR industry, provide answers to the following questions in the course of the discussion:

- How will the demand for employees in a given occupation change in the upcoming year? Will it increase, decrease, or remain the same?
- How will the relationship between the available workforce and the demand for employees in a given occupation shape? Will there be a deficit or a surplus of work seekers, or will demand and supply balance out?

Changes in the classification of occupations into a deficit, balanced, or surplus group illustrate well the changes occurring in the local, regional, and national labor market, including the expectations of employers.

In the microeconomic dimension, the research subjects were labor offices[1]. Labor offices are institutions that study and analyze the labor market, provide information to the unemployed, and engage in job placement for work seekers. The research was conducted in the form of interviews. It was an in-depth study to clarify the changes that have occurred in employers' expectations of job candidates due to the COVID-19 pandemic. The interview questionnaire consisted of two sections: header and substantive section. The header section recorded such information as the date of the interview, the start and end time of the interview, the form of the interview, the name of the respondent, the held position, and the respondent's seniority. The substantive section consisted of ten questions, which are presented in the aggregated form in the last main point of this article. The validity of the posed questions was also verified during the interview.

The research was carried out between October and December 2022. Prior to conducting an interview, the secretariats of the labor offices were contacted by phone and asked to speak with the director or deputy director. Interviews were carried out in offices where the directors agreed to conduct such a survey. A total of 10 interviews were conducted. The average duration of an interview was 1 hour. The respondents were eight employment agents and two career counselors from various labor offices in the Silesian voivodeship.

6. Changes in the Labor Market in Poland in 2019-2022 in the Light of Macroeconomic Indicators

The announced and implemented state of the epidemic in Poland in March 2020 caused changes in the labor market. Companies reduced their employees' working hours, sent workers on furlough, or dismissed them. In the initial and following stages, the labor market in Poland was in a worse condition than in previous years. In December 2019, the unemployment rate in Poland stood at 5.2% (Table 1). In March 2020, at the outbreak of the pandemic, the unemployment rate was 5.4%. The unfolding pandemic caused a significant increase in the number of unemployed people. At the end of 2020, the unemployment rate was 6.8%. Such a level of unemployment persisted until April 2021. In the following months, the level of unemployment in Poland decreased slightly – at the end of 2021, it was 1 percentage point lower compared to the same period in 2020. After the pandemic slowed down, the level of unemployment in Poland decreased and stabilized – from May 2022 to April 2023, it remained within the range of 5.2-5.5%.

[1]The research was conducted by a research team led by Waldemar Jędrzejczyk. The main research stream concerns the issue of competencies, both currently desired and prospective, regarding sectors and types of organizations, occupational groups, and key positions in organizations. In the area of labor market changes caused by the COVID-19 pandemic, the head researcher was Agnieszka Mańka-Goncerz.

Table 1: The Registered Unemployment Rate in Poland in 2019-2023 (data in percentage)

Month/Year	2019	2020	2021	2022	2023
January	6,1	5,5	7,0	5,9	5,5
December	5,2	6,8	5,8	5,2	-

Source: Compiled based on current GUS data (https://stat.gov.pl/obszary-tematyczne/rynek-pracy/bezrobocie-rejestrowane/stopa-bezrobocia-rejestrowanego-w-latach-1990-2023,4,1.html)

The highest increase in the unemployment rate was recorded in the first year of the pandemic in March 2020–March 2021. Over the course of 1 year, the unemployment rate increased by 1.5 percentage points. The increase in unemployment halted in April 2021, and a downward trend could be observed from May onward.

With regard to the increase in the unemployment rate caused by the outbreak of the COVID-19 pandemic, the question must be asked: has the decline in employment affected all industries and occupations to the same extent? The occupational barometer was used to find the answer to this question. Occupation barometers for the years 2020-2023 (developed respectively in 2019 and 2022) were analyzed. The main focus was on deficit and surplus occupations.

In these two categories, the number of deficit occupations, that is, professions in which the number of vacancies is greater than the number of people interested in taking a job or meeting the requirements of employers, predominated each year on a national scale. By contrast, there were virtually no surplus occupations – in which the number of vacancies is lower than the number of people interested in taking a job or meeting the requirements of employers. Surplus occupations were indicated only in the 2020 and 2021 barometers – in both cases, these were economists.

Deficit occupations pose a far more significant problem. There are occupations in which it has been difficult for employers to find job candidates for many years. These include such professions as (these appear on the lists of deficit occupations in the occupational barometers in all analyzed years): woodworkers and construction carpenters, roofers and sheet metal workers, electricians, electromechanics and electrical fitters, physiotherapists and massage therapists, bus drivers, truck and tractor drivers, cooks, doctors, warehouse workers, motor vehicle mechanics, construction fitters, bricklayers and plasterers, practical vocational training teachers, vocational subject teachers, earth-moving equipment operators and mechanics, machine tool operators, caregivers of the older people and people with disabilities, nurses and midwives, construction finishers, construction laborers, independent accountants, welders, and locksmiths.

The pandemic has caused a shift in demand for some occupations. In the 2021 occupational barometer, unlike in 2020, hairdressers and accounting and bookkeeping workers were absent from the group of deficit occupations (due to the lockdown and closure of hairdressing establishments and other service establishments in many industries, which reduced, among other things, the scale of outsourcing in financial and accounting services), while tailors, garment production workers (due to a change or expansion of the business profile - many entities began sewing protective masks, suits, and aprons for health care), and paramedics (as a result of a very high increase in severe illnesses caused by the SARS-CoV-2 virus) appeared. The second year of the pandemic also brought changes in the group of deficit occupations. In the 2022 occupational barometer, tailors and garment production workers disappeared from the group of deficit occupations, while psychologists and psychotherapists appeared (as a result of widespread isolation, especially among children and adolescents - education in most schools was provided remotely), and accounting and bookkeeping workers reappeared.

The slowdown of the pandemic has again brought some changes in the group of deficit occupations. In the 2023 occupational barometer, bakers, woodworkers, carpenters, and paramedics disappeared from the group of deficit occupations, while general education teachers and teachers of special schools and inclusive departments appeared – a trend unrelated to the pandemic phenomenon.

The COVID-19 pandemic exacerbated the deficit crisis for certain professions. In particular, there was a shortage of medical, construction, and IT workers – programmers and database administrators, as well as workers in the transportation industry – drivers and warehouse workers. The pandemic also caused a crisis of demand for some occupations. The crisis particularly affected professions in the industries subject to restrictions, namely catering, trade, tourism, and hospitality management, and the mining, manufacturing, and automotive sectors. There was a deficit of job listings in the Labor Offices for occupations in these industries. Only since May 2021 has there been an increase in job offers and occupational activation, while the number of unemployed people has fallen.

In 2021, despite the ongoing pandemic, employers were more open to new hiring processes than 12 months earlier. The caution from the beginning of the pandemic was replaced by a rational personnel strategy. There was an increase in the number of employers seeking employees in the sectors most affected at the beginning of the pandemic and in the second wave – catering, hospitality management, and the HR industry (*OLX labor* …, 2022). Businesses have opened up to home offices due to the pandemic. As early as 2021, there was an increase in the number of job offers with remote work options compared to the beginning of the pandemic. It proves that the remote work form found many enthusiasts. It was also a safe choice that allowed work continuity, at least in some sectors. Remote work became widespread in industries such as marketing, PR and media, accounting, telephone customer service, and IT (*OLX labor* …, 2022). Not every trade could afford to switch from onsite to remote work. Certain businesses do not allow remote work, i.e., the construction or manufacturing industries.

7. Changes in the Labor Market in Poland in 2019-2022 in the Light of Labor Offices

Interviews conducted with employees of labor offices aimed to find answers to the following problem questions:

- Which industries, occupations, and positions have been most affected by the COVID-19 pandemic?
- What impact has the COVID-19 pandemic had on employers' requirements for candidates for recruited positions?
- What changes have occurred in the processes implemented by labor offices as a result of the COVID-19 pandemic?
- What impact has the COVID-19 pandemic had on the situation of the unemployed?
- Has the COVID-19 pandemic caused an increase in interest in remote or hybrid work?

Respondents included hairdressers, catering assistants, cooks, waitpersons, bartenders, beauticians, nail stylists, bus drivers, truck and tractor-trailer drivers, travel agents, and tour guides among the occupations most severely affected by the pandemic in the labor market. The prolonged lockdown has primarily caused great caution in the employment of people in industries exposed to restrictions. Temporary and contingent workers and employees with short job seniority were the first to suffer the fallout of the lockdown. They were the first to receive notices of termination, were not offered another contract, or had no job offers in their occupations. Employers who received state assistance, such as the Anti-Crisis Shield, did not dismiss workers for whom they obtained support, but the majority did not increase employment.

The worst period in the number of job offers on the market was the early months of the pandemic – from March to June 2020. By the same period in 2021, most occupations had already returned to relative balance. Job offers were plentiful, and employers' interest in subsidized employment increased. The phenomenon of rebranding has also intensified. Many people dismissed from industries impacted by restrictions declared a desire to retrain – they were leaving their professions and looking for work in more stable industries.

Among the occupations positively affected by the pandemic (as a result of the pandemic, the supply of these occupations in the labor market increased), respondents included: couriers, food delivery drivers, IT specialists, warehouse workers, logistics specialists, salespeople, and cashiers. Due to the increased interest in online sales and the transition of some restaurants to selling food with home delivery, interest in food delivery drivers and couriers was particularly pronounced.

The pandemic has highlighted and exacerbated staff deficits in the healthcare sector the most. It has been difficult for medical facilities to find candidates for medical and nursing vacancies. Interest in medical registrars, caregivers for older people, and health carers has also increased.

Since the loosening of restrictions, demand has begun to increase for low-skilled occupations, such as cashier, salesperson, and warehouse worker. Employers requirefrom such candidates only the willingness to work and availability, understood as the willingness to work shifts and the ability to start working "immediately." The high supply on the labor market for such employees stemmed from high rotation. Employers also forwent requiring work experience for such positions. Depending on the industry, employers requireprimary or secondary education.

In the case of more complex products or sales processes involving middle-skilled occupations, i.e., sales representative, customer services advisor at a bank or insurance institution, or salesperson of specialized equipment or high-tech products, employers' requirements increased and, apart from a willingness to work, professional education and experience were required.

For high-skilled occupations, such as positions requiring credentials, licenses, and a certain level of professional education, the COVID-19 pandemic did not affect employers' requirements for job applicants. They remained the same before, during, and after the pandemic.

During the pandemic, job seekers usually contacted labor offices by phone or email. Many treated such contact as confirmation of their willingness to work. Only a few inquired about job offers that were lacking in the market. The unemployed reported on suspended recruitment processes and the lack of vacancies.

The pandemic highlighted the phenomenon of digital exclusion. A high percentage of people were unable to adapt to the new pandemic reality due to their living situation (difficult financial conditions, homelessness, illness, addictions) or lack of digital competencies. The implemented lockdown and recommendations for the administration to work remotely caused many services to be available only in the remote form. The pandemic further aggravated the problem of exclusion of certain groups of the unemployed. The situation has particularly worsened for the long-term unemployed, who entered the pandemic already with severely limited social contacts. The pandemic has caused even further isolation. A phone call or email contact with the unemployed did not create convenient conditions for frank conversations about professional issues.

The trend, observed in Poland and abroad, of employers offering remote or hybrid work opportunities was not clearly confirmed in the intermediation provided by the surveyed labor offices. Employees did not notice significant interest from employers cooperating with labor offices in such forms of work.

8. Conclusions

The COVID-19 pandemic has had a profound impact on the labor market in Poland and caused many changes. As it was presumed, the demand for particular occupations and forms of work organization changed, with the strength of the impact varying from highly negative to highly positive. The adopted main objective was therefore achieved.

The answers to the posed research questions were also found. The COVID-19 pandemic has had a negative impact on the labor market. In its initial period, it caused an increase in the unemployment level and a decrease in the overall number of job offers reported to labor offices, which was influenced by the centrally introduced restrictions aimed at limiting the transmission of the virus (restrictions on the use of services, restrictions on leaving homes and on traveling, restrictions on the ability to gather in closed spaces, mandatory quarantines for people infected with the SARS-CoV-2 virus and their families) and changes in how work is performed (remote work was practiced more frequently; some sectors, such as education, outsourcing of financial and accounting services, and outsourcing of IT, switched entirely or to a large extent to remote work), and also by the uncertain scenario of the pandemic, which may have translated into personnel decisions in organizations.

The labor market crisis has particularly affected occupations in the industries subject to restrictions, namely catering, trade, hairdressing and beauty services, tourism, and hospitality management. Professions in these industries have become surplus. Some people left their occupations, retrained, and sought work in more stable industries.

The pandemic also contributed to the emergence of deficit occupations. Such occupations, both immediately after the outbreak and during the pandemic, were IT specialist, logistics specialist, salesperson, cashier, and courier. Personnel deficits worsened the most in the medical sector.

Above all, the pandemic contributed to the proliferation of remote work and recruitment. In these cases, the company's location was not an issue for candidates. The new pandemic reality has forced a change in the previous habits of companies and employees at all levels. The hybrid work model, which combines working from a company's headquarters and performing work duties remotely in a home office, became the most common work style during the pandemic.

After the initial stagnation, the labor market has returned to normal – the unemployment level has fallen to the pre-pandemic level, and employment dynamics have increased. In job offers, employers often reported their willingness to train employees for a specific position. The availability and willingness of candidates to take the job mattered the most. If the candidate agreed to be trained for a job, the level of professional education mattered less to employers, especially in deficit occupations. The exception was recruiting for specialized positions which required specific competencies, such as in the IT or medical sectors.

The conducted analyses and research showed that the changes in the labor market caused by the COVID-19 pandemic were temporary. The most significant changes occurred during the first year of the pandemic. Today,

after the cessation of the epidemic threat and the revocation of the pandemic, the situation in the labor market has returned to normal - to the pre-pandemic state. The only change in the labor market that has not returned to the pre-pandemic state is the number of people working remotely. Also, in many organizations, administrative and office work in particular, the hybrid work model remains in use. The adopted hypothesis is therefore confirmed.

The considerations presented in the article do not exhaust the issue and require further research. The limitation of the study is the narrowing of the analysis of macroeconomic indicators to one country and the size of the research population – the study was conducted on a small research sample. Verification of the adequacy of specific changes in the labor market should be carried out on the basis of a higher number of countries and a larger group of respondents.

Reimaging Power and Micro-Politics in Project Organizations

Birgit Helene Jevnaker and Johan Olaisen
BI Norwegian Business School, Oslo, Norway

Johan.olaisen@bi.no
Birgit.h.jevnaker@bi.no

Abstract: The empirically investigated problem of our paper is: What impact do micropolitics and Power have on project management in an organization? Informal Power and micropolitics played a massive role in the projects, and personal and relational knowledge appeared in all projects to achieve the expected results. The project manager uses personal networks, personal relations, and mentor's network with cognitive, affective, and emotional influence as Power and politics if needed to achieve expected results. Power and micropolitics were necessary skills and tools for a successful project manager. The findings relate to the manager's intentions. The informal power and micro-politics process are reused in every project because informal Power and micropolitics are a part of project work. Power accumulation and wise handling are essential leadership tools for every manager. Employees work for managers who have Power over those who do not. The former can get them what they want: visibility, upwards mobility, and resources. Micropolitics and Power represent a unique competence (i.e., knowledge, experiences, and attitudes) and tool for handling any project. Power is significantly underrated as a tool to control and govern projects. Micropolitics is a part of that tool to get the decisions the project leader wants, maybe with future promises. A democratic and consensus-oriented decision process opens for power games and micropolitics rather than hedging them in more hierarchical organizations. A complex matrix organization involving employees in many projects is also open to micropolitics and Power. Micropolitics and Power might prolong and complicate decisions processes in ordinary projects and improve processes in fast-track projects. Micropolitics and Power both increase and reduce the effectiveness and efficiency of an organization. The higher complexity, the higher returns on using Power and micro-politics to get the expected project results.

Keywords: Power, Micropolitics, Project management, Power games, Power model, Influence

1. Introduction

Norway has a corporate culture for consensus and compromises, fostering micropolitics and Power. However, Power and politics are considered non-issue in Norwegian project management. This peculiarity is that the Norwegian organization's image is democratic and equal, involving all employees (Olaisen & Revang, 2017). Project management is the temporary leadership of teams and the management of working groups compared to more permanent organizational forms. To succeed in project management, you need both to deliver results and be reappointed by your peers for new projects. The project manager role fosters micropolitics and Power in the role intentions and experiences, even if not included in any of the four investigated companies' role descriptions. The rules of the project management process are learned on the road as streetwise project tools and attitudes and by that as critical success factors (Olaisen and Revang 2017, 2018).

There is a knowledge gap in project management between what we know and what we need to learn about the function of micropolitics and Power. Micropolitics and Power represent what we formally do not know. However, everybody sees the importance of handling micropolitics and Power, and we may then say our problem represents what we need to know. The practical usefulness of micropolitics and Power for project management is evident, and the theoretical need for knowledge about the concepts is thus also overdue.

The problem with the paper is:

What impact do micropolitics and Power have on project management in an organization?

The research problem has resulted in four research questions:

- How do Power and micropolitics appear in projects?
- How does the project manager use Power and micropolitics to influence the result of his project?
- How are the findings related to the actor's intentions in the projects?
- How do the employees regard the manager's use of Power and micropolitics?

The paper is further organized in a methodology, a literature review, findings, a discussion, a conclusion, practical implications, limitations, and further research.

2. Methodology

We reviewed the literature as the basics for an open survey study of twelve managers to answer the research questions. We followed up the knowledge from the survey study with twelve in-depth interviews with project

managers in four Norwegian companies in the oil and gas business, where all activities are based on project management.

The methodological approach has been conducting a survey study as fundamental knowledge for interviewing twelve project managers in four Norwegian hydro, oil, and gas companies. We need more theoretical knowledge about the role of Power and micropolitics in projects. The questionnaire survey was done to get a knowledge base of Power and politics in projects. We started by surveying the twelve project leaders in a 25 questions questionnaire. The knowledge from the questionnaire was used to make an interview guide with ten questions for a 90-minute personal interview. The sequence of 10 questions is set up in the following way: Question 1 seeks to clarify formal/informal power and micropolitics' definitions to proceed from a joint base. Questions 2 and 3 evaluate the perceived importance of formal vs. informal power/micropolitics. Questions 4 and 6 try to determine the interviewee's level of knowledge and ability to handle the subjects. We designed the questions to uncover potential gaps between the rated importance of questions 2 and 3 and our skills. Questions 5 and 7 evaluate whether the interviewees are happy with their answers to questions 4 and 6 or would like to learn more. Questions 8 and 9 are phrased as open questions and ask for their experience. Question 10 concerns personal incentives and reward mechanisms for participating in the power and micropolitics game. We conducted a 90-minute follow-up meeting with all twelve managers to discuss the findings.

The questionnaire and interviews were combined to secure better validity and reliability for the results. All the companies practice project management throughout the whole organization. We got access to twelve project managers, each handling projects averaging three billion NOK (i.e., 250 million EURO). The interviews were done in 2016 as a spin-off through an executive education offer in project management by BI Norwegian Business School. Access to the project managers was secured through the executive program. The empirical investigation represents the best-conducted investigation of the importance of Power and micro-politics in project management.

3. A Selective Literature Review

3.1 The Game Concept

Crozier and Friedberg (1979) assume that formal structures will never sufficiently describe or predict individuals' behavior in an organization. The behavior runs in contradiction to traditional theoretical approaches. Assuming that an organization can only be successful by its individuals' combined activities, Crozier and Friedberg's thesis (1979) implies that its success is finally not dependent on structures, processes, and procedures. As professional as it might be, this framework always has uncertainties, which individuals will use for their interests. Each actor's primary goal is to increase his control over uncertainty areas, i.e., to become less controllable or predictable. In other words, each actor seeks to accumulate Power over others to push through his agenda, which can but must be outside the organization's goals since Power and micro-politics are informal processes (Kieser & Walgenbach, 2007, p. 57). Two fundamental thoughts are hedging the game:

The game's essential rule is that no actor seeks to destroy what he is an integral part of the game. Instead, he must accept a particular organizational framework like a project. The second important parameter is that all actors seek to stay and preferably rise in the organization. The effect of such a structure we do not negate. This ambivalence seems to meet practical experience: a company or a team needs structure, but only partial renunciation of the given framework and the acceptance of uncertainties provide room for change, adjustment, and efficiency according to the formal and informal needs of the stakeholders (Fischer, 2005, p. 89).

Significantly, this is eminent in project teams, which require a high level of flexibility and whose matrix - organizations have fundamental conflicts of authority. So, when looking at Power and micropolitics in projects, the thoughts mentioned above describe the team's underlying theory and the surrounding organization. The main question is how an actor can best explore and use uncertainties to extend Power. The extension of Power will be reused in new projects and strengthen the use of micropolitics and Power in projects. The more agility and flexibility, the more Power and politics. Delegation and involvement are essential parts of the Norwegian equality model, and equality in this respect offers a paradox of more informal Power and politics in addition to rumors and backstage decisions (Olaisen & Revang, 2017) Olaisen and Revang (2018) found that "some of the stakeholders had been talking to each other and the decisions were already taken before the formal meetings."

3.2 Power

> *"Power defines and governs all human relations, including all organizations" (Foucault, 2005, p. 103).*
> *“Power is the potential to allocate resources and to make and enforce decisions” (HBSP 2005: xi).”*

> *"Power dressed as a cognitive authority delivers all the results you need (Olaisen, 1984, p. 47)." The more bullshit you deal with as a manager, the more you need to bend the processes your way" (Olaisen & Revang, 2017, p. 149).*
>
> *" When you are standing to the shoulders in the dirt, it is important to keep your head high" (Interviewed manager)." The master of the power game is the master of the project" (Interviewed manager)." You do what you must to get the results needed, and using your Power is the only way to deliver on time (Interviewed manager)." Power implies keeping your position and getting better positions and projects (interviewed manager)."*

We find essential insights about how Power constitutes itself in French and Raven (1968). The authors state that seven bases of Power exist:

- Legitimate, which is solely based on role, position, or title
- Coercive Power to negatively sanction a behavior
- Reward power to grant another person what that person desires
- Expert Power administers information, knowledge, or expertise
- Information powers are based on the potential to utilize the information
- Referent power is often regarded as the admiration or charisma of a role model
- Incentive power as bonuses, positions, resources

Often, several power bases constitute themselves in the same actor, either openly assigned or hidden (Martin, 2003, p. 154). Several individual power bases lead to a further elaborated differentiation of Power into formal and informal sections in conjunction with the initial definition. However, no transparent allocation can be made since they are mixed. We may add coalition power, network power, and rhetoric communication power (Olaisen & Revang, 2017). Jevnaker and Olaisen (2022) reimagined the organizational world and found that traveling less traveled roads for success involved handling relationships and role clarifications through Power.

According to Foucault (2005), relationship power influences today's knowledge society. Foucault stresses the importance of the career pipeline and network relationships on the road to the top. "As a manager, you want to come as close as possible to the top, and you do what you must do to come there" (Interviewed manager). Foucault (2005) defines Power as the essential tool in all relationships, especially in all leadership and management forms. Nonaka (1985:203) concluded in his book "The knowledge-creating company" that personal and relational knowledge handled through Power and politics are the key for managers. Olaisen and Revang (2018) concluded that having a leader as a team member of the top management group will secure the transfer of explicit and tacit administrative knowledge needed for resources and decisions. The skills of politics and Power are tacit but explicit in their consequences. Any leadership position involves Power, and not using Power in a leadership job is not the essential tool you have. Without Power no leadership.

3.3 Micropolitics

As per definition, Power is a potential that, to be realized, needs a form of expression. Power often expresses itself as micropolitics in organizations: the ability to change, direct, or influence others' behavior without openly ordering or threatening them. In other words, micropolitics describes using formal and informal Power to push through our agenda.

The intended outcome is encouraging other people to do what we want them to do, preferably - but not necessarily- through the semblance of their own choice (Bosetzky, 2010). Micropolitics might help, but if not, we do what we must to achieve decisions and results (Nonaka, 1985; Foucault, 2005; Olaisen & Revang, 2018). Power and micropolitics in projects are often two sides of the same coin. However, they might also be applied with a Janus face where we both see the smiling face and the revolver face." Tacit and explicit pressure are used in any relations to get what we want" (Foucault, 2005, p. 129). "You get an offer so good for your career possibilities that you cannot reject the offer" (interviewed manager)." Somebody is talking to each other at the back office, and what is discussed at the front office is already decided" (Interviewed manager).

3.4 Influence and Persuasion

Influence and persuasion are two elements of micropolitics: Influence is a mechanism through which people use Power to change behavior or attitudes. Unlike Power, influence can produce an effect without the apparent exertion of force, compulsion, or direct command. The strength of one's influence is generally a function of one

or another form of Power and others' level of dependencies. However, to influence others, one must be open to influence from them; the key is to understand what others want or value (HBSP 2005, 43).

Persuasion is a process that enables a person or group to change or reinforce others' attitudes, opinions, or behaviors. It is essential for success in all relationships - personal and business alike. Persuasion has four elements: credibility, an audience understanding, rhetorical argumentation, and effective communication (HBSP 2005, 73). Credibility is a cornerstone of persuasion. Influence and persuasion are linked to cognitive, affective, and emotional reasons (Olaisen, 1984). Knowing when to show loyalty and when to raise one's voice is a part of persuasion.

4. Findings

4.1 Appearance of Power and Micropolitics in Projects

As one result, all twelve interviewees agree with the definitions of Power, informal Power, and micropolitics (Question 1). Nothing is added or changed. Hence, we conclude that a common understanding exists and forms the base when answering the subsequent sections.

In all cases, formal Power is rated as necessary for controlling the project (Question 2). In 8 out of 12 cases, informal Power and micropolitics are rated as very important, and in 4 cases, they are rated as necessary (Question 3). In general, informal Power and micropolitics are deemed more important or at least as necessary as formal Power. Our finding aligns with the theory; Kotter (2012:181) evaluates organizations empowering employees, resulting in extended use of the accumulated Power. Wong (2007:226) conclude that informal Power and micropolitics are essential but limited by the hierarchy. Our finding is that the top management does not limit Power and micropolitics but encourages it based on their belief in the efficiency of Power and micropolitics in project management. Also, it leads to the question of what precisely the formal Power among project managers represents.

The experience of using informal Power and micropolitics ranges from 4 x good and 8 x perfect (Question 4). The 100% confidence in applying informal Power and micropolitics is higher than the knowledge level. The knowledge level about the effect of Power and micropolitics ranges from poor (3 cases) to good (3 cases) to 6 outstanding cases (Question 6). Considering that "People generally distrust and fear power and those who seek it" (HBSP 2005:14), the results are remarkable as they could be expected to be lower. On the other hand, the interviewees' group consists only of project managers, each with many years of experience. These managers must have had closer contact with the subject than a randomly chosen group. They are all seeking more competence (Questions 5 and 7 wholly answered with No) and support the conclusion that mastering is vital for the perception and project result. The results show that the knowledge about Power and micropolitics is good and that the project managers are ready to use micropolitics and Power whenever needed. The managers rank it as their most effective project management tool.

We use preciseness together with expert Power to overcomplicate things. The managers agreed, "It is better to be roughly precise than precisely wrong. «If these experts are contractors, the personal agenda is often to justify their positions and extend working contracts. The project manager must restrictively adopt the practical framework to move his project forward and not end up in inefficient theoretical expert exercises. He must rely on his knowledge, experience, and skills to consistently make his project's target priority. To do this successfully, he needs to have support from key stakeholders. In all the interviews, the support of key stakeholders is essential for running the project and getting enough resources to handle the project's milestones. The stakeholders might represent other companies than the project manager, but these companies might also be the project manager's next job.

Power must be investigated in how far a culture of "democracy and consensus" is open to power processes and micropolitics. The research monograph of Pahlke and Alexander (2009) characterizes Norwegian companies by:

- Flat hierarchies with a consensus and harmony orientation
- Low expression of formal Power or strong decision making
- Avoidance of open external conflicts but allowance of internal conflicts
- Decision processes involve many people, and decisions can permanently be changed.

The findings are entirely in line with the results of our interviews. Accepting that organizations need the Power to exist, it can generally be anticipated that their informal counterpart's lack of formal Power will be compensated. The more unclear who will finally make the call within a considerable team, the more room opens

for micropolitics. Consensus-oriented discussions "at the coffee corner" replace open conflict management. The longer the process takes or, the more often it changes, the more unclear why decisions are made. These appearances might honorably be called signs of a democratic process. However, in capitalism, a company is, per se, not set up as a democracy. Leaders are neither elected nor the opinion of the majority, finally dominating. Instead, when benchmarked internationally, the processes are time-consuming (i.e., costly) and create uncertainty for partners and suppliers. Both aspects have the potential to damage efficiency and effectiveness seriously.

The issue was described as "no badmouthing on my project! All must propose a way forward for success". Alternatively: "We do behave externally in our project, but we are fighting hard internally," and: "We have to hire communication people for managing the stakeholder politics." Handling the politics decide upon what resources we get," and "We must use our authority for what it is worth. «All the interviewees supported formal and informal politics and Power as essential to handling projects.

Most interestingly, the interviewees proposed a new power base: endurance. For a long time, it seems to lie within persons in the same organization that everybody anticipates they "must somehow be important." As a result, they are being followed without any visible reason or conspicuous achievement. They are, over time, accepted as cognitive authorities owing to their long experience and the stories of what they have accomplished. In a way, their personal story gives them endurance. The project manager uses these storytellers to convince the project members and stakeholders that "this is the way we are doing business, or "this is business as usual" (interviewed managers).and "this is the way we have achieved our success" (Interviewed manager). The storytellers are however instructed by the project managers about what stories to tell in different settings. Any disagreement might be settled by "this is the way we are doing it around here" or "we have always tried innovative and new ways of doing things. » As a manager expressed, "There is a story for everything, and a good storyteller works like a wandering cognitive authority for any project."

4.2 Active Handling of Power and Micropolitics

Essential points mentioned in the interviews about the usage of informal Power and micropolitics are

- The ability to phrase things and the rhetoric to convince
- The knowledge of whom to ask and whom to use
- Acting by example externally and by Power internally
- One-on-one conversations within the exemplary network
- Using pipeline networks given on the road up as a manager
- Identifying and using upward mobility among employees
- Using personal relations and stakeholder coalitions
- Using endurance as corporate stories of historical success
- Using political compromises to get a best possible result
- Finding the mix that works for the actual project and actual case

Formal power exertion must be backed up by informal Power to work. What is needed is multiple skills and tools found in coalitions and networks. The attitudes and strengths to use the experiences, skills, and tools are required for success. A title, education, or position does not help in a project where the outcome for the members and the project are the two most important factors. That outcome judges a project manager and must do what is necessary to achieve the outcome if that is accepted in the corporate culture. All interviewees believed consensus does not finally drive decisions but is often created to push through an agreed-upon decision. Decisions are often taken because "Somebody has talked together in the back office where everything is decided. «There might be hefty discussions when the project leaders met the stakeholders, but the decisions remained as anticipated.

The most successful actor is the institutional project manager, who controls his stakeholders and makes decisions that he and not necessarily his team can finally justify. The institutional manager knows the game and how to play his cards and knows the team will appreciate his results. He must keep his career in mind and cannot act independently, but informal Power and micropolitics are significant assets used all the time. This institutional manager is the team's hero, and members are lining up both to be on his team and support him. The team members are followers working their way up the pipeline. The followers will always remember who gave them a reward and a position and will keep together throughout their careers and protect each other. There needs to be more conservatism in how to handle the project business. However, there is a possibility for change and innovation simultaneously since managers protect each other from risk and punishment. Balancing stability and

creativity might be the reason for high effectiveness and efficiency in Norwegian oil and gas production. All the managers mentioned the fast-track projects that aim to finish a project in half of the planned and required time. Firstly, all these managers denied managing fast-track projects, and then the managers proposed that half of the projects should be fast-track projects and the other half ordinary projects. The fast-track projects were better planned and staffed, and there was less time for micropolitics but more time for Power. The balancing act of ordinary and fast-track projects was also the balancing act of leadership and management through Power and micropolitics.

4.3 How are the Findings Related to the Actor's Intentions

The actors' intentions raise the following four questions, which are answered elaborately:

- How does Power constitute itself (formal/informal), and how does the actor apply it?

In its entirety, Power constitutes a sum of formal and informal parts. An actor primarily applies it as a mixture: Pure application of formal Power is not sustainable in consensus-driven teams, and informal Power alone needs more authority. A project manager is more on the "informal side." A high level of situational awareness must carefully balance the elements of Power to push through a case.

- What kind of Power - is the manager the actor? What motivates him when applying Power?

The affiliative manager who wants to be liked rather than apply Power to succeed is often found. Avoiding conflicts would be in line with Pahlke and Alexander (2009). The project manager applies Power open and directly and indirectly, and hidden. What is his agenda, and how does he influence and persuade?

Within these corporations, Power is often applied indirectly and hidden. It can take considerable time for a new person in the organization to understand how and why decisions are made, crucial parameters, and who has the authority. Influence and persuasion are often "low profile" and long discussions in long meetings, including virtually everybody. The manager's agenda is often consensus and team harmony, giving him informal Power to proceed even though he does not fully comply with his team's opinions. It is fascinating how far these rather time-consuming processes move the organizations in a more competitive position than the market or whether the opposite is the case.

- How does an actor express micropolitics?

Actors want to rise in the organization or at least secure their position. The position is often secured by exerting expert or information power, which is used to drive discussions and decisions in a specific direction. In Norwegian organizations, where everybody is heard at length, an expert or information holder has a strong position that can be used for his agenda (i.e., delaying decisions, influencing the allocation of resources, and making himself essential). An institutional manager might use cognitive authority to speed up or delay a process and get the decisions the manager wants. The process might be time-consuming and challenging to understand since hidden agendas exist. The institutional project manager muddle through formal and informal Power and micropolitics.

> *"Power for me is friendliness and the explanation of expected results and the contributions to get the results. There is a reward for a contribution and a penalty for not contributing. If you want to grow and to get new possibilities, you will be contributing and you will do your outmost to get the project to deliver on time for cost and quality."*

4.4 How are the findings Related to Answering the Remaining Research Questions?

- How do Power and micropolitics appear in projects?

Informal Power and micropolitics played a massive role in the projects, and personal and relational knowledge appeared in all projects to achieve the expected results. Power and micropolitics appear through main coalitions of stakeholders and project managers talking together in the backroom or forming alliances.

- How does the Project Manager use Power and micropolitics to influence the result of his project?

The project manager uses personal networks, personal relations, and mentor's network with cognitive, affective, and emotional influence as Power and politics if needed to achieve expected results. All the project managers use micropolitics and Power as critical success factors and, as such, a tool for successful project management.

- How do the employees regard the manager's use of Power and micropolitics?

Employees would work for managers who have Power over those who do not. The former can get them what they want: visibility, upwards mobility, and resources. In contrast, subordinates of bosses who have no power are usually dissatisfied with their situation. The upward pipeline is open for those supporting the power and micropolitics practice. The staffing of fast-track projects is based upon loyalty, long-term knowledge, and practice of Power and micropolitics. The division into ordinary and fast-track projects is based on the availability of project members trained in using Power and micropolitics to achieve their results.

- What organizations foster and hinder Power and micropolitics?

A democratic and consensus-oriented culture opens for power games and micropolitics rather than hedging them than more hierarchical organizations. Informal micropolitics and Power mean a high potential to prolong and complicate decision processes and significantly reduce or increase efficiency and effectiveness. The Norwegian democratic consensus model and a complex matrix organizational model participating in many projects foster a power and micropolitics game essential for project management. The result fosters a higher degree of effectiveness and efficiency in the projects based upon long-term professional attitudes, experiences, and knowledge, developing a unique competence for handling Power and micro-politics in projects.

5. Conclusion

The findings relate well to the manager's intentions. The power and micro-politics process is reused in every project in the way that formal and informal Power and micropolitics are a significant part of project work. Actors with a leadership role and cognitive authority power are the primary beneficiaries. The accumulation and wise handling of Power and politics are essential leadership exercises for every project manager. Political influence, persuasion, and compromises are also used in all projects. Handling large projects requires balancing leadership and management and understanding Power and micropolitics as craft tools. All project managers accepted Power and micropolitics as critical success factors. The managers have developed a unique competence (i.e., knowledge, experiences, and attitudes) in handling Power and micro-politics as an essential tool for handling stakeholders, project members, and the end project results. The training in Power and micro-politics keep the managers together as a project manager tribe. They secure the recruitment of further project managers and project members trained in handling the tools of Power and micropolitics. These are used in new fast-track projects (i.e., projects taking half the time of ordinary projects), serving sound project effectiveness and efficiency.

Although it could be assumed that a flat hierarchy and consensus-oriented decision processes prevent power games, our paper concludes that the opposite is true. Strong informal power bases exist within all four investigated companies, positively affecting the efficiency and effectiveness of a project. The main reasons are a need for more discipline and urgency in the Norwegian consensus model for decision-making and a complex matrix organizational model. The result might positively and negatively affect the four companies involved since the companies need more costs (ordinary projects) and fewer costs (fast-track projects) to come to the same conclusions as other companies.

6. Practical Implications

Which recommendations can be given for handling the daily project management work subjects? The project manager should make the following clear for his project:

- What does the game look like, who are the actors, and where are the areas of uncertainty?
- Which power and micropolitics bases do each actor have, and how do they constitute?
- What are the relationships (coalitions, dependencies) between the actors?
- Which types of managers are involved, and what drives them?
- Which hidden agendas can be assumed, and how will they be pushed through the project?

In parallel, it is essential, to be honest about one's situation and define the following success factors:

- What is our personal goal? Is it in line with our project's goal?
- What is the minimum/maximum achievable outcome independent of our work order?
- What are our power bases, dependencies, and coalitions?
- Who do we need to influence or persuade, and what is the best way to succeed?
- How do we create a sense of urgency and healthy pressure on the stakeholders?

7. Limitations

The study is done in a Norwegian branch context for oil and gas producing companies, and there is undoubtedly a cultural and branch bias. Temporary project organization is vital to how these corporations organize their activities which might imply a much higher degree of micropolitics and power games than in more permanently organized organizations. Norwegian organizations are flat and democratic and might invite micropolitics and power relations more than hierarchical organizations. The respect for solution-based equal professionals versus more position-based elite professionals might also invite more micropolitics and power games.

8. Further Research

We need to investigate if the Norwegian model for project management fosters micropolitics power and micropolitics while the hierarchical model hinders micropolitics and Power. What are the consequences of different models concerning micropolitics and Power? Likewise, we should investigate the corporate culture's Power and micro-politics in project management. We should also investigate the costs and benefits of power and micropolitics games in project management.

pauloselig@gmail.com

Abstract: For several years now, we have been living in a society called the knowledge society, in which the primary resource is knowledge. It is no longer just a personal input but also a strategic asset in the development of organizations. In this context, we have an area dedicated to studying and analyzing organizational knowledge flow (KF), which is defined as the process of transferring knowledge between people and/or knowledge processing mechanisms. A lack of studies compiling the most recent scientific production on KF has been identified in the literature analysis. This makes it difficult to understand the current context of the field, identify the main knowledge gaps and trends in this area of study. Thus, the research objective was to map the characteristics of scientific production on the knowledge flow construct by analyzing bibliometric and sociometric indicators to discover the state of the art and suggest future research in the field. An analysis was performed based on over 3,000 articles and reviews extracted from Scopus, Web of Science, and IEEE Xplore databases. The results indicate that (i) research on the flow of knowledge has been stable since 2013, with a constant number of studies and publications in recent years; (ii) the main authors are from the Asian, European, and American continents without having a hegemony; (iii) prominent approaches are the relationship of knowledge flow within knowledge management processes and within the innovation ecosystem; and (iv) the analysis of the flow of knowledge gains potential importance, mainly in guiding action plans in knowledge management (KM) and in the search for better results in organizations.

Keywords: Knowledge flow, Scientific production, Bibliometrics, Sociometry

1. Introduction

Knowledge is not only essential for the survival of organizations but also for their competitive advantage (Meher and Mishra 2022; Marjerison, Andrews and Kuan 2022; Ferreira et al. 2022). Technological advancements have resulted in the accumulation of information, making knowledge a crucial organizational resource (Dalfovo et al. 2010). Since knowledge has an interdisciplinary characteristic, the term has different interpretations, depending on the adopted epistemology (view). Hence, there is no universal definition among different areas of interest. Venzin, Von Krogh, and Ross (1998) have identified three main epistemological perspectives for the term "knowledge": the autopoietic, connectionist, and cognitivist approaches.

In the autopoietic view, the term "knowledge" is believed to reside within people and groups, as it arises from the transformation of information that individuals gain from their experiences and observations. On the other hand, the cognitive approach holds that knowledge is obtained through the identification, gathering, and dissemination of information. As information can be stored in databases, files, manuals, and also within individuals, knowledge is not exclusively confined to people's minds. Finally, in the connectionist perspective, knowledge creation arises through the interaction (connection) between actors (Venzin, Von Krogh and Ross, 1998).

Regardless of epistemology, knowledge management supports all processes related to knowledge as an organizational resource. According to the Asian Productivity Organization (APO 2010), knowledge management is based on "an integrated approach to identifying, creating, storing, sharing, and applying knowledge to increase organizational productivity, profitability, and growth" (p. 43). Within this context, Kurtz, Sierra, and Varvakis (2013) emphasize that the flow of knowledge is a stage within the knowledge-sharing process, which is an important phenomenon to be mapped and researched. However, given the lack of studies in the literature that compile research on knowledge flow (KF), this study aims to identify the current scenario and indicate possible paths to follow in the field of KF, using bibliometric and sociometric analysis.

The following section will present the definitions of the knowledge flow construct, as well as the bibliometric studies that have been previously conducted.

2. Concepts

2.1 Knowledge Flow

There is no consensus in the literature on the definition of KF, but it essentially revolves around the exchange, diffusion, or movement of ideas, knowledge, and concepts within an organizational setting (An, Han, and Park, 2017). Within this perspective, Zhuge (2002) defines KF as the process of passing knowledge between people or knowledge processing mechanisms. With a similar approach, Nissen (2006) considers it to be dynamic knowledge. That is, the flow works in an activity of knowledge conversion, transfer, sharing, integration, reuse, movement, and application over time. Laihonen (2006) points out that KF refers to knowledge that is transferred from one person or place to another, where the receiver relates it to their own mental model and creates their interpretation of the original knowledge they received.

2.2 Bibliometric Analysis

The emergence date of the term "bibliometrics" is a controversial issue, as there are debates regarding who coined it and when it was first used. However, one of the studies that contributed to introducing the theme was the work by Cole and Eales (1917). In the 1960s, Pritchard (1969) defined bibliometrics as the application of mathematical and statistical methods to books and other communication media. Therefore, when applied to science, bibliometric analysis is referred to as scientometric analysis and is a scientifically recognized methodological approach. It is a mapping technique of the primary authors, countries, and keywords on a given topic, developed through statistical methods capable of presenting these data and information, which are extracted from scientific databases (Santos, Maldonado, and Santos, 2011).

There are several bibliometric indicators that can be employed to measure the scientific production of a particular research field. Among them, three are commonly used: Lotka's Law, Bradford's Law, and Zipf's Law. Lotka's Law pertains to the productivity of researchers, Bradford's Law refers to the distribution of scientific production, and finally, Zipf's Law is related to the occurrence of terms in the text (Machado Junior, 2016).

In this study, the three aforementioned laws were employed with a secondary objective: to assess whether the research findings were in line with the principles espoused by these laws, thereby serving as a complementary approach.

2.3 Bibliometric studies on Knowledge Flow

The first step of the current research was to verify and confirm in the literature the existence of other bibliometric reviews about KF. Therefore, a search was conducted in several databases including Scopus, Web of Science, and IEEE Xplore using the protocol ("knowledge flow*" OR "knowledge passage*" OR "knowledge movement*") AND (bibliometric* OR scientometric*).

The results indicated a lack of reviews. However, six studies were identified, two of which were directly related to the KF construct and bibliometric analysis, but in very specific contexts. These studies did not aim to map and verify the field of study and the state of the art of the construct. Table 1 presents some of these findings.

Table 1: Bibliometric Studies on KF

Authors (year)	Title	Goal
Ming-Yueh Tsay (2015)	*Knowledge flow out of the domain of information science: a bibliometric and citation analysis study*	To analyze, through bibliometrics and citation analysis, the knowledge flow construct outside the discipline of information science. The survey data were gathered between 1998 and 2010.
Ponomariov and Toivanen. (2011)	*Research and development: Bibliometric analysis of knowledge flows of Brazilian research 2005-2009*	To analyze, through bibliometrics, the dynamics of knowledge creation in order to discover how knowledge flows. The survey data were gathered between 2005 and 2009.

Source: Authors 2023.

Given the above, the importance and, at the same time, the need to carry out a scientific mapping about KF was verified.

3. Method

In order to identify the state of the art of the KF construct with scientific rigor, this literature review was developed through four steps. Figure 1 presents each of them.

Figure 1: Research Method Used

Next, each of the developed steps is detailed.

3.1 Review Planning

In the initial phase of the research, known as literature review planning, several essential elements were formally defined. These included the research objective, the selected electronic database, the descriptors, data management tools, search locations within articles, and eligibility criteria, as presented in Table 2. It is worth noting that the research methodology employed drew on various established works in the literature, including significant contributions from authors such as Arksey and O'Malley (2005) and Patil and Kant (2014). Therefore, specific stages and phases from these sources were selectively integrated, rather than being adopted entirely.

Table 2: Review Planning

Criterion	Description
Purpose of the literature search	Map the characteristics of scientific production on the KF construct.
Source of information	Scopus, Web of Science and IEEE Xplore
Search strategy	"knowledge flow*" or "knowledge passage*" or "knowledge movement*"
Data management	*EndNote©, Google docs©* and *VOSViewer©*
Search locations in articles	Title, keywords and abstract
Eligibility criteria, exclusion criteria and inclusion criteria	Research involving and/or synonyms. Any language. Any publication period. Any type of study. Research published in papers or reviews. Research in the final stage, that is, completed

Source: Authors 2023.

3.2 Database Search and Portfolio Definition

Once the strategies had been established, the next step, known as database search, aimed to locate publications that met the predetermined criteria on Scopus, Web of Science, and IEEE Xplore. This research phase was conducted from December 2022 to February 2023. In the third stage, publications were selected to form the research portfolio, which would provide support for the final stage. In the initial search, 4,192 studies were retrieved, but after applying filters and removing duplicates using the EndNote© tool, the research portfolio was reduced to 3,352 studies. Table 2 provides a more detailed breakdown of the filtering process.

Table 3: Planning of Literature Review

Activity	Databases		
	Scopus	Web of Science	IEEE Xplore
Initial query with defined search string	3.317	2.667	366

Activity	Databases		
	Scopus	Web of Science	IEEE Xplore
Research published in the form of papers or reviews, magazines or conference proceedings	1.995	1.834	363
Elimination of duplicate searches			840
Total studies selected for the job (portfolio)			3.352

Source: Authors 2023.

3.3 Bibliometric and Sociometric Analysis

The last stage of the research, called bibliometric and sociometric analysis, was supported by the VOSViewer© software, version 1.6.15. This tool provides graphs of bibliometric and sociometric networks (Van Eck and Waltman 2010) through the importation of CSV files extracted from scientific databases (e.g., Scopus).

4. Findings and Discussion

In this section, the research results will be presented along with discussions. Initially, we will discuss general results such as the evolution of the number of articles since the first publication that mentions the knowledge flow construct, as well as the authors and journals with the highest number of publications. Following that, we will present the sociometric analysis, including co-citation networks and co-occurrence of keywords.

4.1 Evolution of the Field

The 3,352 studies identified were published in 881 journals. The number of publications per year is shown in Figure 2.

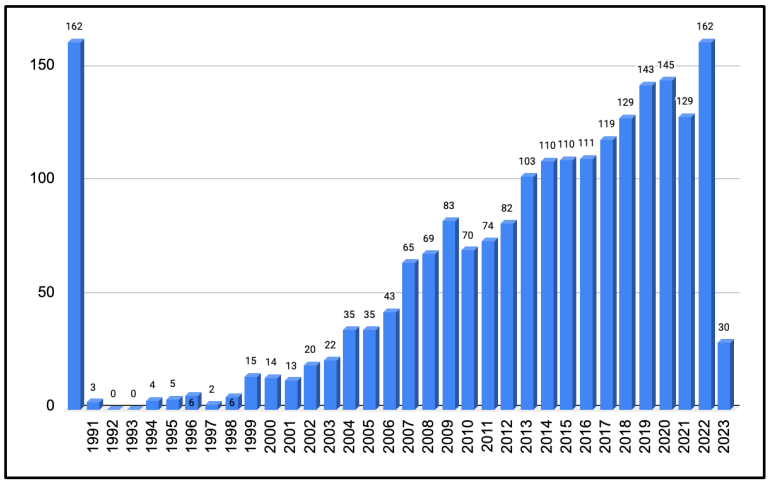

Figure 2: Number of Publications per Year

The first article to address the KF construct was published in 1953 by Harvey S. Perloff, titled "Planning Concepts and Regional Research." In this article, the author analyzed the flow of knowledge between academia and public policy. Until 1990, there was discrete production of studies about KF, with several periods without any publications. The construct started to gain momentum in 1991, when three studies were published, coinciding with the advancement of organizational theories such as the Knowledge-Based View of the Firm (KBV - Grant, 1996), which considers knowledge as an organizational resource and expanded studies on organizational knowledge. After that, there was strong growth in publications, reaching its peak in 2022 with 162 publications. It is worth noting that stabilization in the number of publications about the construct has been observed since 2013. The year 1999 represented the inflection point in the production growth curve of the subject, with a 150% increase compared to the previous year. It is worth mentioning that in the 1990s, the process of digital

transformation began with the digitization of documents, which, in some way, contributed to significant advances in research.

4.2 Authors With More Publications

The author with the highest number of publications is Yongtae Park from Seoul National University in South Korea, with 10 published studies. Two Canadian researchers followed: Ajay K. Agrawal, who is affiliated with the Rotman School of Management, and Harald Bathelt, who is affiliated with the University of Toronto. The list is completed by researchers from Europe (Netherlands and Italy) and the United States. Table 4 presents the authors ranked by the number of publications.

Table 4: Authors Ranked by the Number of Publications

Author	Number of articles	Affiliation	Country
Park, Y.	10	Seoul National University	South Korea
Agrawal, A.	9	Rotman School of Management	Canada
Bathelt, Harald	9	University of Toronto	Canada
Cantwell, John	9	Rutgers Business School	United States
Bathelt, H.	8	University of Toronto	Canada
Nissen, M.E.	8	Naval Postgraduate School	United States
Verspagen, B.	8	Universiteit Maastricht	Netherlands
Montobbio, F.	7	Università Cattolica del Sacro Cuore	Italy

Source: Authors 2023.

4.3 Journals With More Publications

The 3,352 articles identified were published in 881 journals, representing an average of 3.8 articles per journal. Table 5 presents the top 10 journals.

Table 5: Main Periodicals

Journal	Number of articles
Journal of Knowledge Management	61
Scientometrics	61
Research Policy	59
Regional Studies	25
European Planning Studies	24
Technological Forecasting and Social Change	23

Journal	Number of articles
Knowledge Management Research and Practice	21
Strategic Management Journal	20
Journal of International Business Studies	19
Journal of Business Research	19

Source: Authors, 2023.

4.4 Highest Impact Article

With 2.303 citations, the article that has had the greatest impact is "Knowledge Flows within Multinational Corporations" authored by Anil K. Gupta and Vijay Govindarajan, which was published in the Strategic Management Journal in 2000. The research describes the application and evolution of a framework that refers to intra-corporate knowledge transfer within multinational corporations.

The next article, also published in the Strategic Management Journal, is titled "Creating and Managing a High-Performance Knowledge-Sharing Network: The Toyota Case," authored by Jeffrey H. Dyer and Kentaro Nobeoka, which has almost the same number of citations as the first.

Following these impactful works in the field of knowledge flow, there are two works with approximately 1,000 citations each: "Motivation and Barriers to Participation in Virtual Knowledge-Sharing Communities of Practice" published in the Journal of Knowledge Management, and "Overcoming Local Search through Alliances and Mobility" published in Management Science. Table 6 presents the ten most referenced works in the field.

Table 6: Highest Impact Articles

Author (year)	Title	Journal	Number of quotes
Gupta and Govindarajan (2000)	Knowledge flows within multinational corporations	Strategic Management Journal	2303
Dyer and Nobeoka (2000)	Creating and managing a high-performance knowledge-sharing network: The Toyota case	Strategic Management Journal	2254
Ardichvili, Page and Wentling (2003)	Motivation and barriers to participation in virtual knowledge-sharing communities of practice	Journal of Knowledge Management	1036
Rosenkopf and Almeida (2003)	Overcoming local search through alliances and mobility	Management Science	905
Decarolis and Deeds (1999)	The impact of stocks and flows of organizational knowledge on firm performance: An empirical investigation of the biotechnology industry	Strategic Management Journal	863
Meyer, Mudambi and Narula (2011).	Multinational Enterprises and Local Contexts: The Opportunities and Challenges of Multiple Embeddedness	Journal of Management Studies	716

Author (year)	Title	Journal	Number of quotes
Singh (2005)	Collaborative networks as determinants of knowledge diffusion patterns	Management Science	667
Grossman and Helpman (1991)	Trade, knowledge spillovers, and growth	European Economic	632
Caloghirou, Kastelli and Tsakanikas (2004)	Internal capabilities and external knowledge sources: Complements or substitutes for innovative performance?	Technovation	617
Oxley and Sampson (2004)	The scope and governance of international R&D alliances	Strategic Management Journal	570

Source: Authors 2023.

4.5 Knowledge Areas

As shown in Figure 3, it is evident that the topic of KF is researched with greater emphasis in areas such as Administration, Management, Social Sciences, and Computer Science, which together account for almost 50% of all publications. However, in several areas, the scientific interest in the construct is still in its infancy, as indicated in the same figure by the percentage of 7.4%.

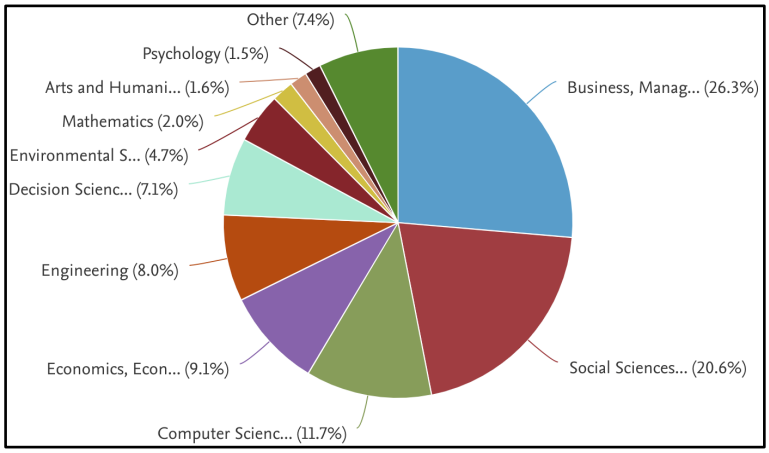

Figure 3: Publications by Area of Knowledge

It should be noted that the databases used for this research do not employ standard classifications for the areas of knowledge. Hence, a mapping between the areas was conducted before generating the graph.

4.6 Co-Citation Networks

Through co-citation analysis, it is possible to identify how often two authors are cited together. Two authors are considered co-cited when they are both cited by a third author. Therefore, the more frequently two authors are co-cited in documents, the stronger their co-citation relationship will be (Van Eck and Waltman 2014).

By setting a minimum threshold of five documents per author, meaning that authors must be co-cited in at least five articles, Figure 4 displays the groups of authors. A total of 177 authors were identified, grouped into nine clusters, with the largest cluster consisting of sixteen authors who interact frequently.

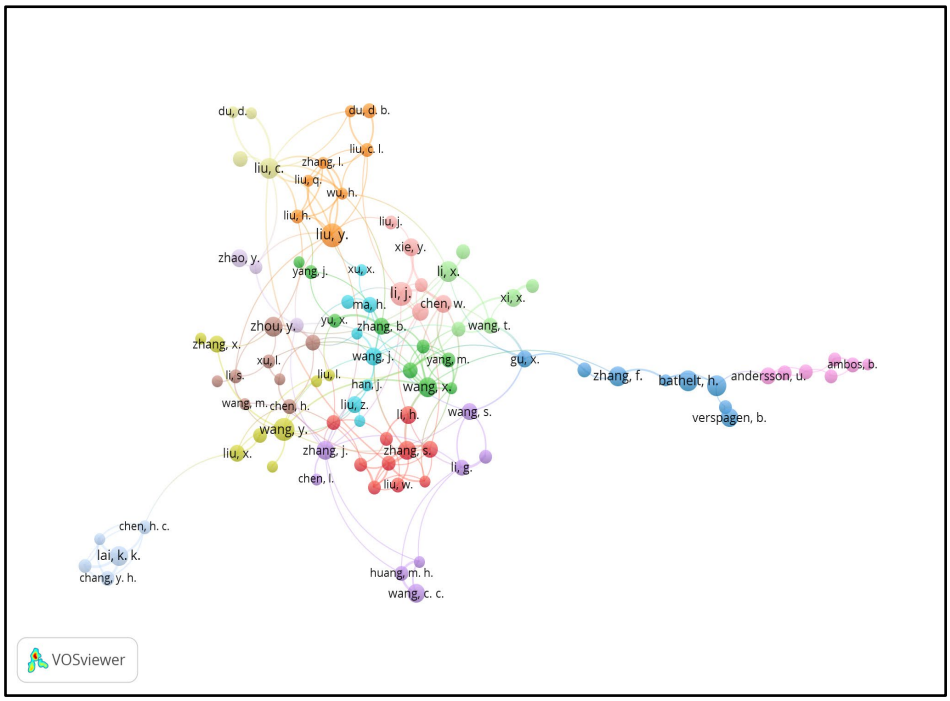

Figure 4: Co-Citation Networks

4.7 Keyword Co-Occurrence Networks

The co-occurrence relationship between two keywords is determined by the number of articles in a portfolio of documents in which both keywords occur simultaneously in the title, abstract, or keywords section (Van Eck and Waltman, 2014). Figure 5 depicts the network of keyword co-occurrences for the portfolio analyzed in this research.

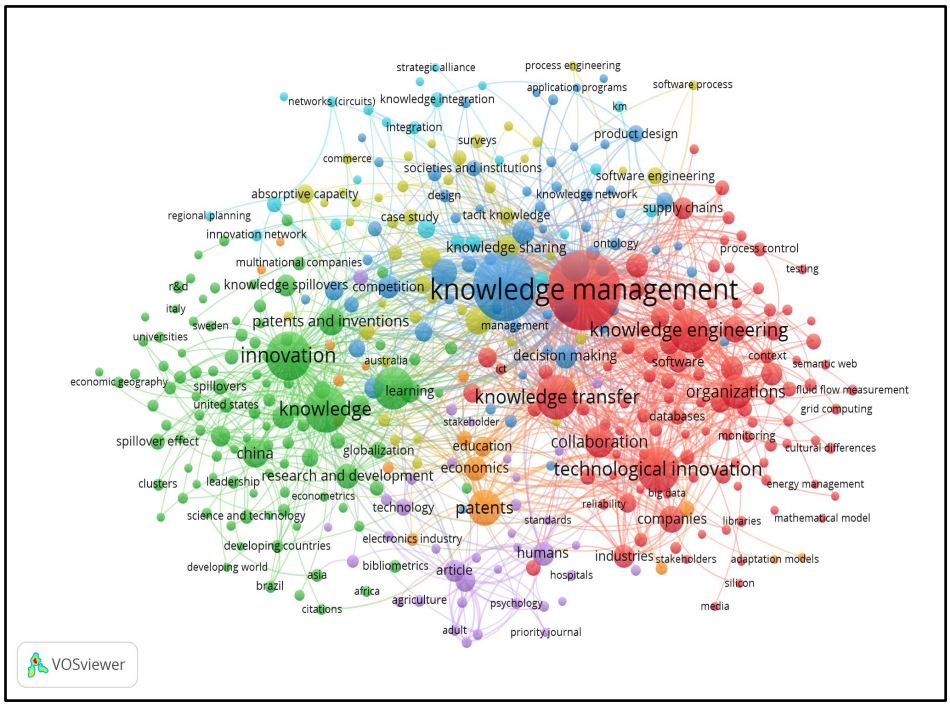

Figure 5: Keyword Co-Occurrence Networks

By setting a minimum frequency of 5 occurrences of keywords in documents, we identified a total of 517 co-occurring keywords, which were divided into seven clusters. As shown in Figure 5, two main research groups are clearly visible: Knowledge Management and Innovation. Other groups can also be observed tangentially to these main clusters, such as technological innovation, knowledge transfer, and the concept of knowledge itself.

5. Future Research in the Area of Knowledge Flow

The research has shown that the construct of Knowledge Flow (KF) is being studied in various fields of knowledge, with a greater emphasis currently in the social sciences. This provides opportunities for research in areas that have not yet been explored or have been little explored, such as engineering and security, where knowledge is a fundamental aspect for development and is considered a strategic resource. Interestingly, other themes and areas, such as organizational learning and health, are also being approached in research related to the flow of knowledge.

The study has demonstrated that two themes, Knowledge Management and Innovation, are correlated and associated with the construct of knowledge flow, indicating future research trends. It is important to note that the flow of knowledge is not considered a distinct process in knowledge management, but permeates the tangency between consolidated processes. Therefore, topics such as knowledge sharing, knowledge-based systems, knowledge acquisition, and information management are potential areas of research for future work. Table 7 presents a compilation of future research paths.

Table 7: Findings From the Research

Findings	Themes or areas for future research	Description
1	Safety engineering, healthcare, and organizational learning	Promising themes and areas to explore in the study of knowledge flow
2	Knowledge management and innovation	These two themes exhibit a clear relationship with the construct of knowledge flow. Thus, there is a need to further explore and delve into this correlation

Source: Authors 2023.

Regarding innovation, the terms with the highest frequency are knowledge, research and development, patents, and technological development. Future research in this area could focus on the flow of knowledge in innovation ecosystems and the creation of knowledge through patents, providing a second line of research.itself.

6. Conclusion

This research aimed to map the characteristics of scientific production related to the construct of knowledge flow, through bibliometric and sociometric indicators, in order to understand the state of the art and provide suggestions for future research in the field.

To enhance the validity of the results, the number of databases used was expanded. The study revealed that the author with the highest number of publications, Yongtae Park, is from South Korea. All three main bibliometric indicators - Lotka's Law, Bradford's Law, and Zipf's Law - were verified and confirmed in the research. Regarding Lotka's Law, the analysis of the networks generated in the research demonstrated that the construct of knowledge flow has reached a stable point, with the number of publications remaining constant over the past 10 years.

The study successfully achieved its objective by not only presenting bibliographic data but also identifying two areas for future work related to the flow of knowledge.

Acknowledgements

This study was conducted as part of the Human Factors Project (HF Project) at the Pontifical Catholic University of Rio Grande do Sul (PUCRS), funded by the Libra Consortium, with support from the National Agency of Petroleum, Natural Gas, and Biofuels (ANP), associated with the allocation of resources from the R,D&I Clauses - Regulation No. 03/2015 (process 2019/00105-3).

pauloselig@gmail.com

Abstract: Resilience, viewed from an engineering perspective, refers to a system's inherent ability to regulate its operation before, during, and after disruptions. Knowledge is a critical resource that enables resilient responses, as it is essential for responding, monitoring, anticipating unforeseen events, and learning from their occurrences. However, despite the importance of knowledge in promoting resilience in operational safety, there is a lack of tools in the literature that provide evidence and explanation of knowledge resources. To address this gap, this article presents the development stages of an instrument based on the Critical Decision Method to elicit critical knowledge in Operational Safety Events (OSEs). The instrument includes a set of questions that guide the identification of decision-making points and the exploration of knowledge resources mobilized at each stage, founded on situational awareness, resilience engineering, and knowledge engineering. Prospective analysis sessions and retrospective OSE analyses were conducted with teams of workers from offshore oil and gas production and exploration platforms to assess the instrument's feasibility. The instrument enabled the identification of critical knowledge in both scenarios, which served as valuable input for promoting security and resilience. The instrument also facilitated the identification of opportunities to promote organizational learning and the development of effective actions to strengthen intangible resources that influence resilient responses, thereby enabling a thorough exploration of knowledge resources in retrospective analyses or prospective sessions of accidents and severe operational safety events.

Keywords: Critical knowledge, Resilience, Knowledge management Operational safety

1. Introduction

In high-risk sectors such as aviation, oil, gas, and energy industries, accidents can have significant human, social, environmental, and economic consequences. These accidents and incidents often arise not only from unintentional or individual factors but also from social and organizational factors (Hovden et al. 2018). In complex operations, it is impractical to anticipate all potential occurrences. Additionally, the organizational environment is becoming increasingly complex due to factors such as the advancement of digital technologies, the digitization of market and work relationships, the data revolution, and the emerging demands and challenges of society (Hirose and Sawaragi 2020; Reiman et al. 2021).

Given the unpredictability and constant need for adaptation within complex systems, a new paradigm named Safety II has emerged in the realm of safety management. Resilience engineering is viewed as a means of implementing and operationalizing this novel approach. Safety II provides an alternative to conventional safety management concepts (Safety I) that rely on division and predictability.

Hollnagel et al. (2006) define resilience as the inherent capability of a system to regulate its functioning before, during, and after disruptions, enabling it to sustain essential operations even in the face of serious accidents or ongoing stressors. Efforts have been made to enhance resilience engineering through the development of tools and research. One such tool is the Resilience Analysis Grid (RAG), devised by Hollnagel (2015), which offers a practical means of assessing resilience. However, these tools do not provide a specific direction from a knowledge perspective, as they fail to explicitly recognize knowledge as an active organizational resource. According to Hollnagel et al. (2006), knowledge plays a pivotal role in bolstering the resilient capabilities of complex socio-technical systems. Therefore, there is a need for an instrument that can identify and extract critical knowledge from Operational Safety Events (OSEs) to strengthen a system's resilience potential.

This article presents the development of a tool, named the CDM Roadmap, for eliciting critical knowledge to support resilience potential using the Critical Decision Method (CDM). The CDM Roadmap is designed to guide the qualification of critical knowledge in recognizing system conditions (based on principles of situational awareness) and implementing responses (based on the perspective of resilience engineering).

2. Concepts

2.1 Resilience Engineering

The concept of "resilience engineering" gained prominence following the inaugural Resilience Engineering Symposium held in Sweden in 2004, and the subsequent publication of the book "Resilience Engineering: Concepts and Precepts" by Hollnagel, Woods, and Leveson in 2006.

Hollnagel (2014) introduced the terms "Safety I" and "Safety II" to differentiate between two perspectives on safety in complex systems. Safety I primarily focuses on retrospectively analyzing failures and accidents to understand their causes and prevent similar incidents in the future. In contrast, Safety II takes a complementary approach by incorporating knowledge about how and why things go right. Within the Safety II paradigm lies the discipline of Resilience Engineering, which aims to design, manage, and evaluate the resilience potential in complex systems, thereby enhancing safety and resilience.

Hollnagel (2011) identified four fundamental capabilities that characterize a resilient system: (1) Responsiveness, which pertains to the ability to manage regular and irregular interruptions and disturbances, either through prepared responses or by adjusting the system's normal functioning; (2) Monitoring Ability, which involves the capacity to monitor current and potential short-term threats; (3) Anticipation Ability, which encompasses the ability to anticipate future events, threats, opportunities, including possible changes, interruptions, pressures, and latent risks; and finally, (4) Learning Ability, which is the capacity to learn from experience, particularly to extract the appropriate lessons from relevant experiences, both successes, and failures. Figure 1 illustrates these four capabilities.

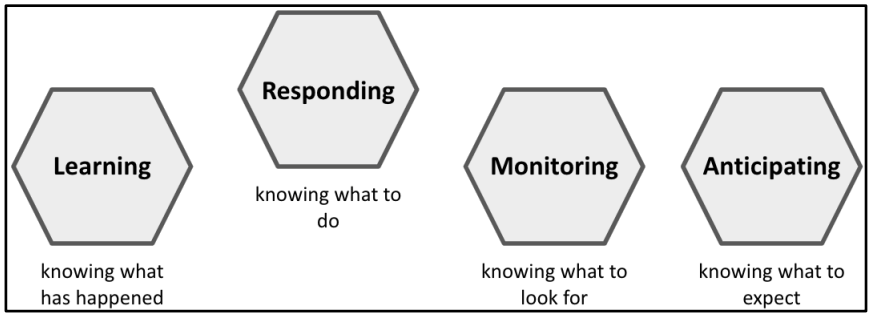

Figure 1: The capabilities of a Resilient System. Source: Hollnagel, 2011

Resilient systems aim to enhance the security of complex systems by developing and bolstering adaptive technological and organizational capabilities (Saleh, Veitch and Musharraf, 2020). Resilience engineering has introduced innovative approaches to understanding and operating within complex systems. In terms of safety improvement, it deviates from the traditional practice of retrospectively investigating adverse events and instead emphasizes proactive learning from everyday work processes, including the identification of successful outcomes (Hegde et al., 2020). Within this framework, knowledge emerges as a pivotal factor in fortifying the resilient capacities of complex systems (Hollnagel, Woods and David, 2006).

2.2 Critical Knowledge

The term "knowledge" lacks a clear conceptual consensus in the literature, as its understanding varies depending on the context, worldviews, and analytical perspectives. It can be viewed as a result of research across multiple disciplines and generated in various spheres such as scientific, theological, common sense, or philosophical (Pacheco, 2016). Within the organizational domain, Nonaka and Takeuchi (1995) introduced the concept of "knowledge" and argued for its management as a valuable asset. APQC (2014) defines the knowledge, in the organizational context, as the collective understanding possessed by employees regarding work-related disciplines, products, processes, customers, interpersonal relationships, mistakes, and successes.

The term "knowledge" is associated with at least three epistemologies: cognitivist, autopoietic, and connectionist. The cognitivist perspective posits that knowledge is acquired through the identification, collection, and dissemination of information. The connectionist view emphasizes communication and relationships as sources of knowledge creation. In contrast, the autopoietic view regards interpretation as the generator of knowledge. Irrespective of the chosen epistemology, the notion of critical knowledge can be determined. Huang and Cummings (2011) propose that critical knowledge encompasses expertise, ideas, and

vital insights that enable individuals to accomplish tasks, representing the highest quality knowledge within an organization that is shared among its members.

The literature presents various models for analyzing the level of criticality of knowledge, one of which is the Critical Knowledge Factors (CKF) model developed by the Paris Knowledge Management Club. This model comprises 20 criteria for assessing criticality, organized into four thematic axes. This study adopts this model due to its simplicity and comprehensiveness. The criteria are displayed in Table 1.

Table 1: Criteria of Criticality

Thematic axis	Criteria
Rarity	Number and availability of experts, outsourcing, leadership, originality, confidentiality.
Utility	Correspondence with strategic objectives, value creation, emergent, adaptability, and use.
Difficulty capturing knowledge	Identification of sources of knowledge, mobilization of networks, tacit knowledge, the importance of tangible sources of knowledge, and speed of obsolescence.
Nature of knowledge	Depth, complexity, appropriation difficulty, the importance of past experiences, and dependence on the environment.

Source: Ermine, Boughzala, and Tounkara (2006).

2.3 Critical Decision Method (CDM)

The process of identifying and extracting expert knowledge in a specific domain can be simplified through various elicitation methods and techniques. The literature offers several tools for this purpose, including the Critical Decision Method (CDM), concept classification, repertoire grids, ladder grids, and limited information tasks (Shadbolt and Smart, 2015).

The CDM, a method based on critical incidents, involves conducting cognitive investigations to evaluate and qualify specific situations and identify decision-making processes during incidents. These investigations are carried out through retrospective interviews focusing on real non-routine incidents that required judgment or decision-making (Klein et al., 1989). The selection of the CDM for this study is justified by two main reasons. Firstly, the CDM focuses on non-routine events, which are particularly relevant to safety incidents. Secondly, the CDM facilitates the identification of decision-making points, aiding in the identification of the knowledge applied in a given situation.

According to Klein et al. (1989), the CDM stands out as a unique knowledge elicitation technique due to its distinctive characteristics, which include:

(i) Focus on non-routine cases: The CDM concentrates on non-routine or challenging incidents that provide abundant data and tacit knowledge that may not be formalized in domain procedures. (ii) Case-based approach: The CDM employs a case-based approach, which proves valuable in gathering specific and relevant information when investigating concrete and non-routine incidents. (iii) Cognitive probes: The CDM's questions require decision-makers to reflect on the strategies and foundations of their decision-making, revealing their underlying knowledge and reasoning. (iv) Semi-structured survey: The CDM adopts a semi-structured approach that strikes a balance between a fully structured and free-form interview. While specific questions are asked for each decision point, the ordering and wording can follow the flow of the interview dialogue.

These characteristics render the CDM a valuable tool for eliciting and comprehending the knowledge utilized by experts in non-routine situations. The steps of the CDM are presented in Table 2.

Table 2: CDM steps

Step	Name	Description
1	Select incident	Select incidents (events) that exemplify non-routine aspects within a specific domain.
2	Get an unstructured incident report	Request the interviewee to provide a detailed account of the incident, starting from the moment they first noticed it until it was considered under control. The account should be provided without interruptions, except for minor clarifications.
3	Build the incident timeline	Construct a timeline of the incident, outlining the sequence and duration of each event.
4	Identification of the decision point	During the construction of the timeline, identify the specific decisions that were made at various points during the incident.
5	Decision point investigation	For each decision point, inquire about relevant aspects such as clues, objectives, knowledge utilized, and assessment of the situation, among others.

Source: Adapted from Klein et al., (1989).

3. CDM Roadmap Development Process

The CDM Roadmap serves as a comprehensive tool to facilitate the identification and extraction of critical knowledge in operational safety events, along with the associated factors that either foster or hinder resilient responses. Its applicability extends to organizations and systems engaged in critical safety operations, encompassing both retrospective analysis of past events and prospective analysis of potential events. Industries such as aviation, healthcare, civil construction, nuclear power plants, and the oil and gas sector exemplify domains that exhibit these characteristics.

By providing a structured approach, the CDM Roadmap enables the implementation of the Critical Decisions Method for extracting critical knowledge and its corresponding factors within operational safety events. This systematic approach proves valuable across a range of organizations and systems involved in critical safety operations, facilitating both the examination of historical events and the anticipation of future scenarios. Sectors such as aviation, healthcare, civil construction, nuclear power plants, and the oil and gas industry represent notable fields wherein the CDM Roadmap can be effectively employed to extract critical knowledge and foster resilient responses.

The development of the CDM Roadmap was founded upon the Critical Decisions Method (CDM), employing the five-step process depicted in Figure 2.

Figure 2: Research Method Used. Sources: authors, 2023

During the initial phase of the study, the research team conducted a comprehensive literature search in electronic databases to identify key elements and factors contributing to a resilient response. This search was conducted in five distinct phases, and the identified variables were meticulously organized, refined, and reviewed. A total of 34 variables were identified and defined, all of which were found to play a critical role in enabling a resilient response. These variables were subsequently categorized into twelve distinct groups, including situational awareness, monitoring ability, organizational learning, response-ability, analytical management, participation and decision-making, knowledge repository, resilience, contingency capabilities, safety margins, available resources, and monitoring systems.

In the second phase, specific questions were formulated based on the identified elements from the previous stage. Five overarching questions were devised and aligned with the study objectives. The initial question aimed to elicit the interviewee's identification and characterization of the operational safety event under discussion.

The subsequent question focused on extracting vital information and knowledge pertaining to the diagnosis of the security event. Another question was designed to uncover information and knowledge associated with the intervention or actions taken. Finally, the last question sought to identify factors that either facilitated or hindered the security event. It is important to note that the questions within the CDM Roadmap aimed to capture and extract knowledge relevant to the critical knowledge factors (CKF) axis, which presents a unique challenge, as discussed in the section on critical knowledge.

Table 3 displays the questions, their objectives, and their connection to the CDM, thereby forming the initial version of the instrument.

Table 3: Questions from the CDM Roadmap Developed

Purpose of the question	Questions	Relationship with the steps of the CDM
Interviewee identification	What is your name, job title, and/or role? How many years of experience do you have in this field, both at your current organization and at other companies? Could you provide a brief overview of your daily activities?	----
OSE identification	Could you tell me an episode where your experience helped in solving a problem?	Select incidents. Get an unstructured incident report. Construct the incident timeline.
Diagnosis	How did you realize that the event would be unusual/difficult? What were the primary pieces of information or clues available when you first realized an accident was imminent? What knowledge did you employ to interpret this information?	Identification of the decision point
Intervention	Considering the perception of the event, what action plan was established? What information and critical knowledge were used to develop this plan? How were the necessary skills mobilized for the implementation of the action plan?	Decision point investigation.
Difficult or facilitating factors	Were there any factors that impeded the design or implementation of the action plan?	---

Sources: authors, 2023.

During the third phase, the CDM Roadmap was applied in storytelling sessions involving professionals engaged in oil and gas exploration operations. These sessions took place virtually between 2020 and 2021 as a result of the COVID-19 pandemic. The roadmap served as a guiding framework for non-participant observation during the sessions, which were facilitated by two researchers. The participants were five professionals from diverse roles in the industry, such as engineers, managers, and safety officers. They were encouraged to share stories and insights about potential safety events that could occur on oil production and drilling platforms, while also discussing contextual factors and industry practices. Two additional researchers acted as participant observers and utilized the CDM Roadmap to identify critical knowledge on security events. Subsequently, the observations were validated through interview transcripts. The findings emphasized the significance of identifying and enhancing critical knowledge for fostering resilient responses, including aspects related to formalization, accessibility, and barriers and enablers to knowledge utilization.

During the fourth phase of the CDM Roadmap development process, the initial version of the instrument was evaluated and analyzed based on its application in the previous phase. This stage involved a critical assessment of the instrument's efficacy and identified areas for potential improvement. To accomplish this, validation cycles were conducted involving both researchers and professionals with expertise in complex sociotechnical systems.

Table 4 presents an overview of the validation cycles carried out during this stage, highlighting the key activities and participants involved.

Table 4: CDM Roadmap Validation Cycles

Date	Activity
May/2022	1st validation of the roadmap with researchers
Jun/2022	2nd validation of the roadmap with researchers
Jul/2022	3rd validation of the roadmap with researchers
Aug/2022	4th validation of the roadmap with researchers
Aug/2022	Validation of the roadmap with a professional from the oil and gas industry
Aug/2022	5th validation of the roadmap with researchers

Source: Authors, 2023.

Through each validation cycle, valuable insights and recommendations were incorporated into the development of the instrument. The most notable suggestion for improvement involved separating and distinguishing the Roadmap into two distinct instruments. The first instrument is intended to be utilized in the aftermath of an accident or incident, focusing on understanding the factors that led to the failure. Conversely, the second instrument is designed to be applied in regular work situations, with a focus on identifying successful practices and extracting knowledge that can be utilized to prevent future accidents or near misses. Tables 5 and 6 provide a detailed breakdown of the two disassembled CDM Roadmaps, each tailored to its specific purpose.

Table 5: CDM Roadmap - Positive Perspective

Goal	Question
Interviewee identification	What is your name, job title, and/or position? How many years have you worked in this field, both at your current company and at other companies? Can you provide a brief overview of your daily work activities?
OSE identification	Briefly describes an operational safety event that could have led to a serious accident but did not and why.
Diagnosis	How and why was this event perceived as atypical, outside of "normal work"? What were the main pieces of information (clues) available at that time that allowed for the identification of the operational security event? What knowledge was utilized to interpret this information and generate possible solutions?
Intervention	Has an action plan or similar been established based on the diagnosis/analysis of the event? If so, how and for what purpose? What were the primary sources of information used to define and implement the necessary actions? What were the critical or essential pieces of knowledge required to implement the actions, based on the operational safety event that occurred? How was the mobilization of the necessary skills for the action plan carried out?
Difficult or facilitating factors (resources)	Is there any element or factor that hindered or facilitated the development and implementation of the action plan?

Source: Authors, 2023.

It is important to acknowledge that both Roadmaps incorporate checkpoints for each objective to validate the interviewee's responses. However, due to space constraints, these checkpoints have not been included in the tables.

Table 6: CDM Roadmap - Negative Perspective

Goal	Question
Interviewee identification	What is your name, job title, and/or position? How many years have you worked in this field, both at your current company and at other companies? Can you provide a brief overview of your daily work activities?
OSE ratification that culminated in the accident	Could you describe, in your vision, how the accident happened?
Diagnosis	Did you at any point realize that this was going to be an OSE that would culminate in an accident? If yes: What were the main pieces of information (clues) available at that time that allowed for the identification of the operational security event? What knowledge was utilized to interpret this information and generate possible solutions? What knowledge was utilized to interpret this information? With whom and where were this knowledge? What were the main pieces of information (clues) available at that time that allowed for the identification of the operational security event? If not: When did you realize and/or were informed about the accident? Upon learning about the accident, can you identify any contributing factors that led to it?
Intervention	How was the action plan established based on the perception of the described OSE? Were there any other suggestions to mitigate future accidents that were not implemented? What information and critical knowledge were used to define this objective? How were the necessary skills mobilized to implement the action plan?
Difficult or facilitating factors (resources)	Were there any factors that hindered or facilitated the design or implementation of the action plan?

Source: Authors, 2023

The final step, which will be detailed in the following section, involved the subsequent implementation of the CDM Roadmap in an operational security event, integrating the modifications derived from the validation cycles.

4. Application of the CDM Roadmap

4.1 Context and Description of the Second Application

Considering the revised structure of the CDM Roadmap, which now incorporates distinct sets of questions for examining positive and negative aspects of events, the positive perspective Roadmap was chosen for the second implementation. An operational security event (OSE) was selected, wherein professionals successfully averted a potentially hazardous situation and prevented an accident from transpiring.

This specific OSE was identified during an interview conducted in 2021 by two researchers with a professional from the oil and gas industry. The objective of the interview was to investigate three operations performed on an oil exploration platform: (i) offloading operations; (ii) high-pressure converter operations; and (iii) cargo handling. Additionally, the researchers sought to identify any non-routine situations related to these operations that had a favorable outcome without any accidents. Based on the interview transcript featuring an experienced oil and gas industry professional with over thirty years of expertise, an OSE was highlighted wherein a sailor's foot became entangled in a rope while retrieving the armature cable. A summary of the feasibility analysis scenario where the Roadmap was employed is presented in Table 7.

Table 7: CDM Roadmap Application Scenario

Activity	Description
Complex sociotechnical system	Oil and gas industry
Performed operation	Offloading: is the process of transferring oil or gas from one ship to another
OSE within the operation performed	"when the cable was being collected from the frame, a professional who was working on the operation got his leg caught"

Source: Authors, 2023.

The findings obtained from the application and the subsequent discussions will be presented in the forthcoming section.

4.2 Results and Discussions

The application of the CDM Roadmap was based on an interview transcript with an oil and gas industry professional. It is essential to acknowledge that not all questions were addressed since the CDM Roadmap was not utilized as an interview guide. Table 8 provides the principal evidence pertaining to the set of questions in the CDM Roadmap that adopts a positive perspective.

Table 8: Main Evidence of Application of the CDM Roadmap

Block	Description
OSE identification	*"Within the offloading operation, we were collecting the frame cable, which is the "sanso", between the connections of the two tiles, which makes the mooring between the tiles, and there was a moment when the sailor who was working with me, he went, trying to remove, the cable, which we call it in maritime language, the guy died, when it gets stuck between one leg and the other, so it got stuck there, and he went to hit it with his foot to remove it, something you should never do, the what happened, when he crashed, the cable wrapped around his foot and he went over the winch..."*
Diagnosis	*"So in operation, we will never put our hand, hit the hand, hit with the foot. Because it's very fast, hit the cable is tensioned, as you hit there, it will create flexibility, the first thing it will do is wrap it around your foot, your leg, your hand and you hit everything …"* *"I saw the cable swing, I said (person's name) what are you going to do with that cable there – (person's name) said: No, No, I'm going to tap my foot. But I stayed tuned, I said, look, don't do that, and at that point he started to pull, pulling slowly, because it was a slow operation. And there I became more aware, and my attention divided back and forth, dividing my attention into two radios, so, you get you to feel pressured, whether you like it or not, you are being pressured. When he did it the first time, I said, don't do it, but he didn't appreciate it, it happened again, the cable tensed, he put his foot in ..."*
Intervention	*"So I had at that time other solutions to avoid the problem of cable strangulation on the spool …"* *"But then, at that moment I was very calm, I called the ship's guard. I told them to stop collecting the cable and release the cable, and then, I moved the winch, calmly over here, it got stuck with my foot, I kept turning the winch in reverse, his foot gave way, I went there, I distorted the cable and took him out …"* *"Past experience offshore is a way to bring security home."* *"His approach time is slow, when he reaches 2/3 Miles he comes at 4/5 knots, he doesn't come..."*

Block	Description
	"There are ships that are bow and bow, this ship only has a hose in the flesh, but most of the ships I worked on had two hoses …"
Difficult and/or facilitating factors (resources)	*"... I was wearing headphones talking to a guy in English, giving him an order in Portuguese..."* *"Today there is no exclusive training for this type of work, the training is on the ship itself, in the operation, the younger workers are always accompanying the more experienced ones …"*

Source: Authors, 2023.

The identification of the interviewee and the specific operational security event (OSE) played a crucial role in providing context and assessing the relevance of the situation. Once confirmed, the questioning process proceeded. It is evident that professionals in the industry must possess a substantial amount of technical and procedural knowledge to execute offloading operations successfully. This entails understanding various ship types, equipment, and following step-by-step procedures. However, as evidenced by the Diagnosis and Intervention blocks, the interviewee's extensive field experience proved essential for accurately diagnosing the situation.

The information obtained during the diagnostic phase, particularly regarding meteorological aspects and the interviewee's actions during the activity, proved fundamental in identifying an atypical scenario and formulating an action plan. The interview also shed light on critical aspects, such as communication challenges among workers and the psychological pressure that workers encounter in such scenarios.

5. Conclusion

The main objective of this article was to present and evaluate the development process of the CDM (Critical Decision Method) Roadmap, a tool designed to support the identification and extraction of critical knowledge from operational safety events. The tool aims to assist organizations in learning from past events and improving their responses to future situations. The article emphasizes the positive outcomes of the CDM Roadmap, particularly in refining the instrument and enhancing its effectiveness in steps four and five of the development process. Furthermore, the division of the roadmap into two parts with different perspectives proved beneficial, allowing for more targeted and specific questions regarding the context.

The CDM Roadmap revealed significant insights into critical knowledge and knowledge transfer within organizations. A noteworthy finding was the often tacit nature of critical knowledge for preventing operational safety events, which is predominantly held by individual team members. This highlights the importance of formalizing this knowledge and finding ways to share it within the organization, preventing the loss of valuable information and ensuring that all team members have access to the necessary tools for effective responses. Another crucial finding was the need for specialized training programs for offshore activities. The reliance on observation and conversations with experienced colleagues among newer professionals highlights the significance of structured training to ensure a solid foundation of knowledge and skills for all team members. Lastly, the CDM Roadmap identified barriers that hinder knowledge flow and task execution. By acknowledging these barriers, organizations can take measures to remove them and foster a supportive learning and collaborative environment, thereby enhancing their ability to respond to operational safety events and other challenges. Overall, the CDM Roadmap appears to be a valuable tool for organizations seeking to learn from operational safety events and enhance their resilience. By guiding the identification and extraction of critical knowledge, it facilitates organizations' understanding of the factors that facilitate or hinder resilient responses, enabling them to implement corrective measures.

As a next step in the research, further application of the CDM Roadmap is anticipated, with the interview process being guided by the roadmap itself. Additionally, a potential area for future work would be the development of a roadmap to better qualify the knowledge that arises from the CDM Roadmap, establishing targeted actions for knowledge management (KM).

GLAM Wikiprojects as a Form of Organizational Cooperation Between Wikipedia and Cultural Institutions

Anna Karczewska
Czestochowa University of Technology, Poland

anna.karczewska@pcz.pl

Abstract. The development of new communication technologies enabled the digitalization of the knowledge resources of cultural institutions all over the world and made them available to a wider audience. This was possible through the cooperation of cultural institutions with Wikipedia's WikiProjects and engagement of the users from numerous countries. It seems important to recognize if this form of cooperation between Wikipedians and institutions is effective and attracts enough participants. The article takes up the subject of the character and effects of this cooperation. The aim of the paper is to study the activity of Wikipedians, including newcomers, in GLAM (Galleries, Libraries, Archives, and Museums) WikiProjects in several language versions of Wikipedia as an open knowledge project. The research questions concerned the characteristics of the activity of Wikipedians in GLAM WikiProjects and the differences between the behaviour of Wikipedians in GLAM WikiProjects in different language versions. The method used in the research is the content analysis, which includes quantitative tools. The author acquired and calculated the data on the activity of GLAM Wikiprojects participants thanks to the Wikipedia *xTools* tool. The calculations were made on participants of GLAM WikiProjects from five language versions of Wikipedia. The main conclusion from the research is that the results of this kind of organization of work, especially in terms of newcomers, are not satisfactory. The most effective participants are the coordinators of the projects or/and the Wikipedians with the highest seniority. Newly acquired participants most often do not continue their activity for long time. However, there are some differences in different language versions of Wikipedia. English one has better results in retaining and engaging new users. What is interesting is that despite the wide popularization and engagement of the GLAM institutions in the collaboration with Wikipedia, there is a relatively low interest of new Wikipedians in GLAM Wikiprojects. In order to reach a successful cooperation, it is significant to improve the effectiveness of welcoming, engaging, and retaining newcomers in the projects. The results may be of use to the practitioners of the virtual communities of practice which focus on creating and sharing knowledge.

Keywords: Cooperation, Knowledge management, Cultural institutions, Online Open source project, Organization

1. Introduction

The tremendous advances in information and communication technologies in recent years have enabled the development of the phenomena of online groups and collectives, which are generally referred to as online communities. Many of these communities have developed their separate cultures, with their own norms and codes of behaviour. A term that is often applied to them, namely, "community of practice", denotes a group of like-minded people (often professionals) whose purpose is to support, learn from and promote mutual understanding through collaboration amongst the electronic group (Wenger 1998). Such a community was formed around the idea of open knowledge resources, i.e. Wikimedia. Wikipedia and its related projects of Wikimedia are one of the public document repositories (PDRs), which are essential resources made available on the Internet. They are maintained by voluntary contributions from readers and users who are not remunerated for their activity in the project (Peddibhotla and Subramani, 2007).

In Wikipedia, the online global encyclopaedia, the creation of articles is organized, among others, in the form of WikiProjects. These are Wikipedia pages (different from article pages) that enable collaboration by providing access to the tools, tasks and goals of the project, as well as discussions focused on coordinating group work. WikiProject user groups operate through the afore-mentioned sites by using various coordination mechanisms to motivate and structure member contributions to create and improve articles related to specific topics (Gilbert et al., 2013, p. 1). WikiProject pages "provide a centralized repository of design tools, tasks, and goals, while also discussion for explicit group coordination" (Gilbert et al., 2013, p. 1). These tools enable the creation of shared awareness of members and non-members by editing articles relevant to the project WikiProject members, working on a narrow specialization, may perceive themselves as experts in their field, which provides them with the identification and motivation to be active in Wikipedia.

Lessig (2009) indicates that there is great creative potential in virtual communities actively involved in the creation of a global culture. Likewise, the amount of digital data created and collected by cultural heritage institutions such as museums, galleries, libraries and archives is constantly growing; many repositories publish data as raw dumps, but often without any structure and semantics, which limits the ability of users to put this information into context. Many institutions also face technical challenges related to the digitalization and

sharing of resources (Nishanbaev et al., 2019, p. 1471). One of the ways of sharing resources in more structured way is the cooperation of cultural institutions with the community centred around Wikimedia.

Relationships between cultural heritage organizations and the Wikimedia communities working on Wikimedia projects date back to the beginning of cooperation with museums and archives, for example with the British Museum in 2010. They are designed to encourage GLAM organizations (Galleries, Libraries, Archives and Museums) to participate in Wikimedia communities of which WikiProjects in Wikipedia are a part. Early GLAM-Wiki partnerships focused on uploading digital content to Wikimedia Commons, placing Wikimedia-appointed experts called Wikipedians in Residence and organizing editathons, namely, collaborative editing actions with experts on Wikipedia (Stinson, 2018, p. 1).

> *In recent years, partnerships with cultural heritage institutions have been changing. For example, libraries are collaborating with Wikimedia communities as part of sharing their digitized resources, which are either in the public domain or made available under an open licence. At the same time, partnerships with specific cultural institutions are being formed around Wikiproject pages. The aim of this article is to examine the activity of Internet users within WikiProjects focused around cultural institutions - GLAMs (Galleries, Libraries, Archives and Museums) in five language versions of Wikipedia: Polish, English, Swedish, Italian and French. The research may be of interest to the theoreticians and practitioners specializing in virtual communities creating and sharing knowledge.*

2. Literature Review

The development of the Internet and new communication technologies has enabled people to collaborate on an unprecedented scale, but the effectiveness rules for organizing such extensive cooperation between people from different cultural backgrounds are not clearly established. Wikipedia is a very effective example of such large-scale, decentralized collaboration. One cannot generalize the terms and conditions of operating from offline to online groups (Choi et al., 2010, p. 1). Therefore, examining the successes and failures of the particular forms of organizing online group collaboration is a particularly important research topic, especially the recruitment and retention of new members for community tasks.

One of the forms of work organization in Wikipedia is that of WikiProjects. In compliance with the approach used by researchers on the subject, one can define WikiProjects as "collections of pages that enable persistent group collaboration around particular subject matter domains or editing tasks" (Morgan et al., 2013, p. 1), collections which have their own code of conduct. Each WikiProject has a dedicated page that exists in a namespace separately from the article content. Participants can join a project by adding their name or nickname to the list of members on the site. WikiProjects provide mechanisms for the self-identification of members - they can place project banners on their user pages. This identification appears to have a positive effect on their level of motivation and editing activity. After joining a Wikiproject, editors dedicate most of their work to creating articles for the project (Kittur et al., 2009).

The GLAM WikiProjects were created in order to coordinate cooperation between cultural institutions and Wikimedia. Cooperation with Wikimedia can take place on several levels. As part of Wikipedia, they may provide resources to help those writing articles and assist with research. Under Wikimedia Commons (free media repository), they may contribute images, video, and other media, as well as meta-data and media descriptions. In cooperation with Wikisource (library of primary sources), the institutions may provide manuscripts for scanning and uploading, while in terms of Wikidata they can integrate Wikidata into existing meta-data projects and donate openly licensed data to Wikidata (https://outreach.wikimedia.org/wiki/GLAM/Get_started).

Thanks to these projects, the Wikimedia community expands the sources of knowledge, learns from GLAM specialists in the field of structuring and protection of knowledge (the so-called Wikipedians in Residence) and gain new editors. On the other hand, the representatives of institutions gain experience in the area of the openness of resources and open cooperation, while also extend their influence on domain-specific knowledge. Residents work with the institution's employees on the digitization and organization of resources that can be made available in Wikipedia, while also organizing events and teaching employees how to cooperate with Wikipedia (Stinson, 2018, p. 17). On a global scale, Wikipedians in residence played formal roles in almost 200 institutions (Wikimedian in residence, 2023). An example of successful cooperation in the Polish version of Wikipedia is a project created with the National Ethnographic Museum that is aimed at documenting the culture of the Carpathian region. The project required in-depth training for the volunteers, and close supervision of the museum staff to ensure that the knowledge of the communities documented was gathered

accurately (Szafran-Kozakowska, Pędzich, and Moraczewska 2016). Skolik (2017) examined in more detail the institutionalization processes in Wikimedia projects in Central-Eastern Europe.

Tharani (2021, p. 1) points out that libraries have started to cooperate with Wikidata, e.g. through WikiProjects, to improve global access to their collections of knowledge. Wikidata has great potential to become a repository for data disambiguation and merging in terms of its sustainable integration with library operations, which remains a huge challenge. McKenna et al. (2018, p. 7) conducted a survey among 185 information professionals from various cultural institutions. The results show that there is a number of usability challenges with Linked Data tools that create barriers for professionals working around Linked Data. Specialized LD tools designed for work and expertise of information professionals can help overcome these problems.

Wikiprojects are a specific form of coordination of online collaboration. Morgan et al. (2013, p. 1) analysed the content of 788 discussions related to working on 138 WikiProjects to recognize the role that WikiProjects play in cooperation with Wikipedia. Their results indicate that WikiProject collaboration is more open and less structured than in other virtual teams, while WikiProjects function more like FLOSS (Free/Libre/Open Source Software) projects than traditional ones. Some WikiProjects are not formally structured and usually consist of a few contributors maintaining project communication who support the work activities of a large number of peripheral contributors (often non-members). Project coordinators are largely self-assigned and their activities are carried out independently (Morgan et al., 2013, p. 9).

Kittur et al. (2008) showed the existence of a relationship between a high level of activity on article talk pages and the quality level of articles in the initial stages of their creation. Viegas et al. (2007) and Schneider et al. (2010) found that discussions on article talk pages focus mainly on coordinating editing individual articles (Morgan et al., 2013). However, the research does not provide clear conclusions regarding the relationship between the coordination work and the quality of articles created. Ung and Dalle (2010) investigated 644 French WikiProjects in terms of the relationship between discussion activity on the project's talk page and editing activity and concluded that the most active discussion participants were not the most active editors. In most cases, a small group of active discussion participants played a major role in organizing the work of a wider group of peripheral members rather than being involved in the larger article content production. These smaller groups of project members may function as a hub acting as facilitators and technical support by answering questions, providing feedback etc. (Morgan et al., 2013, p. 8).

Although encyclopaedia articles are the most noticeable product of the work of Wikipedia editors, they spend a great deal of their time on organizational activities not directly related to extending or writing new articles (Kittur et al. 2007). Their meta-work is very important for supporting the editorial community and maintaining the quality of Wikipedia (Wilkinson and Huberman, 2007). These include activities related to maintenance, administration and quality assurance, such as the prevention of vandalism, mentoring, new user onboarding and conflict resolution (Morgan et al., 2013, p. 1). Usually this work is undertaken voluntarily by more experienced users, whose activity does not require controlling.

Maintaining the efficiency of editorial work is important for the implementation of community tasks. Platt & Romero (2018) analysed the relationship between the structural properties of WikiProject's editor networks and their effectiveness. Their results suggest the potential benefits of decentralized collaboration in smaller, tightly-knit teams.

An insightful study conducted on the users of Amazon.com resources showed the relationship between the type of motivation of the user and the contribution to the discussion on the article. "Self-oriented motives are positively related to the amount of input, while other oriented motives are positively related to the quality of the input" (Peddibhotla and Subramani, 2007, p. 22). Individual motivation includes: self-expression, personal development and personal satisfaction. Other oriented motivations include the following: social affiliation, reciprocity or altruism. The authors suggest that similar patterns occur in other online repositories such as Wikipedia. In turn, Choi et al. (2010, p.115) examined the impact of various socialization tactics on the involvement of newcomers in projects. In the study of online groups, in contrast with studies of offline groups (…), standardized tactics (uniform for all) were negatively associated with the input of a new user, while more personalized tactics were positively associated with it. These results are significant for Wikipedia community striving to acquire and retain new users for its projects.

There are a number of studies on the effectiveness of work within WikiProjects and the retention of new users involved in projects, but that type of research does not focus specifically on the effectiveness of GLAM

WikiProjects. On the other hand, the existing research mainly concerns problems and technical barriers related to library and Wikimedia databases (McKenna et al., 2018; Tharani, 2021). Thus, there is a research gap that this article attempts to fill by examining the activity of Internet users with different language backgrounds within GLAM WikiProjects.

3. Methodology

The aim of the conducted research was to study the activity of Internet users within WikiProjects focused around cultural institutions - GLAMs in five language versions of Wikipedia: English, French, Italian, Polish and Swedish. The research questions asked in the research process were as follows:

Q1: What are the characteristics of the activity of Wikipedians in GLAM WikiProjects?

Q2: Are there any differences between the activity of Wikipedians in GLAM WikiProjects in different language versions?

The method used in the research is the content analysis method, which included quantitative tools. The calculations were made on a random sample of 406 users – the participants of GLAM WikiProjects - from five language versions of Wikipedia. At the first stage of the research, the candidates were chosen from randomly selected Wikiprojects of five language versions. Then, the *xTools* tool was used to generate the data about the activity of selected participants. *XTools* collects statistical data for each registered account on Wikipedia and its related projects. The collected data included the following:

- the number of the articles created by the user in the space of Wikipedia,
- the number of deleted articles created by the user,
- the number of all editions made by the user in Wikipedia,
- the number of editions on the user page discussion (a page discussing the particular user's activity in Wikipedia),
- the number of editions in the "talk" space (discussing the content and quality of articles; interaction with others),
- the number of editions in the "meta" space (discussing the organization of work on Wikipedia),
- date of registration of the user,
- date of last activity of the user,
- ID number assigned to the user while registering,
- number of times thanks was expressed to the user for his input,
- number of times thanks was expressed by the user to other users.

At the second stage of the research, the data was collected and statistically analysed using Statistica software. The ratios of the chosen data was counted as follows: talk editions of a user to all editions of a user and meta editions of a user to all editions of a user to obtain respectively the indicators of the social activity and organizational activity of a user. The seniority of a user was determined by calculating the difference between his first and last edition (in terms of years and days). The Rho-Spearman statistical measure of correlation between variables was used (with the adopted $p<0.05$). Descriptive statistics were also used to investigate the main trends in the behaviour of Wikipedians in GLAM WikiProjects and the differences in their behaviour in different WikiProject language versions.

4. Research Results

In order to answer the research questions, the descriptive statistics concerning the studied variables were counted and analysed. The median and quartiles of the number of created articles were determined. As results from the calculations, a huge number of participants did not create any articles in GLAM WikiProjects or Wikipedia. The details are included in Table 1.

Table 1: Descriptive Statistics of a Variable: Number of Created Articles

	Descriptive statistics					
	N	Median	Minimum	Maximum	Upper quartile	Lower quartile
number of created articles	406	1.0	0.0	11336.0	0.0	22.0

The median of created articles in Wikipedia was only 1. Around 75% of participants created up to 20 articles, including 66% with no more than 6 articles. Almost half of the participants did not create any articles (43%). The results are presented in Figure 1.

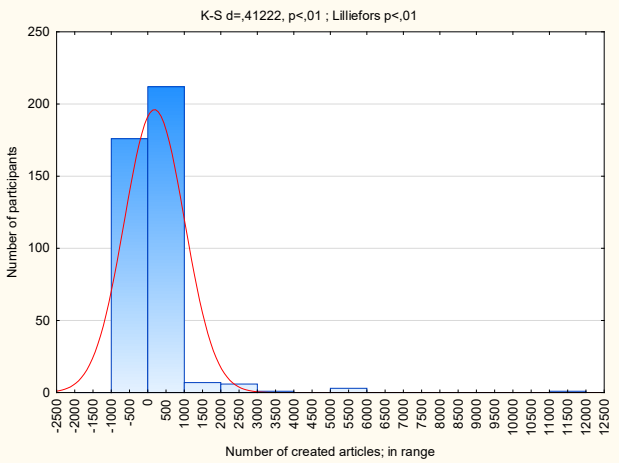

Figure 1: Number of Participants who Created a Particular Number Articles (in ranges)

A similar situation occurred in various language versions of Wikipedia, however there were small differences between them. They are presented in Table 2.

Table 2: Descriptive Statistics of a Variable: Number of Created Articles in Different Language Versions of Wikipedia

	Descriptive statistics					
	N	Median	Minimum	Maximum	Upper	Lower
number of created articles in English	68	9.0	0.0	5938.0	0.0	179.5
number of created articles in French	112	5.5	0.0	11336.0	0.0	98.0
number of created articles in Italian	92	0.0	0.0	2256.0	0.0	3.0
number of created articles in Polish	77	0.0	0.0	5694.0	0.0	6.0
number of created articles in Swedish	58	1.0	0.0	113.0	0.0	3.0

A small amount of articles created for a significant number of users was characteristic for all of the researched language versions. Yet, the median of articles created in English language version was 9, whereas 5.5 in French, while in Italian, Polish and Swedish it was 0. The English language version stood out positively from the rest of the researched versions.

As a second aspect of the trends in activity of Wikipedians in WikiProjects, the seniority and the amount of articles were studied. It turned out that 20% of the most experienced users created 73% of articles. (Table 3).

Table 3: Descriptive Statistics of a Variable: Number of Created Articles in Different Language Versions of Wikipedia

Cumulative percentage of the oldest users	Cumulative percentage of created articles
5%	27.1%
10%	41.9%
15%	56.8%
20%	72.7%
50%	80.0%

The length of activity of a participant in Wikipedia was most often 1.6 years. Only a small number of participants represented the higher ranges of seniority in Wikipedia activity. This trend may be observed in Figure 2.

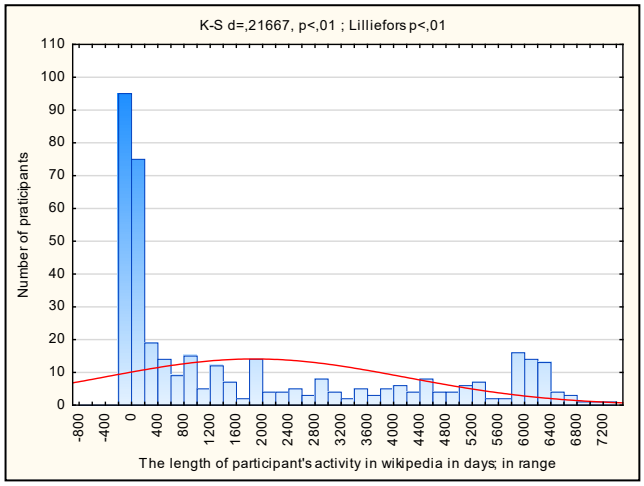

Figure 2: The Length of a Participant's Activity in Wikipedia in Terms Of Days

Moreover, the length of the activity of a participant in different language versions was counted. The differences between versions were noted and are shown in Figure 3.

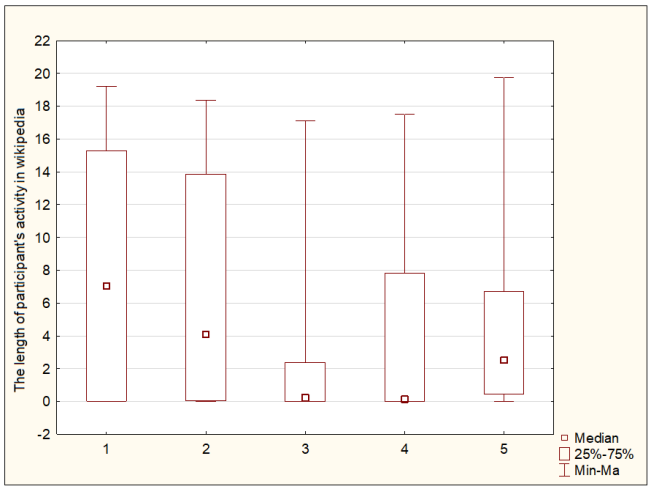

Figure 3: The Length of a Participant's Activity in Years in Different Language Versions of Wikipedia (1- English; 2- French; 3- Italian; 4- Polish; 5- Swedish)

The English language version stands out positively from other versions. The median there is around 7.

Subsequently, the correlations between some variables describing activity in the creation of content and activity in "quality control" space and organizational (meta) space in Wikipedia were calculated and the results are presented in Table 4.

Table 4: Seniority of the Wikipedians and Their Activity in Creating the Content and in the social Spaces of Wikipedia

	ratio of talk editions/all editions	ratio of meta editions/all editions
seniority in years	0.493	0.438

The more experienced a user is, the more he/she controls the quality of the content and organizationally active he is in the space of Wikipedia. With the rise of experience, the self-confidence of the user may rise and the number of interactions with other members of the community increases. In WikiProjects, usually the most engaged participants are those who organized the project and encouraged others to join.

Another analysed variables related to thanks expressed to a user and thanks expressed by the user to other users. They were correlated with the level of activity of a user represented by the number of all his/her editions. The details are included in Table 5.

Table 5: Relations Between the Size of Editions in the Wikipedia and the Numbers of Thanks Expressed and Received by the User

	thanks expressed to the user	thanks expressed by the user
number of all editions	0.685	0.357

Together with the input of the user, thanks expressed to others and by him/her are rising. He/she can feel appreciated and this can enhance him/her to do more work for the community.

The following investigated issue was the relations between the activity in creating articles and the number of deleted articles by users and the activity of a user in "talk" space and "meta" space in Wikipedia, representing "quality control" and the organizational activity of a user (Table 6).

Table 6: Relations Between the Amount of Created Articles and Deleted Articles and the Number of Editions in the "Meta" and "Talk" Space in Wikipedia

	number of editions in the Wikipedia "talk" space	**number of editions in the Wikipedia "meta" space**
number of created articles	0.845	0.766
number of deleted articles	0.732	0.709

The more created articles the user gets, the more activity both in the meta and talk space is shown. The more articles the user creates, the more activity beyond the content creation he/she develops. Likewise, the more deleted editions the user has, the more activity in the "meta" and "talk" space he/she shows. One of the explanations may be that the deleted amount of articles could provoke discussion about the reasons and legitimacy of this decision on the talk pages.

5. Discussion

According to the findings of conducted research concerning characteristics of participants activity in GLAMs, around 75% of participants created up to 20 articles including 66% with no more than 6 articles. Moreover, almost half of the participants did not create any articles (43%). It appears that one of the aims of the GLAM WikiProjects, which is to engage members of cultural institutions in the edition of articles, is only realized to a small extent. Additionally, the participants do not stay in the projects for long – 40% only register and do not show any activity. The length of activity of participants in Wikipedia was most often 1.6 years (median). Only a small number of participants represent more seniority in Wikipedia activity. As Choi points out (2010, p. 1), generally most new users in Wikipedia have made fewer edits over time, but declines in editions have slowed or reversed for those greeted with welcoming messages, offered help, and constructive criticism. Perhaps the way newcomers are invited and treated at the beginning of their activity in GLAM WikiProjects should be analysed and organized in a new way.

Morgan et al. (2013, p. 9) suggest that community builders and coordinators wishing to support WikiProjects or other similar self-organizing volunteer projects in open collaboration systems should provide coordination mechanisms that work not only for large, well-organized groups, but also for smaller, more open and less formal groups. In particular, new users in communities such as Wikipedia face social and technical barriers that hinder the acquisition of knowledge and may discourage them from engaging in a project (Halfaker et al. 2013).

What is interesting in terms of activity of participants from different cultures, among the five studied language versions of Wikipedia, the English version stood out positively in terms of the median of created articles and length of participation time in Wikipedia. It is a popular and well-developed language version, which is edited by people from different cultures and has a long tradition of engaging newcomers. It is worth analysing the practices of English Wikipedia in a qualitative study in order to draw conclusions on what determines its effectiveness in this respect. From the point of view of the retention of new users, it is important to provide various types of means related to navigation in the working environment and provide support in using them. Newcomers may feel overwhelmed by the rules of article creation or the software used (Preece, 2001). The way of expressing criticism and communication style during the quality control process of articles plays a role in the retention of newcomers. Choi et al (2010, p. 107) distinguished seven useful tactics that may increase

the engagement of newcomers: offers of assistance, invitations to join, welcoming messages, requests to work on tasks, constructive criticism, positive feedback, as well as personally related comments.

Another analysed aspect of the activity of WikiProject participants was editing the activity of different types of users – more and less experienced ones. The data indicates that 20% of the most experienced users create 73% of articles. The results are in accordance with the critical mass theory. The critical mass is "a small segment of the population that chooses to make a big contribution to the collective action, while the majority do little or nothing. These few individuals are precisely those who diverge most from the average" (Oliver, Marwell and Teixeira, 1985, p. 524). These disproportions are reflected in subject-related literature. Some studies claim that even 88% of the content is created in Wikipedia by 3% of users (Wikipedia Statistics English, 2023).

In WikiProjects, coordination work and content creation are loosely connected, while editors do most of their work independently of each other (Morgan et al., 2013, p. 8). As correlations calculated in the conducted research shows, the more experienced a user is, the more he/she controls the quality of the content and organizationally active he/she is in the space of Wikipedia (0.493). What is more, the more articles the user creates, the more activity beyond the content creation he/she develops ("meta" space in Wikipedia) (0.766), regardless of the criticism he/she faces (deleted articles). Likewise, the appreciation in terms of thanks expressed for the user's activity is a useful tool that may enhance the motivation for editing (0.685).

Success in online cooperation may be aided by greater decentralization or conformity-based decision-making, while also closer collaboration between smaller teams (Platt and Romero, 2018, p. 10). Hence, the GLAM WikiProjects are a good place in the space of Wikipedia to reach this success, provided some of the problematic aspects of motivating and retention of new users are addressed.

6. Conclusion

The considerations undertaken in this article may make a contribution in recognizing the conditions for engaging new participants in GLAM WikiProjects. The findings of the research indicate that the engagement and retention of new participants is not satisfactory (around 40% do not create content nor stay in the project) and the majority of the content is created by a small percentage of the more experienced users. It seems that the more experience a user gains, the more active in the organizational sphere he/she becomes, while also the more appreciation he/she receives and more motivated he/she becomes.

However, the partnerships between Wikipedia and cultural institutions have brought numerous advantages for both sides, especially in the sphere of sharing resources and expanding mutual knowledge of both sides of the working environment, which is a good start for future cooperation. The limitation of this research concerns the limited scope of language versions of Wikipedia. The future study might expand the number of language versions as well as participants of WikiProjects as well as include qualitative data for more in-depth conclusions.

As McKenna indicates (2018, p. 16), in today's world where the Internet is the first and most often the main place where users look for information, it is essential that cultural institutions make data resources available online. Partnerships with Wikipedia's GLAM WikiProjects play an important role in this process, so it is worth improving the effectiveness of welcoming, engaging, and retaining newcomers in the projects.

Aesthetics as Knowledge: An Aspect in the Future of KM?

Clemens Kerschbaum
Vienna University of Economics and Business, Austria

Clemens.Kerschbaum@wu.ac.at

Abstract: Knowledge Management (KM) is concerned with the process of capturing, organizing, sharing or utilizing knowledge within an organization. At least since the works of Nonaka and Takeuchi in the 90s, it is a commonplace that the term knowledge, as understood from the perspective of KM, includes both explicit and tacit elements. However, it seems that the focus of many KM initiatives and resulting KM systems still lies mostly on the more explicit facets of knowledge. This has two implications for the field: the first is the obvious danger of confusing knowledge management with information management. The second, which is actually a consequence of the first, is that the focus on technology and explicit knowledge can lead to a diffusion of the field of KM towards more technical domains such as Semantic Web, Knowledge Graphs or Machine Learning and Artificial Intelligence. Those fields have arguably become way more capable of managing explicit knowledge and draw the attention of companies away from 'traditional' KM systems (Davenport, 2015). Thus, in this paper, I argue that KM research should somewhat reconsider its strengths which lie in the management of tacit knowledge that is closely tied to humans. Following this argument, I propose organizational aesthetics as one of many promising avenues for KM research in the future. The idea for this stems from a recent literature review on organizational aesthetics that identifies three perspectives on the topic – one being *aesthetics as a knowledge tool* (Baldessarelli, Stigliani and Elsbach, 2022). According to this perspective, aesthetics is seen as a form of knowledge that originates in sensory perceptions and is permanently deployed in the interaction with organizations, organizational artifacts, and social settings. The present paper hence aims to contextualize the notion of organizational aesthetics for the field of KM to give an overview of the idea and offer a basis for discussion on whether aesthetics could be a useful field for future inquiry.

Keywords: Organizational aesthetics, Tacit knowledge, Future of KM, Perspectives on knowledge, Knowledge creation, Capacity to act

1. Introduction

Most people will, at first glance, not associate aesthetics with knowledge. Probably even less so would practitioners - and maybe even researchers - in the area of Knowledge Management (KM) connect aesthetics to their field of study. However, with this paper I want to break down the concept of aesthetics, and more precisely, *organizational aesthetics* in relation to knowledge types and definitions for the field of KM. As I will show, aesthetics is indeed not so far from knowledge, as understood by the KM community, and it could potentially be an interesting avenue for contemporary and future KM.

I present the idea of aesthetics in the context of KM because I perceive the field as in a state where new streams are being thought of and start establishing themselves. Examples include the notion of *responsible KM* (rKM) that has been coined by Susanne Durst (Durst, 2021) and taken up for example by Raysa Rocha, Florian Kragulj and colleagues (Rocha, Kragulj and Pinheiro, 2022) in the context of wisdom in organizations, or also the movement towards spiritual KM that has been developed by a group of researchers around Constantin Bratianu and Alexander Kaiser (Bratianu, 2015, 2017; Kaiser, 2023) in an attempt to include purpose and personal development into the field of KM. Such initiatives currently broaden the scope of KM that seems to have been very focused on technology and the rather mechanistic 'production' of knowledge, as argued by some.

Already in 2015, Thomas Davenport had written an article for the Wall Street Journal in which he argued that KM had faded since the 2010s. According to his view, the field had over-emphasized those technical facets of KM which led to an abundance of many KM initiatives because people did not change their behavior towards acquiring new, or sharing their knowledge just because a new system has been put in place. In addition, the advance of other technologies such as powerful search engines for external knowledge (e.g. Google) made in-house databases of explicit knowledge relatively obsolete. Ultimately, Davenport argues, despite its technical focus, KM seems to have failed to properly incorporate up-to-date data analytics in its study area which subsequently led to the cannibalization of traditional KM in most cases through more innovative, data driven analytic approaches. Hence, following this view and taking up the recent efforts towards a more human-centered approach to the field of KM, I would like to bring aesthetics to the table in an attempt to get a particularly human aspect back into the loop of knowledge-generation. Why it is particularly aesthetics that I believe in as a potential driver for the relevance of future KM will be shown after a brief introduction to the concept.

2. Organizational Aesthetics

Aesthetics, seen from a scientific perspective, describes all sorts of meaning and knowledge that sensory perceptions elicit in a human being (Baumgarten, 1988; Taylor and Hansen, 2005; Baldessarelli, Stigliani and Elsbach, 2022). Contrary to the terms usage in colloquial language, aesthetics hence includes beauty and art, but is not limited to those concepts. Instead, there are plenty of other aesthetic categories such as, for example, the comic, the sublime, the ugly or the grotesque (Strati, 1992), just to name some. Apart from those explicit categories, aesthetic perceptions can lead to all sorts of perceived meanings. Aesthetic perceptions are by definition highly subjective and always root in direct personal experience. Thus, aesthetics can also been seen as a precursor to knowledge because we first experience the world, and are hence subject to aesthetic perceptions, before we can engage in intellectual and conceptual thought about the world. However, how a person aesthetically perceives an artifact, a situation, or basically anything that can be experienced through the senses, may vary and naturally differs from each individual to another.

With regards to organizations, the scientific field of organizational aesthetics is concerned with the study of organizational life as experienced and understood through the senses of organizational members (Strati, 1992; Gagliardi, 2006). So whenever there are people involved, there will necessarily be aesthetic perception. Thus, the concept has been researched in different fields e.g. in terms of creative work in an architecture firm (Ewenstein and Whyte, 2007), medicine (Creed, Taylor and Hudson, 2020), innovation (Akgün, Keskin and Kırçovalı, 2019) or also in the leadership domain (Hansen, Ropo and Sauer, 2007). According to the respective research interest and the design of a particular study, aesthetics can be seen from different viewpoints.

Reviewing the field, Taylor and Hansen (2005) in this regard identify different scopes of organizational aesthetics: aesthetics understood as an epistemology, as criteria for judgement or as establishing connection (Taylor and Hansen, 2005). A more recent review of empirical studies on the concept has shown that there are three main perspectives on the role of aesthetics in organizations: aesthetics can be understood as (a) a directed stimulus that influences the behavior of people in and around organizations, (b) an open-ended outcome that describes the personal aesthetic experience of a person engaging in, or with an organization and, (c) as a knowledge tool which describes how people make use of their aesthetic perceptions and the meaning therefrom to execute work (Baldessarelli, Stigliani and Elsbach, 2022). What makes aesthetics appealing from an organizational perspective is its holistic character i.e. that it integrates all sensory perceptions and respective meaning generated from them, focusing primarily on the effect – the meaning generated from such perception. Respectively, the notion of aesthetics has been a popular concept in pragmatism especially in William James' and John Dewey's works. Aesthetics later also appears in Chester Barnards seminal "Functions of the Executive" where he builds on pragmatist views to argue that management is to a large part about sensing the organization as a whole, which is best described through the terms "feeling, judgement, sense, proportion, balance or appropriateness" (Barnard, 1938, p. 123). However, notions of aesthetics, although not explicitly stated as such, can be also found in more contemporary management theories such as Scharmer's Theory U (Scharmer, 2007) or the, by now, well-known Design Thinking framework for innovation (Shrivastava et al., 2017).

3. Conceptualizing Aesthetics in Terms of Knowledge Management

The above-mentioned examples already suggest some connection between aesthetics and topics of KM. This section hence takes a more systematic look at the intersection of the two fields.

When looking at the purpose of Knowledge Management that derives from a knowledge-based perspective on organizations, we know that its main goal is to support the combination and application of knowledge that is embedded in culture, identity, routines, policies, systems, documents and individual employees (Grant, 1996; Spender, 1996; Alavi and Leidner, 2001). However, it is not merely the amount of existing knowledge that matters most but the ability to apply it and also the ability to generate new knowledge on top of the existing (Alavi and Leidner, 2001). Let alone, the term knowledge can mean different things depending on the context that it is used in, and accordingly, a multitude of definitions for knowledge have been proposed.

Hence, we first have to locate the term aesthetics within those definitions to create an understanding of how it can be useful for KM.

3.1 Perspectives on Knowledge and the Role of Aesthetics

To this end, I will draw to Alavi & Leidner's (2001) overview of knowledge taxonomies and perspectives on knowledge and reflect their relation towards aesthetics and vice versa. I use their paper as a starting point,

because it is one of the most cited accounts of knowledge definitions in the field and has served as a basis for many consecutive studies on the topic. Table 1 contains an overview of the perspectives on knowledge, enhanced by a brief description of the potential relation to aesthetics. As we will see, some perspectives have a closer connection than others, while some have no noteworthy connection at all. The latter are marked N/A (not applicable) in the table.

Table 1: Enhanced Overview of Perspectives on Knowledge. Adapted from Alavi & Leidner (2001)

Perspective	Explanation	Implications for KM	Relation to Aesthetics
Knowledge vis-à-vis data and information	Knowledge is personalized information on the basis of processed data	KM must expose individuals to potentially useful information	N/A
State of mind	Knowledge is the state of knowing and understanding	KM involves enhancing individuals learning and understanding through provision of information	Enabling individuals to expand personal knowledge through aesthetic experiences
Object	Knowledge as an object to be stored and manipulated	KM must build and manage knowledge stocks	Aesthetic perception of objects (both physical and intangible). Aesthetics as a frame of reference for knowledge
Process	Knowledge is a process of applying expertise. Simultaneous knowing and acting	KM focuses on knowledge flows and the process of creation, sharing and distributing knowledge	Aesthetics as a knowledge tool deployed in organizational work
Access to information	Knowledge is a condition of access to information	KM focus is organized access and retrieval of content	N/A
Capability	Knowledge is the potential to influence action	Building core competencies and understanding strategic know how	Aesthetics as precursor of knowledge, necessary requirement to gather experience and build competence; 'link to the future'

As for the perspectives *Knowledge vis-à-vis Data and Information* and *Access to Information,* there is no noteworthy connection to aesthetics, as those perspectives focus primarily on explicit knowledge and its representation. The knowledge captured within this perspective is rather objective due to its explicit nature, in a sense that the knowledge itself is the same for everybody i.e., it does not include a subjective component in its representational form. Both of these perspectives can be considered rather mechanistic accounts which assume that knowledge can be 'managed' in a technical sense, or that its distribution can be more or less controlled.

Knowledge as a S*tate of Mind* means the sum of what has been perceived, discovered or learned (Schubert et al., 1998 cf. Alavi and Leidner, 2001). Here, especially the aspect of perception establishes a link towards aesthetics. Since aesthetics means the sensorial perception and meaning elicited through such perception, aesthetics is a part of the acquisition of new knowledge. Within this perspective, enabling the acquisition of individual knowledge and its application to organizational domains is focal. Thus, the provision of opportunities for learning are crucial and can be supported through considerations of aesthetics within the process. This could mean to give people as many opportunities as possible to perceive artifacts or situations in the organizational context in order to facilitate their individual learning and broaden their knowledge.

If knowledge is understood as an *object,* it can itself be subject to aesthetic perception. An illustrative example would be an organizational process that is typically considered organizational knowledge. That process can elicit different meanings for organizational members. Some may find it useful and important while others might consider it annoying or outright grotesque. Hence, aesthetics can act as a frame of reference for the evaluation of artifacts that people encounter in an organization (Creed, Taylor and Hudson, 2020) – such as knowledge. Although the authors did not explicitly coin it as such, we see an example for that mechanism of

evaluation in Nonaka & Takeuchi's (1995) Knowledge Creating Company where the authors argue that organizational intention is "*the most important criterion for judging the truthfulness of a given piece of knowledge*" (Nonaka, 1995, p.74). Such intention is heavily value laden and aims to foster commitment towards the organizations purpose that roots in a positive aesthetic evaluation of the organizations purpose (Kerschbaum, 2022).

Knowledge as a process of applying expertise (that includes simultaneous knowing and acting) opens up a broad connection to aesthetics. This view aligns neatly with Baldessarelli, Stigliani and Elsbach's (2022) perspective of aesthetics as a *knowledge tool.* This perspective includes all studies of aesthetics in which aesthetics is deployed in everyday work. The authors differentiate between aesthetics as a knowledge tool to *accomplish creativity* and aesthetics as a knowledge tool *intertwined with organizing.* Here, the first describes the notion that aesthetics is basically activity that creates value. Illustrative examples are the design of new fragrances or the work of a chef when creating dishes and therefore applying his or her senses of smell and taste. In this understanding of aesthetics, the human senses are used to create or manipulate artifacts in order to generate a desired outcome (Baldessarelli, Stigliani and Elsbach, 2022). For the view of *knowledge as a process*, aesthetics can hence be seen as a constant companion in the application, creation or the sharing of knowledge which naturally involves the senses. This is particularly the case with tacit knowledge, a type of knowledge that roots in and is generated through the personal experience of the knower (Polanyi and Sen, 2009).

Knowledge as a capability emphasizes the potential to influence future action, based on the capacity to interpret information that is necessary for decision making (Alavi and Leidner, 2001). This perspective is in line with later accounts of knowledge as a capacity to act (e.g. Sveiby, 2001). Central to this view is the consideration of individuals as "*primary intangible resource"* as Sveiby (2001, p.355) puts it. The view of knowledge as a *capability* or *capacity* to act is often associated to organizational strategy and includes both elements of rational planning and emergent properties (Bolisani and Bratianu, 2017). The emergent properties stem from individual learnings or the experience of an organization's members and pay tribute to the fact that not everything can be rationally analyzed in a complex environments. Accordingly, it has been proposed to rely on forms of knowledge such as *self-transcending knowledge* which can be acquired through high states of attention and being grounded in the present (Scharmer, 2007; Flowers *et al.*, 2011; Kaiser and Peschl, 2020). From the description of such knowledge, it has probably become evident already that aesthetics is at the core of the perception of this knowledge. Apart from its role in strategic decision-making in modern-day complex environments, it has been proclaimed that to a large extent, organizational life as such is built on tacit knowledge and aesthetics respectively (Strati, 1999; Down, Sternberg and Horvath, 2000).

3.2 Aesthetics as Knowledge

From the brief analysis above, we see that aesthetics can play a role for the acquisition of individual knowledge (state of mind-view), the evaluation of existing or new knowledge (object-view), the application of knowledge (process-view) and, integrating those, if we consider individuals as our *primary intangible resource* (capacity to act-view). However, in more explicit accounts of knowledge (data & information-views) it is rather underpart.

Thus, in terms of KM, we can probably focus on the "soft side" of the field that follows the idea that knowledge sharing and creation, and respectively the creation of organizational knowledge is a dynamic process between individuals and the organization (Nonaka, 1995). According to Nonaka and Takeuchi, the root for knowledge creation lies in the transformation of tacit into explicit knowledge and vice versa. They describe the transformation process through a four-phased model (known as the SECI knowledge spiral) that contains knowledge exchange from tacit to tacit, tacit to explicit, explicit to explicit and explicit to tacit knowledge. Yet, an organization, according to Nonaka and Takeuchi, "*cannot create knowledge by itself"* (Nonaka, 1995 p.72)*,* but requires individual *tacit* knowledge for that purpose. Their understanding of tacit knowledge is based on the original conceptual thoughts of Michael Polanyi (Polanyi and Sen, 2009).

Taylor and Hansen (2005) on the other hand argue that aesthetics in organizations finds its strongest voice in exactly that tacit knowledge coined by Polanyi which Nonaka and Takeuchi see as a basis for knowledge creation in the firm. In fact, Taylor and Hansen (2005) mention tacit knowledge when they speak about aesthetics as an epistemology. They state that tacit knowing corresponds roughly to sensory/aesthetic knowing and is commonly juxtaposed to explicit/rational knowledge.

Going into detail in Polanyi's original argument, he describes that tacit knowledge roots in sensory perceptions that, altogether, elicit a particular meaning. However, only through that elicited meaning, we can even think

about what perceptions elicited that meaning, an insight that manifests in the famous quote that *"we can know more than we can tell"*. To illustrate that point, Polanyi gives the example of humans' ability to recognize physiognomy on a face: we can recognize it, but it is almost impossible to tell what led us to the perception. Furthermore, only through the meaning i.e. the particular facial expression and mood, can we even think about the features of the perception that made us perceive that particular meaning (Polanyi and Sen, 2009, pp.12). The same concept applies in many other activities that involve skill or ability, from someone riding a bicycle to a surgeon performing a complicated surgical procedure. This ultimately leads to the conclusion that "our body is the ultimate instrument of all our external knowledge […]. And, we are *relying* on our awareness of contacts of our body with things outside for *attending* to these things." (Polanyi and Sen, 2009, pp.15).

Yet, identifying the features that led us to some particular meaning is usually not and end in itself but a means to understand the comprehensive entity they constitute. Put differently, according to Polanyi, it would make no sense to analyze every entity towards its constitutive elements in all detail. Doing so, could even destroy our tacit (holistic) understanding of complex matters (Polanyi and Sen, 2009, p.18).

This line of argumentation explains why tacit knowledge is so important for organizations - because it enables the understanding organizational issues in their full complexity. It allows an understanding of situations, contexts or problems that can hardly be depicted in a reductionist, analytical manner let alone be understood or solved through analytical means. Aesthetics, in that regard, hits exactly the same notch as it emphasizes the holistic meaning that arises from all sensory perceptions.

Strati (2016), coming from the field of organizational aesthetics explains the roots of aesthetics in a philosophical sense as (a) an antithesis to Cartesian rationality, (b) the sensitive judgement that evaluates feelings etc., and (c) the aesthetic judgement of something being perfect or imperfect (taste). To all of which the act of perceiving is a central element. He argues that aesthetics in organizations takes into account (amongst others) the importance of the human person in the process of organizational knowledge, the corporeality of personal knowledge in organizational life and the socially constructed character of aesthetic knowing in organizational settings. Thus, for organizational learning – and this will also apply to KM – Strati (2016) argues that the generation of knowledge cannot rely solely on the translation of all knowledge into "cognitive knowledge" (explicit knowledge in KM terms). Instead (citing Polanyi) one should take account of tacit knowledge, that is the awareness of knowing how to do something without being able to tell why or how, for which the aesthetic understanding is fundamental. Strati then proceeds to identify tacit knowledge as the common ground between Organizational Learning and organizational aesthetics (Strati, 2016).

To conclude the section on tacit knowledge and organizational aesthetics, we can see a considerable overlap of the two fields. Yet, to my personal understanding, from the literature, it is not becoming entirely clear which relation the concepts actually have. Indeed, both concepts are concerned with inexplicable types of knowledge that require subjective, personal experience and after all appear very similar. What aesthetics adds however, is the criteria for judgement on the basis of organizational knowledge which is "*personal and collectively socially constructed at once"* (Strati, 2016, p. 4). This insight takes into account, the socially constructed taste of individuals who prefer some things, situations, styles, appearances, etc. over others on the basis of their previous experiences in society as such. Thus, especially *organizational* aesthetics adds a more collective flavor to tacit knowledge in an organizational context (Erden, von Krogh and Nonaka, 2008), making it an interesting concept to address calls from contemporary KM ideas, like those illustrated in the introduction.

4. Findings and Conclusion

The first insight we can draw from this brief overview, is that the more mechanistic the definition of knowledge, and with it the more technical the management of such knowledge is, the fewer are the points of contact with aesthetics. This is no surprise, because when knowledge is seen as *access to information* or *personalized information on the basis of structured data*, it is well feasible to make it explicit and describe its structure. Such definitions of knowledge put less emphasize on the tacit component of knowledge that is highly subjective and inexpressible.

Conversely, the strongest tie between KM and (organizational) aesthetics can be found in those approaches that assert high value to individual, subjective knowledge.

When looking deeper into the notion of individual knowledge, in particular tacit knowledge, we find that this knowledge roots in subjective personal experience, which is very similar to, and in part also building on the concepts of aesthetic perception and organizational aesthetics. From the descriptions and definitions in the literature, the concepts appear even so similar that it may be questionable, what the actual differences are.

This would be the first interesting area for further research that I would like to point out. So far, from my experience with both fields, my assumption is that conceptually, tacit knowing and aesthetic knowing appear almost identical in its structure and epistemic roots. However, the difference seems to lie in the aims of the concepts: (organizational) aesthetics is much more about a holistic perspective on organizations (Strati, 1992) and their meaning to us. Aesthetics also has a different "flavor" in that it is about the coherence of a given system (be it a thing, a visual image, a situation or an organization as a whole). This includes the element of connection that manifests in the feeling of *'belonging to'* a system instead of just being *in* a system (Ramirez, 1991). Tacit knowing on the other hand has less of a systemic orientation but rather addresses the individual *knowing* of skills and the capacity to find and solve ill-defined problems.

By any means, if we seek to expand our knowledge of organizations in general, and also facets of particular organizations, we might want to consider aesthetics as an additional source for valuable insight. The knowledge that aesthetics promises, concerns in particular knowledge about belonging to a system or what fits or does not fit into a given system, context or organizations respectively.

From the perspective of KM we could inquire into aesthetics by asking (for example) questions about how to implement a particular aesthetic, how to describe such an aesthetic, how to sensitize people for aesthetic perceptions or how to enable meaningful experience in an organizational context. Knowledge derived from aesthetics could be especially beneficial to deal with uncertainty (Kerschbaum, 2022) and to develop an organizations intention, vision (Nonaka, 1995; Nonaka and Takeuchi, 2021) but also to influence an organizations shared frame of reference to facilitate change (White, 1996).

Yet, the big question in the end is, whether these questions are (still) in the scope of KM, and will hence be an area of interest in the future. Is it just the *management* of knowledge (providing ideal solutions for a mostly given problem) and the focus on making knowledge tangible, or is it rather about *facilitating* holistic knowledge to lead innovation – the appreciation of a sense of *responsibility for the pursuit of a hidden truth, which demands his services for revealing it* (Polanyi and Sen, 2009, p. 25)*,* that drives the field of KM in the future?

Abstract: Innovation is becoming a survival strategy for academic libraries, which strive to preserve their relevance and contribution. Knowledge sharing (KS) is believed to be an important factor in creating innovative capabilities and improving innovation. Yet, only scant empirical research has investigated the possible effect of KS on service innovation (SEI). This study adopted a research model to analyze the effect of KS on SEI as well as the mediating effects of information technology innovation (ITI) and management innovation (MIN) on the relationship between KS and SEI. The results are derived using a data set from two large academic libraries in Egypt. Although KS has a significant total effect on SEI, its role in augmenting SEI is only secondary since it depends mainly on the mediating roles of ITI and MIN. These results are interesting because they deviate from the assumptions and results of many previous studies on KS and SEI.

Keywords: Service innovation, Knowledge sharing, IT innovation, Management innovation, Academic libraries

1. Introduction

Academic libraries have recently experienced immense pressure to maintain their value and service to user communities (Brundy, 2015; Yeh and Walter, 2017). With the emergence of numerous information technology (IT)-related innovations, the transition to digital services, and increased demands for new services, users have been abandoning academic libraries (Islam, Agarwal, and Ikeda, 2017). Hence, academic libraries consider service innovation (SEI) a strategic imperative for sustaining value and transforming their service in the emerging digital environment (Li, 2006; Islam, Agarwal, and Ikeda, 2017; Goddard, 2020).

However, the extant literature recommends knowledge sharing (KS) as an important factor influencing innovation capabilities and innovation performance (e.g., Darroch and McNaughton, 2002; Kaewchur, Anussornnitisarn, and Pastuszak, 2013; Pacios, 2020). KS presumably increases accessibility to new knowledge, improves decision-making, and augments innovation capability (Nonaka, Von Krogh, and Voelpel, 2006). Yet, research on innovation in academic libraries is scattered (Brundy, 2015), and quantitative studies investigating KS and innovation services in libraries are limited (Islam, Agarwal, and Ikeda, 2017).

This study proposes that KS may not necessarily improve SEI if it doesn't simultaneously improve IT innovation (ITI) and management innovation (MIN) (Darroch and McNaughton, 2002). It adopts a research model to hypothesize and test the mediating effect of ITI and MIN on the relationship between KS and SEI in academic libraries. The results of this research will provide empirical evidence that contributes to the growing body of knowledge on KS and innovation and help academic library leaders chart directions for improving service innovation (Brundy, 2015).

2. Theoretical Background

Damanpour and Aravind (2012) classify innovation into technical and non-technical categories. The non-technical innovation includes the overlapping MIN and administrative innovations (Birkinshaw, Hamel, and Mol, 2008; Khosravi, Newton, and Rezvani, 2019). Technical innovation refers to product, service, or process innovations (Walker, Damanpour, and Devece, 2011; Damanpour, 2014). In this study, ITI is considered a technological innovation, which denotes the adoption of advanced information technologies and systems to significantly improve organizational processes, management practice (e.g., MIN), and organizational outcomes (e.g., SEI). Innovation, particularly SEI, is central for academic libraries to continuously grow and survive (Li, 2006; Vaughan, 2013; Brundy, 2015; Islam, Agarwal, and Ikeda, 2017; Yeh and Walter, 2017). SEI in academic libraries may include changing the existing library service programs in response to the changing needs of users, introducing new IT-enabled service programs, and presenting new services that support new paradigms of teaching and research (Walter and Lankes, 2015).

KS is viewed as the process of transferring experience and organizational knowledge to business processes through communication channels between individuals (Oyemomi, Neaga, and Alkhuraiji, 2016). KS is an essential process for innovation. Through KS, employees can mutually exchange their knowledge and contribute to innovation (Ye, Liu, and Tan, 2021). Besides, through interaction, modification, and common consensus, an idea

or concept transforms into a different innovative idea, and the knowledge grows in a spiral cycle that helps boost innovation performance (Wang et al, 2021). Academic librarians could generate creative and implementable SEI ideas based on organizational knowledge and knowledge from direct user contact. Although KS is assumed to play a significant role in SEI generation and improvement, we argue that this role could be augmented and mediated by ITI and MI.

ITI includes the creation or use of new technologies to facilitate and provide services to customers (De Vries, Bekkers, and Tummers, 2016). The service innovation capability of a library depends on its employees' and users' knowledge and skills, culture, IT adoption, and routines for new service development (Islam, Agarwal, and Ikeda, 2017). The innovative use of IT capabilities could, and has, transformed library services from traditional services (e.g., card catalogs, printed books and periodicals, bibliographic instruction, in-person, or face-to-face reference) to new services and delivery modes such as electronic collections (e.g., e-books, e-journals, and databases), virtual reference services, and other online services. Academic libraries need to continue exploiting new IT systems to offer services in innovative ways to meet the changing needs of users (Moyo, 2004).

MIN denotes the development and use of new approaches for performing the work of management, new organizational strategy and structure, and new processes that produce changes in the organization's managerial procedures and administrative systems (e.g., Birkinshaw, Hamel, and Mol, 2008; Damanpour and Aravind, 2012; Damanpour, 2014; De Vries, Bekkers, and Tummers, 2016). MIN presents a distinct departure from traditional management principles, processes, and practices to the establishment of new management practices intended to enhance organizational performance (Mol and Birkinshaw, 2009). To facilitate SEI, managers should be innovative leaders who foster an innovation-supportive culture, tie performance evaluations and rewards to innovation outcomes, and create dedicated innovation teams with high levels of decision-making autonomy (Yeh and Walter, 2017).

3. Research Model and Hypotheses

3.1 Research Model

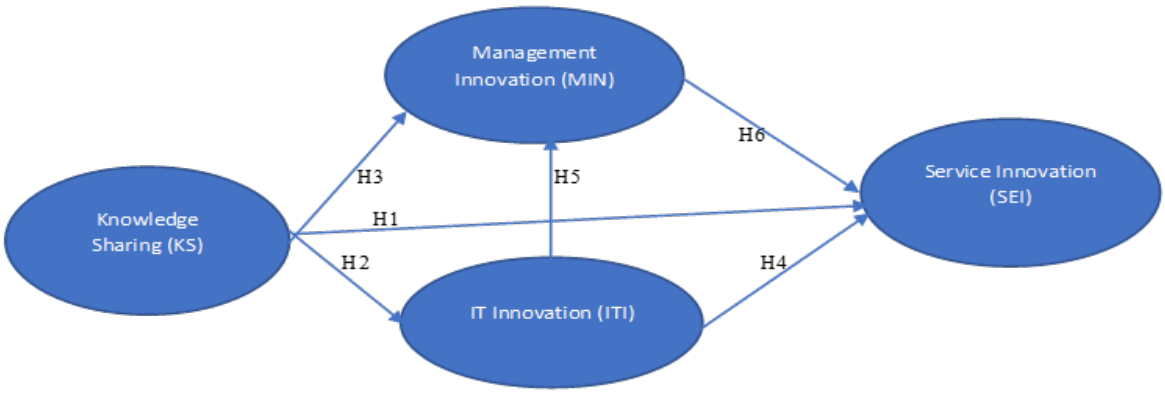

Figure 1: The Research Model

Figure 1 depicts the research model. The model has been constructed based on our review of the relevant literature. The model examines the possible influence of KS on SEI and evaluates the mediating roles of MIN and ITI in the relationship between KS and SEI.

3.2 Research Hypotheses

3.2.1 Knowledge sharing (KS) influence

The extant literature suggests a strong link between KS and innovation performance in organizations (e.g., Kamaşak and Bulutlar, 2010; Wang and Wang, 2012; Saenz, Aramburu, and Blanco, 2012; Kaewchur, Anussornnitisarn, and Pastuszak, 2013; Podrug, Filipovic, and Kovac, 2017; Pacios, 2020; Goddard, 2020). As such, innovation depends on KS (Castaneda and Cuellar, 2020). Although the results of the scanty research on the relationship between KS and SEI in academic libraries are inconclusive (e.g., Islam, Agarwal, and Ikeda, 2017), we predict KS will influence SEI in the investigated academic libraries.

H1: Knowledge sharing (KS) has a positive effect on service innovation (SEI).

Numerous studies (e.g., Davison, Ou, and Martinsons, 2013; Witherspoon et al, 2013; Norek, 2013; Ibrahim, Mohamad, and Shah, 2020; Yepes and López, 2023) report assumptions and results in support of a directional relationship from IT to KS. However, we propose that KS is a likely antecedent of ITI. Since KS is a social and organizational process, it arguably influences ITI. A fitting human resources practice in an organization could create a commitment-based environment and establish an appropriate organizational social climate (Nahapiet and Ghoshal, 1998), which motivates employees to work together and share knowledge. This, in turn, may drive the need to adopt a contemporary IT infrastructure to facilitate KS (Collins and Smith, 2006). Although the literature is short on empirical evidence on the effect of KS on ITI, we propose that KS will influence ITI.

H2: Knowledge sharing (KS) has a positive effect on IT innovation (ITI).

Mol and Birkinshaw (2009) underline the importance of knowledge sources as stimuli for the introduction of new management practices. In addition, resource-based and knowledge-based views claim that organizations with large stocks of resources and knowledge are more likely to successfully introduce new MIN (Mol and Birkinshaw, 2009). Also, knowledge management (KM), which aims to acquire, share, use, and develop knowledge (Chang and Lee, 2008), and organizational learning, which allows the development, acquisition, and transformation of knowledge, should help develop novel ideas for management practice (Camisón and Villar-López, 2011; de Souza Bermejo et al, 2015; Khosravi, Newton, and Rezvani, 2019). Hence, we predict that KS will influence MIN in the investigated academic libraries.

H3: Knowledge sharing (KS) has a positive effect on management innovation (MIN).

3.2.2 IT innovation (ITI) influence

Effective utilization of ITI (e.g., communication infrastructures, groupware, e-mail, document management, data warehousing, workflow software, decision support systems, portal sites, social networks, on-line knowledge sharing, and discussion support systems) enables employees to interact and share knowledge and information, which could in turn influence service or product innovation (e.g., Pérez-González, Trigueros-Preciado, and Popa, 2017; Islam, Agarwal, and Ikeda, 2017). Also, information synergy and IT capability can enhance an organization's capacity to generate new ideas and improve organizational performance (Kaewchur, Anussornnitisarn, and Pastuszak, 2013). Hence, we predict that ITI will influence SEI in the investigated libraries.

H4: IT innovation (ITI) has a positive effect on service innovation (SEI).

The introduction of new IT and new information systems for management purposes is an important dimension of MIN (e.g., Walker, R. M., Damanpour, F., and Devece, 2011; Hecker and Ganter, 2013; Kraśnicka, Głód, and Wronka, 2016) and a source for innovation (Borins, 2001). In addition, Hecker and Ganter (2013) believe that KS and organizational practices evolving from the use of modern IT are important elements of MIN. Similarly, Černe, Jaklič, and Škerlavaj (2013) denote that KS improves MIN by utilizing IT systems to facilitate information and knowledge flow. Therefore, we predict that ITI will influence MIN in the investigated libraries.

H5: IT innovation (ITI) has a positive effect on management innovation (MIN).

3.2.3 Management innovation (MIN) influence

MIN practice provides valued working practices and organizational flexibility that could expand the ability to adopt new processes or technological innovations (e.g., products and services) (Le Bas, Mothe, and Nguyen-Thi, 2015; Kraśnicka, Głód, and Wronka, 2016; Khosravi, Newton, and Rezvani, 2019). Moreover, innovative managers can inspire their employees to be innovative and to search for new ideas, products, services, or processes (Mol and Birkinshaw, 2009; Cavagnoli, 2011; Hollen, Van Den Bosch, and Volberda, 2013). Yet, empirical studies on the relationship between MIN and SEI are sparse (Khosravi, Newton, and Rezvani, 2019). We propose that MIN will influence SEI in the investigated libraries.

H6: Management innovation (MIN) has a positive effect on service innovation (SEI).

4. Research Method

4.1 Measurement

The constructs in the research model were operationalized and measured using multi-item reflective measures, based on measures previously used in the relevant literature (e.g., Yu et al., 2010; Walker et al., 2011; Islam et al. 2017; Awais and Ameen, 2019; Gunjal, 2017)) and revised as necessary. The measuring scales include KS (10

items), ITI (9 items), MIN (8 items), and SEI (10 items). Examples of KS items are "I share my knowledge and service-related lessons learned with my colleagues across the library" and "I share my knowledge on users' needs and ideas for service improvement with my colleagues through conversations and dialogues." Examples of ITI items are "The library provides links to full-text search results through its online catalog" and "The library has a technical support staff that helps initiate and provide first-rate services." Examples of MIN items are "The library management adjusts its organizational structures on a regular basis" and "The library administration occasionally changes policies to enhance library services." And examples of SEI include "The library offers new services as a result of users' needs analysis" and "The library innovates new services and programs through knowledge sharing among its staff." All items were measured using five-point scales, ranging from "1" (strongly disagree) to "5" (strongly agree).

4.2 Population and Sample

The population for this research includes only the librarians who are directly involved in providing library service in the academic library at Cairo University (110 employees) and the academic library at American University (89 employees). A survey was developed to collect the data using a non-probability convenience sample. A total of 105 complete responses were collected (55 responses from Cairo University and 50 responses from the American University), with a response rate of 52.7%.

4.3 Sample Profile

The female informants in the sample are 50.5% (n = 53), and 90.5% of the informants hold bachelor's or higher degrees. In addition, 42.9% have degrees in library and information sciences, 27.6% are managers, and 53.3% have at least 15 years of experience.

5. Analysis and Results

We first performed a preliminary evaluation of the measurement model via a confirmatory factor analysis to describe relationships between hidden variables of the model (Wu et al, 2016) and to verify the reliability and convergent validity of the constructs. Table 1 summarizes the resultant measurement model. Notably, some items have been excluded to enhance the reliability of the measurement model. In addition, the SEI construct analysis reveals the emergence of two factors: 'personalized service innovation' (PSI) and 'web-enabled service innovation' (WSI). The results suggest that, aside from WSI, all constructs in the model have adequate reliability ($\alpha \geq 0.70$), convergent validity (AVE ≥ 0.50), and factor loadings (≥ 0.60; Hair, Barry, and Rolph, 2010).

Table 1. The Confirmatory Factor Analysis Results

Dimensions	Factor Loading	Reliability Coefficient (α)	Average Variance Explained (AVE)
Knowledge Sharing (KS)		0.800	0.636
KS2	.772		
KS3	.786		
KS4	.766		
KS7	.661		
Management Innovation (MIN)		0.912	0.742
MIN3	.821		
MIN4	.724		
MIN5	.812		
MIN7	.701		
MIN8	.807		
IT Innovation (ITI)		0.865	0.656
ITI3	.625		
ITI4	.639		
ITI5	.787		

Dimensions	Factor Loading	Reliability Coefficient (α)	Average Variance Explained (AVE)
ITI6	.706		
ITI7	.682		
Personalized Service Innovation (PSI)		0.807	0.640
SEI1	.721		
SEI2	.748		
SEI4	.627		
SEI5	.638		
Web-Enabled Service Innovation (WSI)		0.677	0.608
SEI7	.645		
SEI8	.731		
SEI9	.751		
OVERALL MODEL		0.926	0.691

We revised the research model and hypotheses to reflect the results of the confirmatory factor analysis. Table 2 displays the original and revised research hypotheses.

Table 2: The Original and Revised Research Hypotheses

Original Hypotheses	Revised Hypotheses
H1: Knowledge sharing (KS) has a positive effect on service innovation (SEI).	H1a: Knowledge sharing (KS) has a positive effect on personalized service innovation (PSI). H1b: Knowledge sharing (KS) has a positive effect on web-enabled service innovation (WSI).
H4: IT innovation (ITI) has a positive effect on service innovation (SEI).	H4a: IT innovation (ITI) has a positive effect on personalized service innovation (PSI). H4b: IT innovation (ITI) has a positive effect on web-enabled service innovation (WSI).
H6: Management innovation (MIN) has a positive effect on service innovation (SEI).	H6a: Management innovation (MIN) has a positive effect on personalized service innovation (PSI). H6b: Management innovation (MIN) has a positive effect on web-enabled service innovation (WSI).

Table 3 provides descriptive statistics for the research variables. Overall, and based on the means and the related p-values, the respondents agree that they share significant knowledge and experience with colleagues, their libraries adopt various ITI innovations, their administrators adopt diverse forms of managerial innovations, and their libraries provide user communities with both innovative personalized service (PSI) and innovative web-enabled service (WSI).

Next, we used the Partial Least Squares Sequential Structural Modeling (PLS-SEM) method to further verify the measurement model fit, evaluate a predictive model for the data set, and test the research hypotheses. Hence, we utilized the Smart PLS 4.0 software, and the bootstrapping method run by 5,000 subsamples (Sarstedt et al, 2016) to assess both the measurement and structural models.

Table 3: Descriptive Statistics

	Min	Max	Mean	Std. Dev	t-Value	P-Value
KS	1.00	5.00	3.9281	.64014	14.856	<.001
MIN	1.00	5.00	3.6935	.80901	8.783	<.001
ITI	2.60	5.00	4.2079	.63893	19.373	<.001
PSI	2.01	5.03	3.9193	.67606	13.934	<.001
WSI	1.61	5.00	4.0529	.63537	16.981	<.001

Note: The difference from 3 (the midpoint of the scale) is significant at $p \leq 0.05$.

5.1 Assessment of the Measurement Model

The measurement model assessment further verifies the reliability and validity of the constructs. The assessment entails examining the internal consistency, reliability, convergent validity, and discriminant validity of the adapted measures (Marcoulides and Saunders, 2006). Table 4 summarizes the results. Except for WSI, all alpha coefficients fall within the recommended range (0.70–0.95; Hair et al, 2019). Also, each construct explains greater than 50% of the indicator's variance, thus providing acceptable item reliability (Hair et al, 2019; Sarstedt, Ringle, and Hair, 2021). All composite reliability coefficients are well above the recommended threshold (≥ 0.50; Hair et al, 2019), which demonstrates the reliability of the adapted measures. We also assessed the convergence validity of the measurement model by examining the AVE values, and all AVEs are above the recommended threshold (≥ 0.50; Hair et al, 2019). We finally assessed the discriminant validity of the measures following Fornell and Larcker's (1981) criterion. The results indicate the existence of discriminant validity since the square root of the latent variables' AVEs is greater than the correlation that each construct has with the other constructs.

Table 4: Construct Reliability and Validity

Constructs	Cronbach's Alpha (α)	Composite Reliability	Average Variance Extracted (AVE)
KS	0.808	0.815	0.636
MIN	0.913	0.915	0.741
ITI	0.868	0.875	0.655
PSI	0.812	0.818	0.640
WSI	0.677	0.708	0.606

5.2 Assessment of the Structural Model

We adopted procedures that have been specifically designed to assess the adequacy of the prediction-oriented PLS-SEM models (Shmueli et al, 2016) to assess the structural model. Figure 2 depicts the consequential model, which shows the direct effects of the different paths. The R^2 values for the two endogenous variables in the model (PSI and WSI) are 0.468 and 0.367, respectively. These results suggest that the model has moderate explanatory power as well as a modest predictive relevance (Hair, Barry, and Rolph, 2010). In addition, since the SRMR index is 0.078 (< 0.08), the model is adequately fitted, although the NFI index (0.726) is relatively lower than the recommended threshold (≥ 0.90; Henseler, Hubona, and Ray, 2016).

5.3 Testing the Hypotheses

Table 5 depicts the causal relationships (paths) between the exogenous and endogenous variables in the structural model, along with It also shows the total path coefficients, t-values, and p-values. The total path coefficients, which determine the magnitude of the direct and indirect effects that the exogenous variables have on the endogenous variables, are used to test the revised research hypotheses. Although KS has non-significant direct effects on PSI and WSI, its significant total indirect positive effects make its total positive effects on PSI and WSI significant. KS also has significant positive effects on ITI and MIN. In addition, ITI has significant positive effects on PSI and MIN. MIN, however, has a significant positive effect on PSI and a non-significant positive effect on WSI. These results support the acceptance of all hypotheses except H6b.

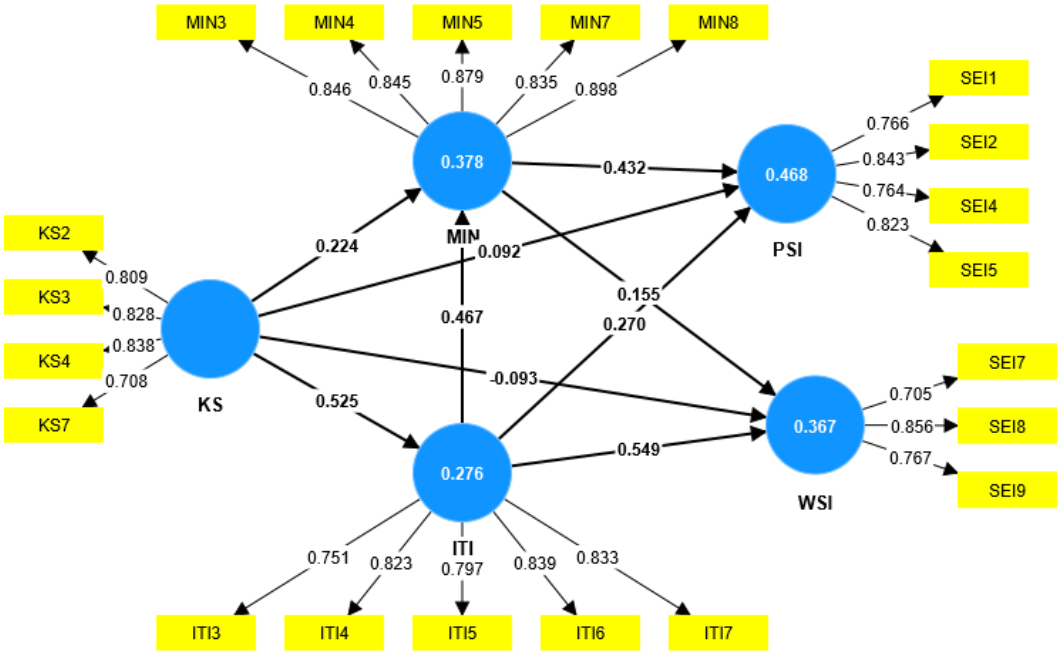

Figure 2: The Consequential Model

Table 5: Path Coefficients

Paths	Path Coefficient	t-Value	P-Value	Significance*	Hypothesis
Total Effects:					
KS -> PSI	0.437	4.235	0.000	S	H1a
KS -> WSI	0.268	2.4	0.016	S	H1b
KS -> ITI	0.525	6.076	0.000	S	H2
KS -> MIN	0.469	4.542	0.000	S	H3
ITI -> PSI	0.472	5.133	0.000	S	H4a
ITI -> WSI	0.622	5.818	0.000	S	H4b
ITI -> MIN	0.467	5.029	0.000	S	H5
MIN -> PSI	0.432	4.341	0.000	S	H6a
MIN -> WSI	0.155	1.387	0.166	NS	H6b

* S = Significant, NS = Not Significant

6. Discussion

Our results disclose that the investigated libraries provide noteworthy innovative services (SEI) to their user communities. More specifically, they offer personalized service innovation (PSI) and web-enabled service innovation (WSI). The PSI includes new services and programs (e.g., digital publishing for various information sources, seminars, and workshops on online and library search, etc.) for different user groups based on the analysis of users' needs and the sharing of knowledge among staff members. The WSI includes IT-enabled services made available to users via the web (e.g., service to scientific research projects, use of RSS to inform users about new collections, reservation of library resources and collections, inter-library loan service, etc.). In addition, the results demonstrate that KS, MIN, and ITI are important drivers of the two types of service innovation (PSI and WSI). Collectively, KS, MIN, and ITI explain 47% and 37% of the variances in PSI and WSI, respectively. Subsequently, our research model has moderate explanatory power and modest predictive relevance.

Notably, the employees in the investigated libraries reportedly share personal and organizational knowledge via different communication channels; and KS has significant total effects on PSI and WSI, although the direct effects

of KS on these two types of service innovation are insignificant. In particular, the significant total indirect effect KS has on PSI occurs through the significant indirect specific effects of the KS-ITI-PSI and KS-ITI-MIN-PSI paths, and the significant total indirect effect that KS has on WSI occurs through the significant indirect specific effect of the KS-ITI-WSI path. Compared to MIN, ITI plays a stronger mediating role between KS and service innovation (i.e., PSI and WSI).

These results, however, challenge the assumption of the existence of a direct relationship between KS and organizational performance (e.g., SEI) reported in numerous previous studies. They confirm that KS plays only a supporting role in generating service innovation. Sharing knowledge and experience among employees improves service innovation only when it brings about improvements in other innovation areas such as MIN and ITI practices. This supporting role of KS in stimulating service innovation substantiates Darroch and McNaughton's (2002) conclusion that KS provides only indirect support for innovation.

7. Implications

The results of this study have both theoretical and practical implications. As to the theoretical implications, this study supplements the scanty empirical research on innovation, particularly in service organizations. Its empirical results contribute to the growing body of knowledge on innovation management and its influencing factors in academic libraries. Although KS has been recognized in the literature as a significant contributor to product/service innovation development, it is important to recognize that the role of KS is only secondary and is contingent on whether it simultaneously contributes to the development of other innovations (e.g., ITI and MIN) in an organization. This is an intriguing result since it departs from the assumptions and results of previous studies on KS and SEI. In addition, innovations (e.g., ITI, MIN, and SEI) are seemingly interrelated, and the relationships among innovation types are likely bi-directional. Researchers may therefore further investigate and verify the assumed two-way relationships among innovation types and between innovation types and KS in different settings.

Libraries need to develop innovation strategies bearing in mind that innovations (e.g., managerial, IT, service, process, social, etc.) are interrelated. If they seek to improve service innovation to meet the demands of their users, they should simultaneously promote their management and IT innovations and encourage their employees to share more knowledge. Hence, the innovation strategy for a library should guide the preparation and execution of plans designed to develop an innovation portfolio suitable to the library's mission and objectives. The plans should be backed up with the requisite human resources and IT infrastructure (Vaughan, 2013). Senior managers should manage the human resources allocation and training processes to create a team of "movers and shakers" (Yeh and Walter, 2017). Senior managers should manage the human resources allocation and training processes to create a team of "movers and shakers" (Yeh and Walter, 2017), who willingly share knowledge and experience among themselves and with users.

8. Conclusions

Knowledge sharing (KS) is viewed as an important factor in creating innovative capabilities and improving innovation (Kaewchur, Anussornnitisarn, and Pastuszak, 2013; Pacios, 2020). Yet, quantitative studies investigating KS and service innovation (SEI) in academic libraries are limited (Brundy, 2015; Islam, Agarwal, and Ikeda, 2017), and information on the possible interdependence of the different types of innovations and their potential effect on SEI is deficient. This study provides empirical evidence on the effect of KS on SEI as well as the mediating effect of management innovation (MIN) and IT innovation (ITI) on the relation between KS and SEI in the investigated academic libraries. The results imply that KS plays only a secondary role in influencing SEI, and the mediating roles of MIN and ITI are essential for KS to spawn SEI. These results, however, should be interpreted considering their limitations, as they are derived from perceptual, cross-sectional data drawn from two Egyptian academic libraries. Particularly, the generalizability of these results may be challenged by potential cultural and policy differences across libraries and nations.

Abstract: Value orientations are fundamental in the development of young people as individuals. Values play a special role in shaping the behavior and attitudes of young people, have a significant impact on their goals and beliefs. The main focus of the study is the values and social issues of students at the Kazakh National Women's Teacher Training University. The University was established on August 15, 1944. In this research, we particularly define future goals of the students at Women's Teacher Training University, their opinion about the University and the learning process. The main purpose of this study is to assess the attitudes of students towards obtaining a mixed (joint) education. Mixed education, also known as blended learning, co-education (abbreviated as co-ed or coed), is an education in which male and female students study/learn together. The study involved 5 005 female students of all faculties at the undergraduate, graduate and postgraduate levels, as well as college students (University has its college) at Kazakh National Women's Teacher Training University. Survey dates: October 15, 2021 - November 15, 2021. In the course of the study, it was found that the value orientations of students are focused, first of all, on the priorities in the field of education, that is, the orientation towards obtaining a unique education in a prestigious university, the preference for free education; location of the university, favorable socio-cultural environment, the level of information and technical support of the educational process. In addition, expectations for the future are focused on getting a prestigious, interesting, high-paying job that matches individual abilities and opportunities. The results of the study obtained during the survey can be used to analyze the attitude of female students towards mixed education; to study the quality of the provision of university services; studying students' satisfaction with the educational process; studying the difficulties faced by students in the learning process; and to determine what opportunities provided by the university are used by the student for personal development and activity.

Keywords: Value orientations, Values, Youth, Students, University, Educational process, Gender education, Mixed education

1. Introduction

The current stage of development of society, the individual and the state stimulates and determines the formation of new types of thinking. In the context of informatization of society and education, new opportunities appear to improve the effectiveness of the educational process. Society has undergone dramatic changes over the past ten years. The model of behavior and value orientations of modern society is changing. Education also cannot remain outside this process. The problem of developing young people's values, their structure and dynamics in a reformed society always remains relevant at all stages of society's life. Value orientations are fundamental in the development of young people as individuals. Values include a special role in shaping the behavior and activities of young people, values have a significant impact on the actions of young people and are reflected in goals, ideals, and beliefs.

Value orientations - is the attitude of the individual to material and spiritual goods, which are considered as objects, goals and means of meeting the needs of the group.

Each person has different value orientations and value systems. They change under the influence of internal attitudes, environmental conditions, including the socio-cultural environment of the university. At this stage of professional training the personality of the students is formed, their moral and professional qualities are improved, and the range of their values is determined.

The factors that form value orientations include material and economic; socio-psychological; socio-demographic (gender); age demographic; educational, etc.

Young people are most often a social group that indicate changes. They are prone to experiments, constantly changing their image, are more flexible (including ideas about gender norms and relationships) [Ioffe et al., 2020]. However, at present, the youth environment is heterogeneous, gender norms and the corresponding

roles can differ significantly in different social groups. Significantly increased the role of the subject of personality, manifested in the activity, independence, initiative of a person in professional, social and personal life, demonstrating at the same time a huge range of content of uniqueness, and their variability. That is what J. Butler called the structuring of similarity in acts of self-expression and self-presentation [Butler, 2000], later J. Kroger called this the illusion of similarity or inevitability [Kroger, 2007].

Kazakhstan is a large country, and there are contradictions in the development of the capital city and regions in terms of the specifics of socio-cultural, economic and educational conditions. We can assume that there are significant differences in the mentality of students living in big cities and smaller towns. The problem of youth is currently relevant in all aspects, however, there is incomplete elaboration of youth issues, absence of monitoring work, and also due to the fact that the views of young people are not asked and are not taken into account when considering important issues. Therefore, the Center for Social and Gender studies conducted a sociological study among students, undergraduate and graduate students of Kazakh National Women's Teacher Training University, in order to find out their opinions and thoughts.

The Kazakh National Women's Teacher Training University was founded on August 15, 1944 and ever since is educating only girls. . It has become the "forge of teachers" and strives to improve the quality of educational services and research potential provided by one of the leading pedagogical (teacher training) universities in Kazakhstan. It is only university in Central Asia that provides education only for female students. After 1954, government was considering of closing the university several times, but the authorities decided to keep the university [Kazakh National Women's Teacher Training University, 2019]. However, over time, the question arose whether this university was needed only for girls, or whether boys could also be taught there. In this regard, in order to determine this opinion, the idea arose to conduct such a sociological study among students of this university.

In determining the significance of the study, the focus was on the social problems of students at the university, the definition of their goals and the strategies used to achieve these goals, as well as the study of important questions and opinions about the educational institution during the educational process at the university, defining opinions about the present and future of the university. The main purpose of the study is to assess the attitude of students to obtaining a mixed education of boys and girls at the university. It is planned to determine the directions for further development of the university by determining the opinions of students on these issues. In connection with modern global changes, by defining the purpose of the study, the value orientations of young people studying at the university and their opinions on important issues related to the university will be identified, and recommendations will be developed to improve the quality of education and develop infrastructure in Kazakh National Women's Teacher Training University.

2. Literature Review

Value orientations of students of various universities of the CIS countries and the world

Various studies have been carried out on this topic of value orientations of students. In the literature, attention was paid to various aspects related to the study of moral ideals, they are reflected in the work of H.A. Berdyaeva, S.N. Bulgakov, F.M. Dostoevsky, I.A. Ilyina, P.N. Milyukova, V.V. Rozanova, V.S. Solovyova, P.A. Sorokina and others.The psychology of value orientations was studied in the works of B.G. Ananyeva, L.I. Bozhovich, B.I. Dodonova, A.G. Kovaleva, K.K. Platonova, S.L. Rubinstein, T.G. Sukhanskaya and others. A significant contribution to the foundation of the theory of values orientations was made by the sociologists W. Thomas and F. Znanetsky, who developed the concept of "social value". G. Rickert and M. Weber substantiated the method of "value relation". On the other hand, recent research focuses on the value orientation of university students, the transformation of value orientations of students; generational differences in value orientations towards higher education, etc. Thus, according to Slávka Čepelová and Silvia Barnová, along with a value orientation, focusing on the values of knowledge, education and economic aspects leads to an improvement in the quality of life; a better quality of life is determined by a value orientation focused on areas of knowledge, education, and economic values [Čepelová, Barnová 2020].

Value orientation research raises important issues presented by research on a range of topics, including the content of student value orientations that are transformed by virtual behaviors (Akhmadieva et al. 2016). The sensitivity of orientations at the level of both generations to the influences of gender and status (Meier 1970), assessments of students' views on the role of the online learning environment in shaping the value orientations of university students (Shabden et al. 2022).

The analysis of value orientations, at the cultural level, are analyzed in the studies of Geert Hofstede. Hofstede carried out his studies in the 1960s and 1970s and examines cross-cultural differences. Hofstede developed the

theory of cultural dimensions, that was based on value orientations of national cultures (Hofstede 1991; Hofstede 2014). Today, Hofstede's cultural values are used in the field of business, management, and organizational psychology (Soares et al. 2007; De Mooij, Hofstede 2010; Dubina, Ramos 2019). Hofstede's cultural dimensions can be taken into account in the analysis of value orientations of university students. Some studies show that the study of value orientations at the individual level can be helpful in examining the university students' personal and professional development (Bogomaz, Atamanova 2017).

The social-cognitive approach emphasizes the important role of students' beliefs and their interpretations of actual events, and the role of the achievement context for motivational dynamics (Weiner 1992; Pintrich et al. 1993; Wigfield, Cambria 2010). Social cognitive models of achievement motivation have several motivation constructs that can be organized in two broad categories: students' beliefs about their capability to perform a task, also called expectancy components, and their motivational beliefs about their reasons for choosing to do a task, also called value components (Pintrich et al. 1993). The literature on motivation constructs is extensive (Wigfield, Cambria 2010). In order to gain a comprehensive picture of the relation between students' motivation and their academic achievement, we can look at a traditional personality model of motivation, the theory of the achievement motive (McClelland et al. 1953). This model shows that students' motivation is conceptualized as a relatively stable trait. Students' goal orientations are broader cognitive orientations that they have toward their learning and reflect the reasons for doing a task (Dweck, Leggett 1988). McClelland et al. distinguish the achievement motives hope for success and fear of failure (McClelland, Atkinson 1953). In addition, the need for achievement is theorized to be domain-general and, therefore, assessed without referring to a certain domain or situation (Steinmayr, Spinath 2009).

3. Method

Questionnaire design

Method. On the basis of the designed questionnaire, the method of surveying students was used, that is, a quantitative research method, using descriptive statistics.

Research coverage. Sociological research conducted on the basis of Kazakh National Women's Teacher Training University.

*The target audience***.** Undergraduate and graduate students of the Institute of Pedagogy and Psychology; Institute of the Kazakh and world languages; Institute of Physics, Mathematics and Computing; Institute of Natural Sciences; Institute of Social Sciences, Humanities and Art; students of the College of Professional Education.

Total number of respondents: in total 5005 students, undergraduates and graduate students (1.2 courses), and college students of all faculties of the university took part in the study.

Research tool. The questionnaire was compiled by specialists from the Center for Social and Gender studies at Kazakh National Women's Teacher Training University. An anonymous survey was conducted based on a stratified random sample.

Online questionnaire was used to collect the data. Survey responses were automatically collected in Google Forms and IBM SPSS 22 (Statistical Package for the Social Sciences) was used to process the overall numerical information. This study do not require formal ethical approval because an anonymous survey was used to collect data. Questionnaires in Kazakh and Russian languages were developed.

The number of questions in the questionnaire is 17.

Survey Dates: October 15, 2021 - November 15, 2021.

4. Results and Discussion

Demographic data contains accurate information about the age, nationality, place of birth, status of settlements, marital status, financial situation of the respondents' families. The study involved 5005 respondents – undergraduate, graduate students, and college students of the university. In percentage terms, the age groups are distributed as shown in Figure 1.

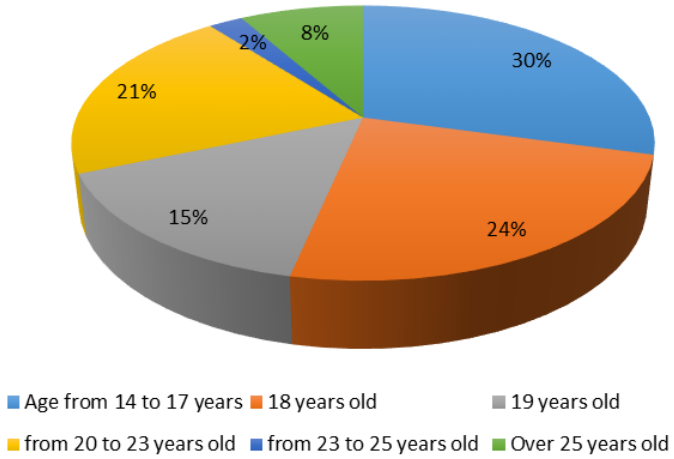

Figure 1: Age of Respondents

In the course of the study, an analysis of students was carried out according to national characteristics. Respondents' answers about their nationalities were the following: 89.77% - Kazakhs, 1.30% - Russians, 3.76% - Uighurs, 0.06% - Dungans, 0.32% - Tatars, 0.14% - Koreans, 0.02% - Armenians, 0.02% - Belarusians, 0.02% - Greeks, 0.22% - Azerbaijanis, 0.02% - Kurdish, 0.22% - Karakalpaks, 0.06% - Kyrgyz, 0.04% - Germans , 3.78% - Uzbeks, 0.02% - Polish, 0.02% - Gypsies, 0.18% - Turkish, 0.02% - Ukrainians and 0.02% - Chechens (Figure 2).

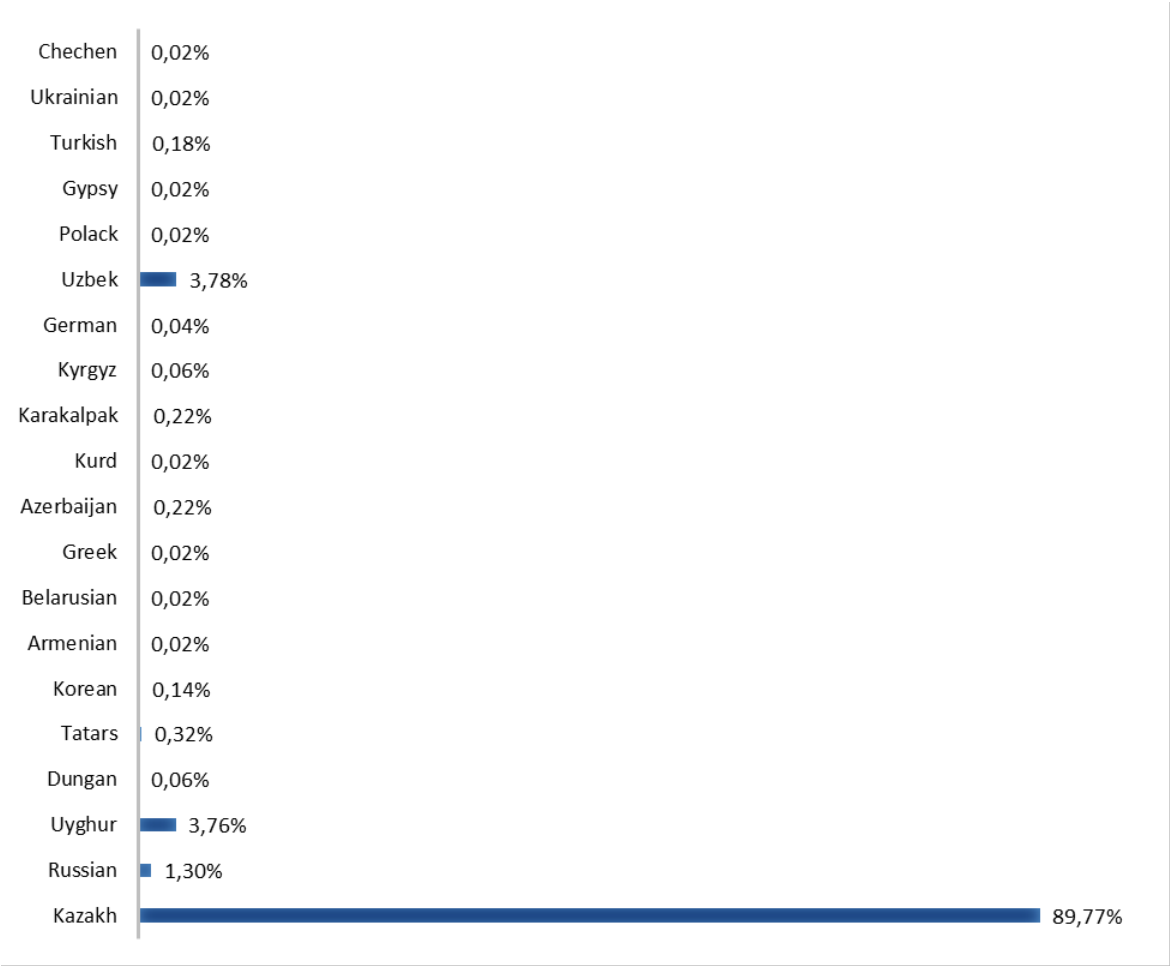

Figure 2: Nationality of Respondents

The majority of respondents (56%) are from the rural areas. Thirty percent of the students are from the cities (Figure 3).

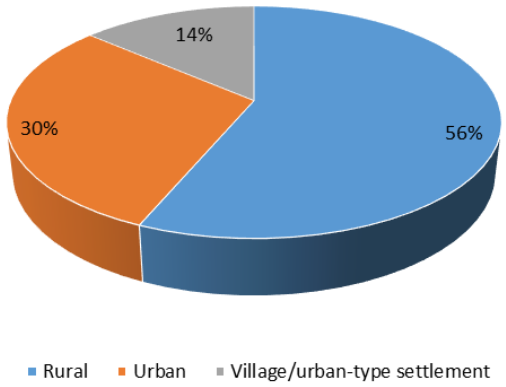

Figure 3: Place of Settlement of the Respondents

In addition, some factors determining the choice ask the following questions.

The research covers respondents studying at all levels of education: from undergraduate 1-4 courses to Master and PhD students. Particularly, 1st year students - 40.94%, 2nd year - 21.36%, 3rd year – 12.33%, 4th year bachelor's degree - 10.79%, master's degree - 3.80%, PhD student – 0.74%, 1st year (college) - 6.61%, 2nd year (college) - 2.94%, 3rd year (college) - 0.50% (Figure 4).

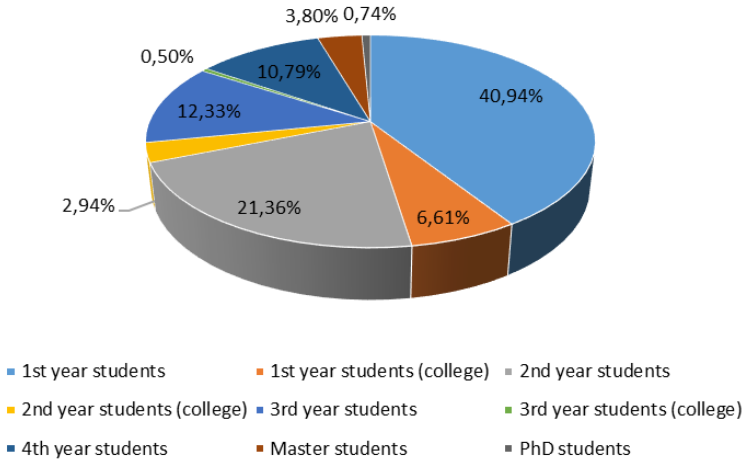

Figure 4: Distribution of Respondents by Course of Study

The overall distribution of respondents by institutes and colleges is presented as follows (Figure 5):

- Institute of Pedagogy and Psychology - 24%;
- Institute of the Kazakh and world languages - 23%;
- Institute of Physics, Mathematics and Computing - 16%;
- Institute of Natural Science-13%;
- nstitute of social sciences, Humanities and Art - 14%;
- College of Professional Education -10%.

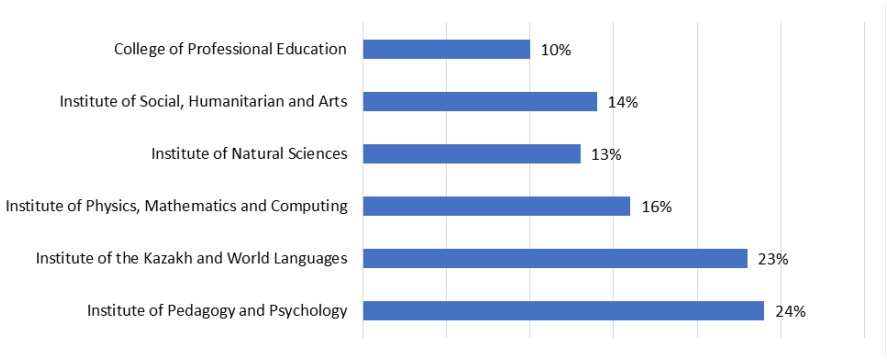

Figure 5: Distribution of Respondents by Institutes and College

82.54% of respondents indicated that they are not married, 15.57% are married, 0.68% - divorced, 0.24% - widows, 0.76% - were in a legally unregistered marriage (Figure 6).

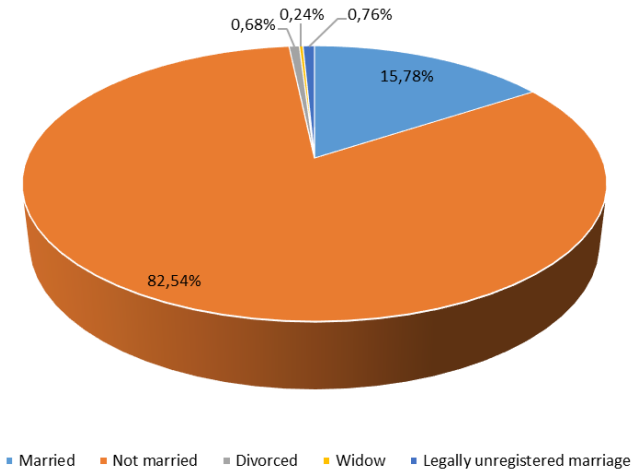

Figure 6: Marital Status of Respondents

The analysis of the financial situation of the families of the respondents was based primarily on the personal assessment of the participants. Three percent of respondents said that “there is only enough money for food”; 9% of respondents claimed that “there is enough money for food, but buying clothes is difficult”, 8% - “currently there are difficulties with buying a TV, refrigerator and washing machine”, 9% -“we have enough money to buy large household appliances, but not enough money to buy a car”, 30% - “our income is enough to buy all things, but not enough to buy apartment or a house”, 25% - “there are no financial difficulties, if necessary, we can also buy an apartment” (Figure 7). Sixteen percent of the respondents found it difficult to answer and attribute themselves to one of the listed groups.

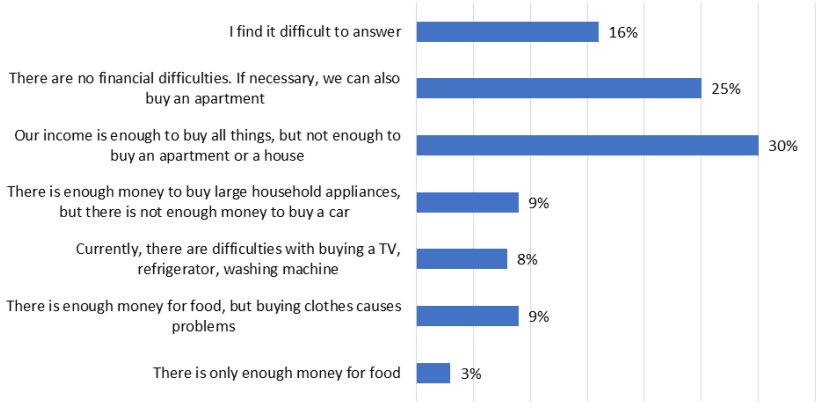

Figure 7: Financial Situation of Families of Students

Choosing a university is an important aspect in a young person's life. Some do it consciously, while others do it unconsciously due to a combination of external circumstances. The choice of an educational institution and a specialty in Kazakhstan leads to objective and subjective problems. The main objective problems are unemployment among graduates who are not in demand in their specialty, as well as profile fluctuations of graduates from law and economics schools. The subjective problem is the unwillingness to work in the specialty, since the profession was chosen incorrectly when enrolling to the university.

The study showed that the main motivation of the interviewed respondents to enroll to the Kazakh National Women's Teacher Training University was "the desire to have a profession in accordance with their abilities" (41%). 30% of students indicated the reason for choosing this university - "it was a joint decision with parents and relatives". Other relatively significant criteria are "by the advice of teachers" (3%), "by the advice of friends" (2%), "limitation of choice" (3%), "remoteness of the desired educational institutions from the place of residence" (1%), "the possibility receiving a scholarship" (6%), and "due to availability of educational state educational scholarship" (14%) (Figure 8).

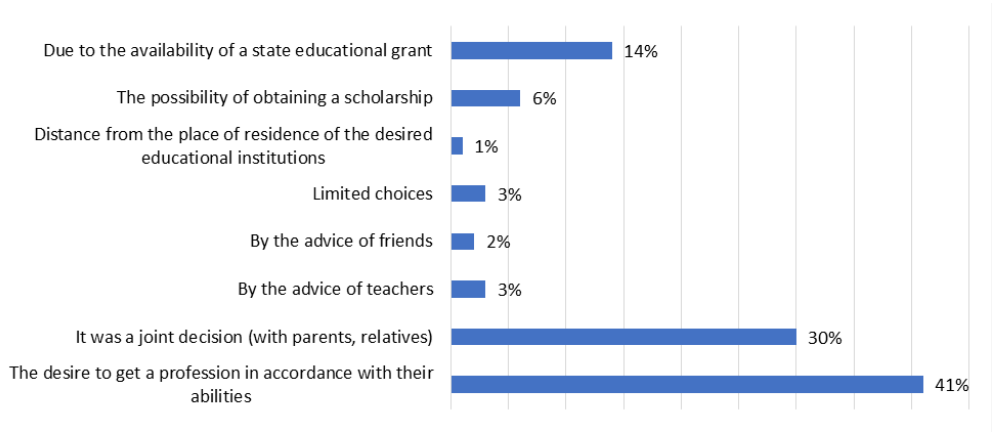

Figure 8: Reasons for Respondents' Choice of Kazakh National Women's Teacher Training University

In a market economy, the choice of a future profession for young girls is the most important task and reflects the actions of many motives of the individual. They arise from various needs and interests formed in public and private life.

Awareness of the choice, satisfaction with the chosen profession are considered in the answers:

- "I would choose this profession again in this educational institution" - 60%;
- "I would choose this specialty, but in another university" - 8%;
- "I would choose another specialty and another university - 13%;
- "I would choose another specialty in this university" - 19% (Figure 9).

Particular attention should be paid to the answers of 13% of respondents that would choose another profession and another university. Because such an answer suggests that students are not only not satisfied with their choice of profession, but also with the university.

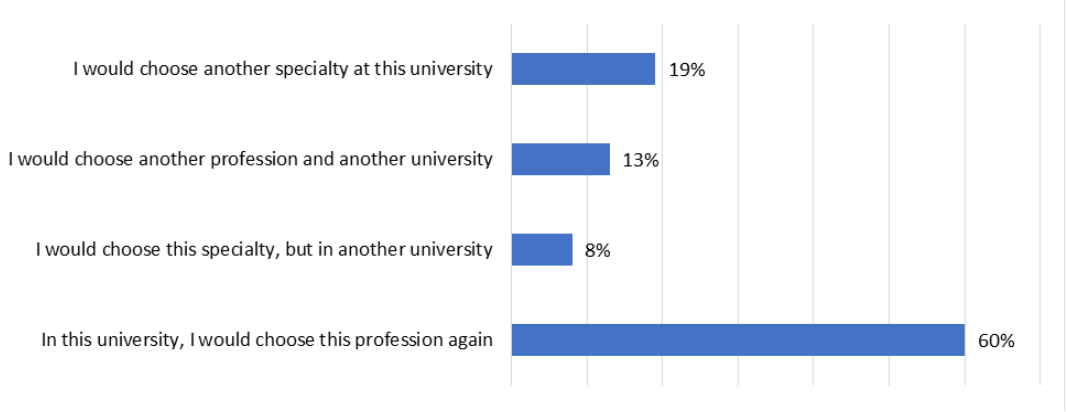

Figure 9: Opinions of Students About the Opportunity to Re-Select a Specialty

The question of the attitude of students to learning is directly related to the quality training of future specialists. Misconceptions about the profession, the quality of education in the univeristy, inadequate workload in subjects (too much or too little), attitude towards independent work, development of one's own skills in the specialty, all these form attitudes towards education and profession. The results of the survey showed that the statement “I study with great pleasure” was supported by 65%, 32% of students answered that they were only interested in certain subjects, 1% were indifferent to learning, and 2% have painful attitude to learning (Figure 10).

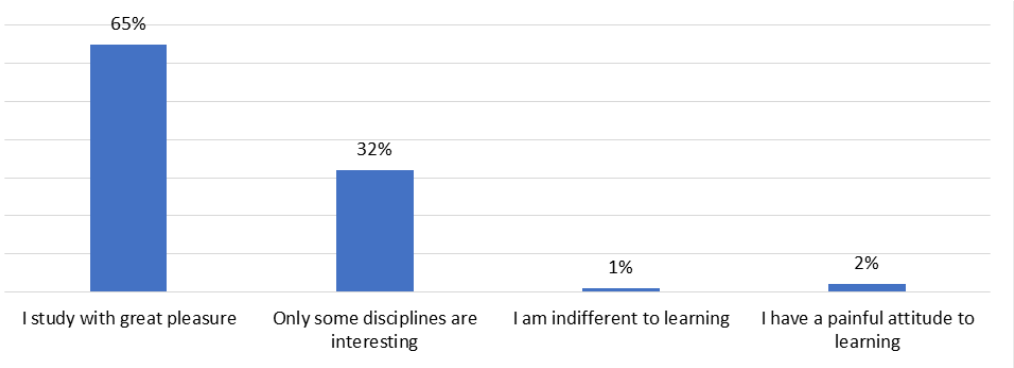

Figure 10: Respondents' Attitude to Study

At present, the issue of academic performance is especially relevant, as it is directly related to the quality training of the future specialist.

The reasons for the student’s poor performance in the classroom are the lack of motivation to learn, the inability to learn, the inability to study well, the wrong choice of profession and, as a result, the loss of motivation to learn, etc.

Poor academic performance can negatively affect the future both on the person himself and on the economy and society as a whole.

In this survey, we relied on the assumption that the future profession is chosen correctly, that the students like their majors and are satisfied with their studies. 64% of respondents answered that their academis performance is “good”, 28% answered that their performance is “very good”, 6% answered “satisfactory”, 1% answered “not very good”, and 1% find it difficult to answer (Figure 11).

The results of the survey showed that students with good academic performance have a special motivation for learning. Their success is in good organization of the learning process, dedication of time for learning at home and at the university, and using additional literature along with compulsary literature. Another important key to success is the constant desire for self-development.

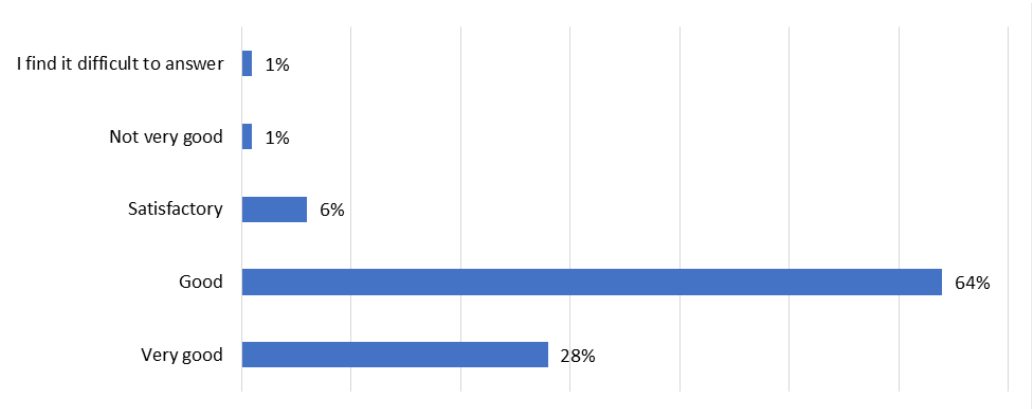

Figure 11: Academic Performance of Students at the University

Upon graduation, 67% of respondents are sure that they will find a job in their specialty, they believe that the profession of a teacher is always in demand and it will not be difficult to find a job in any educational institution in Kazakhstan, and 11% doubted they would find a job in their specialty. 17% are sure that they will find any job, but not in their specialty. 21% of respondents are skeptical about finding a job that meets their requirements.

21% of the respondents hope for help from their parents and relatives (Figure 12). According to the survey, the majority of respondents will work in their specialty after graduation.

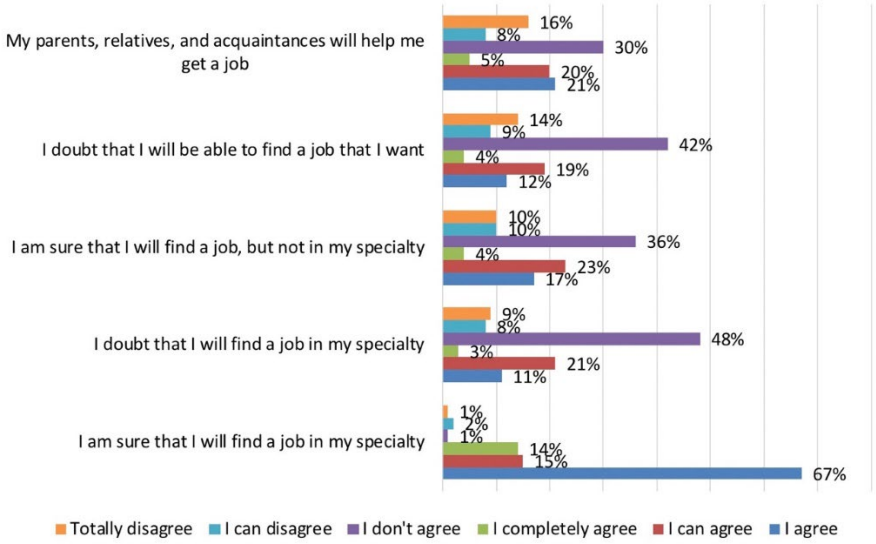

Figure 12: Students' Assessment of Employment Opportunities After Graduation

And the final topic of the survey is about the attitude of students at Kazakh National Women's Techaer Training University to the studying with boys (blended learning).

The question of the advantages and disadvantages of joint and separate education is not only a psychological and pedagogical, but also a socio-anthropological issue.

In this survey aothors tried to analyze the specifics of modern gender education, its role in shaping the gender culture of society.

The degree of satisfaction with the university is reflected in the following respondents' statements about why they have decided to study at Kazakh National Women's Teacher Training Univetsity:

- there is an individual approach for students (33.91%);
- financial aid for students (state and internal schollarships) (32.03%);
- encouragement of self-study (15.36%);
- university is equipped with a modern library (7.73%);
- the ability to independently choose the training program (5.65%);
- support for foreign students (5.31%) (Figure 13).

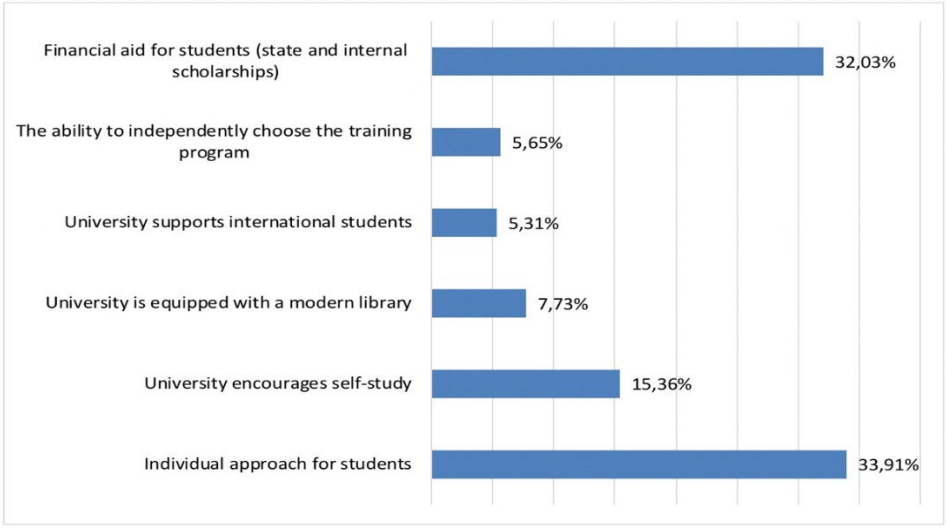

Figure 13: Reasons why Students Choose to Study at Kazakh National Women's Teacher Training University

Gender education implies gender differences in features of physical and mental development and related problems in learning. The resondents answers about the question if they want to stusy with male students was the following: 39% of respondents agreed that they would like to have a blended education in Kazakh National Women's Teacher Training University, 21% state that they would rather disagree, 14% have neutral point of view, and 25% did not think about blended (mixed) education (Figure 14).

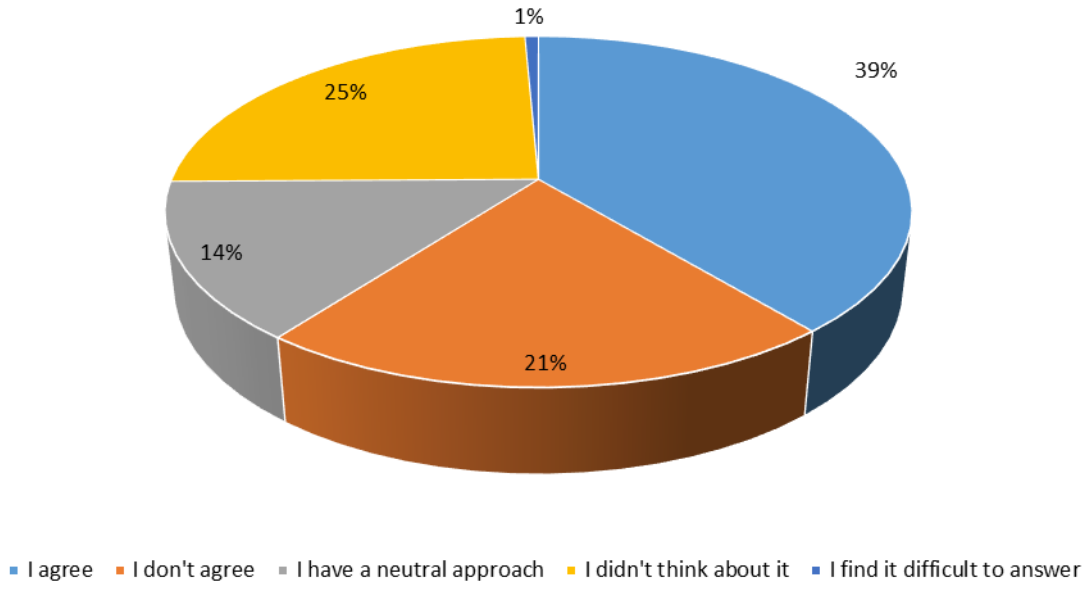

Figure 14: Respondents' Opinion About Having Male Students at the University

The survey results showed that 56% of students disagree with this statement "Will the university lose its uniqueness if both female and male students study at the university?", and 44% agree (Figure 15).

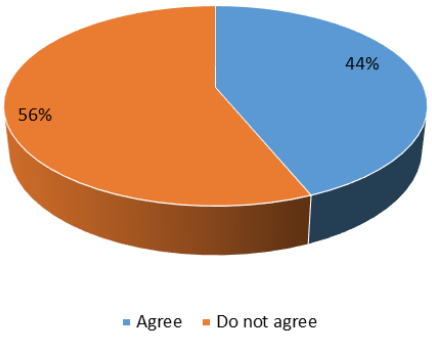

Figure 15: The Students' Views on the Question: "Will the University Lose its Uniqueness if Both Female and Male Students Study at the University?"

Analyzing the results obtained, we can conclude that the student understands the importance of higher education, has a strong attitude to entering a university. The student also appreciates such qualities as responsibility and good breeding, they are aimed at achieving their goals and obtaining the necessary knowledge (this is evidenced by rather high values - such means as strong will and self-control, courage in defending their views).

The data of the conducted research as a whole show the value of knowledge and education. Education is considered, on the one hand, as a factor in raising the social status and quality of life, a means of career development and improving material well-being. On the other hand, as a factor in the development of the individual, which allows one to join the achievements of culture and realize the creative potential of the individual.

5. Conclusion

As a result of the study, the following conclusions can be drawn:

The most important values for the respondents are professional, intellectual, family, social and financial values.

Value orientations that determine a person's life goals form the most significant vectors of their further social development.

Among the reasons why the respondents chose Kazakh National Women's Teacher Training University are "the desire to get a profession in accordance with their ability" - 41%; and "it is a joint decision (with parents, relatives)" - 30%. Based on these answers, we can conclude that the majority of young people come to the university in order to obtain a specific specialty.

It also turned out that 60% of respondents would choose this specialty again at Kazakh National Women's Teacher Training University.

Students highly appreciated the professionalism and individual methods of teaching (33.91%) in Kazakh National Women's Teacher Training University, noting that the main difference of the university is that it sets the goals of quality education for students.

Authors also found that 67% of respondents noted that they fully agreed with the statement "I am sure that I will find a job in my specialty". Therefore, students have positive about duture employment opprtunities.

One of the main objectives of the study was also identifying the opinions of university students about belended education (studying with boys). 39% of respondents said they would like to study with male students at the university, and 25% are against. Students support the idea of blended education in Kazakh National Women's Teacher Training University.

In addition, 44% of respondents claimed that the university will lose its uniqueness and status if there will be a blended education (with male students), and 56% of respondents do not agree with this statement. Respondents also noted that the university should be renamed and have common name, without specification that it is a women's university. And if in the future male students will be taught at this university, then it will be possible to introduce new educational courses and majors in STEM, in order to attract more talented boys and girls.

Abstract: The focus of higher education in the developed economies of the Global North has steadily shifted since the 1970s from being dominantly rooted in academic knowledge and learning as an end in themselves towards a wider perspective. The needs of the professions, careers and employability were present then, but were generally a secondary concern for the HEIs. The expansion of HE across more diverse populations has produced successive changes in curriculum and more broadly in purposes, strategies, and philosophies of HE. Against the background of global, economic, societal, and technological changes, the need to maintain 'traditions' but with wider relevance to society, personal adaptability, and capability as well as support for lifelong careers and learning have come to impact, HE main agendas. Most undertakings in life require the ability to define requirements, shape responses and form processes which will lead to achieving desired goals. In short, this is the nature of 'project' as a concept and of project management as a means to undertake what is necessary. *This paper reports on how the concepts and techniques of Project Management (PM) can be beneficially transferred in a process of soft skill development for life-long enhancement in the transitions from HE to employability and career*. A project was set up at University of West London as part of their knowledge transfer activities. The researchers have established 'proof of concept' and are currently trialling pathways for providing learning opportunities with knowledge transfer and soft skill enhancement. The opportunity to adapt the root concepts of PM to any domain carries enormous potential for enhancing HE outcomes and for wider continuing education and skills development across communities.

Keywords: Soft skills, Employability, Dissemination of PM knowledge and techniques, Independent learning, Experiential learning, VLE-supported study

1. Introduction

The ongoing effects of the contemporary digital transformation evident at a global scale are receiving critical attention from the academic and scientific communities, policymakers, industry and commerce, the public media and not least from 'digital citizens' who are impacted directly and indirectly by the changes arising from the technologies. There are perceived benefits in terms of economy, costs, productivity, dissemination of information and facilitation of wealth creation. Yet, there are growing concerns about information security, cybercrime, impacts on underprepared users and citizens, the growth of surveillance, boundaries to expression and challenges to legal policy and law making. There are questions of relations between the nation states and 'powers' and the impacts on individuals and citizens. If these issues are coupled to the challenges of Artificial Intelligence (AI) and the crises of energy supply, global sustainability, and health of populations, then the horizon sometimes looks gloomy.

So much for planting our theme in the wider context. As a counterpoise to the turbulence that seems to follow in the wake of technology, the idea that appropriate education and learning will contribute as much, if not more, to our survival and thriving than (digital) technology alone needs examination. However, we choose to define a collective future and give it a name like 'digital citizen / citizenship' there is an irreducible human factor which must enter any calculation about the future. There is no doubt that technologies of any kind have enhanced human reach and competence, but human physical endowment in body, mind and spirit are and will remain fundamental to the identity of the human species. There is consensus about how to prepare for life and the future, although we immediately have to face up to global disparities in opportunities, inheritance, structural conditions and resources.

2. Academic and Institutional Support for the DAPMK Study

The specific project presented in this paper received seed funding under an internal UWL (University of West London) call to stimulate initiatives and innovations in knowledge transfer. The formal support was applied to the project between April 2022 and March 2023. Subsequently, support is moving to the possibilities of stakeholder engagement both internal to UWL and external. A putative business plan is under development, and this is pointing to further stages of development towards ways to engage with several broader agendas.

3. The DAPMK Project Concept and its Goals

As a response to the multiple transformations outlined, the concept of *'Domain Applications of Project Management Knowledge (DAPMK)'* was proposed as a beneficial means to promote knowledge transfer and soft skill development for life-long enhancement of personal development. Our discussion builds on an independent learning project underway at University of West London. Project management (PM) is a well-established and autonomous discipline and field of practice with established focal points; for-example, in engineering, construction and infrastructure; in business and commercial enterprises for areas of planning, design, implementation and re-engineering. Beyond these core applications there is massive potential for transferring PM knowledge and techniques into many other fields. This holds the promise of upskilling the workforce at large to meet future needs. PM is truly a utility and a competence of great value and applicability. Only a modest number of the staff are PM specialists but the case for wider propagation to generalists is strong.

The approach uses a sequence of activities examining Project Management as a component of soft skills acquisition in higher education in the context of developing employability, building soft skills competences in graduates, and the integration of knowledge, skills, activities, and practices. These activities develop employability, build soft skills competences in graduates, and facilitate integration of knowledge, skills, activities, and practices as the learner moves on into employment in their chosen occupation, as well as supporting them for the inherent dynamism and uncertainties of the labour market in varied sectors.

The project extends the range of application of well-established project management (PM) knowledge and techniques to diverse and non-standard curriculum areas. A *Root model of Project Management* provides the basis for a module prototype. A trial using students from UWL Schools is revealing useful results for continuing development. Conventional higher education can only achieve so much. Thus, independent learning using collective engagement to develop transferable knowledge and skills is a vital step in the long-term transformation of human capacity to meet the challenges of the digital transformation wherever and whenever it is encountered.

At this stage (mid-2023) we have accomplished a pilot study for development purposes, and this will be further trialled on a larger student group at UWL. What have we learned so far from our efforts and how can the like-minded practitioners and researchers enhance our collective knowledge in this field of soft-skills development?

4. Background Studies

A literature search was carried out to establish a baseline. A search was conducted using Google Scholar before a database search was employed using the ERIC, CORE and Science Direct databases identified as containing relevant archives of literature. This identified that there was a considerable amount of literature on teaching of soft skills, study skills and employability skills but *little relevant to the use of zero credit or low credit modules specifically teaching project management outside of the discipline of project management using a VLE*. The full search was carried out up to late 2022.

The following search terms were used:

- Virtual learning environment project management
- Project management VLE
- Blended learning project management
- Virtual learning environment project management soft skills
- Zero credit modules

The search yielded ten relevant journal articles and conference proceedings and a further two articles from the grey literature as well as a case study from Sheffield Hallam University. The main themes from the literature included the effectiveness of using VLEs with project management (Ojiako, et al., 2011) (González-Marcos, et al., 2016) (Puplampu & Tutesigensi, 2008) (González-Marcos, et al., 2017); the benefits of teaching project management outside of the project management field (Ojiako, et al., 2013) (Vanhoucke & Wauters, 2015) and ways in which micro credentials and zero credit modules can be delivered to improve student soft skills.

VLEs and project management and soft skills. The use of virtual learning environments has developed considerably since 2020 when COVID-19 restrictions required universities to switch to teaching remotely, necessitating the use of VLEs for almost all teaching and assessment.

Several papers are quite positive on use of VLEs for teaching project management skills with a study of graduate students undertaking distance learning courses using VLEs in Indonesia did find that students felt that they had

gained soft skills from through the use of these methods that could be delivered in a virtual environment (Ratnaningsih, 2013).

Teaching project management as a soft skill. In the papers surveyed there was a consensus that it was valuable to teach project concepts for its benefit as a soft skill that can be widely applied and that is valuable to employers when assessing the suitability of candidates.

Micro credit/zero credit modules and teaching project management. Shu-hui et al (2018) argues that micro credit courses can be a good way of encouraging students to study independently on a wide range of topics as the need for ever great scope of knowledge is required in fields such as ICT.

Carins et al. (2018) have written on their experience of introducing project management soft skills modules developed in partnership with students that aimed to give students transferrable skills. Their method was aimed to go beyond a "bolt on" method whereby they are entirely separate from the rest of the course content but was not fully integrated into the main curriculum of the courses it was delivered to. They found that this partnership model is good for transferring knowledge from one department to a broad audience.

They received limited student feedback on the programme which suggested low discontent but also significant apathy to the programme while some students felt the content unnecessary especially as it was compulsory (Ibid). The main challenge they found to implementing their model were the existing structures at their institution that created obstacles for working in partnerships across departments. Therefore, they concluded that their method of offering transferrable skills in a pseudo "bolt on" style of teaching of transferrable skills is viable but requires significant staff buy-in and enthusiasm (Cairns, et al., 2018).

Oxley & van Rooyen have written that the challenge for developers of micro-credentials based on skills is to focus on the needs of students with the argument that currently the focus is on needs of large companies. They also assert that zero credit modules often fail to motivate students. (Oxley & van Rooyen, 2021).

University of Sheffield reported success with a skill based zero credit module teaching soft skills to mathematics students. The approach incentivised students by becoming part of their transcript and was taught across all three undergraduate years (Rowlett & Waldock, 2017).

Recent studies report positive outcomes for game-based learning in PM (Jääskä and Aaltonen, 2022). A systematic review identified tutor training and delivery planning in PM courses as success factors (Farooq, Hamid, Alvi, & Omer, 2022). In Australia, Afzal & Crawford (2022) observed that VLE used in combination with communication platforms produced good performance on PM courses.

Emerging conclusions from studies. Project management skills are valuable to many fields and students benefit from learning transferrable skills associated with project management. There is some consensus in the literature that the best way to deliver skills-based modules with low or zero credits is to involve students in the design of skills modules to increase usefulness to of skills obtained and deliver modules at times that complement students' wider studies.

Experience from our trial is providing evidence of student usability, which will inform further development and post-course evaluation will explore the question of student contribution to design. We used non-monetary incentives to engage and reward trialists (student membership for a period to the professional body and university certification as evidence). We have identified two periods in the student year which can prove attractive to trialists without 'clashing' with other priorities in their study year.

Virtual learning environments offer a means to deliver project management skills and it has been demonstrated that it can be used as a way to give students new knowledge and skills. However, this research study project provides a case study highlighting the validity of this approach. Overall, there is limited research directly into the use of VLEs to deliver project management skills to students in diverse and non-curriculum areas and the field would benefit from further study. This project study is helping to break new ground in this area of independent learning in PM for soft skills and employability.

5. Pedagogical Underpinnings for Soft Skills Development

The project environment of this study reflects the HEI setting of UWL. UWL is a UK post-1992 university representing an example of the fifth or sixth generation of UK HEI in its historical setting. These are typically institutions of diverse and local origin, serving predominantly urban areas, and designed to promote access to their communities. After 30 years of 'new' governance they are nationally outward looking to support their regions, industry, commerce, services and employment needs; in addition, these HEIs are making international

links and partnerships. More specifically in the UK these institutions are profiling their academic offer towards the changing economy, engaging broadly with the digital technologies, and blending traditional university and higher education roles and values with national needs. Employability (of graduates) is the current overarching motif, and for the HEI means responsibilities for workforce enrichment, upskilling and maximization of individual capacities to prepare the graduate for a life of change, challenge, and flexibility in a highly competitive world.

The DAPMK project has emerged in this setting. Classic project management (PM) provides an ideal canvas to broaden experience for general graduates – that is for those who are not specializing in the discipline or in its close proximate disciplinary areas. Thus, the project is focused on '*domain applications (DA)*' – those which have few historic links to classic PM applications. In this approach the DA is the target for the PM application as a means of soft skills development to enhance employability. The processes engender knowledge transfer (from PM to DA) and then play a part in shaping the learner in ways useful and relevant to the emerging knowledge-based economy, exploiting both the digital / technology dimension as well as the social and personal dimension.

The learner population in the majority of undergraduate studies (Level 4 to 6) and postgraduate studies (Level 7) is faced with a heavily structured and loaded curriculum. There is a resource problem to be solved and pedagogical norms have been empirically determined and codified in HE quality assurance. The core parameters within course length are ones of study mode, study calendars, course and module credits, formal study/contact hours and recommended learning hours. Experience and reality shows that the margin to provide formal 'tool support' within courses is very low, although much is made of support and acquisition of technique within the learning structure. There is a strong belief in experiential processes of learning and consequential building of skills and techniques, but some doubt about formal effectiveness of these in producing personal transformation post-HE. An underlying intention of DAPMK is to address a widely usable alternative to the 'status quo'.

There are a number of approaches to 'extra-curricular' or voluntary learning where a motivated individual uses learning materials for independent study. In the pre-digital era providing support to learners beyond the printed page was rare if there was no means to support distance learning or to provide tutor support. What learning was achieved was undertaken in a linear mode with minimal external support. This mode was solitary and limited in scope. Dealing with complex tasks, extending assessment, and allowing for the benefits of group work, interaction and sharing study and outcomes was usually out of scope of these approaches. True the student could work at their own pace and location but this isolation from the hegemony of the classroom was limiting. The historical model of institutionalised learning and teaching was the only practical alternative. The 'school' model was not universally effective for achieving rapid, advanced, and more complex outcomes. But, change was inevitable and still continues with force to transform learning in formal and informal education as well as in industrial and workplace education and training.

Educationists stepped up their interest in skills and learning facilitation on the back of the great expansion of HE after the 1960s especially in the Anglo-American world and those influenced by it (e.g., Canada, Australia, New Zealand and to an extent in Scandinavia). Continental European HE traditions tended to follow rather than lead on these trends, but by the 1980s these issues were matters of global interest and concern. Since the 1990s and by 2000 the digital technologies have impacted very strongly on skills and learning facilitation. The evolution of educational technologies and the contemporary dominance of digital resources and platforms now provide clear means of support. The structures and resources available facilitate learning in all directions, synchronously and asynchronously, with interfaces and embedded tools to assist the learner (as well as the tutor) to be focused, creative, adaptable, communicative, and interactive

6. Learner Engagement Within the DAPMK Knowledge Transfer Pedagogy

This paper (*and the associated conference presentation*) provides a first report on a research micro area. At present, the methodological perspective is one of exploratory inquiry in the qualitative tradition, which if developed would be towards multifactorial real-world research. Our experience is offered as a case to those within a broader field of knowledge transfer pedagogy. So far, one prototype trial had been carried out (n=15) and the lessons learned from this will be incorporated in a larger UWL-based trial (n=60) with a more ambitious testing and proving plan with various stakeholder groups to follow. An active business plan could emerge from this phase. Gathering the trial groups required timely and delicate liaison with course leaders, as well as extended communication, explanation, reassurance and briefing with the triallists.

The project team has also had the experience of scheduling the project work within the student year, with its varied workflows, pressures, and priorities. The research subjects have to let their participation be governed by their main student priorities (of class attendance, study time, and assessment deadlines) irrespective of their

enthusiasm to participate and willingness to devote their time to personal development in terms of additional voluntary study time, with potentially high payoffs in terms of soft skill acquisition, employability and tangible benefits (student association with APM (Association for Project Management), certificate of participation, and additional experience to add to CV and profile).

The project team recognize the difference between the idealized work plan, and one tested by the reality of implementation. Yet, the experience and knowledge gathered from the 'gap' once again shows the value of pilot studies when the improvement to practice is incorporated into the subsequent work.

There are key components which have been brought together in the initial DAPMK project and its products.

- A model proposal outline which can be used to replicate the application in future settings.
- A distillation of the principles of PM by creating a Root Model of Project Management (RMPM).
- A synthesis of PM knowledge derived from a working experience of teaching project management in several universities and reflecting the contemporary culture of business and management education.
- The preparation of a model package for outlining the learning process (the DAPMK Study Guide for Participants).
- The engagement of student subjects to take part in trials of the DAPMK package.
- The interaction with course and staff tutors in the schools from which students have been engaged.
- The creation of a VLE platform to carry the package and materials to support links to other resources.
- Guidance processes and protocols for learner trialists.
- Arrangements to support a cycle of delivery of the package from inception and recruitment to monitoring and support over the cycle.
- Development of research instruments to support delivery as part of the research and to allow transformation into support materials for group and self-managed study in operational settings.
- Provisions for maintain student motivation & effort in a self-sustaining independent study situation.
- An evaluation of alternative settings and modes for delivery.

7. Expectations and Realities (Designers and Learners)

The recognition of the diversity of learner circumstances, their situation for participation in the experience and the personal resources they can bring to the task are crucial factors in generating expectations and determining the 'reality' of the experience. Factoring in the substantial higher education teaching experience of the tutor-researchers and their access to the experience of colleagues inevitably created a certain level of expectation on their part. Tutors develop senses of expectation about how their students and learners will engage and be impacted by the learning experience offered. This is no less true in the DAPMK approach even in a limited setting. Nevertheless, the tutor-researcher expectations are set high as their task has been to design techniques to reach a high standard of potential achievement. As the team shared the project idea with course leaders and tutors and engaged with students who could be potential trialists, the initial outcome was three convergent sets of views.

The project team had a strong belief in the approach, potential stakeholders were very interested and showing positive support, and student enthusiasm was strong (reflecting positive pre-disposition to such activities, employability, and career concerns as well as a sense of value to be gained and a motivation to undertake what was required of them). Pre-test and post-test instruments have provided indicative evidence of expectations and realities. Between the prototype phase of October 2022 to January 2023 and the next scaled up trial there is an ongoing recalibration of expectations and realities between stakeholders.

The responses from the pilot are qualitative and indicative only. The number of respondents (n=15) is below the threshold for drawing any generalizable conclusions, but the observations collected are valid for the context. To go further in this process will require more research resources to collect, process and evaluate data yielded.

Yet, there are some significant observations and pointers which can be elicited.

The study guide was purposefully explicit in what could produce effective outcomes, but how far can task progress be assumed (and tracked by products provided and uploaded to the VLE, or by monitoring the use of the VLE)? Logs and diaries and internal reporting was recommended but the yields are variable.

- The model used in the study guide provided for group activities, evaluation, reflection and progress tracking through tasks. This provides material for assessment by the learners (and by any external mentor, tutor, or assessor).

- Creating the study guide, the VLE and setting the whole process in train required a substantial effort. The first two elements are capital investment, but the operation of the process is a variable burden (and cost).
- Guidance was provided formally at the start of the process and then on a weekly basis. The lead tutor adopted a 'hands off' position so as to respect the autonomy of the learners.
- Questions emerged in the minds of the design team as the process progressed. The pilot was a good way to capture incidents and concerns, and a number of operational matters were resolved for future practice.
- Recorded outcomes, documents generated, and presentations made indicate that the learner experience has at least brought qualitative changes in experience and outlook.

8. Interests and Partnerships – a way Ahead

However, the DAPMK project has marked up a number of concrete gains which have wider significance:

The project is located within the literature on independent learning methods in the specific area of project management (PM) and confirms that there is a gap in provision.

A conceptual model has been created for the development of a learning platform for broadening the knowledge, skills and application of PM towards non-traditional domains. This concept has been embodied in both the project vision, goals and name DAPMK (Domain Applications of Project Management Knowledge).

The project has stimulated contacts with course leaders and students in other Schools to explore current practice and potential for domain applications of PM. In essence an internal knowledge transfer activity.

There is now a substantial fit for purpose independent / collaborative learning platform for the DAPMK project using the Root Model of Project Management as the knowledge framework. This platform has been developed on the UWL BB VLE with potential replicability to other platforms.

A fit for purpose curriculum and syllabus with a module compatible pedagogy has been elaborated and tested. Conventional PM teaching resources have been leveraged into the platform and curriculum to provide technical and knowledge support for the independent learners.

Trialling of the DAPMK module and platform is feasible for delivery. The underlying dynamics of implementing independent collaborative learning in real time in an HE environment are evident.

The project achieved key performance indicators in response to the HEI institutions requirements.

With the initial seed funding from UWL, strong support from the APM and some strong and positive feedback from course leaders at UWL there is momentum for further development. Initial indications for future development of a hybrid independent- collaborative learning platform and resource are favourable.

Students appear to respond to the idea of additional independent learning in the context of developing their soft skills for employability, as well as for experiencing learning about PM as non-specialists up to the level of acquiring a usable generic transferable skill. From a developer and educator perspective there is a need for initial investment in concept, programme, and platform development, as well as a system of supportive administration and necessary feedback and guidance methods. Course leaders are forming their own impressions and potential uses for such a non-specialist PM learning application with clear added value for the learner in terms of soft skill acquisition and employability.

9. Models for Development

The UWL Seed Fund provided a small but critical financial resource for the project group to initiate development in terms of making their proposal and contracting to deliver a response. UWL staff and technology resources have exploited sunk costs underpinned by tutor obligations to undertake development and research. The work done suggests considerable field potential and there is ambition to pursue this. Any future development will need a cost model to address development overheads and operating costs. A number of stages have been identified towards a possible 'business plan' which is compatible and replicable within the HEI environment.

UWL / HEI Internal Exploitation as a model for wider application: In this model the DAPMK platform would be developed as a conventional validated module. To date, this development is pending although there is known interest in it from participating Schools.

Under this model of university Internal Exploitation, the Schools would need to make the budgetary case for development in the normal manner. Once the module was validated for use it would be appropriate to seek professional accreditation from bodies like APM, with whom the team have explored development. The validated module could be delivered for full credit, but also could be considered for zero credit use in a course, where the module is mandated as part of the qualification.

UWL / HEI Enterprises and the enterprise skilling model: The DAPMK learning platform has feasible commercial potential to generate revenue for stakeholders and investors. Part of the model of university enterprises is to exploit intellectual capital for commercial gain. In reality the corporate notion of a university is one of a collective of stakeholder interests, who can profit by recognizing their mutual interests and potential for collaborative endeavour. UK universities started to develop a business and commercial 'face' from the 1970s: UWL with its initial foundation priorities has been a later comer to the possibilities of adjunct commercial enterprises. However, many Schools have had a very long industry facing culture even in its FE/HE days of ECHE (Hospitality, Tourism, Arts, Media, Music, Law) but these were not seen as institutionally strategic and were poorly represented in the organizational arrangements. In the last ten years there has been progressive and substantial change. The DAPMK project is well suited to leverage into this environment.

'Enterprise' is now recognised as a school axis as much as one that can be run through a Central Agency (e.g. university company or similar vehicle). The universities have been developing an enterprise environment with commercial possibilities, but it may not be widely appreciated, understood, or fully encouraged (given the many demands on the university and its staff at large).

Investments required, resource costs, market characteristics, delivery requirements, pricing and revenues, budgets and commercial strategy are all factors within university expertise. However, these models may not be flexible and/or innovative enough to respond to market conditions and opportunities.

The DAPMK has considered how their 'IP' can be developed equitably to the mutual advantage of all stakeholders. The university has organizational, business, and financial capacity as well as legal authority to contract, but the academic and research stakeholders provide the substantial majority of the "*knowledge, IP and pedagogical resources"*.

Training Partnerships (TP): multiple stakeholders: A third model is a Training Partnership. Different capabilities from different partners would be recognised in a coalition. Over the last year the DAPMK team has been surveying the field of potential partners.

A collaborative TP would need to be created so that it could identify a degree of freedom and commercial autonomy as the basis for its sustainability, operations, and creation of beneficial surplus. The DAPMK team are modelling the design of such an entity and to move ahead would need to identify suitable specific partners to develop a workable business plan. The TP would establish a number of 'delivery platforms' with support required and offered. Packages could be delivered to various segments:

- Independent groups with direct delivery
- Supported franchises for a) industrial and commercial clients who can be of small, medium and large scale; b) public sector bodies; c) Voluntary and third sector, which may also cover SME social enterprises.

This model is usable at both national and international levels.

10. Platform and Pedagogy: The way to Transformation and Success

The DAPMK approach exemplifies and exploits the utility of blended learning. Multiple dimensional uses of digital technology are showing the way to a global standard for all education and training. Clearly, the imbalances in access and resources still inhibit global reach, but the expectation has been created and realization will follow in stages. Blended formulas provide a flexible menu across the range of techniques, exploitation of knowledge and communication. These become the main routes to knowledge transfer, skills enrichment, employability, innovation, productivity, and wealth creation.

11. Assessment of the 'Learning Experience and Transformation'

The indicative outcomes, even at this early stage show the possibilities. The experiences observed show that learner curiosity, desire for engagement and constructive motivation provide the catalysts for experience, which

when allowed time, opportunity, and space to follow the DAPMK module led to greater knowledge, improved competences, and a positive consolidation of learning outcomes.

Our goal has been to demonstrate that classic project management can be transferred to domain contexts, with beneficial outcomes for participants. The constraining factors are not surprising. Giving a realistic allowance of time for the process to transform is a critical success factor. The interaction that can be developed for experiential learning and what learners can contribute to the process are parameters with qualitative impact. Experienced tutors in HE possesses an accumulated corpus of knowledge and technique which suggests what will work and what will not. If the outcome from DAPMK type experiential learning follows the overall grade outcomes across HE courses (in different countries, cultures, and systems) the predicted outcomes will be at least as good as the 'normal' curve for the HE learner population

12. Maintenance, Development, and Transformation

Human capability is the other side of the coin of technology. We have built a case for PM as a generic toolset which can be exported to non-classic domains. The DAPMK model offers a route to transformation in a world of digital technologies, where extending soft skills and knowledge are driving forces in improving employability, investing in people and workforce to achieve personal, collective and sustainable wealth creation in any context.

This paper reports on how the concepts and techniques of Project Management (PM) can be beneficially transferred in a process of soft skill development for life-long enhancement in the transitions from HE to employability and career. What can we draw upon form our experience so far? We have established 'proof of concept' for a developable process of skills and knowledge enhancement which offers great possibilities for career and personal development and employability.

The prototype was designed with independent collaborative learning in higher education in mind. There are learners who can engage in the challenge of a higher order of task demand that is required (*similar to real world conditions*) and who are prepared to bring personal discipline and application to the tasks. Achieving the outcomes certainly indicate a higher order of employability and soft skills. To widen the volume of successful outcomes in normal HE operating conditions will require increased levels of tutor support (or even AI-assisted support). Our initial experience suggests there are many maintenance and development issues we have yet to tackle. What we have learned about the modality of DAPMK in an HE environment also needs to be adapted to the wider industrial and organizational world, and this will be explored in future collaborations.

There is a 'PM learning gap' at the centre of discussions and actions on employability and skilling for the ongoing digital transformation. Thus, we encourage collaborators in every arena to provide focus and resources to assist in overcoming the knowledge and skills gap in Project Management.

Knowledge Management in Multimedia Communication with the use of Software Agents

Leszek Kiełtyka
Czestochowa University of Technology, Faculty of Management, Poland

leszek.kieltyka@pcz.pl

Abstract: This paper presents the problem of knowledge management related to software agents and agent systems (i.e. systems composed of communicating and cooperating software agents). The author presents basic theoretical issues, but the main focus is on the areas of application of software agents in multimedia communication - both existing and prospective applications. Particular attention has been paid to the applications of software agents for: supporting customer service processes through the Contact Centre system; supporting the distance learning system; creating virtual assistants in the form of conversation bots; searching for information in the Semantic Web, and assisting in setting up a video conference call. Software agents are often referred to as 'intelligent' - due to their intelligent behaviour. At their core, they involve: perception, reasoning, learning, communication and operation in complex environments, using all multimedia techniques and procedures. Software agents and agent systems, as presented in this article, represent a new approach to the analysis, design and implementation of complex (usually decentralised and distributed) computer systems, offering a whole range of concepts, techniques and tools to significantly improve the software development process. The ability of software agents to make autonomous decisions have been a subject of considerations. Among other things, they are based on the example of cognitive sciences, which deal with modelling real processes of information processing in humans and building programmes that imitate these processes. Research on the common understanding of shared knowledge and knowledge management in agent-based systems focuses on ontologies, understood as a description of the relationship between the way knowledge is represented and the concept represented by that knowledge. In contrast, research on knowledge sharing has focused on communication languages and their associated - interaction protocol and message transport protocol.

Keywords: Software agents, Agent systems, Distance learning, Conversation bots

1. Introduction

In the era of the Knowledge Based Economy (KBE), information and knowledge constitute key resources of enterprises. The activities of economic entities depend very much on the information technologies they use, which encompass much more than just computers and their software; they also include know-how and, consequently, intellectual capital.

Knowledge management, as a young management field, encompasses the latest methods and techniques to ensure the most effective use of knowledge resources, especially those accumulated in organisations. The literature on the subject is abundant in the definitions that characterise knowledge management (Kiełtyka, 2013). One of them that could be quoted here is the definition proposed by Polanyi (Polanyi and Sen, 2009), in the following wording "Knowledge management is a set of processes allowing to transform the tacit knowledge possessed by the employees of an organisation and its environment into explicit knowledge resources valuable to the organisation, allowing it to gain a competitive advantage".

The importance of managing information, and subsequently knowledge that is based on it, is increasing with the process of globalisation and the tightening of cooperative ties between companies. Without the ability to quickly acquire and transfer information, as well as to skilfully use the knowledge accumulated within a company, it is impossible to manage effectively, make decisions or create effective strategies.

The paper presents principles and methods of creating and using multimedia messages in the field of knowledge management. The basic idea and at the same time the main idea of the study is the thesis that it is possible to distinguish a group of software agents supporting various forms of knowledge management carried out on the basis of multimedia messages. The decision-maker's cognitive system, supported by an isolated group of software agents, is the essential regulator of knowledge and information selection, guaranteeing the effectiveness of decision-making. The measure of quality is adjustment to individual needs and human characteristics. The decision-maker is a specific system that assimilates and generates information. Learning about the peculiarities of this group of software agents and associating them with multimedia is crucial in creating effective decision-making tools.

2. Multimedia Communicators

Multimedia communicators are a heterogeneous group. The most basic solutions are used for direct communication on the Internet. They offer modern audio and video chat technology, spell-checking, the ability

to change 'skins', support avatars, drag & drop image transfer, multiple conversations in a single window and built-in radio. These solutions are mainly intended for private (individual) users. Therefore, despite their many versions and improvements, they are characterised by their ease of use and installation, while the creation of contact lists is still intuitive and simple, and new services are available at the click of a button.

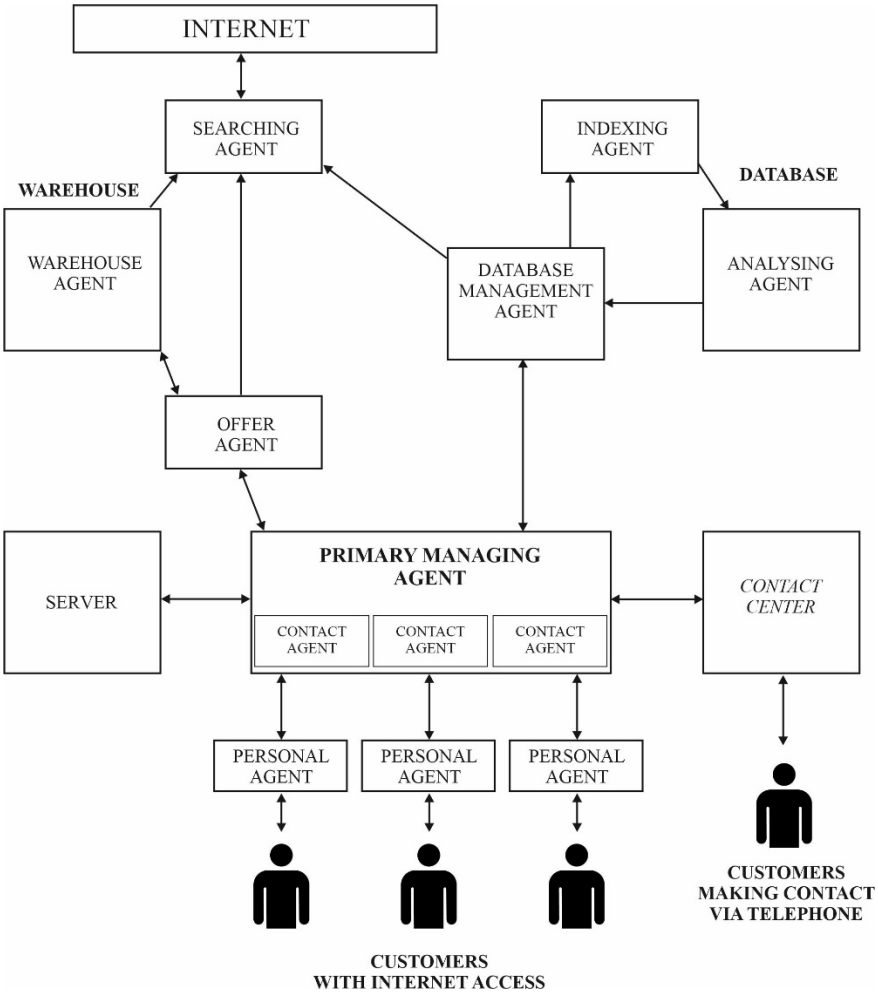
The popularity of instant messaging is also influenced by the fact that versions are available for many platforms, including Linux, PocketPC or PalmOS, from which users can freely exchange information. The more advanced multimedia communicators contain usability features such as video conferencing and HD video chat.

In accordance with the thesis that it is possible to identify a group of software agents supporting various forms of knowledge management based on multimedia messages, we should try to use commercial solutions available on the market for this purpose, such as: Windows Live Messenger or Camfrog Video Chat. Instant messaging producers also create solutions intended for specific groups of users. The group of so-called social communicators includes, for example, Xfire (a global communicator for gamers, which enables text and voice chat during gaming) or Evermotion Communicator (instant messaging created by one of the largest portals in the computer graphics industry). Although solutions for individual users comprise the largest part of the instant messaging market, business solutions constitute a technologically developed group. Examples of popular business solutions on the market include GGPro or LIVECHAT Communicator. These are used not only for chatting, but also manage the company's communication and enable the sharing of business and private contact lists, and thus manage the use of other communicators in the company, perhaps also through software agents.

It is generally accepted that a software agent is software that assists managers and functions on their behalf. "A software agent, as opposed to the reactive software of the past - reacting to user instructions - is supposed to be proactive, i.e. once the user's needs have been specified, it will perform tasks for them. The agent must be equipped with a specific set of skills and knowledge (heuristics) and other activities (cooperation, communication, command and control) (Kiełtyka, 2020).

In turn, a multi-agent system is a system made up of communicating and cooperating agents pursuing common goals. When creating enterprises for the new era, the features, advantages, areas or skills of using multimedia programmes should be taken into account, especially by software agents.

Multimedia communication is realised by displaying information in a number of multimedia formats. These include static and dynamic images, video, graphics, audio, text and animation. A single instance of multimedia communication does not necessarily have all the components listed. Multimedia communication presents information in interesting, creative way that helps many different types of information to internalise data. Multimedia communication proved particularly useful during the COVID-19 pandemic. The outbreak of the COVID-19 pandemic was a shock to education systems around the world and forced the closure of schools. Remote continuity of learning became a particular challenge for vocational education, a key component of which is practical classes that are difficult to deliver remotely. Multimedia communication has proved particularly useful in preserving the continuity of both education and business entities. Students felt comfortable with multimedia because the Internet itself is filled with all types of media and they could find the type of multimedia that would particularly benefit their communication and learning style (Grewening et al., 2021).



Software agents and agent systems built on them are inspired by real systems and organisations. Particularly close links can be observed with the fields of Artificial Intelligence (AI) and Cognitive Science (CS). Therefore, software agents are often referred to as 'intelligent' (Kieltyka, 2013), and the degree of their intelligence is also analysed in the literature on the subject. The set of characteristics attributed to software agents and agent systems is as follows: reactiveness, autonomy, interactivity, intelligence, reasoning based on collected knowledge, mobility, reliability, capacity for reasoning), ability to communicate, goal orientation, adaptivity, predictivity, capacity for cooperation, learning ability (Paprzycki, 2021). An important issue in open systems is the cooperation of software agents developed by different manufacturers. This is only possible if the used technological solutions are compatible (Kieltyka and Niedbal, 2015).

The article focuses on several application areas of software agents using multimedia communication.

3. Agent System Supporting Operations of Contact Centre

Not so long ago, the standard customer contact centre (call centre) consisted of a few telephone lines for communicating with agents - people. Today, this is no longer enough to meet customer expectations. Nowadays, a large proportion of customers prefer to use Internet services and e-mail, only as a last resort opting for a telephone call. For this reason, the call centre is now transforming into a contact centre. This is an organisational

and technological solution which allows for the integrated and equal treatment of all channels of communication with the customer, such as telephone, e-mail, SMS (Short Message Service), Live chat (live conversation), contact via a form placed on a website, and visual contact. The Contact Centre unifies the standard of customer service regardless of the communication channel and makes it possible to build an information base of all contacts occurring at the meeting point of the enterprise and its customers. The functions of searching, displaying information about the caller, their previous problems currently can be performed by a software agent. The Contact Centre system is a virtual environment, which makes it a natural environment for software agents. A group of software agents operating within an agent system could, for example, be used to run a contact centre in a web shop (Al-Jaljouli et al., 2018). The software agents would then take on the role of collecting customer data, analysing the collected data, contacting customers to provide an offer (Fig.1).

Source: Own elaboration

Figure: 1: Agent System Supporting Operations of Contact Centre

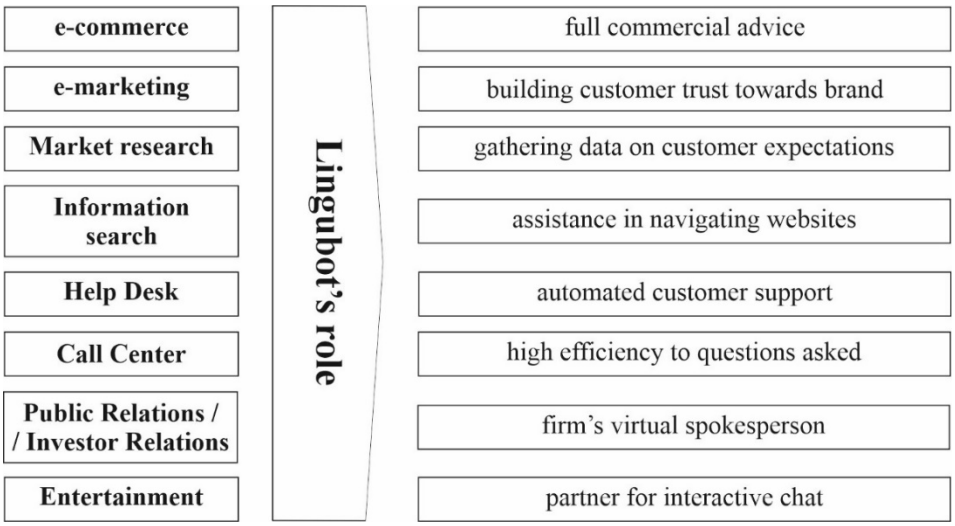
The server running the agent system supporting Contact Centre operations receives the data from the database and then converts the data for the customer into the appropriate format, thus creating knowledge packages. For example: if the communication is to take place via e-mail, it converts the data into a text or HTML (HyperText Markup Language) document; if, on the other hand, the customer has requested an SMS, the data is converted into the appropriate format and sent via the GSM (Global System for Mobile Communications) mobile phone network. Communication between agents within the system is in ACL (Agent Communication Language), with the exception of database agents, which communicate in RDQL (RDF Data Query Language).

4. Supporting Distance Learning System

In distance learning, software agents can be used to assist the 'virtual' learner. The software agent can suggest to them specific content on the web, where there are materials facilitating learning (Aldhelai et al., 2015). It can also keep track of a given student's learning progress, suggest what he or she still needs to work on and select appropriate tests for him or her. The use of software agents relieves the workload of humans controlling

students. In addition, instructor's fatigue or a wrong adjustment of the materials to the students' level of knowledge can be associated with a loss of interest and desire to acquire knowledge. It is possible to automate repetitive, routine tasks performed by a teacher (human). Tasks such as, for example: answering simple questions, reminding learners of the necessity and deadlines for sending in solved assignments or checking computer code can be performed by a software agent - called in this case a knowledge robot or knowbot. Knowledge robots are placed between the teacher and the learner, enabling interaction.

Currently, there are numerous IT solutions that support distance learning. Some of them are based on software agents and agent systems built from them. For example, there is a proposal by researchers at the University of Tokyo called Web On-line Force-Directed Animated Visualisation (WebOFDAV for short) (Kulej-Dudek, 2012). Other examples include the system developed at Tottori University (Japan), based on P2P architecture and mobile software agents (Kulej-Dudek, 2012) or the DILE (Distributed Intelligent Learning Environment) system developed at Pelotas University (Brazil), based on the FIPA-OS platform (Hyla, 2005; Aldhelai et al., 2015).



5. Virtual Assistants in the Form Of Conversation bots

Software agents equipped with artificial intelligence elements are so-called conversation bots, also called lingubots, chatbots or chatterbots. These are computer programmes, placed on social networks and considered in the field of online marketing communication as innovative solutions (Van den Broeck et al., 2019), with which a human can converse - primarily using a keyboard. During the conversation, they can express their own emotions. The high level of interactivity in communication compensates for the impersonal nature of the chatbot (Go and Sundar, 2019).

Conversational bots that use human speech and respond in the form of a question are also called virtual advisors, personal assistants, digital assistants or virtual assistants (Gentch, 2019; Corti and Gillespie, 2016; Mehrotra et al., 2017).

The person seeking information is not forced to mundane browsing through individual pages, tables or links, as the lingubot presents the relevant data, opens the right page, and assists in filling in forms. This approach increases user satisfaction, which leads to more frequent visits to a particular organisation's website, use of the service for a longer period of time and an improved brand image.

As an example, one can point to the implementations of the technology developed by Artificial Solutions (http://www.artificial-solutions.com/). Virtual assistants created with this technology are 'hired' by companies to help those who visit their website. The role of virtual assistants is primarily to provide information, although they are also capable of conversing on other topics. User interaction with conversational bots is mainly carried out using instant messaging embedded in websites. The design of bots often also includes elements of artificial intelligence to assist them in recognising the context of a conversation with a human.

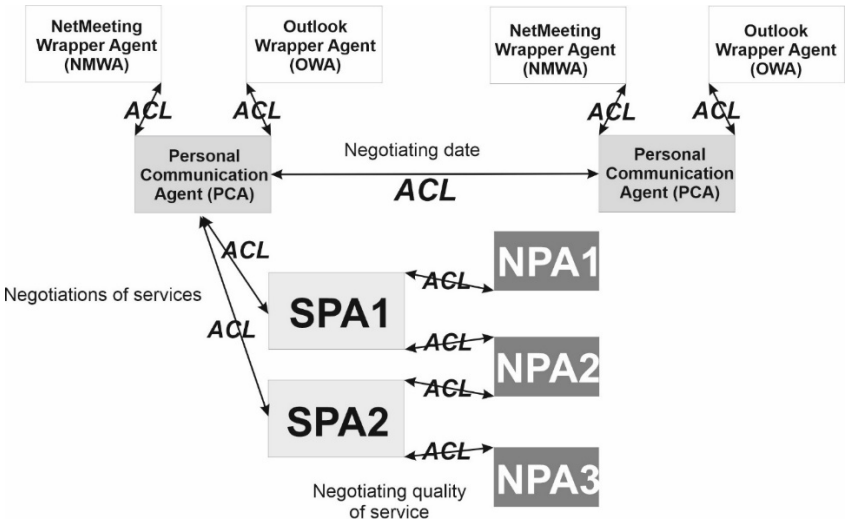
Source: Own analysis

Figure 2: Possible Applications of Lingubots

All conversations are anonymously recorded and can serve as valuable material for various marketing analyses of customer preferences, tastes and expectations. Websites supported by virtual consultants carry out efficient

provision of information about commercial offers to customers [Kieltyka, 2020). The virtual salesperson, thanks to their extensive commercial knowledge, 'patience' and friendly interface, encourages and assists in concluding transactions. By leaving a positive impression on the user, it creates an opportunity for repeated contact. However, the role of the virtual advisor does not end with providing information on the details of the commercial offer and support during the electronic transaction. The technology is used in many related fields (Fig. 2).

An interesting solution is offered by the company Oddcast226. This is a tool called SitePal™, which is used to build animated, talking assistants - so-called avatars. The SitePal™ animated avatar is constructed using an online interface. The avatar is included in the HTML page code and implemented in Flash technology.



6. Knowledge Accumulated in Semantic Web

The concept of the semantic web is sometimes associated with 'machine-readable data', 'intelligent agents', 'distributed database' or 'automated infrastructure'. The Semantic Web makes it possible to systematically assign meaning to elements of web pages so that the programs that read them, called software agents, can perform complex tasks assigned to them by users. The Semantic Web is not created from scratch, but is created as an extension of the existing World Wide Web - by precisely defining the meaning of the data available in it, allowing for closer human-computer collaboration.

In order to realise the idea of the Semantic Web, a common terminology is needed for the exchange and management of information and knowledge between the various applications, describing the domain that these applications deal with. Information about the links between them is needed. Such a collection of terms and linkages is an ontology (Haliżak, 2015). Ontologies provide the terminology for the need of such a description. It can be drawn from classified domains, not necessarily dependent domains. In addition, ontologies need to define logical relationships between terms, in order to provide a deep level of analysis, as well as to improve search methods and intelligent inference by computer programmes (Gladysz, 2017).

This draws a comparison between the Semantic Web and an ontology-based knowledge management system, where ontologies provide tools for the formal description of knowledge. On the basis of such a description, computer programs can perform data retrieval and processing. It is thanks to ontologies that it is possible to integrate the huge number of heterogeneous documents currently existing on the Internet. The concept of ontologies can also be viewed in the context of a model of a fragment of reality representing the objects of interest and the relations occurring between them, as well as containing the required properties (attributes) of these objects (Śnieżko, 2015).

Setting up a videoconferencing connection over the Internet is a challenging task to build a complex distributed information system. A solution may be to implement such a system in the form of an agent system. Such a concept has been proposed by P. Faratin, N.R. Jennings, P. Buckle and C. Sierra (Fartin et al., 2001) (Fig. 3).

Source: (Faratin et al., 2001)

Figure 3: Using an Agent System to set up a Videoconference Call, Where: PCA - Personal Communication Agent, SPA - Service Provider Agents, NPA - Network Provider Agent, ACL - Agent Communication Language

Various individuals and organisations are involved in setting up a videoconference call. End users can be represented by Personal Communication Agents (PCAs). Each of the units providing services on the network - consisting in, among other things, organising videoconferences - can be represented by Service Provider Agents (SPA). In contrast, the telecommunication infrastructure through which these services will actually be transmitted can be represented by so-called Network Provider Agents (NPAs). Since applications such as NetMeeting or Outlook are not agent-based applications, it is necessary to use what is referred to in the literature as "Wrapper Software" - which converts a form of communication into an ACL (Agent Communication Language). In Figure 3, the NetMeeting Wrapper Agent (NMWA) and the Outlook Wrapper Agent (OWA) perform these functions.

The concept behind the operation of the proposed agent system is based on mutual negotiation between different types of programme agents. The PCA agents negotiate with each other in order to find a suitable date for a videoconference call. If they reach an agreement, then one of the PCA agents negotiates with the various SPA agents providing videoconferencing services. These negotiations mainly concern the cost of the call and the required quality of service. The SPA agent that wins the contract then negotiates with the various NPA agents to determine which one is able to deliver the required quality of service - at the best price. Software agents should be responsive to changes occurring in their environment. For example, an NPA agent providing network access may need to obtain additional lines from another NPA agent - to maintain the agreed quality of service in the event that part of its own network fails. Also, if there is a need to adapt to new targets when they arise - for example, two SPA programme agents may discover that they have the capacity to provide complementary services. They may therefore decide to work together to gain the capacity to provide new services. In order to set up a videoconference date or select a suitable service provider or network access entity, the software agents go out with proposals, commercial offers, make concessions - and eventually come to an agreement. The programme agents shown in Figure 3 communicate by exchanging messages in ACL (Agent Communication Language).

7. Summary/Conclusions

Based on the few areas selected in the paper, where the applicability/use of software agents has been signalled, the thought often arises that intelligent software agents will be the next revolution in computing and communication. In my opinion, this will particularly apply to the use of agents as a software development methodology. Increasingly powerful supercomputers may lead to a breakthrough of human contact with a personal computer agent. The future of software agent applications and agent systems seems promising. The way in which computers or other electronic devices are perceived increasingly resembles communication and interaction with other people. We are also increasingly dealing with applications that operate in a global environment of networked devices. The above insights open up a wide area of applications for software agents and agent systems. Therefore, when analysing the role of agent technologies in the construction of the information society, can it be assessed in terms of synergy or contradiction? In addressing the issue of agent technologies, it is important to bear in mind the general view that it is increasingly popular to replace personal human contact with contact in the form of electronic communication. New types of 'connector' are needed that more closely correspond to the natural behaviour of people contacting each other. Agent technologies are such a form of 'connector' between humans and information systems. Currently, work is still underway to build the standards needed to implement the idea of the Semantic Web. This should result in making the information available on the web processable not only at the level of individual characters in the text, but also taking into account the structure of the document and the concepts contained in the text. The aim is to create and disseminate standards for describing content on the Internet in such a way that it can be processed by machines and programs taking into account the meaning and context of the information (Folta and Stolinska, 2012). The Semantic Web is based on ontologies (Abramowicz et al., 2011) and software agents.

An ontology, as a specialised conceptual apparatus, 'is intended to support and be responsible for the efficient and unambiguous exchange of information/knowledge between its users'. The recipients of the ontology are agents operating in information systems and within the concept of the Semantic Web. The manager (human) will still make the key decisions, but agent technologies and the information systems built using them will represent them to some extent (playing an autocratic role) and will assist them in decision-making (playing an advisory role). The role of agent technologies in building an information society defined in terms of people's work should be assessed in terms of contradiction (mutual contradiction, divergence) rather than synergy (cooperation). The situation is different when identifying the role of agent technologies in building a digital society. A key issue for the development of agent technologies is the continuation of work related to the creation

of Semantic Web standards, and in particular the popularisation of ontologies as a method of knowledge representation in an information system (Niedbal, 2015).

The Concept of a Subsystem to Support the Management of the Protection of Intangible Assets of Companies in a Behavioural Perspective

Paweł Kobis
Faculty of Management, Czestochowa University of Technology, Poland

pawel.kobis@pcz.pl

Abstract: The human factor is the biggest challenge for enterprises in providing the expected level of security, whereas the lack of educated personnel is one of the key problems in building an effective system for protection against data and information threats. A human being is a non-programmable element of the system and it is difficult to predict his or her behavior in information management processes and in the face of a specific event. Humans cannot be programmed like some security applications or hardware solutions with predictable performance. Human actions very often have a stochastic effect on the operation of the system. They can be ill-considered, haphazard, affected by emotions, and taken without due attention and adequate knowledge and experience (Pham et al., 2019). All these imperfections are exploited by those whose goal is to destroy or obtain information. According to data published by several information security companies, attacks carried out by purpose-built bots and web applications that exploit a technical factor (e.g., system vulnerabilities) are becoming increasingly rare, and are being replaced by attacks in which human interaction is a key factor. The curiosity and trust, leading well-meaning individuals to click, install, open, and send information, are being exploited by cybercriminals who are increasingly adept at using social engineering techniques. The aim of the present paper is to discuss the theoretical basis of information security issues from the behavioral perspective and to present the concept of a subsystem that implements measures to minimize the impact of the human factor on the emergence of threats to the intangible resources of a business entity. The concept is to create an information and organizational space to support the operation of the traditional information security management system in small and medium-sized enterprises. The concept is presented using the object-oriented approach which focuses on the functional elements of the system, and the subject-oriented approach, which takes into account the relationships between the various individuals who affect the security of the information system. The author's models of each approach were presented along with a description of how they work.

Keywords: Information management, Information security, Human factor, Data protection, Information security management system

1. Introduction

The concept of information security is strongly correlated with the information security management process and the established security policy (Kim and Han, 2018; Paananen et al., 2020). In the case of modern enterprises, this management occurs at the level of information systems, taking into account the security of data and computer devices themselves, software, and the security of the communication network connecting computer devices, where information is in the form of a string of bits. Information can be represented by a text, graphics, video, or a binary file in the form of a computer application. Analysis of information security in this aspect translates into an analysis of the security of the system in which the information is processed. A huge challenge for information systems today is also the excessive amount of data and information that needs to be analyzed (Jabir et al., 2022; Maroufkhani et al., 2020).

The security of digital information resources boils down to the development of a specific information security environment (Mirtsch et al., 2021; Nel and Drevin, 2019). The concept of information security is now very broad, and its dimension is proportional to the development of information systems. It should be approached as a parallel system that ensures effective and uninterrupted information management. The security system consists of certain components, with the most important including (Kobis, 2021):

- security devices;
- security software;
- procedures, regulations, ordinances, analyses, policies, etc. concerning the ways, requirements, and scope of information protection;
- humans.

The information security system represents a part of the IT system (its subsystem). It is inherent in this system and shares hardware and software resources.

2. Theoretical Background

Modern information security system considers people as the most risky element of the system (D'Arcy and Teh, 2019; Karjalainen et al., 2020). Employees of business entities are increasingly exposed to social engineering activities (Aldawood and Skinner, 2019; Salahdine and Kaabouch, 2019). It is easier for attackers to deceive people than a professionally designed security system (Al-Shanfari et al., 2020; Steinmetz et al., 2021).

How can we make the term "humans" more specific? For business organizations, we can classify human resources as employees, business partners, customers, and third parties (Figure 1). One can, of course, extend this classification, for example, to include positions held by employees, define types of business partners, etc. However, for the purpose of the present paper, the above-mentioned division was adopted. It defines specific groups of people who influence the management of intangible resources in an organization.

The employee is understood to mean any person who performs any information management activities for the benefit of an enterprise and is paid by that entity for such work. Therefore, we are talking about employees who work based on employment contracts, so-called "junk contracts," management contracts, self-employed, etc. Furthermore, the described meaning of the employee is also extended to CEOs, directors, owners, and system administrators.

The term 'business partner' defines any person or group of persons who cooperate with an enterprise on a mutual benefit basis. Therefore, these can be franchisees, all suppliers, and subcontractors.

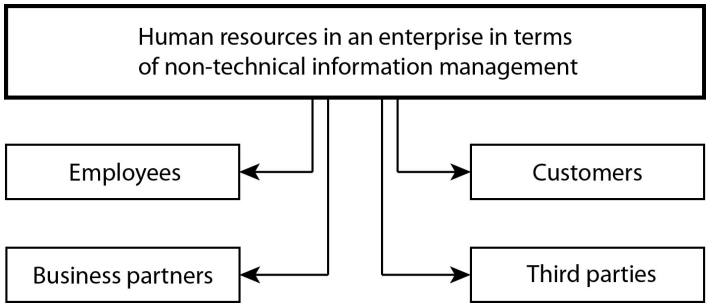

Figure 1: Human Resources in the Process of Non-Technical Information Management

Third parties that influence the management of information resources are: opinion-forming individuals that influence certain activities within the organization, and those seeking to acquire, either legally or illegally, information held by the enterprise. They can also be outsourcing entities (Benaroch, 2020; Feng et al., 2020).

The term customer refers to an entity that purchases a good to be consumed by them or for further distribution and acquires rights to its ownership. According to Encyclopedia of Management (Polish: Encyklopedia Zarządzania), customers are not only individuals but also legal entities and government entities that purchase goods and services offered on the market (Encyklopedia Zarządzania, 2023).

Analysis of human behavior in a business entity and in its closer and farther environments allows for outlining the relevant influences of the human factor on individuals, characterized by specific relationships (Figure 2). Security of information resources requires taking into consideration every person who more or less has or can have an impact on information management (Hadlington et al., 2020; Wiafe et al., 2020). This involves both positive aspects related to the experience of working with customers and business partners, and negative aspects, usually related to third parties classified as potential aggressors, employees of competing entities, individuals or groups of individuals who want to extort and destroy information or blackmail the enterprise while expecting potential profits from such acts (e.g., ransomware) (Kobis and Karyy, 2021; Masuch et al, 2021; Reshmi, 2021). Figure 2 shows feedback communications to third parties marked intentionally with a dashed line. This is because, on the level of information protection, these actions are usually defensive in nature. There is no full interaction with the potential aggressor. These are only specific responses, *ad hoc* actions, or those planned and predicted by prior risk analysis.

The various actors shown in Figure 2, despite the different scales of the human factor in both positive and negative aspects, cannot be easily classified as "good" or "bad." Anyone, whether a customer, business partner, third party, or employee, can, through certain intentional or accidental actions, contribute to both threatening and strengthening the structures of the information system. Hence, it is necessary to develop and

implement a systematic solution that, in addition to purely technical and software risks, will also take into account the behavior of humans who are the main element of the information system.

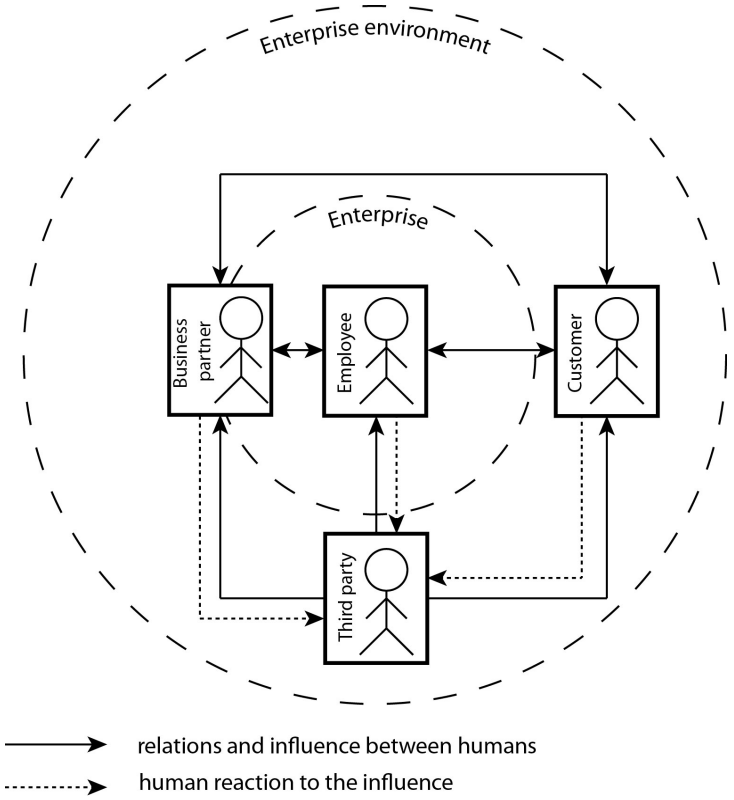

Figure 2: Possible Relationships and Influence of the Human Factor on Information Security Between Individuals

As can be seen in Figure 2, the employee is at the center of the human factor's influence. It is as much a symbol of rank-and-file employees who process certain information resources as of managers of any level, a security system administrator, an owner, or a CEO. These are the individuals with the greatest access to intangible resources, and in the event of a threat, these people are most often exposed to the potential influence of social engineering.

3. Concept of the Subsystem for the Management of Non-Technical Aspects of Information Security

3.1 General Assumptions

To counter information threats, in which humans are a key risk factor, it is necessary to develop the concept of a system solution. The solution should complement the existing information security management system (ISMS) in business entities as its subsystem. The subsystem should include all activities aimed at minimizing the risks associated with the occurrence of threats to information resources. It should include non-technical aspects of security directly related to humans. It should be positioned on the behavioral plane. The author named the system Subsystem for Management of Non-Technical Aspects of Information Security (MNTAIS subsystem). It is a proprietary solution addressing the impact of the human factor on information security. Therefore, the MNTAIS subsystem should be viewed as the implementation of activities and procedures to minimize the risk of threats caused by the human factor within the information security management system in enterprises. The MNTAIS subsystem is a supplement to the ISMS with elements concerning the impact of human beings and human groups on information security. The MNTAIS subsystem is intended to be an additional component of the ISMS, being its extension to include aspects of human impact on information security. It should be noted that modern ISMSs used in enterprises, to varying degrees, consider the human factor as a potential threat to intangible resources, tying it 'incidentally' to procedures, rules, and regulations for traditional security solutions. Thus, there is a lack of systemic solutions that would meet the assumptions of a coherent concept of information protection in an orderly manner. The subsystem presented below is a proposal to fill this gap.

3.2 Implementation and Operation at the Object-Oriented Level

At the object-oriented level, the Subsystem for Management of Non-Technical Aspects of Information Security (MNTAIS subsystem) can be defined as a set of hardware and software solutions that achieve the stated objectives of securing the information resources of a business entity against threats caused by the human factor. These solutions interfere with the information system in a certain way, minimizing the risk of an incident. Figure 3 shows a diagram of the relationship between the components of the MNTAIS subsystem and the components of the information system. The components can be characterized as follows:

- Enterprise Internal Network (EIN): a LAN computer network of a business entity, both physical (cable network) with a specific topology, and wireless, with a specific standard used for data and information exchange.
- Fixed and Cellular Telephony (FCT): all telephone communication systems used in the entity.
- Individual Information Processing Stations (IIPS): all workstations where information resources are processed. These include desktops, laptops, tablets, smartphones, and other devices that allow for processing.
- Collective Information Processing Stations (CIPS): all stations that support individual stations to a certain extent. These include file servers, database servers, application servers, email servers, and other systems with similar functions.

The above components form relationships with elements of the MNTAIS subsystem. Most relationships (except for reporting connections) are bidirectional, as there is a mutual exchange of signals, data, or information in each case. They are as follows:

- Software and hardware solutions for blocking specific services work in cooperation with three components: EIN, IIPS, and CIPS. In the case of EIN, data is collected on services being run in the internal network or computer devices being connected to the network. In the case of IIPS, data is collected on both local and cloud computing applications, and connected peripherals e.g., to USB ports (Universal Serial Bus). In CIPS, on the other hand, the component controls users' privileges of using specific resources, monitors their flow, and checks the external devices connected by employees.
- Detection of illegal actions by employees or third parties that attempt to illegally obtain information triggers a mechanism to block them immediately. This component can operate according to two scenarios, by either blocking predefined attempts or, using artificial intelligence mechanisms, making independent decisions to allow or block the service. Artificial intelligence can also be a complementary solution, similar to the way it works in some antivirus programs, which, using built-in intelligent mechanisms, recognize suspicious codes, even though officially the code is not in the signature database.

The component reports its activities in an automated reporting system.

- Remote access control systems work only with EIN by real-time monitoring connections between the global network and the LAN. They mostly concern remote workers, assigning them specific rights to access resources. At the same time, they block illegal attempts by third parties to connect to the network. It should be noted that these systems are not solutions designed to block malware and other threats automatically distributed by Internet bots. They are complementary to them and are intended to eliminate unwanted intentional or accidental human actions from the Internet. The operation of the component is reported.
- Automated control systems work with EIN, IIPS, and CIPS. They are primarily tasked with watching employees in terms of establishing proper safeguards for information resources. This includes monitoring the passwords for network devices, wireless networks, computing devices, local applications, cloud access, or monitoring users in terms of opening communication ports, etc. All human errors are reported. The reports include both the error identifier itself and detailed information about the person who made the error. Therefore, these systems make it possible to establish a base of training needs.
- Automated identification systems work with FCT and IIPS. These are the two components of the information system that allow communication with the enterprise. The systems identify the people who contact the enterprise. The operation of the component is reported to the extent permitted by law, especially under the provisions of the GDPR.

- Knowledge bases are connected only to IIPS, working simultaneously with online and artificial intelligence systems. This cooperation is expected to make it possible to search the database for information through the mechanisms of the network communicator, which is equipped with a search module. Artificial intelligence mechanisms, also equipped with instant messaging options, can be directly used by ISPI. Furthermore, artificial intelligence tools supported by a knowledge base can "suggest" specific solutions. This synergy allows employees to use a single tool when interacting with an information security supervisor, with an artificial intelligence messenger, and with a knowledge base. It also allows instant messengers to refer users to specific electronic documents during a conversation.
- Systems for controlled, targeted attacks that enable the identification of employee vulnerabilities work with all components of the information system. In the case of EIN and IIPS, they allow simulation that allows for the identification of gaps in the knowledge and experience of employees dealing with the enterprise's IT system. Indirectly, they also allow for checking the reliability of other components of the MNTAIS subsystem that provide security to EIN and IIPS.

In the case of IIPS and FCT, they are used to test the knowledge and experience of employees, especially in social engineering techniques. They allow for drawing a detailed map of training needs.

All elements, both in the information system and the MNTAIS subsystem, are monitored.

Implementation of the subsystem at the object-oriented level requires the following steps:

1. analysis of all elements of the information system;
2. adaptation of elements of the MNTAIS subsystem to the existing configuration of the ISMS system;
3. implementation of individual components.

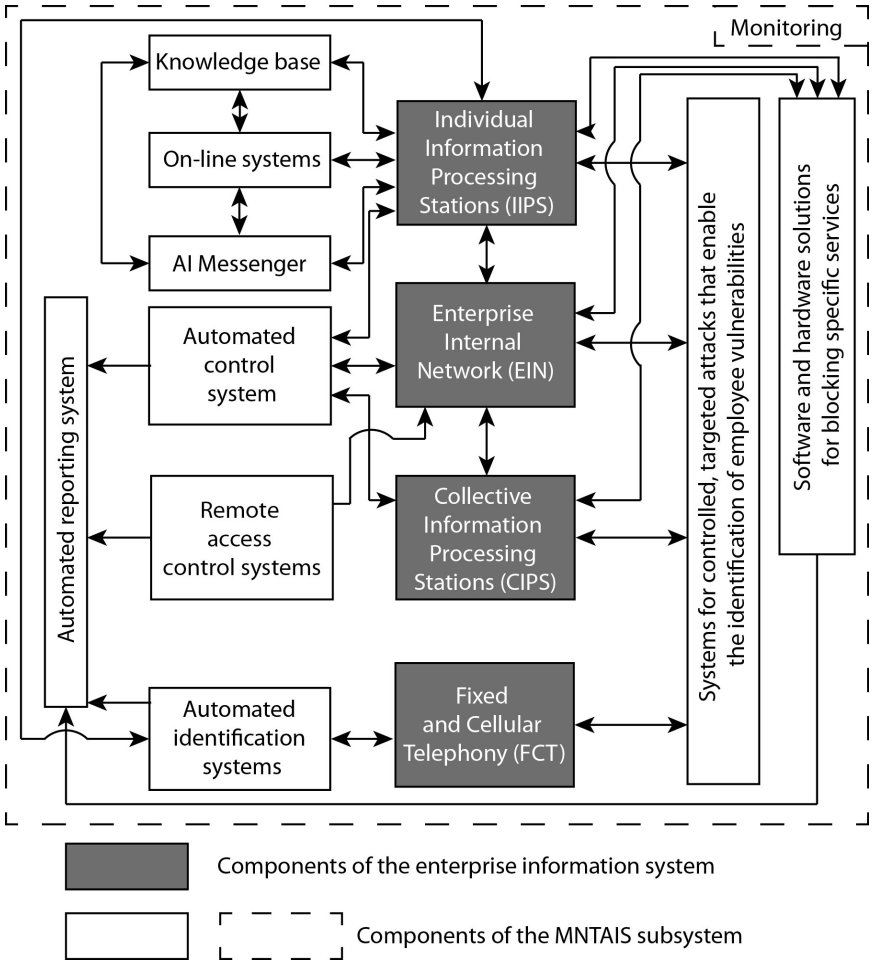

Figure 3: Components of the MNTAIS Subsystem and Relationships Between Components Of The Information System

The first step is used to determine all technical aspects of the existing system, including:

- configuration of devices in the local network;
- existing operating systems;
- existing computer software.

These aspects are necessary to adapt all elements of the MNTAIS subsystem so that data and information can be exchanged between components of the existing information system and those of the solution being implemented (Step 2). The systems for identification, control, and reporting, knowledge bases, and other parts listed in Figure 3 should function using the same communication protocols, encryption algorithms, file formats, and other technical parameters. This is the only way to achieve integrity of information.

Step three, which concerns the implementation process, should include two levels: technical implementation of the new solutions and familiarization of employees and system operators with the new functionalities. These two levels should correlate with each other. Although the individual components of the MNTAIS subsystem are autonomous (hence the order of implementation is not particularly important), their implementation without training may result in the overall deterioration of the operation of the information security system. Therefore, it is necessary to ensure systematic implementation. Each component should be implemented on two levels simultaneously, then the next one, and so on. This allows for regular learning of new solutions, thus fully utilizing the potential of the MNTAIS subsystem. In general, it is important to implement the MNTAIS subsystem into the information system in a comprehensive manner, as only by this method can a coherent and efficient information protection system be developed.

3.3 Implementation and Operation At The Subject-Oriented Level

At the subject-oriented level, the Subsystem for Management of Non-Technical Aspects of Information Security can be defined as a set of relationships between the intangible elements of the subsystem and the individuals who influence the security of the information system, and individuals pursuing the stated objectives of securing the information resources of the business entity against threats caused by the human factor.

A detailed diagram of the relationships is shown in Figure 4. The diagram presents two types of relationships: between individuals, marked by dashed lines, and between subsystem elements and individuals, marked by solid lines.

In the case of interpersonal relations, the following relationships can be defined for the prevention of threats to information resources:

- Between the person responsible for information security and other people. They are of the following nature:
    - with an employee: they concern broadly defined support for the security of processed information, analysis of the employee's actions in terms of compliance with regulations and rules of conduct;
    - with a customer: they concern the imposition of certain rules of conduct when the customer uses the enterprise system (e.g. when creating an account), the assignment of access rights to the information system, definition of customer service policies, and analysis of customer activities in the enterprise system;
    - with a business partner: they concern the imposition of certain rules of conduct when a business partner uses the enterprise system (e.g., when registering a reseller account), the assignment of access rights to the information system, the analysis of business partners' activities in the enterprise system;
    - with a third party: they concern the determination of the level of security against access to the information system, monitoring attempts to breach security, and phishing attempts using social engineering.
- Between the employee and other people, especially:
    - with a customer: they concern maintaining certain standards of customer service in terms of eliminating potential situations in which there may be a possibility of intentional or accidental disclosure of protected information and the ability to counteract social engineering;
    - with a business partner: they concern senior employees responsible for business relations. The scope of the relationships is analogous to that with customers;

- with a person responsible for information security: they concern the employee's reporting of irregularities and suspicious behavior of applications and the operating system during the performance of assigned activities;
- with a third party: they concern the ability to detect a situation in which a third party uses social engineering techniques to obtain information and the ability to counter them.

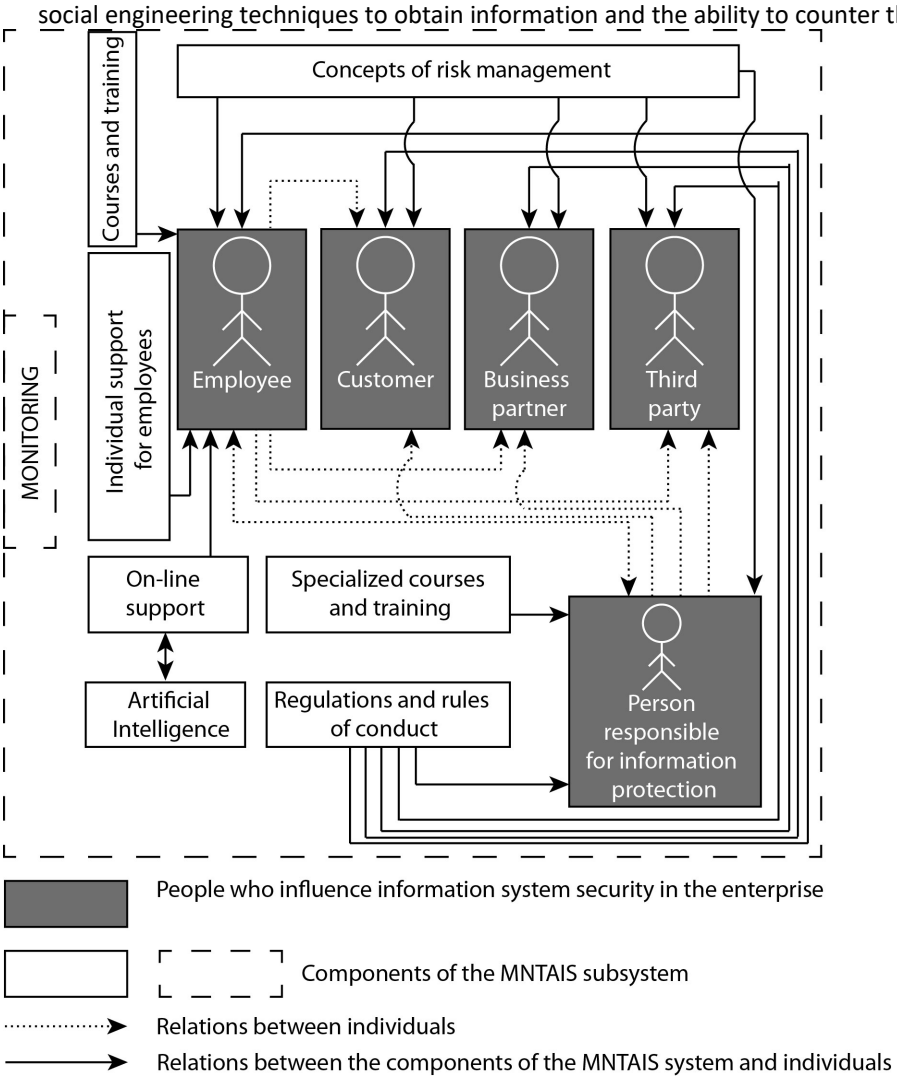

Figure 4: Relationships Between the Components of the MNTAIS Subsystem and Individuals who Influence the Security of the Enterprise Information System

Relationships between individuals in terms of the prevention of information risk are affected, among other things, by components of the MNTAIS subsystem. They influence individuals directly or indirectly. Direct actions are understood to mean performing certain actions in the presence of the person or communicating information or knowledge directly to them. Indirect actions include developing regulations, rules of conduct, and risk management concepts that apply to the person and should be followed by employees who have or may have any contact with such persons. In other words, these activities are aimed to create an area of security in dealing with these persons. Consequently, there are the following components with their respective impact as shown in Figure 4 based on the intangible components of the MNTAIS subsystem:

- Courses and training: organized periodically in the field of information security. Problems discussed can be determined by current issues presented in the literature or as a result of the operation of automated reporting systems (Figure 3). They are aimed at all employees with access to the enterprise's information resources.
- Specialized courses and training: held periodically for those involved in information security. In addition to issues directly related to the positions of these individuals, training can be extended to include human resource management in selected aspects needed to achieve the goal of adequate preparation of employees for secure information management.

- Risk management concepts: regular risk analyses and rules for dealing with risks related to the human factor, taking into account all persons who have access to information resources and those who pose a potential threat.
- Regulations and policies: these are communicated to information security officers and all employees only directly. In the case of customers or business partners, these components may affect them and be communicated both directly (e.g., through a web platform during account registration in the form of terms and conditions to be accepted) or may affect them indirectly by providing guidelines to the business entity's employees on how to contact them. In the case of third parties, there can be only indirect action.
- Individual support for employees: a component that relates to any activities aimed at providing direct support to an employee in a situation of danger or inability to cope with a given situation while processing information resources.
- Online support: a component that relates to any employee provided by an electronic communication system with an intra-organizational chat room using optional artificial intelligence solutions.

All these components are monitored. Monitoring means the supervision of the correct functioning of the subsystem, the proper execution of tasks by its various components and persons who are both part of and beneficiaries of the MNTAIS subsystem. This supervision can be the responsibility of information security professionals (in the specialized area) and managers, owners, directors, and CEOs (in the logistics area).

Subsystem implementation at the subject-oriented level is more difficult and time-consuming than that at the object-oriented level. This is primarily due to the fact that this level involves directly humans. The knowledge acquisition processes, the information contained in regulations, rules, and training are extended over time. Full implementation of the subsystem should not be expected after certain content and documents are presented to employees. Simply familiarizing with them is only the prerequisite for actually following and understanding them. The meaning of understanding refers to the employee's ability to link the acquired theory to the practice of processing information resources.

During the implementation of the subsystem, the individual predisposition of employees to acquire knowledge should also be taken into account. For example, a certain group of employees may understand certain phenomena after studying the prepared documentation and more quickly relate them to the practice, while another group, in order to understand, will have to relate them to daily work and to some extent learn from mistakes. This is inevitable and leads to an extended process of full implementation and comprehensive operation of the MNTAIS subsystem.

3.4 Comprehensive approach to the MNTAIS subsystem

The MNTAIS subsystem is intended to comprehensively encompass safeguards against all types of threats originating in human behavior. Aware of the pace of change in information management processes, the author proposed a subsystem where components can function independently. Therefore, the subsystem is an open solution to which further components (modules) can be added to protect against threats that may emerge in the following years. The only inseparable structure, according to the author, is the need for both planes to coexist (Figure 5). Only in this way, by combining human actions with tangible and intangible components that prevent the loss or destruction of information, can a comprehensive solution be achieved to minimize the risk of threat to intangible resources.

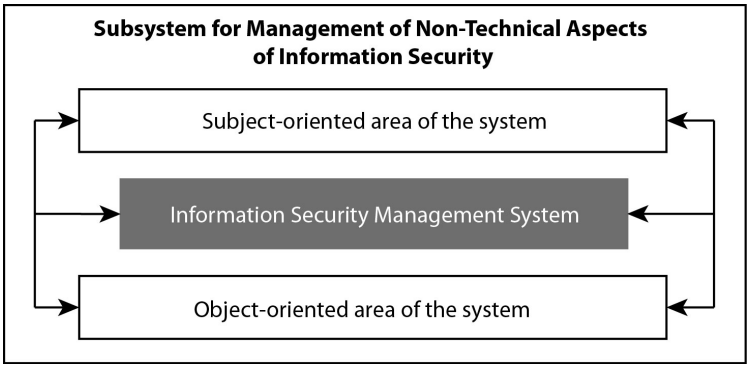

Figure 5: A Holistic View of the MNTAIS Subsystem Against the Background of the Relationships With The Information Security Management System

According to the author, very important and inseparable is the cooperation of the MNTAIS subsystem with the existing security system. This allows for the comprehensive elimination of potential incidents. Furthermore, the spectrum of modern threats is so broad that the various techniques of attacks and attempts to obtain information are beginning to intermingle. The resulting hybrid techniques can only be effectively combated through close cooperation between the MNTAIS subsystem and the ISMS.

4. Conclusion

The subsystem concept presented in this study is in line with contemporary solutions in the field of information resource protection. Its structure and operation use the mechanisms of the information security management system and are a kind of extension with components that take into account the human factor. This approach simplifies the management of the security system in the enterprise as it does not change the current state of affairs, and there is no need to build a parallel hardware and software infrastructure and structure for managing it. The synergy of these two systems allows for holistic risk management and considering potential events comprehensively: according to the existing rules of threat identification and classification, supplemented by factors related to the behavior of employees, customers, business partners, and third parties.

The visualization of the subject-oriented and object-oriented areas of the subsystem and its entirety is only a proposal. The subsystem, according to the author, is coherent and achieves the goal of minimizing risk in enterprises. It can also inspire further modernization of the subsystem or the development of a new solution.

Awareness Level of Information Security Managers in Small Enterprises in Poland

Paweł Kobis and Grzegorz Chmielarz
Faculty of Management, Czestochowa University of Technology, Poland

pawel.kobis@pcz.pl
grzegorz.chmielarz@pcz.pl

Abstract: The security of information assets largely depends on the real level of knowledge of those managing the information system. Particularly important is the knowledge acquired on an ongoing basis through reading and analysing: new reports published by specialised intelligence services worldwide, thematic portals, industry and scientific publications. Today's rapid pace of development of information, communication systems means that knowledge of digital information security acquired a year or more ago becomes partly outdated. Although there are specific, unchangeable canons of behaviour, proceedings in the processes of information protection - they are only a foundation for building an effective system of protecting intangible resources. Special attention should be paid to the fact that information protection is not an individual activity - it is a process running parallel to all processes operating in enterprises. The global pandemic situation has had an irreversible impact on the perception of information asset security. The situation in which most business entities were forced to work remotely necessitated a new approach to information security among its managers. The relatively stable environment of business entities until the pandemic suddenly forced the use of new techniques and technologies enabling work from private, home networks. Have such conditions changed the attitudes of security managers to the need for continuous education, to expand their knowledge in this area? Did those responsible for the security of intangible assets gain more experience with information security during the pandemic? The aim of this article is to present research on the knowledge and awareness of information security managers conducted before the pandemic in 2018 and 2019 among small businesses in Poland on the real perceptions of those responsible for information security and to compare them with the same research conducted in 2022 after the pandemic.

Keywords: Information security, Small businesses, Security management, Information security awareness

1. Theoretical introduction

The human factor is currently the catalyst for most of the risks recorded in modern companies (Hughes-Lartey et al, 2021; Lin et al, 2022; Metalidou et al, 2014). There is a need to implement a number of measures to secure information assets in the area of human information management. For example, cyber-security experts advocate the need to train personnel in cyber-awareness and to become acquainted with new ways of social engineering functioning (Tayouri, 2015; Washo, 2021). Five main recommendations for reducing the risk of information security breaches can be found in the literature (Sedgwick, 2019):

- The need for pre-implementation testing of new technological solutions implemented in companies in order to avoid unwanted actions on the part of users (employees). The design of the system should take into account both the ergonomics of work and minimise the generation of accidental errors on the part of employees.
- The need to organise regular awareness training on IT security.
- Implementation of "cyber hygiene" principles in companies.
- Establishing rules of cooperation between employees and those responsible for information security. Building a support and assistance system for employees.
- Building a system to encourage reporting of information security breaches. Eliminating situations where security breaches are covered up by employees.

In order for the recommendations listed above to be implemented, they must be understood by managerial personnel of enterprises. Those responsible for information system security should be familiar with the realities of modern threats, and be able to transfer them to the operation of a particular enterprise. It is very important to understand the principles of risk management and the impact of the human factor on these risks (Shaikh & Siponen, 2023; Noga & Brzeziński, 2022). It is essential to classify the possible information security risks in the area of organisational functioning and to be able to determine their relevance to individual departments/workstations (Kobis, 2021, pp. 267-268).

2. Research Methodology

The research presented was carried out twice, in the same way, on the same number of: 287 enterprises with a time interval of 3 years. In the second survey, the majority of enterprises overlapped with those in the first

survey, and a small number were new. This was due to the fact that, between the first and second surveys, some enterprises had ceased their activities or developed from small enterprises into micro-enterprises. The research techniques adopted for the survey were the F2F (Face to Face) face-to-face questionnaire interview with the use of a computer (CAPI - Computer Aided Personal Interview), which in some cases was replaced by an interview conducted via instant messaging allowing direct, natural audio-visual contact with the respondent while adhering to the applicable rules for conducting the survey, and the CAWI (Computer-Assisted Web Interview) technique. Thus, the so-called Mixed-Mode was used. The same questionnaire was used in both techniques. The first research took place in 2018-2019, the second in 2022. The inspiration to repeat the same research was the turbulent pandemic period for companies, which, by changing the form of work provision (remote working) in many cases, significantly affected the perception of information security among business entities. Thus, it is the authors' intention to compare the findings obtained before and after the pandemic period. The people surveyed were those in entities who had the greatest knowledge of information security and who were directly involved in the processes of establishing and updating security policies in the organisation. Thus, these included such individuals as heads of IT departments, employees of IT departments, individuals specifically (full-time or part-time) involved in the security of digital information assets, presidents, directors, owners and co-owners.

The presented research results represent a slice (fragment) of the authors' research conducted in the area of the SME sector and concerning the security of information resources.

3. Research Results and Discussion

The starting point in estimating the knowledge regarding the impact of the human factor on information security among those responsible for protecting information assets is to determine its importance in the minds of respondents (Kobis, 2021, p. 268).

Table 1 presents the results of a survey showing the view of the level of effectiveness of IT security safeguards in the information system of an enterprise. These safeguards can be broadly divided into technical and behavioural safeguards. The former refer to all physical and software safeguards that hinder or, in selected cases, eliminate the possibility of an attack on information resources. Behavioural safeguards are a set of measures aimed at training and making employees aware of the principles of proper information security management, so that it does not fall into the wrong hands. It should be noted here that currently available research indicates that the human factor is mostly responsible for the loss or destruction of information in modern organisations. During the first survey in 2018-2019, as many as 57.8 per cent of the respondents said that professional software and hardware security was able to eliminate most incidents of information loss and leakage. Only 25.1 per cent of them held the opposite view. This means that only in one in four enterprises, those caring for information security were aware of the real impact of non-technical factors in reducing the risk of unwanted incidents. The situation changed slightly in 2022, with a predominance of respondents on the side of ineffectiveness of physical security (49.1%) over those in favour of it (41.5%). The percentage of those who could not decide on the question also decreased.

The pandemic period forced many entities to work remotely (Benitez et al., 2023). Thus, employees performed their duties from their homes, private networks, and public networks, often on their own, unprotected computing devices. Many of the respondents, responsible for information security in their own enterprises, realised that it was largely up to the employee to keep information resources secure or not. In remote working, many of the safeguards previously in place on the enterprise's internal network did not directly translate into security on the employee's private network. It is mainly up to the employee to ensure that the information is secure.

Table 1: Respondents' Answers to the Question: Is Professional IT Security a Guarantee of Information Security in the Enterprise?

	2018/2019 research		2022 research	
	Number	**Percentage**	**Number**	**Percentage**
Yes, physical and software safeguards are able to eliminate most incidents of information loss and leakage	166	57,8%	119	41,5%
No, physical and software safeguards do not guarantee the elimination of most threats of information loss and leakage	72	25,1%	141	49,1%
No opinion	49	17,1%	27	9,4%

Source: Own elaboration

Unfortunately, the current figure of 41.5 % is still not encouraging. Many entities believe that technical security is the most important. This mindset may contribute to a significant increase in malware incidents. It justifies the belief among cybercriminals that a more effective form of attack on information assets is through the human factor. This is a very dangerous phenomenon, given the multitude of types of solutions currently in place. In extreme cases, without proper safeguards, malware can operate in a company for months or years. An example of this is spyware, which can continuously collect certain information and transmit it without the owner's knowledge to others. Apart from using part of the hardware resources, the programme does not reveal its presence and is therefore 'invisible' to the user. In the case of modern computers with significant memory resources and high computing power, the load of a spyware programme can be completely unnoticeable in day-to-day operation.

Extending the discussion, the attitudes of enterprises in terms of combating potential risks, it is worth identifying, according to the respondents, the sources of security incidents. Table 2 shows the areas in which enterprises engage their financial and human resources to minimise potential risks.

Table 2: Sources of Possible Threats to the Information System, Together with the Percentage Level of Enterprise Involvement in Terms of Their Potential Combating

	2018/2019 research		2022 research	
	Number	**Percentage**	**Number**	**Percentage**
IT risks (software and hardware)	160	55,7%	104	36,3%
Threats related to the "human factor", social engineering activities	92	32,1%	166	57,8%
Direct physical threats (burglary, theft of equipment, documents)	35	12,2%	17	5,9%

Source: Own elaboration

In the first round of the survey (2018-2019), again, as in the previous survey, the most important area according to respondents is IT (software and hardware) threats. As many as 55.7 per cent of the organisations overall engaged their resources in combating such dangers. Only 32.1% perceived threats from behavioural activities. In the 2022 survey, there was a polarisation of indications after the pandemic. Only 36.3% of the respondents viewed the source of possible threats on the software and hardware side, compared to 57.8% of the respondents. As with the previous question, the reason for the change in view of these aspects can be found in the change in the form of work provision from stationary to remote. It was in the responsibility of the employee that security for information resources was sought.

The least involvement of enterprises (in both the first and second surveys) can be seen on the level of direct, physical threats (burglary, equipment theft). Attempts to illegally obtain information tend to be of a remote nature - via a computer network or human factors: employee bribery, business intelligence, etc. Cases of physical intrusions for the sole purpose of obtaining information are relatively rare. The loss of intangible resources in this way tends to be related to actions aimed at stealing the equipment and tangible assets on which (disks, internal memories) the information was stored.

Table 3 shows the share of companies that allow or prohibit access from computing devices to social networking sites and online chat rooms. Both before and after the pandemic period, this ratio is similar and has not changed much.

Source: Own elaboration

Applications used to communicate over the internet pose risks that can be divided into:

- unauthorised and uncontrolled transmission of information in the form of text or files by company employees;
- accidental or intentional posting of company-related material on social networks; and
- fake news and hyperlinks sent by cyber criminals;
- other activities organised by cyber criminals using social engineering.

It is also important to note whether instant messaging is used for work-related purposes or whether it is only used for private conversations.

Transmission of text or files via instant messaging typically occurs in three cases:

1. Text and file transfer between employees - a quicker and easier path than using official tools (e.g. document exchange system).
2. Transmission of text and files to third parties by dishonest/bribed employees.
3. Text transfer to friends, family.

In the first case, the danger is limited to the transmission of an unencrypted signal (this is the default setting of most communicators) and thus easily accessible to eavesdropping by third parties. In the second case, we are talking about the easy, uncontrolled, difficult-to-monitor transmission of files with virtually no quantitative limits. In the third case, with potentially the least harm, we are talking about the possible disclosure of confidential information during a conversation and eavesdropping by third parties (Curry, 2013).

Posting company-related material on social networks usually involves publishing photos of the workplace and possible information about the nature of the work being done. This information can be used for potential social engineering activities by cybercriminals. In addition, posted photos may reveal information that was accidentally photographed, which may be potentially relevant to criminal activities.

Significant threats from instant messaging and social networking sites include fake posts, spreading information containing hyperlinks to infected sites and malware. The appearance and content of messages crafted by cybercriminals usually inspire a high level of trust among users, which increases the potential risk of the threat. The most common threats are XSS (Cross-Site Scripting), SNS (Social Networking Service) and so-called phishing to extract relevant information from users through social engineering activities (Gruber et al., 2012, p. 356).

A group of socio-technical activities also includes 'impersonation' on social networks and instant messaging sites by persons known or potentially known to a specific employee. When contacting a specific employee, for example, the cybercriminal introduces himself as, for example, "a colleague from another department of the organisation" and tricks the employee into providing certain information under the pretext of performing his duties.

As in the case of instant messaging and social networking, it is important from the point of view of information security to implement general rules for the use of the global network. The multitude of communication solutions and technologies that allow to carry out conversations or send information of virtually any size without the use of any additional programs (e.g. https://wetransfer.com/) should result in the implementation of a set of rules for the use of network resources. At present, any website (store, information portal, theme portal, auction system, etc.) can be a source of threat to the intangible resources of a business organisation.

Establishing internal regulations that normalize the rules of network use, also providing for certain sanctions for employees, can become one of the more effective tools for reducing the risk of information security breaches. According to the survey, as many as 66.9% (in 2018-2019) and 64.8% (in 2022) of enterprises have no regulations in this regard (Table 4). This is not an optimistic result and indicates the need for quick action before business entities. This is an important aspect, as the literature shows a steady increase in reported attacks through crafted and infected websites.

Table 4: Percentage of companies With or Without an Internal set of Rules for Using Internet Resources in Their Information Security Policy

	2018/2019 research		2022 research

Another threat to the security of information resources that has the hallmarks of a human factor is the use and manner in which employees use portable data storage (Pabian et al., 2020). Modern technology makes it possible to store hundreds of GB of data in a volume of 1-2 cm^3. This means that practically imperceptibly any employee with access to information resources can copy them and carry them unnoticed outside the enterprise area. Moreover, the currently popular "flash drives" are for many people the primary storage place for documents and software files used in daily work. This is due to the convenience, speed of access and versatility of such a solution. These solutions, due to their practical advantages, can also be used for private purposes. In practice, situations arise in which users store both "company" and personal materials on portable data stores in parallel. All these situations can lead to such risks as:

- using portable data storage devices to steal information;
- storing, for example, the only copy of a particular document on a memory stick (the employee edits the files directly on the USB drive);
- possibility of disclosing information to third parties, e.g. while viewing private information on the same medium;
- losing the data carrier and, consequently, the possibility of unauthorised persons intercepting the information;
- the possibility of infecting a workplace computer workstation by first connecting the USB storage medium to other (e.g. private) computer devices.

In order to prevent the aforementioned risks, it is recommended to block or review any portable data storage in business organizations. Various software solutions are used for this purpose, allowing to maintain control over these resources in any programmed way. Table 5 shows the results describing the position of the surveyed economic entities on the aforementioned issue. Only 23.3% of enterprises had developed control mechanisms in 2018-2019. Three years later, this percentage has increased very little (25.8%). This is a low result exposing the vulnerability of enterprises' information systems to relatively simple ways of losing information., Interestingly, for three years, 4.8% of enterprises have introduced regulations forbidding the bringing and carrying away of data stores, and only 2.5% have implemented their enforcement. This also shows too little interest on the part of those responsible for information security in this topic.

Table 5. Respondents' Answers to the Question: Is There any Form of Control In Enterprises Over the Bringing and Taking of Portable Data Storage by Employees (SD card, PenDrive, USB drive, CD, DVD, BR)?

Yes	67	23,3%	74	25,8%

Source: Own elaboration

An analogous problem in terms of minimising the risk of information loss is the use of private computing devices by employees on the company's network. The currently popular BYOD phenomenon generates a number of problems in ensuring the security of intangible resources (Barlette et al., 2021; Zahadat et al., 2015). The most important of these is the blurring of the line between the use of a computer for professional and private purposes. From the point of view of information protection (problems analogous to the studies included in Table 5), this type of practice should be prohibited. However, many enterprises calculate the gains and losses of practicing this trend and allow the use of their own laptops, tablets and smartphones in daily work. In the 3-year period under review, the usage rate increased very significantly: from 59.9% all the way up to 91.6%. This is a result of the shift to remote working, where many employees performed their duties on private computer equipment. The very short period of assimilation into remote work meant that many businesses were not prepared for this. As a result, expressing consents to the use of private equipment was a natural consequence. The results are shown in Table 6.

Table 6. Respondents' Answers to the Question: Are Employees Allowed to use Private Computing Devices (Laptop, Tablet, Smartphone) in the Enterprise Network?

	2018/2019 research		2022 research	
	Number	**Percentage**	**Number**	**Percentage**

No	115	40,1%	24	8,4%

Source: Own elaboration

Enterprises that allow the use of private devices in the workplace should implement appropriate systems to monitor the behaviour of these computers on the enterprise's local network. This can significantly minimize the risk of information threats, and in selected cases eliminate them. The basic idea should be to establish a policy that provides for the use of private computers as data processing devices under certain conditions imposed by a properly configured system. At the same time, the possibility of storing any information or data in the memory of these devices should be prohibited. Thus, they should only provide an interface to work on information resources located on the enterprise's server or in the cloud computing (Irsheid et al., 2022). The actual position of economic entities on this issue is shown in Table 7.

Table 7: Measures to Monitor Employees' Private Computing Devices on the Company's Local Network

	2018/2019 research		2022 research	
	n=172		n=263	
	Number	**Percentage**	**Number**	**Percentage**
No need to monitor and authorise employee equipment	135	78,5%	83	31,6%
Devices are authorized in the network, but no one monitors the transmission of information	26	15,1%	166	63,1%
Each device is authorized and monitored against transmitted information	11	6,4%	14	5,3%

Source: Own elaboration

From the research results presented in Table 7, it can be observed that with the transition of economic entities to remote work, the need to authorize employees' devices on the enterprise's local network has increased significantly (Y. Sun et al., 2023). At the same time, it can be seen that the phenomenon of monitoring these devices has not changed (in fact, it has decreased somewhat). This is directly related to the question in Table 6 - in connection with the use of private devices by employees, they should be authorized on the network. However, there are no tools for monitoring private computers. Moreover, in many countries this would be a violation of the law.

A very important aspect in the protection of information is the organisation of work in places where customers and business partners are served. Currently, we can consider these issues on two levels:

- Protection of personal data (compliance with GDPR);
- Protection of business-critical information from accidental disclosure.

Both levels require adequate preparation on both theoretical (general set of rules, regulations) and practical (preparation of premises) grounds. These measures minimize the risk of information threats, reducing the human factor in such situations as the possibility of eavesdropping on employees' business conversations, the possibility of accidentally seeing documents placed on a desk or computer screen, and more direct ones, such as attempted theft. Table 8 shows the solutions to the aforementioned problem operating in enterprises.

The survey shows that 38.7% (2018-2019) and 36.2% (2022) of enterprises receive their customers in a dedicated room. This is a good result compared to other described measures to minimize the risk of information security breaches involving the human factor. Probably also caused by the fact that the requirements of the so-called "clean desk" and "clean monitor screen" appear in the GDPR regulation, which provides for high, financial criminal penalties for violations of personal data protection. However, as many as 49.9% (2018-2019) and 54.7% (2022) of enterprises still do not have practices to counter information security breaches.

Table 8: Places to Serve Customers and Business Partners In Enterprises

	2018/2019 research		2022 research	
	Number	**Percentage**	**Number**	**Percentage**
They are received in specially prepared rooms	111	38,7%	104	36,2%
They are received in one of the rooms in which employees carry out their daily work	117	40,8%	121	42,2%
Customers/business partners can move freely between rooms/departments of the enterprise	26	9,1%	36	12,5%
Due to the nature of the business operations, we do not personally receive customers and business partners at the premises of the company	33	11,5%	26	9,1%

Source: Own elaboration

Another aspect is the allocation of those information resources to employees that are necessary for them to perform their duties. Defining the rules for the use of software and hardware solutions makes it possible to significantly reduce the occurrence of potential risks and provides a set of basic guidelines related to information management in the company. However, additional attention should be paid to the extent and scope of access to information by those who manage it to any degree. The establishment of a resource entitlement policy is, in addition to the aforementioned principles, an elementary measure to prevent the loss or destruction of information. Assigning each employee a well-defined information area ensures that even in the case of deliberate, damaging actions by an employee, only selected intangible resources are at risk. Table 9 shows the results demonstrating the approach of economic entities in terms of entitlements.

It can be seen that during the pandemic period in which employees performed their duties through remote connections, the percentage of enterprises taking care of the proper allocation of resources for each employee increased (from 73.9% to 88.9%). In the case of small enterprises, one should additionally take into account the fact that in many of them there are no separate departments with specific responsibilities, and all "matters" concerning the entity's operation in the area of digital information are handled by one employee or the owner himself, for example. He then automatically has access to all intangible resources and there is no basis for applying any authority and these entities are included in the group represented by the results of 26.1% (2018-2019) and 11.1% (2022).

Table 9: Employees' Rights to Access Company Information Resources

	2018/2019 research		2022 research	
	Number	**Percentage**	**Number**	**Percentage**
Each employee has access to a specific information resource	212	73,9%	255	88,9%
Every employee has access to all information resources	75	26,1%	32	11,1%

Source: Own elaboration

The last issue discussed for the protection of information resources involving the human factor, perceived in the literature on the subject as one of the more effective, but at the same time controversial from the point of view of ethics, is monitoring. In light of modern technological developments, monitoring can cover virtually any aspect of human activity in the process of information processing. In general, regardless of the area in which it operates, it performs three basic security activities:

- preventive - by functioning in the consciousness of employees, it can minimize the number of mistakes made and reduce potential attempts to steal or destroy information;
- in the case of monitoring e-mails, telephone conversations, it can prevent potential intrusions into the network using social engineering activities;
- in a critical situation, after a threat has occurred, it allows to reconstruct to a certain extent the actions that led to the loss or destruction of information, and thus develop effective defence mechanisms for the future.

In the research conducted, an attempt was made to answer the questions: how many enterprises use monitoring techniques, and what areas they cover. The question was multiple-choice, so that respondents could mark any number of techniques used. The results are shown in Table 10. Direct interviews with respondents also show that each monitoring technique was implemented in accordance with the laws in force in Poland and each employee affected by the monitoring was informed about it. In special situations requiring additional authorizations, the appropriate consent was given by the employee.

In 2018-2019, the most popular technique was visual monitoring implemented through a system of video cameras installed in specific locations (25.1% of enterprises). In 2022, the most popular monitoring technique is already "software monitoring of activities performed on the computer" (up from 14.3% to 32.1%), and "control of e-mail correspondence" (up from 15.7% to 28.2%). As with the previous questions, the predominant focus during remote work is control of equipment or control of data managed by the employee. A direct surveillance system in the form of cameras is no longer relevant for obvious reasons.

Table 10: Monitoring Techniques Used in Companies (multiple choice)

	2018/2019 research		2022 research	
	Number	**Percentage**	**Number**	**Percentage**
Camera system	72	25,1%	69	24,0%
Control of e-mail correspondence	45	15,7%	81	28,2%
Software monitoring of activities performed on the computer	41	14,3%	92	32,1%
Print control	34	11,8%	38	13,2%
Recording of telephone conversations	11	3,8%	10	3,5%
Monitoring techniques are not used in the company	157	54,7%	93	32,4%

Source: Own elaboration

Computer monitoring is the most extensive and advanced technique (J. Sun, 2022). The number of activities that can be monitored is virtually unlimited. Advanced software solutions can nowadays monitor practically every mouse movement and record every key pressed on a computer keyboard. In the case of installed webcams, the system has the ability to record employee behaviour (similar to security systems installed in cars). The scope of monitored activities depends on the economic entity and possible arrangements with employees, whose opinion and possible objection according to the current law are not binding on the employer anyway (Kryczka, 2019; Ostrowski, 2014).

4. Conclusion

All the research results presented dealt with aspects of information security involving the human factor. Man, as the most important element of an information system, is at the same time its weakest link in the face of ensuring an adequate level of security.

The pandemic period, like no other period of information functioning as a strategic enterprise resource, has significantly contributed to the perception of information security from both technical and behavioural perspectives. The massive "migration" of employees from a desktop form of work to a remote form, carried out in record time, posed previously unknown challenges for business entities. One of them was to provide access to information resources from outside the company's premises in the most secure form possible. As the research presented here shows, the importance of the human factor as a catalyst for many potential risks was also realized on this occasion. The migration from a relatively secure information environment such as an enterprise's internal network to private environments, completely unknown by IT departments, meant that it was in the human (employee) that the greatest hopes were placed for the secure use of intangible resources of economic entities. The research presented here documents the fact that corporate information security decision-makers have changed their attitudes over the past 3 years in terms of behavioural perceptions of information security.

The research presented also confirms that turbulent periods (relevant to the operation of businesses) directly affect the perception and performance of certain management functions. One can also venture to say that the period of the contemporary armed conflict in Ukraine will also be significant for the perception of information

security. Thus, further research can make a significant contribution to the picture of the contemporary field of information security management.

Business Environment Institutions as a Catalyst for Knowledge and Technology Transfer

Patrycja Kokot-Stępień and Patrycja Krawczyk
Czestochowa University of Technology (CUT), Poland

p.kokot-stepień@pcz.pl
patrycja.krawczyk@pcz.pl

Abstract: Knowledge and innovation are key resources of the modern economy. Innovation, transfer, and use of knowledge determine the pace and level of economic development. The ability to transform knowledge into new technologies, products, services, marketing methods, and organizational solutions is both the basis of entrepreneurship and building a competitive advantage that increases the enterprise's chances of maintaining its market position. However, the market commercialization of new knowledge in the form of cutting-edge technological solutions or new products is a complex process with a high risk of failure, thus requiring appropriate and different competencies. Moreover, there are numerous barriers at the point of contact between the worlds of science and business that significantly impede joint work on innovative projects. Therefore, specialized entities have emerged to transfer knowledge and technology from science to the economy. These entities organize the knowledge flow from entities that have to those that seek knowledge. A professional institutional base in this regard is developed by innovation and entrepreneurship centers that partner with both private and public sectors. These centers act as a catalyst for the flow of knowledge and are responsible for building a platform for dialogue and cooperation between science and business, thereby providing conditions for improving the efficiency of knowledge and technology transfer. Their activities are aimed at meeting the needs of entrepreneurs primarily related to the development of innovation, promotion of experimental activities, technology transfer and commercialization of knowledge, and improvement of competitiveness based on new technological solutions. The aim of the present paper is to indicate the importance of business environment institutions to the transfer of knowledge and technology between science and business.

Keywords: Business environment institutions, Knowledge and technology transfer, Commercialization of knowledge

1. Introduction

One of the elements that shape the activity of entrepreneurs is the institutions that support their activities to reduce uncertainty. Over the past few years, there have been efforts in Poland to create a stable infrastructure to provide long-term support for innovation, with its foundation being knowledge. It is difficult to plan and implement any changes without adequate knowledge potential while innovations create the demand for new areas of knowledge, which are constantly developed. Being aware of these conditions, the governments of developed countries pursue a policy of supporting the transfer of knowledge and technology, using a whole range of means for this purpose.

The basis of contemporary entrepreneurship has become the acquisition of new technologies and knowledge necessary to run a modern business. Knowledge and the ability to transform it into innovations significantly affect the competitive position of the company. Unfortunately, the technology and knowledge transfer at the interface between science and the economy is a complex and multifaceted process accompanied by a high risk of failure. Its implementation requires well-defined and different competencies, which both environments sometimes lack. Specialized institutions have been created to reduce potential risks and overcome any barriers that hinder cooperation between people of science and business. They are an important element in the process of increasing the innovativeness of the Polish economy. Business environment institutions, in particular innovation centres, act as a catalyst for knowledge flow by facilitating the implementation of new solutions into business practice.

In the era of rapid technological change and dynamic expansion of innovation into the areas of services, organization, marketing, and social issues, enterprises are looking for new solutions in which the activities of innovation and entrepreneurship centers, which are a professional institutional base for knowledge exchange and its commercialization, prove helpful. The activity of business environment institutions consists primarily in supporting activities for innovation and development of enterprises in the SME sector. The paper presents the essence of the functioning of support institutions and indicates their importance in the process of technology transfer and commercialization of knowledge.

2. The Essence of Knowledge and Technology Transfer

Nowadays, the innovative development of enterprises is attributed to knowledge, which, in the era of constant competition in the market and dynamic globalization, is considered a unique resource (Wolski, 2018; Rychta, 2022). Unlike other goods, knowledge, which is a mixture of experience, values, the information set in a specific context, and expert insight that provides a framework for the evaluation and gaining new experiences and information, does not wear out (Wiśniewska and Głodek, 2015). Its resources during use do not decrease but increase due to improving skills and generating new ideas (Michalak and Zagórowski, 2017). Knowledge resources are natural assets of research centers, universities, and large corporations, but they also exist among customers and other actors in the economy (Łobejko and Sosnowska, 2013). However, knowledge should not be limited to individual entities but flow to other areas of the economy. Therefore, its dissemination is essential.

The process of knowledge transfer from an entity with knowledge (the technology donor) to an entity that needs it and is willing to apply it to its business activities (the technology buyer) is knowledge and technology transfer (Radło *et al*., 2020; Reit, 2022; Marszałek, 2022). It is composed of two components of transmission involving collecting knowledge and technology and then sending them to a potential recipient, and absorption, that is, the adoption and acceptance of knowledge and technology (Wiatrak, 2018; Stelmaszczyk and Jarubas, 2019). Knowledge transfer requires the need to understand the essence of scientific discoveries, to see the potential possibility of their commercialization and market usefulness, and to know the regulations governing their acquisition, management, and legal actions (Szewc, 2014).

Providing the knowledge and information necessary for one entity to be able to replicate the work of another is part of the commercialization process, which means all the activities related to the transfer of specific technical or organizational knowledge and related know-how to business practice. Commercialization is the process of creating value from knowledge, adapting or making it available for economic and social purposes, and transforming knowledge into competitive products, services, processes, new technologies, and organizational solutions. Commercialization is a specific case of communication and involves a whole set of events aimed at the successful marketization of knowledge, and thus the placement of products using a given technology on the market for the purpose of achieving economic benefits and building the added value of the technology (Bartoszewicz et al, 2019; Łobejko and Sosnowska, 2013; Wiśniewska and Głodek, 2015; Trzmielak and Grzegorczyk 2014; Konopka-Cypiał, 2020; Szewczuk-Stępień, 2016; Radło *et al*., 2020; Jurewicz, 2021). Commercialization is also an essential mechanism for generating innovation because of the strategic importance that innovation has for increasing economic efficiency and competitiveness.

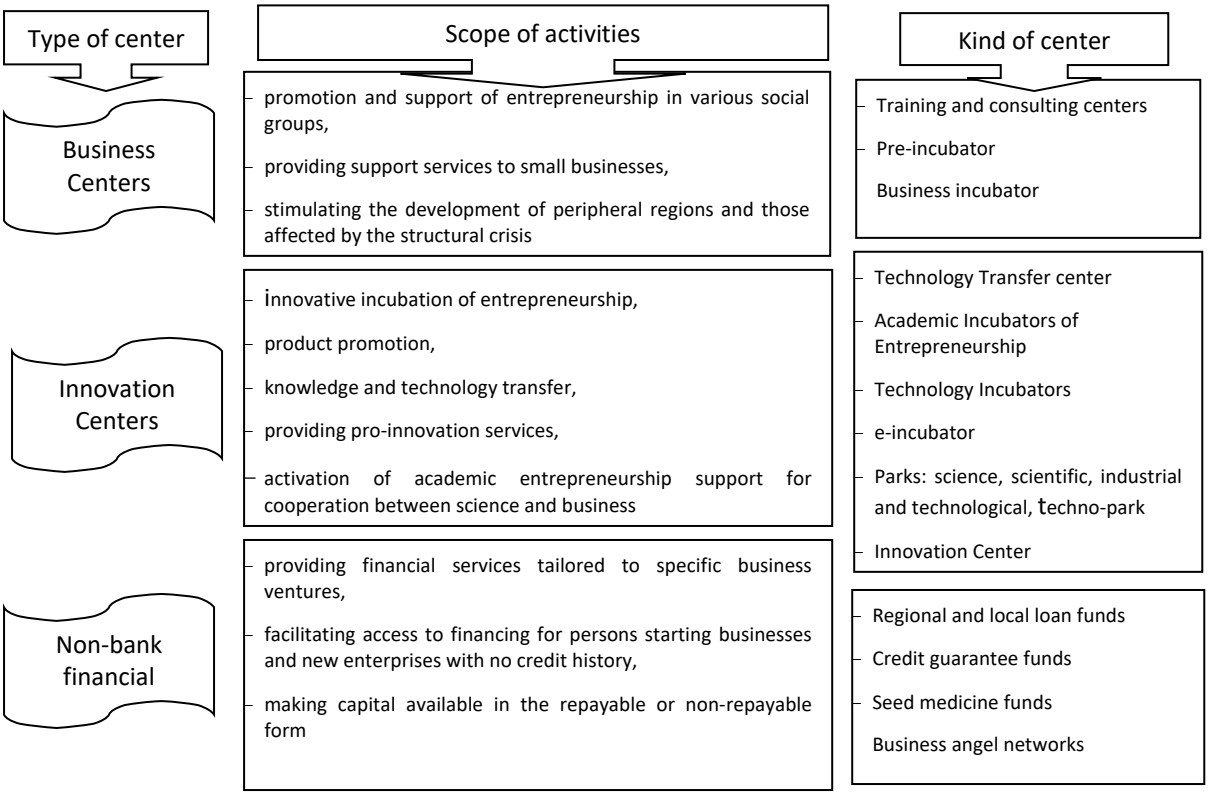
The transfer of knowledge and technology should allow the participants in the process to achieve mutual benefits, which may be commercial (economic benefits) or social (depending on their application, these may include technological, environmental or health benefits). Knowledge and technology transfer strengthens recipients' potential and skills, as well as the conversion of research results to their own needs. At the same time, by selling knowledge and technology, the entities raise funds for the development of research and its subsequent transfer. The prerequisite for receiving each type of benefit is the interest of the recipient, supplier, and intermediary institutions in the transfer and their cooperation in the process of acquisition and application of new solutions. It is important that the knowledge received can be used by the recipient and matched to their capabilities under existing conditions. Therefore, you should prepare for the transfer, taking into account its individual phases (Trzmielak and Grzegorczyk, 2014; Wiatrak, 2018; Radło *et al*., 2020). When preparing knowledge and technology for transfer, it is necessary to determine not only the type, scope, or time of delivery but also to indicate the conditions for their use in practice. Delivery can be combined with consulting and training offered by the business environment institutions to facilitate their implementation and application.

3. Specifics of Functioning and Classification of Business Environment Institutions

Business environment institutions (BEIs) are an institutional form of support for innovative entrepreneurship and technology and knowledge transfer. They are elements of innovation potential seen as a set of characteristics of a given territorial system that foster innovative activity undertaken by business entities operating in that system. Enterprises' innovativeness can be attributed to both their organizational capabilities and their connections with other actors in the environment, while communication, cooperation and coordination are prerequisites for the creation and transfer of knowledge and technology (Golejewska, 2017).

Business environment institutions are nonprofit entities or those that use the profit to reinvest in business support activities or cooperation between the sectors of science and business. These institutions have the necessary material and technical base, appropriate human resources and competencies to provide services to the SME sector (Mażewska, Bąkowski and Rudawska, 2021; Kuchciński, 2021). Their functioning is reduced to the following aspects (Mażewska, Bąkowski and Rudawska, 2021):

- they are service-oriented entities linking businesses with entities in the sector of science, which is at least to some extent publicly funded,
- they are entities that do not operate for profit (non-for-profit) or allocate the profit obtained for statutory purposes, i.e. supporting entrepreneurship and innovation of their beneficiaries,
- they have an adequate base of both tangible (real estate and movable property) and intangible resources (knowledge and qualifications) and adequate personnel to provide services,
- their goal is to support micro, small and medium-sized enterprises at every stage of their development.



Support institutions act as specific partners of the public and private sectors, initiating a new quality of thinking and management of economic and social development. With the non-commercial and statutory orientation of business environment institutions to support the development of entrepreneurship and innovation, they provide services and create a specific network-based institutional infrastructure that allows entrepreneurs to implement their strategies and dynamize development processes. Their peculiarities and the social background of their creation make them an important element in bridging the gap between market mechanisms and public administration actions (Gródek-Szostak *et al*., 2020; Mażewska, 2015; Babuchowska *et al*., 2015; Trzmielak, 2013).

The BEIs designed to support the development of enterprises in the SME sector by providing the right infrastructure to support entrepreneurship and the transfer of knowledge and technology, thereby creating and implementing innovative ventures, are innovation and entrepreneurship centers. Regardless of the organizational and legal forms of these entities, their activities are focused on (Matusiak, Mażewska and Banisch 2011; Glabiszewski, Grego-Planer and Liczmańska-Kopcewicz, 2018; Rudawska, 2020; Gródek-Szostak *et al*., 2020):

- transfer of knowledge and technology from scientific institutions to businesses,
- creating a system of linking enterprises with scientific units and administration,
- development of flexible manufacturing systems at the interface between science and the economy,
- spreading knowledge and skills through consulting and training,
- motivation and preparation for self-employment and comprehensive advisory, technical and housing assistance supporting the start of innovative business activity,
- financial and organizational support for innovative ventures,
- creating clusters of enterprises and animating innovative environment by combining business services and various forms of technological assistance in a specific, developed area.

The activities of innovation and entrepreneurship centers consist in supporting enterprises or potential entrepreneurs in three major areas. The first area relates to financial support, the second is the provision of material (space, access to devices) or formal (legal personality) conditions for starting and running a business, and the third includes all kinds of soft services (providing information, consulting, training, support for technology transfer, etc.). Within the third area, one can distinguish a group of services that are particularly interesting from the point of view of innovation, which are referred to as bridging services, while the units providing them are termed bridging organizations. The focus of their activity is on the organization of knowledge flow from entities with knowledge to entities that seek knowledge. Such activities are referred to broadly as knowledge transfer or narrowly as technology transfer, or most generally the transfer of technological knowledge between organizations (Płoszaj 2012; Lisowska, 2016).

The product offered by the business environment institutions is specific and its special character results from, on the one hand, the needs of the units served – in most cases enterprises, and, on the other , is conditioned by the character of the institution itself. Due to the specificity and scope of activities as well as the target group of recipients, support centers can be divided into three basic groups, presented in Figure 1.

Source: Own elaboration based on (Mażewska 2015; Nowak, 2016; Lisowska, 2016; Rudawska, 2020; Mażewska, Bąkowski and Rudawska, 2021).

Figure 1: Classification and Scope of Activities of Entrepreneurship and Innovation Centers

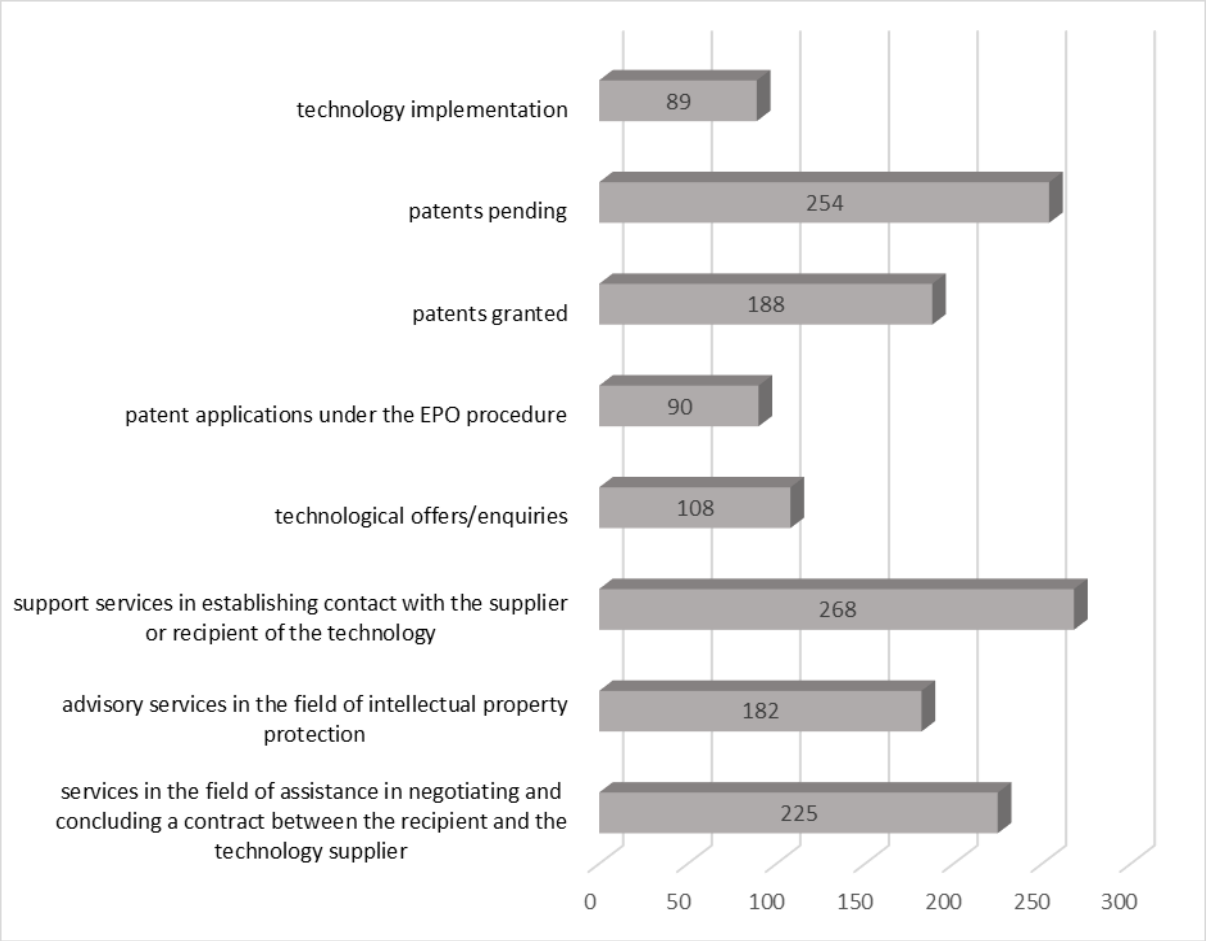
There is no one-size-fits-all organizational or functional model for supporting institutions. They function in various organizational and legal forms, from associations or foundations to limited liability companies. profit oriented. The activities of each institution depend on: resources, adopted mission, efficiency and substantive preparation of employees, their ability to raise external funds for their statutory activities, and their reception by the local community. The effects of their activities often cannot be quantified. The simplest form is training and consulting centers, which focus only on information, advisory and training activities, while the most comprehensive support is offered by technology parks (Nowak, 2011; Wiśniewska, 2011; Matusiak, 2011).

Business environment institutions are very important part of the knowledge transfer and commercialisation. They are responsible for collecting information about scientific discoveries, evaluation of commercialisation potential of those discoveries and supporting scientists in creation and development of their entrepreneurial ventures based on knowledge they are willing to commercialise (Łobacz, 2018).

4. The Importance of Business Environment Institutions in the Knowledge and Technology Transfer Process

Cooperation between the scientific community and business is usually difficult to organize. On the one hand, scientific entities see opportunities in developing cooperation with businesses to a relatively small extent. On the other hand, there is also an apparently low willingness of enterprises (mainly SMEs) to cooperate with other partners, whereas universities and the sector of R&D as a whole are seen as difficult and demanding partners. Furthermore, operating under constant time pressure and focused on the competition in the market, entrepreneurs usually strive to achieve an economic surplus with as little expenditure as possible, somehow forgetting that knowledge and the ability to transform it into innovations allow for achieving a competitive advantage (Łobacz and Niedzielski, 2015; Dominik, 2013). The differences that exist in the approach to the tasks and the nature of work lead to a specific 'communication gap' between science and business, which is being filled by business environment institutions aimed at building the broadest possible relationship between the two worlds, the development of modern technologies and the search for ways to effectively transfer knowledge from science to industry.

The technology transfer and commercialization of knowledge are facilitated by innovation systems that offer a specific type of cooperation between various types of entities and institutions operating in the region, whose main objective is to develop innovative entrepreneurship. In this area, there are mainly activities leading to the transformation of knowledge into new products, services, organizational and marketing solutions, technologies and instruments to support the commercialization phase of an innovative idea. The most important actor in the knowledge transfer and commercialization of knowledge process is the entrepreneur-innovator, who decides to use innovation as a way to improve the competitiveness of the enterprise on the market and takes the risk of introducing it. However, enterprises have different innovative capacity, i.e. access to internal and external sources of applied knowledge, conditioned by their resources and organizational capabilities, largely human potential. In the case of small and medium-sized entities, due to their limited human, technical and financial resources as well as low quality of management, a significant gap is apparent between the innovative capacity and the enterprises' modernization and development intentions, hence the importance of transferring foreign solutions, i.e. providing the necessary information so that a given entity can duplicate the work of another (Robertson *et al*., 2012; Łącka, 2011; Stawasz 2012; Łobejko and Sosnowska, 2013; Trzmielak, 2013). Furthermore, the tasks involved in commercialization are often too complicated for the direct participants in the technology and knowledge transfer, so the efficiency of these processes depends on the operation of professional innovation and entrepreneurship centers in the region. To accelerate the implementation of new knowledge and technology and effectively follow all phases of the innovation process, entrepreneurs, especially from the SME sector, use the innovative services of support institutions, especially innovation centers, whose primary task is to bring representatives of the scientific community closer to entrepreneurs, which is expected to improve the conditions for innovative entrepreneurship of both partners and contribute to the transfer of knowledge and technology from science and research to the economy, and then their commercialization. Thus, the cooperation of key partners and functional links of technology transfer and knowledge commercialization processes is centered around these entities (Matusiak and Guliński, 2010; Łącka, 2011).



Technology transfer, as an interactive process with the interaction between suppliers and recipients, is a special type of communication process that involves various forms of absorption of innovation and technical knowledge. Designed to intensify these processes, the group of innovation support infrastructure entities is aimed at stimulating research and development activities and implementation of their results through knowledge and technology transfer from the world of science to business and activities focused on the activation of the creative potential of internal resources of enterprises (Szopik-Depczyńska and Depczyński, 2013; Dzikowski, 2015). However, effective support for innovative entrepreneurship, technology transfer, and knowledge commercialization must be integrated and comprehensive. All support for innovative ventures is aimed, on the one hand, at stimulating the creation of new technological entities and helping SMEs in their pursuit of technological restructuring. On the other hand, it stimulates research and activates mechanisms for transferring its results to the economy (Matusiak and Guliński, 2010).

Business environment institutions act as an intermediary between the providers such as suppliers of technology and knowledge, and the recipients, who seek them, acting as a catalyst for knowledge and technology transfer. Therefore, during this process, support institutions interact with both the supply and demand sides. In relations with the supply side, they are looking for opportunities to apply the knowledge provided by the institutions of the sector of science and enterprises of knowledge that (at least partially) can be put into practice. Furthermore, in contacts with the demand side, they seek the knowledge that enterprises need to strengthen their market position achieve a competitive advantage based on, among other things, more efficient production technologies or new products. It is worth emphasizing, however, that the effective operation of support organizations should not focus on efforts to control the entire knowledge flow but on the effective linking of producers and consumers of knowledge, who can continue to cooperate without the need for intermediaries or through direct contacts transfer knowledge to other actors (Płoszaj, 2012).

The demand for services of access to new knowledge and specialized advisory and training services in the field of innovation varies significantly depending on the innovativeness of enterprises. Furthermore, limited resources and low levels of management, especially in smaller business entities, and their low propensity and limited ability to assimilate acquired knowledge, are barriers to the use of consulting services. It is therefore important to differentiate the services offered by business environment institutions to different groups of enterprises. This is aimed to support the internal innovative capacity of SMEs, especially the ability to absorb foreign solutions, facilitate access to capital for innovative projects, the effectiveness of knowledge and technology transfer, and strengthen the system of innovative business institutions. Business environment

institutions mediate in contacts between SMEs and the environment and mainly support entities with a small scale of operation, younger and with insufficient knowledge of either foreign sources of innovation or services for innovation. They act as a catalyst for knowledge flow, facilitating the implementation of new solutions into business practice (Stawasz, 2012).

Most innovation centers work on the principle of providing support and advice in the area of commercialization, helping their clients in determining the right commercialization path, searching for partners for implementation, preparing market and patent analyzes necessary to plan technology transfer activities. The result of this work is the implemented new technology or transferred intellectual property. Operation effectiveness of these centers in 2021 is presented in a Chart (Figure 2).

Source: Own elaboration based on (Mażewska, Bąkowski and Rudawska, 2021).

Figure 2: The Activity of Centers Providing Knowledge Commercialization and Technology Transfer Services

However, the decreasing number of the centers themselves is worrying. In 2021, there were 280 entities carrying out the tasks of non-commercial business environment institutions and it was 3 times less than in 2012, when their number was the largest (Mażewska, Bąkowski and Rudawska, 2021). This situation results from the exhaustion of the operating formula of these entities, the change in the business model and numerous structural, systemic, awareness-cultural and competence barriers that hinder or even block the cooperation of scientific institutions with entrepreneurs (Szewczuk-Stępień, 2016; Golejewska, 2017; Kocowska-Siekierka, 2022). An important problem is also the underfunding of the science sector in Poland, low awareness and knowledge about the mechanisms of technology transfer and the principles of intellectual property protection among the teaching staff and the low "absorbency" of Polish enterprises (especially small and medium-sized enterprises) for innovative products, which is caused primarily by the lack of sufficient financial resources. In addition, the offer of business environment institutions operating on the Polish market is quite poor, and the effectiveness of their work is still low. Not without significance is also the high turnover of employees and their poor professional preparation or the lack of specialists as well as the lack of stable sources of financing (Różański and Voytovych, 2019; Gajewski et al., 2019).

5. Conclusions

Access to knowledge and other intellectual resources, especially their absorption, is becoming a key factor in the innovation of enterprises, especially those smaller. The dynamic progress of knowledge and technology as well as growing competition force even the smallest companies to introduce innovations, which have become a necessity and a necessary condition for survival on the market. Small innovative enterprises are usually unable to transform their ideas and concepts into products and services on the market. They cannot create an interdisciplinary research base. To survive, they need to cooperate with others and function in an environment where they can use the knowledge of other entities (Matusiak and Guliński, 2010).

Increasingly, the market success of not only individual enterprise, but also entire economies is determined by the ability to transform knowledge into new products, services, technologies, marketing techniques and organizational solutions. In addition to the entities of business and science, business environment institutions that create a system for supporting, shaping, and promoting innovation and entrepreneurial attitudes and supporting enterprises in knowledge and technology transfer perform a special role. They build partnerships in innovation and establish cooperation between the entities that offer knowledge and those who seek it to create the most favorable conditions for the growth of business innovation (Łobejko and Sosnowska, 2013). A professional institutional base, consisting of various centers of innovation and entrepreneurship, offers a platform linking science and the economy, with its role being to facilitate communication between these environments and provide support by improving the flow of knowledge and technology.

Business environment institutions support the activities of enterprises, affect the absorption of knowledge and innovation, favor the decision-making of location and condition the process of joint learning, thus increasing the competitiveness and innovation of the economy (Lisowska and Grabowski, 2021). However, their number is constantly decreasing, and their share in increasing innovation in Poland is insufficient. This is due to numerous barriers at the interface between science and economy, which hinder the implementation of joint work on the commercialization of knowledge. The process of creating knowledge resources and transforming them into innovations is determined by the ability of multiple actors to work together. Unfortunately, the activities of BEIs are not always professional enough and sometimes deviate from global standards. Therefore, it is important to continuously increase the potential and competencies of such entities, because only well-prepared and qualified personnel and a non-standard institutional base can effectively support innovative entrepreneurship and affect the efficiency of technology and knowledge transfer. It should also be emphasized that like other products, knowledge requires the formation of demand in the environment of its recipients, promotion, and the readiness of the scientific community to identify the demand of the market of recipients, and therefore to analyze the needs of enterprises in terms of knowledge and innovation and invest their time and resources to attract the recipient of this specific product.

The paper does not exhaust the research problem, it is only a contribution to further research on this complex process, which is the transfer of knowledge and technology in the enterprise.

What Drives People to Share? The Relationship Between Working Style and Workplace FoMO

Edit Kővári
Management Institute, Faculty of Business and Economy, University of Pannonia, Veszprém, Hungary

kovari.edit@gtk.uni-pannon.hu

Abstract: Workplace FoMO is defined as the fear of missing important tasks, information, and knowledge. It is driven by the fear of the dread of experiencing the anger or psychological pressure, and indirect expectation of co-workers, managers or other stakeholders at the place of work. The term also refers to the loss of promising opportunities (Fear of Better Options – FoBO) and network possibilities which can lead to another phenomenon Fear of Doing Anything (FoDO) which refers to the state when someone is indecisive. After factorial analyses of the original 5 FoMO types of Alutaybi et al (2020) this study applies the following factors: *valuable information gathering, professional networking, individual contribution to work,* and *social interaction*. One of the influencing factors of FOMO is internal motivation which is connected to working style. Considering the internal motivation and attitude to work, based on Kahler's 5 positive drives (1975) Hay (2009) developed the following working styles: *hurry up, be perfect, please people, try hard* and *be strong*. This research presents the relationship between working styles and workplace FoMO based on a questionnaire filled by 201 employees of an international automotive company. Results shows that expect 'Try hard', the other 4 working styles indicate correlation with at least one of the factors of working FoMO.

Keywords: Workplace FoMO, Working style, Professional networking, Getting valuable information, Please people

1. Introduction

In the fourth industrial revolution (Philbeck & Davis, 2018), it is not a problem anymore to retrieve and exchange information in real-time. The speed and competition at work forces people to stay up to date and be proactive. The introduction of computer-mediated tools and social media platforms trigger instant communication (Hayran et al., 2020), leading to several socially related anxieties. One such anxiety is called "fear of missing out" or FOMO. Fear of missing out (FOMO) refers to the stressful feeling one perceives when excluded or socially disconnected (Budnick et al., 2020),. The distress caused by the awareness that networking opportunities are missed or relevant information is not shared refers to workplace FOMO.

2. Literature Review

2.1 FoMO and Workplace FoMO

Fear of missing out (later referred to as FoMO) as a concept was first used in the late 20th century by Dan Herman, who first formulated it in the field of marketing in relation to consumers as a motivating factor for purchase (Herman, 2000). Yet the current understanding of FoMO, and the popularization of the term itself, can be traced back to McGinnis (2004), who in an article for the Harvard school journal Harbus, described the social structure of students and the 'illnesses' that affect them. According to McGinnis, the fear of missing out on social programs leads to an over-commitment that causes students to cram dozens of programs into a short time span. Due to the novelty of the concept there are not yet many definitions of FoMO. The only generally accepted description is that of Przybylski et al (2013), who described the phenomenon as a pervasive fear of missing out on valuable experiences and good experiences that others might have that we miss out on. For this reason, FoMO is characterized by a desire to stay connected to everything that others are doing. Wiesner (2017) describes the fear of missing out as a two-sided phenomenon that can occur because of the physical inability of the individual to open an incoming message. On the other hand, those who perceive the FoMO phenomenon even when there is no new incoming information or message are unable to reduce anxiety. Focusing on the latter, Wiesner says FoMO is the feeling of missing out on something while trying to communicate with others through social media. This occurs because the individual has a constant need for fresh information or feels the incoming information is not being absorbed. In either case, the individual's goal is to satisfy the need to belong somewhere (Wiesner, 2017). Alutaybi et al (2020) classified FoMO into 5 categories:

- When Others Do Not Interact as Expected
- When Unable to Interact or Connect as Wished
- When Unwilling to Engage in Social Interaction
- When Having to or Feeling a Need to Engage in Continuous Untimed Interactions
- When an Online Social Gathering is Expected

They also listed what causes the development of each type and what countermeasures are possible.

Alutaybi et al. (2020) proposed five types of FoMO that individuals may experience in the context of social media:

- *Social FoMO*: This type of FoMO is related to fear of missing out on social events or activities. People with social FoMO may feel anxious or left out if they see their friends or colleagues socializing without them on social media.
- *Informational FoMO*: This type of FoMO is related to fear of missing out on important news or information. People with informational FoMO may feel anxious or left out if they see their friends or colleagues sharing news or information that they have not seen yet.
- *Experiential FoMO*: This type of FoMO is related to fear of missing out on exciting experiences or adventures. People with experiential FoMO may feel anxious or left out if they see their friends or colleagues sharing photos or stories of fun experiences that they were not a part of.
- *Imaginative FoMO*: This type of FoMO is related to fear of missing out on creative or artistic experiences. People with imaginative FoMO may feel anxious or left out if they see their friends or colleagues sharing photos or stories of creative projects or events that they were not a part of.
- *Object-oriented FoMO*: This type of FoMO is related to fear of missing out on material possessions or consumer experiences. People with object-oriented FoMO may feel anxious or left out if they see their friends or colleagues sharing photos or stories of new products or luxury experiences that they were not able to purchase or participate in.

These five types of FoMO can help individuals identify the specific triggers and situations that cause them to feel anxious or left out, and develop strategies for managing these feelings in a healthy way. It's worth noting that these types of FoMO are not mutually exclusive, and individuals may experience more than one type of FoMO at the same time.

These studies however, are mostly limited to social media-related measures such as setting up automatic replies or status updates.

In his research, Przybylski et al (2013) investigated the impact of FoMO on motivation and well-being, and the demographic factors that influence it. His results showed that higher FoMO scores are more common in young adults, including young men. It also confirmed what had previously been speculated or shown by qualitative studies that FoMO has a negative impact on psychological well-being. It also showed a negative correlation between FoMO and general mood and overall life satisfaction (Przybylski et al., 2013). These findings were supported by Elhai et al. (2016), who, in addition to the factors already examined, also showed an association of FoMO with depression and general anxiety (Elhai et. al., 2016).

Although FoMO is essentially a social media phenomenon, its impact can also be observed in the workplace. Indeed, the study of the phenomenon in this context and the dissemination of these findings is just beginning to take off in national and international research fields.

The first and so far only definition of FoMO in the workplace was provided by Budnick et al. (2020), who transposed Pryzbylski et al's definition to the workplace environment. They defined workplace FoMO based on promising job opportunities and comparisons with colleagues as the fear of missing out on significant career opportunities relative to colleagues if we are absent from work. These missed career opportunities can manifest in missing out on professional networking opportunities, missing out on valuable information, social gatherings, promotions, or even new technologies or tools that are being implemented in the workplace or missing out on key decisions or projects for the organization (Budnick et al., 2020).

Workplace FOMO can have negative consequences on employees' morale, productivity, and job satisfaction, as they may feel excluded, undervalued, or not fully engaged in their work. It can also lead to unhealthy competition, gossip, or resentment among colleagues, and can create a toxic work environment. Employers and managers can help mitigate workplace FOMO by fostering a culture of inclusion, transparency, and communication, by providing equal opportunities for all employees to participate in relevant activities and events, and by recognizing and rewarding individual achievements and contributions.

Budnick et al. (2020) first proposed workplace FOMO measure set up 3 types of FOMO: relational, informational, and work output exclusion. After an exploratory factor analysis, they found a two-factor scale: relational exclusion and information exclusion. Relational exclusion is an employee’s worry that their interpersonal relationships with colleagues may suffer because they cannot maintain business relations (Budnick et al., 2020). Informational exclusion refers to the fear that one has no relevant social or task information. Albers’ (2020)

factor analysis found a similar two factor structure but to some extent altered scopes. Therefore relational exclusion was renamed “opportunity exclusion” to account for the fear that relationships suffer due to missed networking opportunities.

2.2 Working Styles

Working style refers to an individual's preferred approach, habits, and methods of completing tasks and accomplishing work-related goals. It encompasses the unique combination of behaviors, attitudes, and work patterns that a person adopts in their professional life. A person's working style may be influenced by their personality traits, values, past experiences, and the demands of their job or industry (Robbins et al. 2018). Working style can include various aspects, such as: time management, communication, collaboration, problem-solving, decision-making, work-environment, and work-life balance. Understanding one's working style can help individuals optimize their productivity, leverage their strengths, and find job satisfaction (Kinicki and Fugate, 2018).

Motivation plays a crucial role in shaping an individual's working style. When individuals are motivated, they are more likely to adopt a proactive and engaged approach to their work. Motivated individuals may demonstrate a strong work ethic, take initiative, and exhibit a preference for a particular working style that aligns with their intrinsic motivations and values.

Kahler and Capers (Kahler & Capers, 1974) developer of the Process Communication Model (PCM), identified six motivational drivers that influence performance and working style. These drivers are based on his observations of personality types and communication patterns. The six drivers are inclusion, control, affection, achievement, freedom and fun. According to the theory, each person has a unique combination of these drivers, with varying intensities. By understanding these drivers in oneself and others, it becomes possible to communicate and motivate more effectively, tailor work environments, and address individual needs for optimal performance and job satisfaction.

Based on Kahler & Capers (1974) theory Hay (2009) developed the following five working styles:

- *Hurry Up:* People with this working style tend to be action-oriented and enjoy taking charge of situations. They thrive on pressure and enjoy a fast-paced work environment.
- *Be Perfect:* People with this working style strive for excellence and take pride in doing things well. They pay close attention to details and are often self-critical, with high standards for themselves and others.
- *Please People:* People with this working style focus on building positive relationships and ensuring that others are happy and satisfied. They are often team players and enjoy collaborating with others.
- *Try Hard:* People with this working style are persistent and determined, and are willing to put in extra effort to achieve their goals. They are often self-motivated and have a strong work ethic.
- *Be Strong:* People with this working style tend to be independent and self-reliant, and may be reluctant to ask for help or support. They value their own opinions and may be resistant to feedback or criticism.

Radu et al (2017) go further and summaries the advantages and disadvantages of the Hay’s 5 working styles.

Table 1: Advantages and Disadvantages of the Drive Based Working Styles (based own Radu et al. 2017:382, own editing)

Driver	Main belief	Advantage	Disadvantage
„Be strong!”	have to be strong and independent	rational decisions without emotional attachments	weak human relationships
„Be perfect!”	need to be perfect and always do the right thing	well-planned tasks and competent execution	slips due to over-planning
„Hurry up!”	need for speed and efficiency	fast turnaround	ignoring details, resulting in sloppy quality

Driver	Main belief	Advantage	Disadvantage
„Make an effort!”	need to try harder, need patience and persistence	persistence in situations where others have given up	slow decision-making, slipping deadlines
„Get pleasure!”	satisfaction of others comes first	team harmony	underestimating your own work

These working styles can help individuals identify their strengths and weaknesses in the workplace and develop strategies for working more effectively with others. However, it's important to note that everyone has a unique working style, and that these styles can change over time or in different situations. Moreover, working styles are just one aspect of a person's overall personality and behavior, and should be considered in conjunction with other factors such as emotional intelligence, values, and goals.

2.3 Workplace FoMO and Working Style

The relationship between working style and workplace FOMO can be complex and multifaceted. Different working styles can influence the extent to which employees experience FOMO at work, and how they respond to it. For example, employees who have a more extroverted or social working style may be more likely to experience FOMO in social situations, such as team lunches or after-work drinks, and may feel left out or disconnected if they are not included. On the other hand, employees with a more introverted or independent working style may be more likely to experience FOMO related to individual projects or tasks, and may feel like they are missing out on opportunities for growth or recognition (Rozgonjuk et al., 2021).

Moreover, some working styles may exacerbate workplace FOMO, such as perfectionism or competitiveness, as employees may feel like they need to be involved in everything and achieve success in every aspect of their work (Marsh et al. 2022). This can lead to burnout and stress, and can ultimately negatively impact their job performance and well-being (Gorji, 2011). Overall, it is important for employees to understand their own working style and how it may influence their experience of workplace FOMO, as well as for employers to create a supportive and inclusive work environment that values and accommodates different working styles. This can help reduce the negative impact of FOMO on employees and promote a more productive and positive workplace culture.

Hay's (2009) working styles are not directly related to workplace FOMO, which refers to the fear of missing out on social or professional opportunities in the workplace. However, it is possible that individuals with certain working styles may be more prone to experiencing workplace FOMO. For example, individuals with a "please people" working style may feel pressure to say yes to every social or professional invitation in order to maintain positive relationships with their colleagues, even if it means overcommitting themselves and feeling overwhelmed. Similarly, individuals with a "try hard" working style may feel like they need to be involved in every project or opportunity in order to prove their value and competence to their colleagues or superiors, which could lead to feelings of FOMO if they are unable to participate in everything. On the other hand, individuals with a "be strong" working style may be less likely to experience workplace FOMO, as they may be more comfortable with working independently and focusing on their own goals and priorities rather than feeling pressure to be involved in everything that is happening in the workplace (Hay, 2013).

Fear of Better Options (FoBO) and Fear of Doing Anything (FoDA) are two related concepts that describe different forms of decision-making anxiety or indecisiveness.

FoBO refers to the fear or anxiety that people may experience when they are faced with a range of options or choices, and they worry that there may be a better choice out there that they are missing. This can lead to indecisiveness, procrastination, or a sense of regret or dissatisfaction with the chosen option. FoBO can be especially relevant in contexts where there is a high degree of choice or uncertainty, such as career decisions, relationship choices, or purchasing decisions (Boyan, 2022). FoDA, on the other hand, refers to the fear or anxiety that people may experience when they are faced with a task or activity that they feel unsure or unprepared for, and they worry that they may fail or make a mistake. This can lead to avoidance, procrastination, or a sense of overwhelm or stress. FoDA can be especially relevant in contexts where there is a high degree of novelty, complexity, or ambiguity, such as new projects, job tasks, or social situations (McGinnis, 2004).

Both FoBO and FoDA can have negative consequences on individuals' well-being, productivity, and decision-making processes, and may be related to other mental health issues such as anxiety, depression, or perfectionism. Recognizing and addressing these fears can help individuals make more informed and confident

decisions, and lead to a greater sense of fulfillment and satisfaction in their personal and professional lives (Reagle, 2015).

It's important to note, however, that these are just hypothetical examples, and that everyone's experience of workplace FOMO is unique (Ashkanasy et al. 2000). A person's working style is just one of many factors that can influence how they approach their work and relationships in the workplace. Different working styles may have varying levels of susceptibility to workplace FoMO. For example, individuals with a more collaborative working style that involves frequent interaction and networking may be more prone to experiencing FoMO in the workplace. On the other hand, individuals with a more independent or task-oriented working style may be less affected by workplace FoMO (Hay, 2013). Certain working styles may prioritize constant communication, information sharing, and being up-to-date, thus potentially exacerbating workplace FoMO. Conversely, individuals with different working styles may be more focused on individual tasks or require less frequent communication, reducing the impact of FoMO. The organizational culture can play a role in shaping the prevalence and impact of workplace FoMO. Cultures that emphasize constant connectivity, socialization, and inclusion may foster a higher likelihood of experiencing FoMO. In contrast, cultures that prioritize autonomy, task completion, and self-directed work may reduce the incidence of workplace FoMO. Individual traits and mindset also play a significant role. Individuals with a greater need for external validation or a fear of missing out in general may be more susceptible to workplace FoMO, regardless of their specific working style. Personal characteristics such as self-confidence, self-esteem, and the ability to manage one's emotions can impact how individuals perceive and respond to workplace FoMO (Tandon et al, 2021). Those with a strong separation between work and personal life may be less prone to experiencing FoMO, as they are more focused on personal commitments and interests outside of work.

The research of Fridchay and Reizer (2022) indicates that individual differences in FoMO are associated with relatively low levels of job performance, thus this study does not include working style analyses. Although the number of FoMO studies are increasing there are still gap both in theory and applied research considering the relationship of workplace FoMO and working styles.

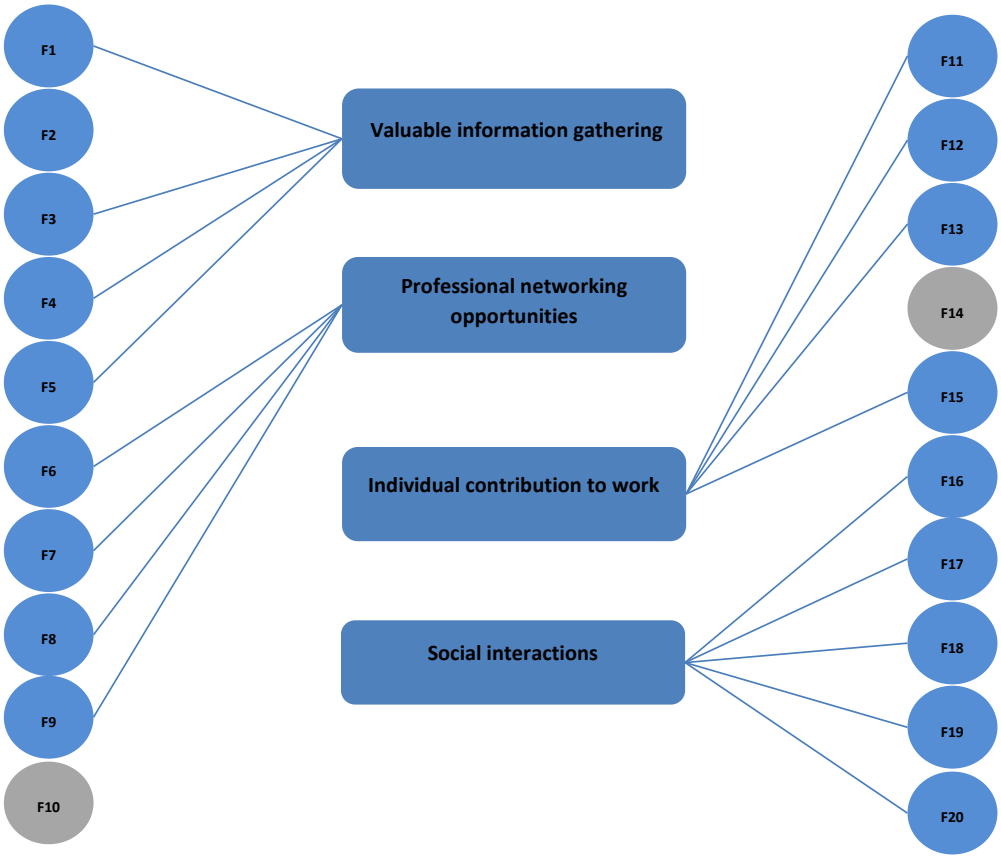
3. Research Question and Methodology

Scholars have suggested that working styles and workplace FoMO indicates some kind of link to each other, thus these implications are rater theoretical or focusing on individual traits. There is lack of understanding regarding the impact of FoMO in the workplace and on working styles. Therefore a research hypothesis is articulated:

H1: There is a relationship between workplace FoMO and drivers based working styles.

A primary quantitative research in the form of a questionnaire was carried out with an international automotive company in Hungary in 2022 winter. The study sample is 1772 employees (total number). The questionnaire first part included demographical and job-related questions. The working style part was based on work of Taibi Kahler questions categorized by Hays applying the The Padfield Partnership consultancy validated questionnaire. This contains 25 statements, where the respondent is asked to give a score between 0 and 8 for each statement. For measuring workplace FoMO Budnick et al. (2020) original questionnaire was translated, validated and completed with questions to adjust to the Hungarian respondents. Two new factors were added. The first factor, individual contribution to work, was also assessed by the researchers themselves in their study, but was dropped in the analysis, reducing the number of factors to two. Since the sample in the original study was independent of industry and company, and the sample was drawn only from the United States the questionnaire was adjusted to automotive industry. The second new factor was named social interactions. This part consists of 20 statements, where respondents indicated on a five-item Likert scale how true the statements were for them.

4. Analyses and Results



4.1 Descriptive Statistics

The descriptive analyses show that out of the 1772 employees 290 people started the questionnaire and 201 completed (148 male and 53 female) it. This is an 11.3% response rate. Regarding job occupations 132 non-managerial employees, 30 non-managerial team leaders (e.g. project managers), 20 team leaders, 16 middle managers and 3 senior managers were identified. The majority of the respondents, 74, have been working for the company for more than 10 years, 49 between 5-10 years, 47 between 2-5 years and 31 less than 2 years. This means that the 61% of the respondents have been working there over 5 years.

As the working style questionnaire was translated to Hungarian, a reliability test needed to be carried out. Based on the results of the reliability test, the Cronbach's Alpha value was 0.717, so the reliability of the questionnaire is acceptable. Regarding working styles the dominant responses were "Get pleasure!" (34.8%) and "Be perfect!" (32.3%). These were followed by "Hurry up!" (13.9%), "Be strong!" (9.5%) and "Make an effort!" (9.5%).

To measure workplace FoMO a reliability test was carried out after the translation. This resulted in a Cronbach's alpha of 0.953, which indicates that the reliability of the questionnaire is excellent. Due to the completion and translation of the questionnaire a new factor analysis had to be applied. The results of the analysis show that 4 factors explain 77% of the information content of the model. The associated KMO value is 0.921, which is associated with a Khi squared value of 284.974 with a significance level of 0. These 4 factors are: *valuable information gathering*, *professional networking opportunity*, *individual contribution to work* and *social interactions*. The first two factor names were kept from the original Budnick et al. (2020) model and the last two were named after the communality test and Goodness-of-fit results. Table 2 shows the result of the factors analyses. Two of the items (F10, F14) cannot be linked to any of the factors, therefore they are disregarded from the analyses.

Table 2: The Modified Workplace FoMO Model at Work After Factor Analysis

4.2 Relationship Analyses

The correlation analysis of workplace FoMO and demographic data shows that workplace FoMO has a weak significantly negatively relationship with the respondents' age (-0.191) and time spam spent at the company (-0.109), while there is no significant correlation with the other variables. This suggests that the younger the employee and the less time they have been with the company, the higher their perceived FoMO at work.

To test *H1, There is a relationship between workplace FoMO and drivers based working styles*, variance analysis has been conducted using dominant working styles as independent variables and principal component describing workplace FoMO as dependent variable. The resultant ANOVA shows (Figure 1.) a 0.043 significance level, which suggests that the null hypothesis that the two variables are independent of each other should be rejected. This implies that there is a significant relationship between working style and workplace FoMO.

ANOVA

REGR factor score 1 for analysis 1

	Sum of Squares	df	Mean Square	F	Sig.
Between Groups	9,743	4	2,436	2,509	,043
Within Groups	190,257	196	,971		
Total	200,000	200			

Figure 1: ANOVA Testing of the Relationship Between Workplace FoMO and Working Style

At the factorial level, it can also be stated that all other factors of workplace FoMO, with the exception of the factor of social interactions, are significantly correlate with working styles. The relationships are shown in Table 3, where the positive significant (sig. <0.05) relationships are highlighted.

Table 3: Strength and Direction of Correlation Between Workplace FoMO Factors and Working Styles

	„Hurry up!"	**„Be perfect!"**	**„Get pleasure!"**	**„Make and effort!"**	**„Be strong!"**
FoMO – Valuable information gathering	0,103 (0,035)	0,076 (0,118)	0,146 (0,003)	0,094 (0,055)	0,069 (0,158)
FoMO – Professional networking opportunities	0,127 (0,009)	0,08 (0,103)	0,136 (0,005)	0,078 (0,109)	0,165 (0,001)
FoMO – Individual contribution to work	0,013 (0,787)	0,109 (0,026)	0,119 (0,015)	0,020 (0,688)	0,061 (0,210)
FoMO Social interactions–	-0,025 (0,603)	-0,021 (0,670)	0,000 (0,999)	0,041 (0,400)	0,018 (0,714)

The Post Hoc analysis confirmed that for all factors of workplace FoMO certain working styles significantly differ from each other.

The results indicate that all working styles except "Make an Effort" are correlated with some factor of workplace FoMO. The *Professional networking opportunities* FoMO factor show correlation with 3 working styles: "Hurry up!", "Get pleasure!" and "Be strong!". *Valuable information gathering* FoMO factor has relation to "Hurry up!" and "Get pleasure!" While "Be perfect!" and "Get pleasure!" working styles display a correlation with *Individual contribution to work* FoMO factor. In contrast, the newly introduced *Social interaction* FoMO factor is not linked to any of the work styles.

5. Discussion an Implications

The result of the present study implies several ways to go further in deeper analyses. First, that employees main drives which influence their working style are either to get pleasure or to be perfect. The weak but significant relation indicates that younger and new employees experience higher FoMO which can be explained by their effort to fit in with a "Hurry up" or "Be strong" working styles. What makes people to share? It might be fear of missing out to get valuable information or professional network opportunities. Those whose working style is "Hurry up" may feel the time squeeze to gain and give information. They are action- and achievement-oriented and enjoy a fast-paced work environment. On the other hand quite large some of the respondents share information and network because they want to "Get pleasure". In other words they would like to keep positive relationships with and/or to satisfied their peers and managers. What is attention-grabbing that "Make and effort" working style is not at all connected to workplace FoMO. One of the explanation can be that that these people are consciously driven, energetic by their nature. These employees have a very strong work ethic and

the drive is not fear but flow. Nevertheless the present study is not complex enough to draw strong conclusions. Future thorough research and bigger database are needed to gain more stable assumptions.

Relatedness and Futureness: Key Pillars for Developing Knowledge-Based Management for Sustainability

Florian Kragulj, Clemens Kerschbaum and Alexander Kaiser
Vienna University of Economics and Business, Austria

florian.kragulj@wu.ac.at
clemens.kerschbaum@wu.ac.at
alexander.kaiser@wu.ac.at

Abstract: Recently, the field of Knowledge Management has seen some movements towards sustainability and more responsible business practices. Especially sustainability has become a hot topic for almost every organization. In this paper, we try to locate the concept of sustainability in the field of Knowledge Management. We argue that lived sustainability is built upon relatedness (the holistic understanding of interdependence and interconnectedness of complex systems) and futureness (adopting a long-term perspective for the management of organizations) that together promote sustainable organizing from the inside-out. We find that in particular two streams, Responsible Knowledge Management and Spiritual Knowledge Management, have taken up ideas that potentially lead to sustainable Knowledge-based Management. Those streams emphasize various forms of non-rational knowledge as a necessary, but previously underrepresented aspect of knowledge, as a counterpart to the instrumental-calculative rationality that has become predominant in the study of organizations and organizational knowledge.

Keywords: Future of KM, Spiritual knowledge management, Responsible knowledge management, Sustainability, Tacit knowledge

1. Introduction

Sustainability has become a societal imperative that companies must meet. It is time to rethink the role of knowledge management and shift the focus from managing a stock of knowledge (Bratianu, 2011) to providing a management tool that enables doing "the right things" (Laszlo & Laszlo, 2007, p. 494).

To contribute to this endeavour, we analyse key literature on sustainability and identify relatedness and futureness as two key characteristics of the concept. Relatedness refers to the complexity of systems, which requires a holistic understanding of their "interdependence" and "interconnectivity" (Bansal & Song, 2017, p. 123). This underscores that "corporate actions [are] inherently connected to the social and natural systems" (Bansal & Song, 2017, p. 124). Consequently, "sustainable development rests on three principles: environmental integrity, social equity, and economic prosperity" (Scherer et al., 2013, p. 259). This highlights that we are not alone but related to others. We should know about our relationships, which means we should know about ourselves, 'the others' (i.e., humans, nonhumans, more-than-humans), mechanisms, and consequences.

Managing an organization sustainably also means "not just to manage resources at a point in time but manage resources across time" (Bansal & DesJardine, 2014, p. 76). Therefore, decision makers need to "fully anticipate [stakeholders'] future needs" (Bansal & DesJardine, 2014, p. 72). They have to adopt a long-term perspective that contrasts with short-termism, which can be defined as "decisions and outcomes that pursue a course of action that is best for the short term but suboptimal over the long run" (Laverty, 1996, p. 826). We refer to this characteristic of sustainability as futureness.

In this conceptual paper, we identify two avenues to knowledge-based management for sustainability. We introduce two approaches for a knowledge-based management for sustainability agenda, i.e., Responsible Knowledge Management (Durst, 2021; Rocha et al., 2022) and Spiritual Knowledge Management (Kaiser, 2023). Both address the characteristics of relatedness and futureness, thus delivering on the sustainability agenda. In doing so, we argue, knowledge management holds the potential to become a key tool for organizations to learn how to do "the right things" from a long-term perspective on sustainability.

2. Sustainability and Knowledge Management

Sustainability has become a social imperative that companies must meet. As a result, it is making its way into all levels and functions of organisations (Lubin & Esty, 2010), the backbone of which is knowledge. Knowledge management has evolved as a response to the infobesity brought about by advances in information technology (Davenport, 2015). Now that we have a solid handle on information processing, it is time to rethink the role of knowledge management in the organisation - and beyond. In other words, shifting the emphasis from managing a stock of knowledge (Bratianu, 2011) towards the question: "will KM [knowledge management] become yet

another approach to help organisations do things right, or will it be a vehicle for government, business and civil society to do the right things?" (Laszlo & Laszlo, 2007, p. 494) In this paper, we answer this question and conceptually identify two avenues to knowledge-based management for sustainability, namely responsible knowledge management (Durst, 2021; Rocha et al., 2022) and spiritual knowledge management (Kaiser, 2023).

Sustainable development has its roots in the late 1960s, although first broadly discussed in the "The Limits to Growth" report by the Club of Rome (Meadows et al., 1972). From then on, several international publications shaped the discussion on sustainability, sustainable development, and sustainable business. Among those is the World Commission on Environment and Development report "Our Common Future" (OCFR) (United Nations, 1987), that has bred the ground for the most recent global sustainability framework, the Sustainable Development Goals of the United Nations (Hák et al., 2016),

Bansal & Song (2017) argue that the OCFR adopts a systems perspective to sustainable development. This means that it regards the world "as a complex system with six interlocking challenges" (p. 123). This shifts the emphasis from "characteristics of elements to the dynamics of connectivity" (p. 124); systems are not linear but complex which makes it necessary to holistically understand "interdependence" and "interconnectivity" (p. 123). This emphasises that "corporate actions [are] inherently connected to the social and natural systems" (p. 124). Consequently, "sustainable development rests on three principles: environmental integrity, social equity, and economic prosperity" (Scherer et al., 2013, p. 259). This highlights that we are not alone, but related to others. Following the logic of systems science, all our (corporate) acting is influenced and influences the entities to which we are related; may it be others in personal and emotional spatial proximity (e.g., family, colleagues) or distances (e.g., society, future generations), the living Earth (e.g., exploitation of natural resources, climate change, pollution), or supra-physical entities (e.g., the universe, God). We should know about our relatedness, which implies we should know about us, 'the others' (i.e., humans, nonhumans, more-than-humans), mechanisms, and consequences. We term this characteristic of sustainability *relatedness*.

Among the most cited definitions on sustainable development is "[meeting] the needs of the present without compromising the ability of future generations to meet their own needs" (United Nations, 1987). It points to the inter-generational focus, reflecting the tension between the present and the future. It calls for not trading future possibilities for current demands. So, time, or more specifically future-orientation is a key feature of (business) sustainability (Kim et al., 2019; Slawinski & Bansal, 2015). Along this line, Lozano (2008) highlights the "dynamic time perspectives" that characterise sustainable development, and argues that the social, environmental, and economic aspects holistically interact with each other through time. The resulting challenge for leaders is to "not just to manage resources at a point in time, but manage resources across time" (Bansal & DesJardine, 2014, p. 76). Therefore, decision makers need to "fully anticipate [stakeholders'] future needs" (Bansal & DesJardine, 2014, p. 72). They have to adopt a long-term perspective that contrasts with short-termism, which can be defined as "decisions and outcomes that pursue a course of action that is best for the short term but suboptimal over the long run" (Laverty, 1996, p. 826). Future-oriented communications (Crilly, 2017) and a "future-time framing perspective" (Liang et al., 2018) can be key to do so. We term this characteristic of sustainability *futureness*.

Hence, we can identify *relatedness* and *futureness* as two key characteristics of sustainability and sustainable development. From a Knowledge Management, we ought to find a way to handle those ideas from an organizational knowledge perspective. In this paper, we point to Responsible Knowledge Management and Spiritual Knowledge Management as two concepts that address relatedness and futureness, and thus answer the call for sustainability and its inevitable role in Knowledge Management.

3. Responsible Knowledge Management

The existential challenges (e.g., climate change, social inequalities), that are on the sustainable development agenda, require wise answers. However, instrumental-calculative rationality and rational knowledge reach their limits in the volatile, uncertain, complex, and ambiguous (VUCA) situations we are facing (Rocha et al., 2022; Kerschbaum, 2022). Using current examples, Durst (2021) illustrates these shortcomings and calls for a new approach to knowledge management, i.e., Responsible Knowledge Management.

For this endeavour, Kragulj (2023) and Rocha et al. (2022) stress the importance of practical wisdom (phronesis). Phronesis dates back to Aristotle and can be defined as "the capacity to put into action the most appropriate behaviour, taking into account what is known (knowledge) and what does the most good (ethical and societal considerations)" (Rowley, 2006, p. 1250). Phronesis is knowledge that enables one to act towards the common good. Emphasising this direction in corporate activity recognizes the relatedness of business with society and

the natural environment, and leads to acting responsibly toward humans and other entities. After comprehensively reviewing the literature, Kragulj (2023, p. 214) characterises a practically wise person as someone who can adopt and act from six perspectives: "subjective-situative", "holistic", "temporal", "communal", and "integrative"; he thereby extends the work of Nonaka & Takeuchi (2011) on the "practically wise leader". More specifically, the "future-oriented perspective" includes both the capability to "prepare for the future" and "shape the future" by "think[ing] and act[ing] future-oriented", "adopt[ing] a broader and long-term perspective", "act[ing] for the good of the community", and "balanc[ing] conflicting interests" (Kragulj, 2023, p. 214f). Responsible Knowledge Management needs to cultivate and foster these perspectives in a way that they serve the organisation as a strategic resource.

Kerschbaum (2022), building on Kragulj, (2022) argues along the same line of reasoning and emphasizes the role of aesthetics as an additional source of knowledge to account for sustainable corporate strategies. Aesthetics in that regard describes a sort of knowledge that is highly subjective and experiential and allows for individuals to 'feel' the aforementioned issues of sustainability in a VUCA environment. As opposed to rational knowledge from instrumental-calculative reasoning, aesthetics recognizes sensorial perceptions and their felt meaning as an important source of knowledge for organizations (Taylor and Hansen, 2005).

4. Spiritual Knowledge Management

Spirituality can be considered as "a belief or value system which permeates all of a person's life, giving life meaning in the context of six basic human relationships: 1) to God, or whomever or whatever is considered ultimate reality, 2) to self, 3) to others, 4) to the environment, 5) to the past, and 6) to the future" (Hoshiko, 1994 cited in Westera, 2016, p. 6); it is the being related to something self-transcendental. Consequently, spiritual knowledge is "about the deep human concerns of our existence, and of our connection with the whole universe" (Bratianu, 2015, p. 72). In this context, the concept of "self" as an analytic tool allows for introspection and reflection on our relationship between ourselves and 'others' (Dyson et al., 1997).

Spiritual Knowledge Management can be characterized as the process of creating, capturing, distributing, and effectively using knowledge to achieve the future best version of myself as a person or the future best version of itself as an organization (Kaiser, 2023). The basic idea of this approach is the fact that a fundamental dimension and key element of spirituality, which can be found in almost all definitions and approaches of spirituality - even if they are sometimes quite different - is the self. Spirituality is connected inseparably with a continuous evolution of the self towards a fully developed and fully unfolded self. The concept of Spiritual Knowledge Management takes this into account and argues that a stepwise development takes place, which can be seen as a transformation from the current version of the self to the future best version of the self. Since the future best version of the self is not (completely) known at the beginning of this path, this process can be thought of as a process of becoming (Clegg et al., 2005) and at the same time as a deep learning process (Kaiser, 2023). During this learning process, knowledge about the very nature and shape of the future best version of the self is created, and at the same time, this knowledge shapes and clarifies not only the future best version of the self, but also the way to achieve it (Kaiser, 2023). Moreover, Spiritual Knowledge Management is informed by and results in self-transcending knowledge that allows us to act on the "relation and interaction with world and with something that is other than it-/oneself" and expands our "boundaries (of the self) and [provides a] bigger picture", including "purpose, meaning and final cause" (Kaiser & Peschl, 2020, p. 534). For its generation, methods such as "learning from the future as it emerges" (Scharmer, 2009) and "learning from an envisioned future" (Kaiser et al., 2016; Kragulj, 2014) may be used. As such, Spiritual KM bridges a gap between the individual and an organisation in a sense that it addresses personal values and beliefs which are embedded in an organisation. Thereby the study of spiritual knowledge facilitates the conscious evocation of meaning in an organisational context.

The following figure-1 shows schematically the approach of Spiritual KM as an entire system.

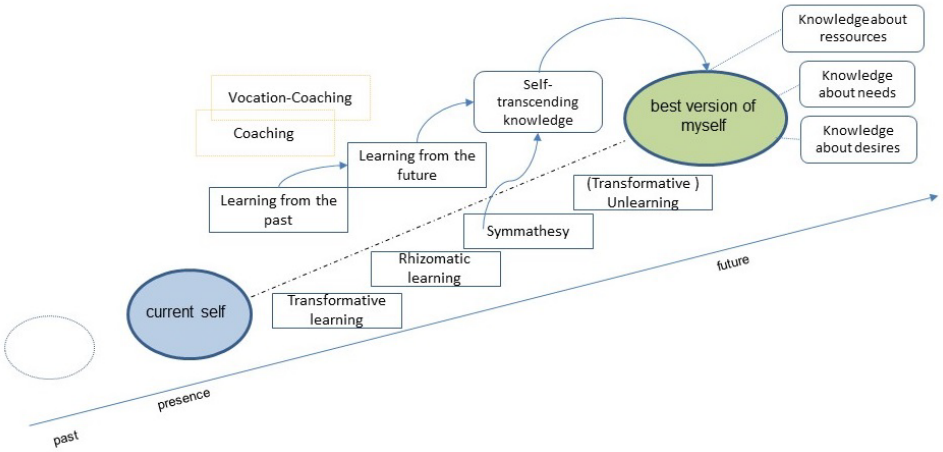

Figure-1: Spiritual Knowledge Management as an Entire System

In the following there are a few comments and remarks on this model:

- Figure 1 shows the evolution process from the current self towards the best version of oneself schematically and in a highly simplified way, since in practice it is very unlikely to be a straightforward process.
- In order to give some structure and direction to the deep learning process from the current self toward a future self, it is important to consider what specifically needs to be learned. Various authors (Kelly, 2004), (Maureder, 2004), (Kelly, 2017), (Kaiser, 2017) argue that the fulfilled self, i.e., the best version of oneself, is defined or characterized by (at least) three dimensions, namely legitimate needs, wants and desires, as well as talents, strengths, and resources. If this holds true, then we need to create knowledge about these three dimensions - knowledge about needs, knowledge about deep wishes and desires, and knowledge about resources and strengths - as part of the deep learning process.
- During this learning process, knowledge about the very nature and shape of the best version of the self is created, and at the same time, this knowledge shapes and clarifies not only the best version of the self, but also the way to achieve it (Kaiser, 2023). Following Nonaka and other scholars, knowledge can be defined as the capacity to act (Stehr, 2012), (Sveiby, 1997), (Sveiby, 2001). Accordingly, it is precisely the knowledge generated in this deep learning process that enables a person to act step by step on the way to becoming the best version of oneself. Consequently, without creating this knowledge, a person would get stuck on his or her path and would not be able to develop and grow (Kaiser, 2023). The same holds true for organizations and companies.
- To enable and support this deep learning process respectively and to bring this process in action, we assume that the methods mentioned in figure-1 (Coaching, Vocation-coaching, transformative learning, rhizomatic learning, symmathesy, (transformative) unlearning, as well as learning from the future and learning from the past, could be helpful. Whether this is really the case will be part and content of future research and investigations.

In terms of relatedness and futureness, numerous links can be identified. The core idea of the Spiritual Knowlegde Management approach is about becoming. Who you become is more important than what you are doing or what you have right now. This radical future orientation is of course not an end in itself, rather it is intended that the so-called future best version of oneself, corresponds to the principles of sustainability and wisdom better and to a higher degree. Finally, this development towards the future should have a significant benefit for all stakeholders, i.e. not only for the person him/herself, or for the company or the organization itself, but also for the (social) systems in which the person or the organization operates. It is precisely because of this that the aspect of relatedness also comes into play to a great extent. Therefore, it could be argued that spiritual knowledge management can be considered as an approach to do "the right things," which is considered one of the most important characteristics of sustainability.

5. Synthesis

What both of the presented lines of research have in common, is that they bring back the emphasize on personal experience and tacit knowledge respectively. Tacit knowledge is, indeed, a concept that has been around in Knowledge Management for decades. It has even been a substantial foundation for a large part of the field that builds on Nonaka and Takeuchi´s (1995) influential theory of knowledge creation in a company. Yet it seems that the meaning of the original idea of tacit knowledge, which was formulated by Michael Polanyi in 1966 (Polanyi and Sen, 2009), had been lost out of sight in the last years. Research in the fields of both Responsible Knowledge Management as well as in Spiritual Knowledge Management hence again emphasize the value of tacit knowledge (although from different angles) in order to address todays challenges in sustainability. It has been argued that rational knowledge alone will be an insufficient means to deal with contemporary problems, because those problems are too complex to be understood as a whole by using instrumental-calculative reasoning. Instead, these problems require practical wisdom on an individual (Nonaka & Takeuchi, 2011) but also on an organizational level (Kragulj, 2022). In its totality, they can only be perceived aesthetically and require individuals and organizations to understand themselves more as 'part of' instead of an 'entity in' the world. This necessarily implies a change in the perception of the individual and organizational self. Individuals and organizations must hence develop and understanding of who they are and what their place in the world is. That process can be understood as a quest for the *best version of one's self* and requires numerous sources of non-rational knowledge and direct experience (Kaiser and Peschl, 2020). We argue that only through recognizing the importance of, and cultivating such kind of tacit knowledge – be it wisdom, aesthetic meaning, spirituality, or else – it becomes possible to achieve true relatedness that will result in long-term oriented decision making, best described as a mindset of futureness.

For all those aspects, we see a strong connection to the field of Knowledge Management that builds on knowledge (and in that regards, knowledge must means all types of knowledge) as a source of competitive advantage (Grant, 1996; Spender, 1996). However, to be coherent, and in the light of current challenges, we shall probably reconsider the idea of *competitive* advantage towards a more conjoint notion of advantage and value-generation for society. This is, because the achievement of true sustainability will require us to move the boundaries from an individual organizational advantages-perspective to a more systemic-societal perspective of value generation. However, this is not to say that organizations will only, or should only operate towards big and noble societal goals. Rather, organizations operating on the basis of principles relatedness and futureness, will still pursue their individual purpose, yet this purpose is likely to be far more grounded in the overall system, hence leading to more and better value creation for society as a whole.

What the discipline of Knowledge Management can bring to the table in this regard is (a) great expertise and insight on individual and organizational knowledge and how to deal with such knowledge in the context of organizations, but also (b) theories and studies about the application, generation and sharing of knowledge (both tacit and explicit). What is more, Knowledge Management could (c) serve as an interface between organizational practice (daily business) and sustainable strategic planning, if it is concerned with collecting and interpreting insight about the value that an organizations seeks to create in world.

6. Avenues for Further Research

The fields of responsible Knowledge Management and Spiritual Knowledge Management are still in their infancy. Thus there are plenty of open ends that would make up for promising ends for further research. In the following, we will give some ideas where this research could go.

First, there could be more in-depth studies on the nature of tacit knowledge and its relationship to knowledge on sustainability, spiritual knowledge, wisdom, or aesthetics and how they can be cultivated and applied in organizational settings. Also, it would be worthwhile exploring, what individual skills are required to apply such forms of tacit knowledge, and also, how people can acquire such knowledge or skills. What are, for example, the implications for the education of business leaders and other decision-makers in organizations?

Second, research could examine how organizations can shift their focus from individual organizational advantages (the classical competitive advantage) to a more systemic-societal perspective of value generation. This could involve exploring how organizations can identify their purpose within the broader system, and how they can measure and communicate their impact on society.

Third, research could focus on the role of conventional Knowledge Management (e.g. KM Systems) in promoting sustainability. This could include investigating how Knowledge Management Systems can be used to capture,

share, and apply knowledge on sustainability, as well as how it can be used to support strategic planning and decision-making against the backdrop of relatedness and futureness.

Overall, there is a need for more research that integrates different disciplines and perspectives, including Knowledge Management, sustainability, wisdom, spirituality and other disciplines that are concerned with notions of non-rational knowledge, in order to address the complex challenges that organizations and society are facing these days.

7. Conclusion

Sustainability has become an essential objective that companies must meet to ensure a better future for all. The shift in focus from managing a stock of knowledge to providing a management tool that enables doing the right things has brought about a need to rethink the role of Knowledge Management. We have argued that sustainability is particularly characterized through notions of relatedness and futureness. Those are important, because they create an interface between Knowledge Management and Sustainability. On the other hand, in the field of Knowledge Management there are already some initiatives towards sustainability, namely Responsible Knowledge Management and Spiritual Knowledge Management that fit well to the ideas of relatedness and futureness and embed them in the area of Knowledge Management. A key finding in this regard is that in order to address sustainability, Knowledge Management ought to focus on non-rational forms of knowledge and tacit knowledge as a valuable counterpart to instrumental-calculative rationality.

Further research should hence address the relationship between non-rational or tacit knowledge and sustainability, spiritual knowledge and wisdom. Additionally, further research should also target individual capabilities necessary to generate or apply non-rational knowledge.

Lastly, if we adopt a mindset of futureness and relatedness as part of Knowledge Management or Knowledge-based Management respectively, we can reconsider what we understand by competitive advantage on the basis of knowledge. Our image of competitive advantage could then undergo a transformation towards a more conjoint, multidimensional notion of advantage for an organization but also value-generation for society and future generations as a whole, instead of the one dimensional advantage over competition.

Intuition - Knowledge Over Management Science: Lesson From the Past Decades

Patrycja Krawczyk and Patrycja Kokot-Stępień
Czestochowa University of Technology (CUT), Poland

patrycja.krawczyk@pcz.pl
patrycja.kokot-stepień@pcz.pl

Abstract: The subject of intuition in management is interesting and has been discussed for decades. Repositories of scientific publications have in their collections hundreds of publications related to the use of intuition in management. It is necessary and reasonable to summarize the achievements of world science in this area. The best tool to do this will be bibliometric analyse. Bibliometric analysis is a popular method for exploring and analysing large volumes of scientific data but it`s application in business research is relatively new. A review of publications on this subject will indicate the state of this area of research. As part of the research, an analysis of the number of publications and the number of citations, and keywords statistics will be carried out. The database will be Web of Science. Zotero and VOSviever program will be the research tools. The review will be carried out following the methodology and will be divided into 5 stages, comprising: preliminary search, full search and literature acquisition, evaluation of collected documents, synthesis and analysis of results, and summary of results. The results will allow for assessing the research activity and the stage of development of the research in the field of intuition in management. A map of keywords related to the described issue will be created. What is the level of interest of scientists in this subject? Is it growing or going down? It will reliably summarise the current state of knowledge, providing information about gaps in the literature. It can also be a way to identify new research areas.

Keywords: Bibliometric analysis, Intuition, Knowledge, Management

1. Introduction

Knowledge is increasingly important in the management process in today's economy. It serves as a strategic resource of the organization (Piersiala, 2014). In this emerging management climate, one resource which is receiving increased attention in such leading publications as The Wall Street Journal, Harvard Business Review, Public Management, and The Bureaucrat is the brain skill intuition. Even leading business schools are now experimenting with a new course designed to help develop intuitive skills for decision-making.

Intuition is a feeling in which a person does not analyze what happens and why, because some other feeling tells them how to act. There is probably no other phenomenon equally important for management and less explored than intuition. Yet, intuitive thinking accompanies every manager and influences the objectives set and the way they are achieved (Laszczak, 2011). Intuition is a characteristic that can be attributed not only to individuals, but also to entire working teams.

Business decisions have always been challenging, but in last decades, as the complexities of global economy have deepened, they have become tougher than ever. The choices managers face and the data requiring analysis have multiplied, even though the time for analyzing them has shrunk. One decision-making tool - human intuition - seems to offer a reliable alternative to a painstaking fact of gathering and analysis (Bonabeau, 2003). The media space offers many articles, recordings of films convincing about this fact. This trend has been joined by the rational world of science. Scientific research should encourage managers just to trust their intuition, when facing complicated choices.

Intuition is an attribute of most living organisms, obviously including humans. On the other hand, intuitiveness is also a characteristic often attributed to technical solutions, including software. In the case of application software, an intuitive interface is just as important as extensive functionality. User satisfaction in terms of the usability of software affects their opinion on the system. Providing full functionality of technology and at the same time an attractive user interface is an uneasy task for business solutions.

One of the first definitions seems to be very accurate: intuition is an inductive skill. It is the ability to "see the big picture," to sense the possibilities and implications of any particular situation or potential decision by looking at the whole problem rather than each of its component parts. It is the ability to come up with a workable solution to a problem even when data for making that decision is inadequate or unavailable (Agor, 1985).

Article will be divided into following sections: introduction, literature revive, research methodology, results, conclusion and future work. The first part shows the intuition in management. Justifications for taking up the subject. The second part includes the overview on the writing in the field of institution in management. The third part describes the methodology of the taken research with the particular emphasis on description of the studied

samples, accepted queries. There will be indicated a tool that support the process of analysis and presentation of the collected research material. The next points presents data and calculates the level of dependence. The later phase interprets the numerical data. The presentation of numerical data in tabular form and graphs can be found in the publication. The entire study will be closed with a conclusions including: general summary of the article, its results and findings, compare to findings of other authors, recommendations for practice, research limitations and some suggestions for future research.

2. Systematic Literature Review

Intuition is a valuable sources of organizational knowledge and learning, and contribute to improved decision making in organizations (Doerfler and Ackermann, 2012; Akinci and Sadler-Smith, 2019). Intuition should be conceptualized as a multidimensional rather than a unitary construct comprised of a variety of general and specific mechanisms and processes, and primary types.

A very interesting publication, summarizing research into intuition and management is Intuition in Management Research: A Historical Review (Akinci and Sadler-Smith, 2012). In this historical review, the authors outlined the progress of research into intuition over the past eight decades. They proposed their interpretation of the chronological sequence of events that make up the history of research into intuition in management. They did not use bibliometric analysis and the research was completed in 2010. They found out that until the turn of the century, the development of research into intuition occurred mainly outside the field of management. Moreover, the concept of intuition itself was undefined or poorly defined. Within the framework of research into management, the image was sometimes confusing and contradictory.

Until the turn of the 20th century, an interest in research into intuition within the circle of management researchers was small. Today, we observe an increased interest in this area (Hodgkinson and Sadler-Smith, 2018). There were two reasons for this: intuition is the perhaps least understood aspect of managerial cognition and without understanding intuition it is impossible to develop any meaningful conceptualization of cognition (Doerfler and Ackermann, 2012). In their article they propose a provisional distinction of two types of intuition which they call intuitive judgement and intuitive insight. This distinction helps in developing a better understanding of creative intuition, which is perhaps the least understood of the various types of intuition.

In recent decades intuition researchers in management have identified different types of intuition (Gore and Sadler-Smith, 2011). These are: ‘creative intuition’, ‘expert intuition’, ‘moral intuition’, and ‘social intuition’ and spiritual intuition (Sadler-Smith and Heliot, 2021). The field of management intuition research itself may also be in something of a state of confusion on matters of epistemology and ontology.

Intuition in management is considered in connection with various areas of management, e.g., the role of intuition in employee selection (Miles and Sadler-Smith, 2014), in different industries or sectors, such as banking and finance (Hensman and Sadler-Smith, 2011), manufacturing(Tsai and Hung, 2023; Wang *et al.*, no date), healthcare (Vazquez-Ingelmo *et al.*, 2020; Mellini and Mileti, 2022), and transportation (Willumsen and Ortuzar, 1985; Chan-Chiao Lin *et al.*, 2003), with a distinction at the management level (Hodgkinson *et al.*, 2009), company size (Marzi *et al.*, 2023).

One should unconditionally agree with the statement that until recently intuition has received scant scholarly attention within and beyond psychological sciences, despite its potential to unify a number of lines of inquiry. At present, the literature on intuition is conceptually underdeveloped and dispersed across a range of domains of application, from education, through management, to health (Hodgkinson, Langan-Fox and Sadler-Smith, 2008). An attempt to organize it has been made in this study. The analysis of the literature and the initially prepared research material allows the formulation of a set of research questions:

RQ1. What are the most relevant scientific categories when it comes to intuition in management?

RQ2. In light of the data analysed, which authors/researchers are the most relevant when it comes to research on intuition in management?

RQ3. In light of the data analysed, which journals are the most relevant when it comes to publishing research results related to intuition in management?

RQ4. What does the association of keywords look like?

RQ5. Which publications should be considered the most important?

3. Research Methodology

Bibliometric analysis is a popular method for exploring and analysing large volumes of scientific data. It enables us to unpack the evolutionary nuances of a specific field, while shedding light on the emerging areas in that field. Yet, its application in business research is relatively new (de Souza Vanz and Chitto Stumpf, 2010; Chen *et al.*, 2020; Donthu *et al.*, 2021). Bibliometric methods have been used to map the fields of strategic management, entrepreneurship, innovation, and others (Zupic and Cater, 2015). The bibliometric analyses scientific publications with a set of indicators under different scopes. It is the aim to recognize scientific trends, to validate statements about scientific development and to look on actors and institutions in the scientific landscape (Tunger and Wilhelm, 2013). The latest systematic and correctly conducted review reliably summarises the state of knowledge to date, reporting any gaps in the literature and the need for new research to be conducted (Mazur and Orłowska, 2018). It is also a way of discovering new research topics. These features make systematic reviews useful in many areas of science and practice, including medicine, education, psychology, management and organisation.

For the bibliometric analysis of keywords program VOSviewer will be used. It is a software tool which can be used to conduct bibliometric analyses and create visualizations from selected databases. This software builds maps based on mathematical algorithms. It is used in other bibliometric studies (Castillo-Vergara, Alvarez-Marin and Placencio-Hidalgo, 2018; Garrigos-Simon, Narangajavana-Kaosiri and Lengua-Lengua, 2018) because it provides especially useful graphical representations with maps based on network data.

To ensure high quality of the analysis, the study will be divided into the following stages:

- Planning, defining the purpose of the review (preliminary search) including testing a few phrases to clarify the topic, testing the issue of non-financial reporting from an accounting perspective;
- Full search and acquiring literature;
- Extraction and evaluation of the evidence collected;
- Result synthesis and analysis;
- Reporting and sharing results.

At the level of Advanced Search Query Builder, various queries were tested. In the final stage, three were analyzed. The first one was TS=(intuition and management), where TS means that the following fields were searched: title, author keywords, abstract, and keywords plus. A total of 1746 publications registered in the database were indicated. However, the in-depth analysis indicated that there were some articles in the results which did not relate to the research questions posed. The second selected research sample was determined and was the result of applying the TS=(intuition) filter with refine by Web of Science Categories: Management. Search); it gave the result of 1110 records, including publications that did not relate to the research questions posed. Ultimately, a sample of 1216 publications was analysed (see Table 1), identified due to the use of the following key:

AK=(intuition AND management) or KP=(intuition AND management) or TI=(intuition AND management) OR AB=(intuition and management)

Table 1: Search Protocol

Criteria	**Reserch sample**
Database	WOS
Download date	06.03.2023
Timespan (year of first publication)	1900 - 01.2023 (1982)
Query	AK=(intuition AND management) or KP=(intuition AND management) or TI=(intuition AND management) OR AB=(intuition and management),
Sample size	1216
AK - Searches the author keywords field **KP** - Searches the keywords plus field (KeyWords Plus® are index terms automatically generated from the titles of cited articles. KeyWords Plus terms must appear more than once in the bibliography and are ordered from multi-word phrases to single terms. KeyWords Plus augments traditional keyword or title retrieval) **TI** - Searches article titles. Title refers to the title of a journal article, proceedings paper, book, or book chapter **AB** - Searches the abstract field

4. Research Results

Knowledge and intuition are two seemingly opposing issues. On the other hand, intuition can be called internal knowledge. How scientists view the role of intuition in management? The study with the help of bibliometric analysis will summarize the research conducted so far in this area.

169 categories were identified, the most numerous of which are Management, Business, and Computer Science Information Systems (see Table 2). Many articles relate to engineering. This a reflection of an increased interest in creating intuitive vehicles (Chan-Chiao Lin *et al.*, 2003), machines and devices, or software algorithms (Lee, 2018). Understanding the intuitive human factor is essential when developing technical solutions.

Table 2: Web of Science Categories

	Record Count	% of 1216
Management	283	23.27
Business	163	13.40
Computer Science Information Systems	93	7.64

Publications on intuition in management are dealt with by researchers from various geographic areas. Scholars from the United States dominate, with over 27% of publications coming from this country. The next position belongs to England with over 11%, and the third position belongs to China (table 4).

Table 4: Publication by Countries/Regions

	Record Count	% of 1216

A historical approach to research into intuition in management is presented in the literature review Intuition in Management Research: A Historical Review (Akinci and Sadler-Smith, 2012). However, this work does not cover the last decade, which has seen a dynamic development of this topic. The first publication in the analyzed sample appeared in 1982 – Management guidelines - don't mistrust intuition (Raudsepp, 1982). In the period of 1982 - 1996, 35 publications were produced, with the annual number ranging from 1-7. From this period, particularly interesting publications seem to be: The road to success (Totten and Keys, 1994), The new religion of risk management (Bernstein, 1996), Intuition in organizations - leading and management productivity (Jourden, 1994). The following years saw an increase in the number of publications. The most were published in 2020 - 95 publications, and 2021 - 94 publications. Only the turn of the 20th and 21st centuries can be considered a moment when research into this topic flourished. Nowadays, many researchers from various fields, including management itself, engineering, and psychology, address this topic. The number of publications is significantly increasing. After 2020, it is already close to 100 publications per year (see Figure 1).

Source: Own elaboration based on Web of Science data (access 06.03.23.)

Figure 1: Publication by Time

The search results indicate a total of 3374 individuals who have published in this field. Most of them are co-authorship. The leader is Eugene Sadler-Smith who has published 17 papers in this area, the vast majority of which are co-authored. His most frequently cited work (193 citations) is: Intuition: A fundamental bridging construct in the behavioral sciences (Hodgkinson, Langan-Fox and Sadler-Smith, 2008). Like other publications

by this author, it is a must-read for those exploring the role of intuition in management. Another three authors have published five works each. These are: Constantin Bratianu, Said Elbanna, and Gerard Paul Hodgkinson (see Table 5.

Table 5: Name of Author who Publish Mostly

	Record Count	% of 1216
Smith, Eugene Sadler (Guildford, Surrey, England)	17	1.398
Bratianu, Constantin (Bucharest University of Economic Studies)	5	0.411
Elbanna, Said (Qatar University)	5	0.411
Hodgkinson, Gerard Paul (University of Manchester, Alliance Manchester Business School)	5	0.411

The papers have been published in over 1100 different publications, which means a large fragmentation of percentage shares (see Table 6). Lecture notes in computer science surprisingly holds the top position, followed by Management decision, Academy of management learning education, and Sustainability.

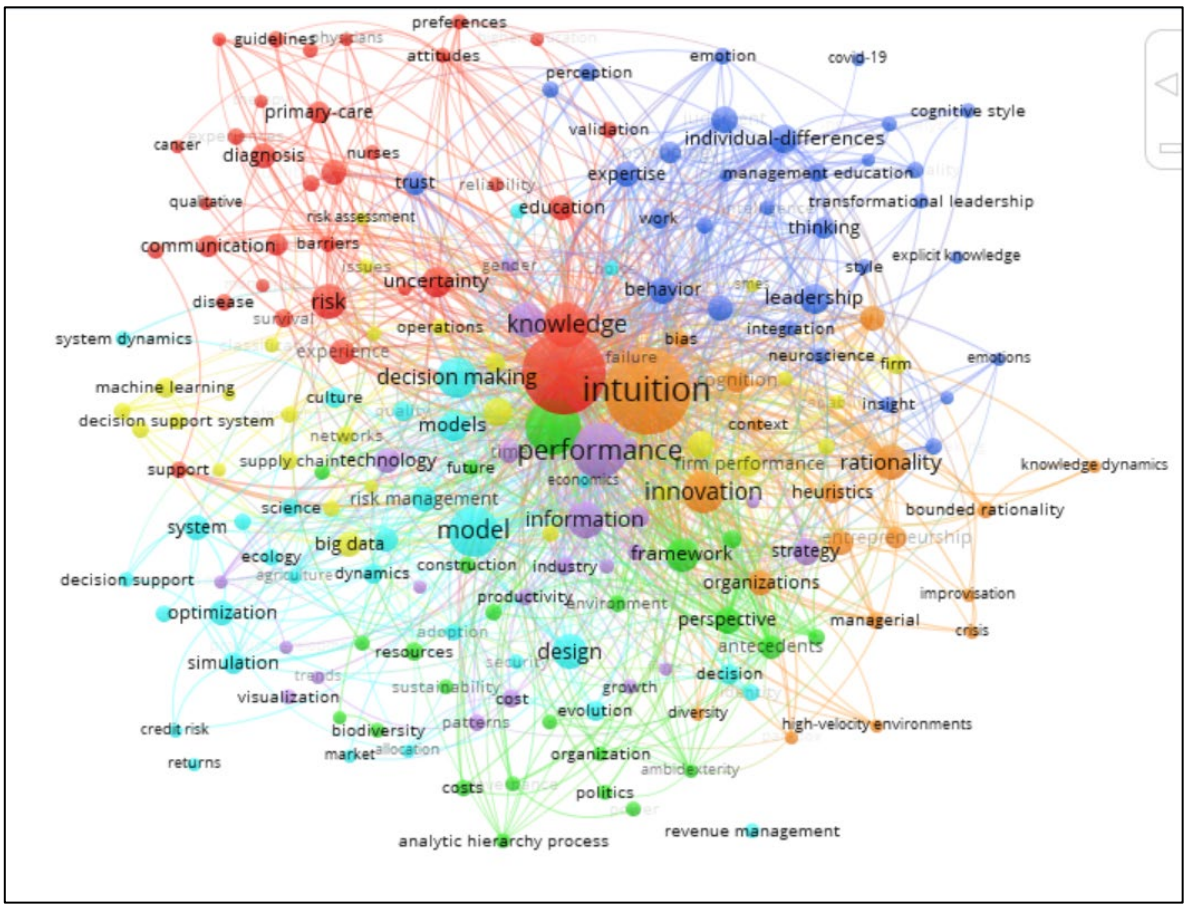

Table 6: Publication Titles

The map of keywords was prepared using VOSviewer software. The map shows the connections between 193 keywords that are combined into 7 clusters, connected by 2765 lines. The paper includes the map in a general sense (Figure 2). The largest cluster, marked in red, contains 33 items, of which the most frequently repeated are: management, knowledge, risk, uncertainty, education, and diagnosis. The second cluster, marked in light blue, is almost as numerous, with 32 dominant words, such as: model, decision making, models, and design. The third cluster, marked in dark blue, contains 31 items: leadership, individual differences, behavior, judgment, tacit knowledge, and expertise. The fourth cluster, marked in yellow, has 30 items, with dominant words such as: systems, knowledge management, firm performance, big data, and supply chain management. The fifth cluster,

marked in purple, has 24 words with a dominance of: performance, information, strategy, industry, technology, and impact. The sixth cluster, marked in green, contains 24 words, including: decision making, framework, perspective, and antecedents. The last cluster, marked in orange, contains 19 items, with dominant words such as: intuition, innovation, rationality, and entrepreneurship.

Source: Own elaboration based on Web of Science data and VOSviewer (access 06.03.23.).

Figure 2. Kye wors map

H-index is 72, citing articles are more than 22 thousand with average per item more than 20. The most frequently cited items are:

- Power management strategy for a parallel hybrid electric truck (Chan-Chiao Lin *et al.*, 2003), cited 855 times;
- Thinking about u: theorizing and testing u- and inverted u-shaped relationships in strategy research (Haans, Pieters and He, 2016) cited 833 times;
- Moral Foundations Theory: The Pragmatic Validity of Moral Pluralism (Graham *et al.*, 2013) cited 826 times;
- Building theory about theory building: what constitutes a theoretical contribution? (Corley and Gioia, 2011) cited 824 times.

5. Conclusion and Future Work

Intuition and knowledge are seemingly opposite terms. Knowledge management is a discipline that has its place in management science. The term "intuition" is associated with something irrational, mystical, and is on the verge of superstition. However, there are many scientific studies contradicting this statement. Their bibliometric analysis is included in this study. In terms of knowledge management, we use our analytical capabilities to take effective decisions. However, step-by-step reasoning is not the only way of knowing. Sometimes we just ‘know’, in a moment without knowing how or why we ‘know’. Thus the knowledge arrived at by means of intuiting we call intuitive knowledge. We should remember that not so many years separate today's risk-assessment and hedging techniques from decisions guided by superstition, blind faith, and instinct .The notion that the future

rests on more than just a whim of the gods is a revolutionary idea. It is also a very young idea. More than any other development, the quantification of risk defines the boundary between modern times and the rest of history (Bernstein, 1996).

The first publications on intuition in management appeared as early as in 1938 (Akinci and Sadler-Smith, 2012). Although these were individual studies, they should be considered valuable and interesting. Only the turn of the 20th and 21st centuries can be considered a moment when research into this topic flourished. Nowadays, many researchers from various fields, including management itself, engineering, and psychology, address this topic. The number of publications is significantly increasing. After 2020, it is already close to 100 publications per year. Most publications are found in the categories of Management, Business, and Computer Science Information Systems. In the Research Areas category, the most numerous are Business Economics, Computer Science, and Engineering. In the category of geographic distribution, the most numerous publications are from the USA. The most frequently repeated keywords are knowledge, intuition, performance, model, innovation, risk, technology, rationality, and ridership. They are grouped into 7 clusters in the graphic presentation using VOSviewer.

The material presented herein provides answers to the research questions posed. It shows the moment when research in this direction began and the time when research into the issue intensified. It also presents a map of the keyword links. On the one hand, it shows the interdisciplinary nature of research.

The material developed has some weaker points. One of them is the restriction to only a selected single repository, namely the Web of Science database. This means that it does not take into account studies published in journals that were not indexed in the database. As a justification for the above, one may state that the chosen database is one of the two largest databases available. A comparison of the two largest ones, i.e. WoS and Scopus, could constitute a topic for another research. The second point that may be debatable is the choice of the search query However, in the opinion of the author, who tested various search combinations when approaching the topic, the adopted [AK=(intuition AND management) or KP=(intuition AND management) or TI=(intuition AND management) OR AB=(intuition and management)], is the most objective and authoritative one.

The study is a summary of previous research into the correlation between two concepts: intuition and management. It shows the interdisciplinary nature of the topic. For the scientific community, it can be the basis for further research into this subject matter. For management practitioners, it is a reminder that, in addition to knowledge, there is another effective tool useful in decision-making - intuition. Going further, it seems justified to distinguish a separate subcategory in knowledge management - "intuition management".

Managing Remote Negotiation Strategies

Joanna Krzywda
Czestochowa University of Technology, Poland

joanna.krzywda@pcz.pl

Abstract: In more recent times, many business relationships have moved online and many companies are taking advantage of the opportunity to talk online with their business partners. This paper attempts to answer the question of how this fact affects business relationships. A survey method was used with 47 companies in Poland that conduct remote negotiations or remote business talks. The respondents were company managers who participate in both traditional and remote negotiations. The conceptual framework for the study was the model of negotiation as recurring events in the history of a relationship (Thomas, Manrodt, Eastman, 2015). The limitations of the study derived from the specificity of the research group: the respondents were from Poland, and the perspective of small and medium-sized companies was taken into account, whereas perhaps the perspective of large companies would have been different. The conclusion outlines the potential of remote negotiation compared to traditional negotiation and implications of conducting remote negotiations.

Keywords: Negotiations, Remote negotiations, Interorganisational relationships

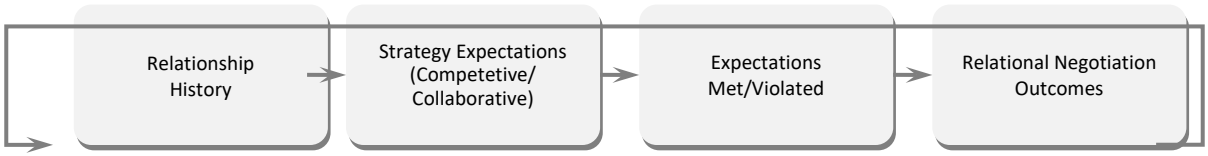
1. Introduction

Negotiation is an essential part of business relationships and at the same time a frequent and relevant part of management tasks. (Saorín-iborra, M. C., & Cubillo, G., 2019) Negotiation is a key interaction in the buyer-seller and supply chain relationships (Zachariassen, 2008) and every business project - and every business relationship - is related to negotiation. Thus, it becomes apparent that negotiation is central to the relationship. If one assumes this to be the case, then it is important to establish what factors influence negotiation.

The recent years have seen an increasing number of business meetings taking place via modern technologies, in particular video conferencing. This is due to the possibilities that these technologies offer and the benefits that this brings, such as saving time, financial resources that would be spent on travel, but above all the belief that remote negotiations can successfully replace traditional face-to-face (f2f) meetings. From the point of view of interorganisational relations, this phenomenon is highly interesting and raises a number of questions about the impact of such negotiations on interorganisational relations and the nature of this type of negotiation itself, particularly in comparison to traditional negotiations.

This paper attempts to answer a number of questions that arise with regard to business relationships that are initiated and sustained by means of remote negotiation: how the fact that negotiations take place by means of videoconferencing affects the attitudes of the participants in the negotiations: their expectations and plans, and how the negotiation situation and the outcome of remote negotiations affect the business relationship.

2. An overview of the Literature

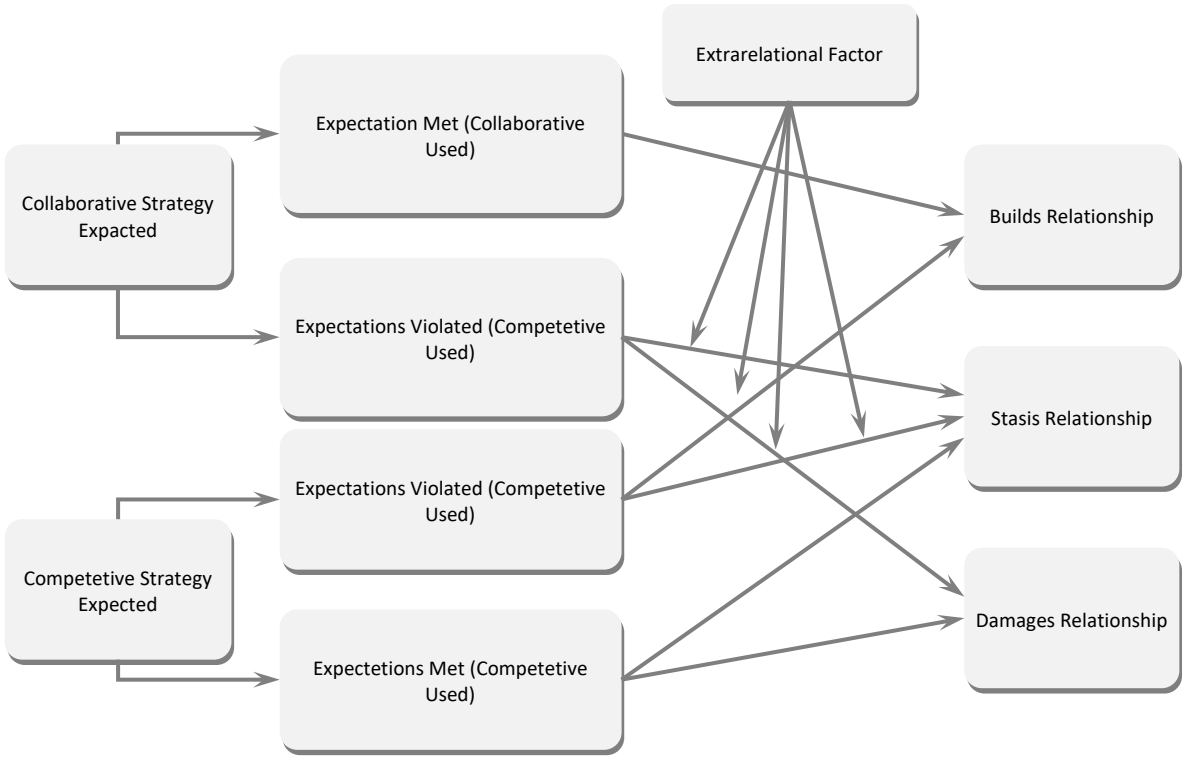


Negotiation and relationships in the academic literature are discussed from many different angles. The literature on negotiation and relationships is very rich and multifaceted. Negotiation is seen as a way of resolving conflicts, including cultural conflicts (Biesaga-Słomczewska, 2011). Cross-cultural negotiation is addressed extensively (Peleckis, 2014), but so is negotiation in specific situations such as selling real estate (Wang, Zionts, 2008) or negotiating salaries (Säve-Söderbergh, 2019). There is also a rich psychosocial current in the negotiation literature, analysing negotiators' behaviour and its socio-psychological background, e.g. face-threat-sensitivity (Miles, Schatten, Chapman, 2020), gender differences in negotiations (Mazei, Zerres, Hüffmeier, 2021; Lee, Pitesa, Pillutla, Thau, 2017), or styles and negotiations behaviours (Ma, 2007). There is also a current dedicated to negotiation tactics and techniques and their typology (Martin-Raugh et al., 2020).

Among these currents, there has also emerged one dedicated to the study of online negotiations also known as remote negotiations or e-negotiations. These are defined as 'any long-distance negotiation process, without physical contact and using audiovisual communication tools, mainly connected to the Internet, which allow immediate and technically fluent communication, but with certain limitations and differences with face-to-face negotiations' (Hernandez, Monne, Sein-Echaluce, 2022). Thus, for example, the role of humour in remote negotiation (Kurtzberg, Naquin, Belkin, 2009), advantages and disadvantages of online negotiation (Yuan, 2003) and non-verbal behaviours in online negotiations (Kazemitabar et al 2022; Holland, Taylor, 2016) have been explored. The differences between remote negotiations and traditional negotiations have also been explored.

The fact that negotiations take place online is among a large group of factors that can influence the course and outcome of negotiations. Among these, BATNA, or the best alternative to a negotiated agreement, is also considered (Fisher and Ury, 1981). There is well-known research on the relationship of BATNA with the negotiation strategy adopted by negotiators (Patton et. al, 2010; Habib et. al, 2015) and on the outcome of negotiations (McAlister et. al, 1986; Roloff, and Dailey, 1987). Other factors influencing negotiators' attitudes include cultural intelligence (Caputo et. al, 2019), psychological factors including cognitions and biases, personality, motivation, emotions and inclination to trust (Brett, Thompson, 2016), emotional intelligence (Kelly, Kaminskiene, 2016), creativity of the negotiator (De Pauw et al. 2010), need for closure, i.e. a construct that describes a motivational tendency to quickly select and prioritize information in the environment (Pietrzak et. Al, 2014) and social-environmental factors including reputation and relationship, gender, power and status, and culture (Brett, Thompson, 2016). Negotiators' attitudes may also be influenced by their religious beliefs (Richardson, Rammal, 2018), history, in particular protracted feuds that developed as a result of conflicting interpretations and invocations of history (Dezső et al. 2015), but also expectations about others' ethics (Mason, et. al., 2018) as well as the language used during negotiations (Alvarez et. al., 2017) or the way the negotiating partner speaks (Swab et al., 2011). The question raised about the differences in how the fact that negotiations take place remotely affects negotiations can hardly be found in the literature. Galin, Gross, Gosalker (2007) found that the negotiation media, as well as the negotiation sequence, barely affects the negotiation outcomes. Face-to-face negotiation was not different than e-negotiation, in terms of the final price, the number of installments for the balance and the sum of the advanced payment. However, both the negotiation media and the negotiation sequence significantly affected the main features of the negotiation process, in terms of time duration and the use of hard or soft tactics. However, there is still a research gap when it comes to the impact of remote negotiation on interorganisational relationships.

3. Conceptual Framework



Understanding the role of negotiation in relationship formation is facilitated by an analysis of the model by S. Thomas, K. B. Manrodt, J. K. Eastman (2015). Taking a broader perspective, the authors of the model assumed that the relationship between suppliers and buyers is a key element in supply chain management practice. The model also assumes that there are two main negotiation strategies: a collaborative strategy and a competitive strategy. Different 'negotiation events' are discrete events that become part of the history of the relationship and then affect the relationship in its longer term. The relationship between the buyer and the seller is built up over a series of transactions. Each interaction contributes to the relationship history as illustrated in Figure 1.

Source: S. P. Thomas, K. B. Manrodt, J. K. Eastman *The impact of relationship on negotiation strategy expectations. A theoretical framework*, in: International Journal of Physical Distribution & Logistics Management. Vol. 45, No. 8, 2015, p. 802.

Figure 1: A Model of the Impact of Relationship History on the Outcome of the Negotiation and the Subsequent Relationship Depending on The Expected Negotiation Strategy

The history of the relationship influences the parties' expectations of the strategy expected from the other party - collaborative or competitive. The outcome of a single negotiation event influences the relationship in the future. Based on the history of previous negotiations, negotiators form their predictions about the strategy that the other party will use. If the negotiator expects the other party to use a collaborative strategy and his or her predictions are confirmed, the existing relationship strengthens. If, on the other hand, the negotiator expects his or her partner to use a competitive strategy and this expectation is confirmed, the relationship does not change or weakens if the negotiator would have preferred a collaborative relationship. If there is a mismatch between the anticipated strategy and the strategy employed by the other party, the impact of this mismatch depends on non-negotiation factors. These relationships are shown in Figure 2.

Source: S. P. Thomas, K. B. Manrodt, J. K. Eastman The impact of the relationship on negotiation strategy expectations. A theoretical framework, w: International Journal of Physical Distribution & Logistics Management. Vol. 45, No. 8, 2015, p. 803.

Figure 2 The Impact of the Expectation of the Negotiation Strategy and the Employed Negotiation Strategy on the Relationship

Non-relational factors are the final component of the model discussed above. They occur outside of the existing relationship and can help the supplier and customer understand why there has been an inconsistency as to the strategy expected and actually employed. Awareness of the reasons for this inconsistency can reduce the potential negative impact of the inconsistency on the relationship. By non-relationship factors, the authors of the model mean, for example, a general increase in commodity prices, which may cause the choice of a competitive strategy, or a weakening of the economy, such as a crisis.

The uniqueness of this model consists in the fact that it takes into account the relationship preceding the negotiation and thus does not treat the negotiation as a discrete event of a transactional nature: previous encounters create a history that influences the following encounters. Based on this model, it is assumed that the way the negotiation is conducted influences the course of the negotiation and, depending on whether the negotiation takes place in a remote mode or in a traditional mode, the participants in the negotiation have slightly different expectations of the other party's negotiation strategy, plan the negotiation event slightly differently, and behave differently and use different strategies during the negotiating stage. Accordingly, the following research hypotheses are put forward:

Hypothesis 1 (h1): As early as at the stage of expectations about the other party's strategy, there are different expectations in remote and f2f negotiations.

Hypothesis 2 (h2): As early as the stage of expectations, the parties plan slightly different strategies in remote and f2f negotiations.

Hypothesis 3 (h3): In remote and f2f negotiations, expectations of the other party's strategy more often or less often differ from the actual strategy.

Hypothesis 4 (h4): Parties change strategies more easily and quickly in remote negotiations than in f2f negotiations.

4. Methodology

A questionnaire-based opinion survey and interview method were used to collect data for analysis.

A total of 47 respondents from businesses in the Silesian Voivodeship in Poland took part in the survey. This number definitely cannot be considered as representative when considering the number of businesses in the Silesian Voivodeship, which is over 450,000. However, it should be noted that data collection is relatively difficult under Polish conditions. In Poland, managers generally cope with a heavy workload, and on top of that they receive a lot of requests to fill in different questionnaires.They are also often reluctant to fill in questionnaires for fear of disseminating confidential or competitor-relevant data (Dyduch, 2020). Therefore, the survey was supplemented with an interview method, which is used and recognised in the study of such concepts as negotiations (Thomas, Manrodt, Eastman, 2015). In this way, a certain triangulation of the study was achieved, nevertheless it could be seen as a lead-in to a larger project.

The respondents in the survey were managers of companies from different industries (trade, construction, manufacturing, insurance) whose responsibilities include negotiating with business partners and who declared experience in both remote and traditional negotiations. The questionnaire consisted of 13 questions designed to verify the study hypotheses, in which the respondents were asked straightforward questions about the phenomena under study with a request to rate them using a Likert scale, which is a measurement strategy used in survey questionnaires and questionnaire interviews to establish the extent to which the phenomena under study can be assessed. It is often employed to measure attitudes towards specific interactions, behaviours, events, objects, projects or problems. Respondents were asked to rate the extent to which they agreed with a given statement about negotiation by marking how strongly they agreed with it on a 5-point scale, where a score of 5.0 indicated the highest degree of agreement and 1.0 the lowest degree of agreement. The averaged agreement ratings of a given statement gave a picture of the respondents' perceptions of negotiation. Thus, for example, if a statement received an average score of 2.0 from the respondents, this means that they tend to disagree with the statement. The study did not use descriptive statistical methods, if only due to the limitations of the size of this study.

Interviews were additionally conducted with 15 respondents in which they commented on the questionnaire questions. Their responses were recorded in the form of personal notes, as most respondents expressed concerns about being recorded. The data thus obtained was subjected to semantic analysis, which complemented the data obtained from the questionnaire.

5. Results

Forty-seven respondents provided their answers. They were employees or owners of companies in industries such as packaging (sales and production), insurance, construction, recycling and services. All declared at least medium negotiation experience.

The first part of the survey included questions to verify the validity of the model. This part of the survey comprised 4 questions and the respondents were asked to provide answers using a 5-point Likert scale. Confirmation of the theses based on the model was obtained: 'the negotiation style depends on the relationship we have with a given company' (4.7); 'if the relationship with a given company has been successful so far, I expect it to be rather good during the next negotiation' (3.85); 'the outcome of a given interaction with a business partner affects how the business relationship is shaped' (4.085); 'there are two negotiation styles, which can be described as competitive and collaborative' (4.46). The subsequent questions included in the survey aimed to verify all four hypotheses adopted.

5.1 h1) As Early as at the Stage Of Expectations About the Other Party's Strategy, There are Different Expectations in Remote and f2f Negotiations

The hypothesis in the study was that at the stage of expectations about the other party's strategy, there are different expectations in the case of remote and f2f negotiations. It was assumed that one of the two strategies - competitive or collaborative - is expected more often by the respondents specifically due to the fact that the negotiation takes place remotely. In order to verify this hypothesis, three questions were asked in the survey. The respondents verified the validity of the statements according to which, in remote negotiations, 1) they more often expect competitive strategies, 2) they more often expect collaborative strategies, and 3) strategy expectations do not depend on whether one negotiates remotely or f2f. The table below shows the results on the adopted Likert scale:

Table 1: Expectations Regarding the Other Party's Strategy in Remote Negotiations

Statement	Validity of the statements on the Likert scale
In remote negotiations, negotiators are more likely to expect competitive strategies	2.44
In remote negotiation, negotiators more often expect collaborative strategies	3.55
Expectations about strategy do not depend on whether you are negotiating remotely or f2f	4.5

Source: Author's own compilation based on the survey

5.2 h2) As Early as the Stage of Expectations, the Parties Plan Slightly Different Strategies in Remote and F2f Negotiations

In order to verify h2), four statements were provided in the survey, which are shown in the table below with the results.

Table 2: Preparation for Negotiations and Negotiation Techniques Used in Remote Negotiations

Remote negotiation event requires slightly better preparation than f2f negotiation	3.08
Remote negotiation event require different techniques than f2f negotiations.	3.02
When preparing for a remote negotiation I am more likely to think about using competitive strategies than collaborative strategies	2.36
When preparing for a remote negotiation, I am more likely to think about using collaborative strategies than competitive strategies	4.27

Source: author's own compilation based on the survey

The survey revealed a fairly 'moderate agreement' among the respondents with the statement that a remote negotiation requires slightly better preparation than an f2f negotiation, as well as the use of different negotiation techniques. It also revealed that the preferred approach in planning is a collaborative strategy.

5.3 h3) In Remote and f2f Negotiations, Expectations of the Other Party's Strategy More Often or Less Often Differ From the Actual Strategy

The third hypothesis concerned the negotiation situation, and in order to verify it, two statements were presented to the respondents for evaluation. These related to the strategies actually used by the negotiating partner compared to the expected strategies and the negotiation techniques used in remote negotiations.

Table 3: Anticipated and Actual Strategies and Techniques Used in Remote Negotiations

In remote negotiations it happens more often than in f2f negotiations that the strategy used by the negotiating partner is different from the one I anticipated	2.0
It is my impression that in remote negotiations the parties are more likely to 'switch' techniques rather than in f2f negotiations	2.12

Source: Author's own compilation based on the survey

Both statements received a low average score on the Likert scale, indicating that the respondents 'only partially' agreed with the statements presented.

5.4 h4) Parties Change Strategies More Easily and Quickly in Remote Negotiations Than in f2f Negotiations

The fourth hypothesis addressed the change in strategy over the course of the negotiations and the chosen strategy versus the predicted strategy. To verify hypothesis h4), the respondents were asked to evaluate two statements.

Table 4: Changes in Negotiation Strategies in Remote Negotiations

In remote negotiations, it is more common than in f2f negotiations for the negotiating partner to change the negotiation strategy.	1.89
In remote negotiations I am more often positively surprised by the attitude of the other party than in f2f negotiations.	4.36

Source: Author's own compilation based on the survey

The statement claiming that the strategy used by the negotiating partner is different from what was anticipated received a very low score and can thus be considered as not validated. A high average score was given to the statement saying that the respondents were 'positively surprised' by the attitude of their negotiating partners.

6. Discussion

It is important to consider whether the fact that a negotiation event takes place on a remote basis is at all a factor that influences expectations and the choice of strategy, because, as we know from the model developed by Thomas, Manrodt and Eastman, the main factor is the relationship itself. As is clear from the model, there are other factors that may influence the negotiation and the strategies, and one of these factors is the fact that the negotiation takes place on a remote basis.

The verification of h1 has shown that there are some, albeit insignificant, differences in strategy expectations in remote negotiation and f2f negotiation. The highest average value was assigned to the statement that strategy expectations do not depend on whether you negotiate remotely or f2f. However, the respondents gave an average of 3.55 on the Likert scale to the statement that in remote negotiations negotiators are more likely to expect a collaborative strategy, and the statement about expecting a competitive strategy received 2.44 points on the Likert scale. Thus, it can be concluded that if there are already some expectations of strategy in relation to the type of negotiation, these are expectations of a collaborative strategy. This means that negotiators approach remote negotiations with enthusiasm, with a positive attitude and this attitude is more frequent here than in f2f negotiations. One can, of course, reflect on the reasons for this specific attitude. In some cases, the respondents explained the reasons in the conversation accompanying the survey. For some, what matters is the mere possibility of having a negotiation, albeit in a remote form, which could not take place at all in the traditional form due to cost or time. Some reported a general positive attitude towards new technologies and the opportunities that they offer. There was an opinion that with the proliferation of remote negotiations, it is possible to have many such meetings, including in the initial phase of a business relationship, and often relationships in this phase are not yet burdened with a negative history. Some also stressed that it all depends on the subject matter of the talks and there are some issues that would be impossible to address in remote negotiations.

It should be noted, however, that the belief that strategy expectations do not depend on whether you negotiate remotely or f2f gained the most points on the Likert scale. This suggests that the form in which the negotiation takes place does not have such a significant impact on the strategy expectations of the other party. In some statements accompanying the survey, the respondents indicated that if the business partner has already been met and the relationship has its history, the form of negotiation does not influence strategy expectations. This leads to the conclusion that the history of the relationship is more important, which, incidentally, is in line with the model developed by Thomas, Manrodt and Eastman.

Slightly more significant differences between remote negotiation and f2f negotiation emerged on the issue of strategy planning. Thus, h2 was successfully verified. The statement that, when preparing for remote strategies, you are more likely to plan to use a collaborative strategy yourself achieved a higher average score on the Likert scale than the statement about planning competitive strategies. When recalling the h1 validation effect, this implies that an enthusiastic attitude towards remote negotiation includes not only the expectation of a collaborative strategy, but also the planning of such a strategy. Some of the statements accompanying the survey confirmed that managers have become somewhat accustomed to remote negotiation and it has become an everyday occurrence for them. They are not a source of stress as they used to be and their level of acceptance as a form of maintaining business relationships has stabilised and is quite high. There have been some voices saying that it is simply a new form of negotiation, not inferior to f2f and even better than traditional negotiation in some respects. Hence the positive attitude and planning of collaboration strategies.

However, hypothesis h3, according to which remote negotiation and f2f negotiation differ in terms of consistency of strategy expectations, was not validated. The hypothesis assumed that, for example, in remote negotiation, negotiating partners use a different strategy than predicted, in other words, they are more unpredictable. This would supposedly mean that if we anticipated a collaborative strategy from a negotiating partner, that partner - contrary to our expectations - used a competitive strategy. The statement that "in remote negotiations it happens more often than in f2f negotiations that the strategy used by the negotiating partner is different from the one I predicted" received an average of 2.00 points on the Likert scale and this means that the respondents only partially agree with this statement. This allows us to assume that remote negotiation is not some special factor that causes negotiating partners to change their negotiation strategy. An equally low average score was given to the statement , according to which in remote negotiations the parties are more likely to 'switch' techniques than in f2f negotiations. This means that remote negotiation, or more precisely its form, does not encourage the parties to use more techniques and remote negotiation is not at all more unpredictable.

The last hypothesis focused on how easily and quickly negotiating partners change their own planned strategies to the opposite strategies. A very low (1.89) score for the sentence: "in remote negotiations it happens more often than in f2f negotiations that the strategy used by the negotiating partner is different from the one I predicted" proves that predictions about negotiation strategy in remote negotiations generally work. This is actually the key finding in the study conducted. This is because, as the model shows, the most desirable situation for building business relationships is when there are expectations of a collaborative strategy and then these predictions are confirmed. After all, this is the situation that builds the relationship. If we assume that in remote negotiations the parties are more likely to assume and expect a collaborative strategy and at the same time plan such a strategy themselves, then if both of these premises occur, we have a situation that is ideal for the relationship history and has a high potential for building a good history and a good relationship.

Even more favourably ranked on the Likert scale was the statement "in remote negotiations I am more often positively surprised by the other party's attitude than in f2f negotiations.", which scored an average of 4.36. This sentence can be interpreted as a general impression of remote negotiations, which respondents evaluate positively. It appears that remote negotiation more than satisfies the expectations of negotiators. If this sentence is interpreted in the context of the Thomas, Manrodt and Eastman model, the conclusion can be drawn that remote negotiation, or more precisely its form, can contribute to building a relationship or at least sustaining it at the existing level.

7. Conclusions

Remote conversations, including remote negotiations, are mainly characterised by the fact that the participating parties are in different locations and the conversation is made possible by modern technology. This important fact changes the very nature of the conversation. It turns out to be impossible to interact informally between people and thus to establish personal interactions. The sharing of knowledge is hindered, the range of negotiation techniques that can be used is reduced, and it is impossible to read certain information arising from the context of the conversation (e.g. body language). On the other hand, remote negotiation means saving time and financial resources and the possibility to have many conversations in a short period of time. Many of the business meetings would not have taken place at all had they not been held remotely. The answer to the question of whether remote negotiation improves interorganisational relationships is therefore complex, but overall it is positive. The study found that participants in remote negotiations are enthusiastic about them, which applies to both their expectations and their strategy plans. They rather expect the other party to choose a collaborative strategy and plan to follow such a strategy. There is also a strong belief that the form of the negotiation does not matter, which is also to be interpreted in favour of remote negotiation: it is not 'inferior' to traditional negotiation, and it is rather the history of the relationship and the topics of the talks that play a more important role.

Remote negotiation is also just as predictable as traditional negotiation and negotiators do not change techniques here differently from traditional negotiation. The most important statement, however, concerns the positive surprise of the other party's attitude that negotiators experience during remote negotiations. While this is a rather general statement, it reveals important knowledge about remote negotiations in terms of their potential for relationship development. Indeed, if we return to the model developed by Thomas, Manrodt and Eastman, what matters most in the shaping of business relationships is whether expectations about the negotiation strategy employed by the other party are confirmed. For the forming of a good relationship, the most favourable situation is when the expectations concerning the use of a collaborative

strategy are confirmed. The negotiation then becomes part of the organisation's good relationship history, building and strengthening it, which is the most favourable situation from the point of view of the relationship.

The findings also allow for the formulation of managerial implications. Negotiation is an important part of the relationship between organisations. Managers undoubtedly strive for the best possible negotiation outcome. Most managers are already familiar with remote negotiation and are willing to use it in their practice. Remote negotiation does not allow for the same degree of interpersonal relations and knowledge sharing as traditional negotiation, but it is not inferior to traditional negotiation in terms of its potential to build relationships between companies. This potential value of remote negotiation is undoubtedly the most important finding of this research and the most important feature of this type of talks. Negotiators are enthusiastic about remote negotiation and certainly managers should take advantage of both the potential of remote negotiation and of this enthusiasm, as remote negotiation can be very helpful in forming good relationships and in building a positive history. Buyers and suppliers should be made aware of the potential of remote negotiation and encouraged to use it. They should also be encouraged to develop their own paradigms for conducting these types of conversations and creating an atmosphere for meetings and making the most of the potential of modern technology.

It should also be noted that regardless of the form of negotiation, preparation is imperative, but this should take into account the slightly different nature of interaction in the case of remote negotiation and the slightly different range of techniques that can be used. Managers should sensitise negotiators to these limitations and choose an appropriate form for the talks. It is important to remember that not every talk can be held remotely because of the subject matter and that a lot depends, on the history of the relationship between the companies.

The above study had its limitations. It might have been appropriate for the research to take into account how long the relationship has lasted and the nature of the relationship, as the application of remote meetings to talks can vary depending on what stage the relationship is at and what history it has. Certainly, further research could explore the preference for remote or traditional negotiation depending, for example, on the age, gender or education of the respondents. It should also be noted that the survey was conducted among respondents from Poland. However, it seems that Polish people have a specific approach to technology, which may be different in any other country. Also, the perspective of small and medium-sized enterprises was taken into account, whereas perhaps the perspective of large companies would be different. In addition, it would be useful to take into account that in the course of carrying out the survey, many respondents provided additional explanations about remote negotiation. This broadened the perspective slightly and represents some triangulation of the survey, but at the same time suggests that future research of this type should be expanded to include interviews.

Gender Differences and Readiness Towards Knowledge Sharing among Remote Working IT Sector Employees

Ewelina Krzyżowska

ewelina.krzyzowska@pcz.pl

Abstract: The COVID-19 pandemic exerted a significant impact on various spheres of the functioning of an individual, including the area of professional functioning. One of these changes was the spread of remote working, which in turn led to the greater interest in this form of work and the search for effective solutions that support labour efficiency in these particular conditions. An important problem of remote working that is associated with the restriction of face to face communication, is the sharing of knowledge amongst the employees. The aim of the paper was to analyse the differences in the readiness to share knowledge in conditions of remote working in the IT sector between women and men depending on the chosen demographic factors and factors relating to work. The study included 112 employees from the IT industry who worked remotely at the moment of conducting the research. A self-designed survey was availed of in the research which encompassed the following: demographic data (sex type and age of those analysed, being in a relationship, number of children), variables associated with work (position held in the firm, job seniority, number of hours of remote work), while also questions relating to sharing knowledge with co-workers. In the analysed group of employees of the IT sector working remotely, a greater readiness to share knowledge was noted amongst men as compared to women. Furthermore, as the effect of intragroup comparisons, the following was noted: older women were more willing to share knowledge than younger women, raising three or more children, while also more than women who do not have children, whereas women in relationships were more willing to share knowledge than single women. In turn, in the group of men the differences were only evident in the sphere of job seniority. Longer job seniority turned out to be favourable towards the readiness to share knowledge. The research findings significantly broaden knowledge in the sphere of the individual factors influencing the effective organization of the process of knowledge management, while particularly knowledge sharing in conditions of remote working. This knowledge may be particularly useful for managers of the IT sector.

Keywords: Knowledge sharing, Gender differences, Remote work

1. Introduction

The COVID 19 pandemic virus strongly disrupted the socio-economic life of humanity worldwide. The consequences of this situation was the implementation of changes to various areas of functioning, including the professional area. Remote working started to gradually spread as the recommended form of employment even in sectors where it had not been utilized prior to this. Prior to the pandemic, it was a form of work that was rather sporadically encountered. In accordance with the data from the 2018 European Labour Force Survey approximately 10% of employees and 30% of self-employed used to work from home at least sometimes, whereas during the pandemic it spread on a wide scale - the Eurofound (2020) survey suggests that 48% of employees worked remotely at least some time in 2020 (Bertoni, 2021). Remote working during the pandemic constituted significant solutions that created the possibility of retaining employment and maintaining safe conditions for health, while simultaneously reducing the fear, as well as facilitating both family and professional commitments. One of the serious problems connected with working in remote conditions is the limitation of direct communication, or the so-called *face to face* communication. This further implies difficulties in other areas of cooperation, among others, in the sphere of knowledge sharing (KS). KS signifies the provision of information associated with the task or *know-how* in order to help others and to cooperate with others in terms of resolving problems, developing new ideas, or implementing the policies of procedures (Wang, Noe, 2010). The significance of KS for the organizational performance is leading to greater levels of interest in this process, while also the enhancement of this process, e.g. in the IT sector knowledge transfer is strengthened by extending the individual beyond the formal communication channels, such as: computer networks, electronic bulletin boards, etc. (Zheng, 2017). Apart from this type of enhancements, it is necessary to remember about the various circumstances that have an impact on the quality of KS and which are associated with technological factors, organizational factors, while also individual factors (Paroutis, Al Saleh, 2009). In this paper, an attempt has been undertaken to verify the significance of the chosen conditions of KS by way of responding to the following question: Do differences exist in terms of the readiness to share knowledge between women and men depending on the chosen demographic factors and factors associated with work?

2. Literature Review and Research Background

KS constitutes a serious challenge for enterprises functioning in times of economies based on knowledge, while also in a time affected by the COVID-19 pandemic. Unfortunately, there is still a prevalence in certain organizations of the tendency to accumulate knowledge than to share it (Ismail, Yusof, 2009). With relation to this, it is absolutely vital to improve the process of KS by means of technological solutions, but also the appropriately designed models that would take account of the various conditions of effective KS. This is particularly significant in the IT sector, which is one of the sectors where the management of information to a significant degree translates to the performance of the enterprises at hand (Wang, Chang, 2005). In spite of the fact that there is a lot of research on the conditions of KS, it would seem that relatively little attention is devoted to the demographic variables, particularly associated with gender types. In this paper, attention has been focused on analysing the significance of these actual variables in terms of the readiness towards KS amongst a group of employees of the IT sector working remotely.

Sex types condition certain differentiation which may be expressed in, among other areas, the area of social behaviour of women and men (Wojciszke, 2012). The findings of the meta-analysis of research indicates, among other things, the fact that women have a greater tendency to confide, particularly in other women with whom they have close relations, while also being better experts in the sphere of controlling the course of social interactions, as well as easing social conflicts more effectively and are more conformist in the case of pressure exerted in a small familiar group. Moreover, women are more prone to anxiety and depression as opposed to men, while also more emotionally sensitive. In turn, men indicate a decisively greater tendency towards aggression and risky behaviour. In the context of organizational behaviour, men distinguish such features as: individualism, competitiveness, as well as self-promotion (Miller, Karakovsky, 2005). In turn, women with regard to their greater emotional and social competences are more likely to support the work of other employees, while also cooperate and build a community culture within the organization (Miao, Humphrey, Qian, 2016; Al. Noor, Ishtiak Uddin, Shamaly, 2011). The differences listed may also justify different approaches to sharing knowledge by women and men. In the case of women, support and close social relationships with co-workers represent the benefits of sharing knowledge (Lin, 2006). Hence, women may display the tendency to search for and share knowledge in a way that is more direct than men (Miller, Karakowsky, 2005). In turn, men may be more engaged in KS with the aid of the latest technological solutions in this sphere (Taylor, 2004).

The conclusions from research relating to gender differences in the sphere of the readiness towards KS are not unequivocal. Some research indicates that gender type does not have a significant impact on KS (Chowdhury, 2005; Mogotsi, Boom, Fletcher, 2011; Ojha, 2005; Razmerita, Kirchner, Nielsen, 2016; Watson, Hewett, 2006), while other research confirms the differences in this area (Abukhait, Bani-Melhem, Zeffane, 2019; Boateng, Dzandu, Agyemang, 2015; Grubić-Nešić, Matić, Mitrović, 2015; Miller, Karakovsky, 2005; Lawal, Oriogu, Ogbuiyi, 2017; Lin, 2006; Pangil, Nasrudin, 2008; Tan, Trang, 2017; Taylor, 2004). The research of Lin (2006) indicated that women are more willing to share knowledge as they are more sensitive to instrumental ties and have the need to overcome traditional professional challenges. Likewise, in the research of Grubić-Nešić et al. (2015) in various Central European organizations women have acquired higher levels of indicators both in the sphere of the intention to share explicit knowledge, as well as the scale of explicit knowledge sharing behaviour. In turn, Boateng et al. (2015) proved that male teachers share knowledge to a greater degree than their female colleagues. Similarly, research findings with the participation of employees in some telecommunication companies (Tan, Trang, 2017), while also the participation of employees from the service sector (Abukhait, Bani-Melhem, Zeffane, 2019) indicate that males tend to share more of their knowledge than females.

Perhaps in the clarification of the differences in the sphere of the research findings relating to the relation of KS with gender type, a significant role is played by other variables, such as, among others, the way of sharing knowledge, or the type of sector and the significance of the behaviour associated with KS. Hence, this research tests the differences in terms of the level of readiness towards KS amongst women and men as employees of the IT sector. By taking the afore-mentioned arguments into consideration, the following research question has been formulated:

Does a difference exist in terms of the readiness to share knowledge between men and women as employees of the IT sector working remotely?

Becoming familiar with these differences among the Polish employees of the IT sector working remotely also justifies the lack of similar empirical work, at least to the knowledge of the author at hand, while conducting such research would be with the participation of such analysed groups. Thus, the findings would constitute an important supplementation of research gaps in this sphere.

3. Methodology

3.1 Participants

The research was conducted amongst the employees of one of the firms from the IT sector with its headquarters located in central Poland. The criteria of selection for the research was the prerequisite of remote work as the prevalent form of work at the moment of conducting the research. Of the employees that fulfilled the criteria of selection, consent to take part in the research was expressed by 131 people. The employees analysed received research questionnaires in a sealed envelope, which, when subsequently completed was passed on to a person designated to cooperate in the research. Ultimately, the research group enumerated 112 people (19 people failed to return the completed questionnaires): 39 women, 73 men aged between 26 and 47 (M=33,82; SD=6,95). A detailed characteristic description of the analysed group is presented in Table 1.

Table 1: Characteristics of the Study Group

		N	%
Employees	females	39	34.8
	males	73	65.2
Education	tertiary	78	69.6
	secondary	34	30.4
Workplace	IT application specialist	38	33.9
	service support specialist	16	14.3
	designer and computer systems analyst	26	23.2
	programming specialist	32	28.6
		M	**SD**
Age (years)		33.82	6.95
Average remote working time per week after the pandemic (h)		17.35	5.29

3.2 Measures

In the research a self-designed survey was availed of which takes account of the following data: sex type and the age of the person analysed, while also education, being in a relationship, number of children, as well as the position held in the firm, the number of weekly remote work hours following the pandemic, while also job seniority in the analysed firm. Likewise, the survey also encompassed a question relating to knowledge sharing as follows: *How often do you pass on your specialized knowledge to other employees (apart from situations of passing on knowledge that is the direct result of orders from a superior)?* The aforesaid question was answered by those analysed on a five-degree scale as follows: 1-never, 2-rarely, 3-sometimes, 4-often, 5-very often.

3.3 Data Analysis

Due to the fact that the assumptions of the normality of the distribution were not fulfilled, while also due to the unequal distribution of the numbers of the sub-groups compared for statistical analysis, non-parametric tests were availed of for the independent groups. For the purpose of evaluating the differences of two independent samples, the Mann–Whitney test was applied, whereas for the purpose of evaluating the differences between multiple independent groups, the Kruskal-Wallis test was availed of. The level of statistical significance was accepted as $p<0,05$. The calculations were performed by the statistical program of STATISTICA 13.3 by the Statsof company.

4. Results

The findings in terms of the comparison of readiness towards KS among the analysed women and men revealed a statistical significant difference (U=325,00; p=0,000). The average values of the declared readiness towards KS turned out to be significantly higher amongst men in comparison with women. The detailed findings of the testing are presented in Table 2.

Table 2: Comparison of Differences Between Findings for Women and Men in the Sphere of Readiness to Share Knowledge

Women				Men				
	M	Me	SD	M	Me	SD	U	p
KS	2.79	3.00	1.00	4.42	3.00	0.74	325.00	0,000

M- average, Me – median, SD – standard deviation, U – value of Mann-Whitney test.

The intragroup comparison which was also conducted revealed significant statistical differences in the sphere of the readiness towards KS between older women (≥ 35 years) and younger women (< 35 years) – the indicators of KS amongst older women turned out to be significantly higher than in the case of younger women (U=86,00; p=0,007). The statistically significant difference in the group of women also related to the following variables: being in a relationship (U=83,00; p=0,038), while also the number of children (H=18,09; p=0,001). Women who are in a relationship declared a higher level of readiness towards KS than single women. In turn, in the sphere of the varying number of children, the post-hoc tests applied revealed the difference between the group of women who have three children or more and the group of women without any children (p=0,003). The indicators for women with more children were higher than women without any children. The detailed findings of testing are presented in Table 3.

Table 3: Intra-Group Comparison of Differences of Findings for Women in the Sphere of KS By Taking Account of the Analysed Variables

		N	M	Me	SD	U	p
Age	< 35 years	24	2.42	2.50	0.65	86.00	0.007
	≥ 35 years	15	3.40	4.00	1.18		
Being in a relationship	single	10	2.20	2.00	0.79	83.00	0.038
	in a relationship	29	3.00	3.00	1.00		
			M	**Me**	**SD**	**H**	**p**
Number of children	0	18	2.33	2.00	0.68	18.09	0.001
	1	6	3.33	3.00	0.51		
	2	9	3.00	3.00	1.00		
	≥3	6	4.40	4.00	0.55		
Work position	IT application specialist	13	2.38	2.00	0.77	6.31	0.098
	service support specialist	7	2.57	2.00	1.13		
	programming specialist	7	3.57	3.00	1.13		
	designer and computer systems analyst	12	2.92	3.00	0.90		
Job seniority	≤ 5 years	23	2.83	3.00	1.03	0.23	0.889
	5-10 years	14	2.71	3.00	0.99		
	> 10 years	2	3.00	3.00	1.41		

M- average, Me – median, SD – standard deviation, U – value of Mann-Whitney test, H – Kruskal-Wallis statistical test, p – level of significance

In effect, the intragroup comparisons in a group of men with significant statistical differences (H=1,13; p = 0,047) in terms of the readiness towards KS were only revealed in the sphere of the varying job seniority. The post-hoc tests conducted revealed that men whose job seniority amounted to less than 5 years differed in the area of the readiness towards KS from the group of men who had worked between 5 and 10 years (p=0,007), while also the group of men with job seniority of over 10 years (p=0.032). The indicators of the readiness towards KS turned out to be higher than in a group of men working in the analysed firm over 5 years with relation to men with job seniority of up to 5 years. The detailed findings of testing are presented in Table 4.

Table 4: Comparison of Differences of Findings for men in the Sphere of KS by Taking Account of the Analysed Variables

		N	M	Me	SD	U	p
Age	< 35 years	43	4.42	5.00	0.76	643.00	0.986
	≥ 35 years	30	4.43	5.00	0.73

5. Discussion

In this research, it has been proven that men as employees of the IT sector display greater levels of readiness towards KS than women as employees of the same sector. The acquired findings are in concurrence with some research projects that confirm the greater readiness towards KS among men (Abukhait, Bani-Melhem, Zeffane, 2019; Boateng, Dzandu, Agyemang, 2015; Tan, Trang, 2017). Nevertheless, the research conducted precisely within a group of Polish employees in the IT sector fills an important research gap in this field. This is of particular significance in the perspective of the widespread nature of remote work and the constant need to enhance this form of organizing work. In order to clarify the difference acquired, it is possible to refer to several arguments. Despite the fact that men are characterized by relatively greater tendencies towards competitive behaviour (Wojciszke, 2012), they can however display greater readiness towards KS in cases whereby they see clear benefits arising from such behaviour, such as, e.g. enhancement of work performance (Lin, 2006). Moreover, the specifics of the sector and the associated virtual space may be of significance for the findings acquired, in which, in the majority of cases it leads to knowledge sharing between the employees under analysis. Generally speaking, men are more connected with technologies and are more associated with them, whereas women would seem to have less experience in terms of availing of technologies (Liu, 2010). Research suggests that this dependency may also refer to the workplace (Van Slyke, Comunale, Belanger, 2002). In his research, Taylor (2004) claimed that the male employees analysed declared to have a higher level of availing of emails, data mining, knowledge repository, while also yellow page components of the knowledge management system by comparison with women. The results in this field are however unequivocal (Gefen, Straub, 1997). Furthermore, what is important is the fact that Panteli, Stack and Ramsay (1999) indicate that women are insufficiently represented in all the areas of the IT sector and refer to research in which they confirm that the IT environment is dominated by men. Albeit the participation of women in the IT sector is systematically growing, it is still a sector that for the most part employs men. According to data from Eurostat in Poland in 2020, women constituted 15% of all IT specialists, while in turn, in terms of the EU as a whole, this figure is 18.5% (Piekarska, 2022). The percentage indicators of the participation of women and men in the herein research confirm the afore-mentioned trend (34.8% women and 65.2% men). This signifies the fact that women participating in the

research described constituted a minority group, while this awareness may translate to employee relations and behaviour associated with cooperation, including the readiness towards KS. As emphasized by Ojha (2005), the team members who acknowledge themselves to be the minority with regard to their sex type, marital status or level of education are less willing to share knowledge with the remaining members of the team.

Additionally, the comparisons conducted revealed that in the group of the analysed women who were older (≥35 years), or were in relationships, while also having three or more children declared greater readiness towards KS with relation to younger women (<35 years), single women and those not having children. This would seem to be a justified description of the dependencies in the mutual ties. The conclusion indicating that older women as employees of the IT sector are more willing to share knowledge than younger female colleagues is confirmed by certain empirical evidence (Burmeister, Fasbender, Deller, 2018; Dunham, Burt, 2011). Younger people may probably be more reluctant to share knowledge due to the fact that there is a lack of sufficient motivation or abilities in this sphere. In the case of women, experiences of life may have an impact on the increase in soft competences associated with cooperation and mutual activities. Importantly, these competences may also rise with regard to motherhood and taking care of offspring. A significant factor that is stimulated by the experience of motherhood and which has a relation with KS is that of empathy. Empathy is a precursor of trust and a factor that is favourable towards the exchange of knowledge (Gurgul, Enkel; 2004). Research conducted by means of the method of illustrating the brain structures made it visible that mothers have a stronger reaction of empathy than women who are not mothers, while the researchers came to the conclusion that motherhood may have an impact on the general affective social perception (Plank et al., 2021). Furthermore, thanks to the relations with a child, a woman develops the feeling of responsibility and competences (Włodarczyk, 2012), which in turn, may translate to the motivation and readiness to adopt KS. In the herein research, the statistically significant difference was only illustrated among women who had three or more children as opposed to women who had no children, probably due to the fact that the experience of motherhood in terms of raising greater numbers of children multiplied the afore-mentioned features in women to such a point that it stimulates the readiness towards KS more than in the case of women who have only one child or two children, or none at all. These dependencies may have a relation with the difference in the sphere of KS between single women and women in relationships (in the herein research, out of 10 single women 9 had no offspring). Moreover, as illustrated by the researchers, single women are more focused on their careers, professional achievements and the pursuit of independence (Jones, Zhang, Chia, 2012; Suk Ha et al., 2018). By way of consequence, they may also be more geared towards rivalry in the workplace, while simultaneously less prone to behaviour associated with KS.

As a result of the intragroup comparisons in the group of men analysed, the statistically significant difference was only revealed in the sphere of job seniority, which signifies that the men under analysis who had worked longer than 5 years declared a greater tendency towards KS than men working in the analysed firm less than 5 years. It is possible that longer work experience is favourable towards the feeling of certainty and stability in terms of employment, which may limit the impact of the tendency of rivalry and simultaneously be favourable in terms of the readiness towards KS. The relationship between KS and job security has been confirmed by some research projects (Bartol et al., 2009; Doulani, Mohammadi, Bradar, 2020; Mehrizi, 2016), while it may be explained by, among other things, referring to the theories of the hierarchy of needs of Maslow, according to which the fulfilment of needs of the lower level (security) facilitates the fulfilment of needs of the higher level (KS) (Maslow, 2013). Furthermore, together with job seniority, professional competences grow, including those that relate to interactions and cooperation in a team, while also knowledge exchange, which is of significance particularly when knowledge exchange occurs in remote conditions. As concluded by Oye et al. (2011), work experience has a strong impact on knowledge sharing in the workplace. Importantly, in the group of men under analysis no difference was revealed in terms of KS in the sphere of age. Thus, this variable may not have such power to determine as the varying job seniority, while moreover it is not identified with it, which in turn signifies that in the analysed group there were men over the age of 35 who had worked in the analysed firm shorter than 5 years. It is also worth emphasizing that in the herein research the difference in terms of the job seniority only related to one man. Perhaps the job seniority of the analysed women who constitute a relatively smaller group in the IT sector does not have the same impact as men in terms of their feeling of job security. Furthermore, no differences were observed among the analysed men in the sphere of KS with regard to the following: the number of children, being in a relationship and job position. It is possible that the variables associated with parenthood and the creation of partnership relations are of greater significance in the case of women. In turn, in the case of the variable of the job position, differences were not noted in any of the groups analysed. This suggests that this factor is of no significance in the context of KS in the group of employees of the IT sector working remotely. A generalization of this conclusion would however require further detailed research.

6. Conclusions

The aim of the herein research was to provide an answer to the following research question put forward in this paper: Does a difference exist in terms of the readiness to share knowledge between men and women as employees of the IT sector working remotely? The research findings acquired from a group of employees of the IT sector working remotely indicates the existence of differences between women and men in the sphere of KS. The analysed men declare greater readiness towards KS than the analysed women. Furthermore. greater readiness in the sphere of KS was declared by older women (≥ 35), those in relationships and those having three or more children, while also men who had worked in the analysed firm for over 5 years. These conclusions are of significant importance in the context of the organization of work, particularly in conditions of remote working. In spite of the fact that this form of work in the IT sector was a practice that was frequently encountered prior to COVID-19, its specifics and the current requirements of the labour market force, while also constant enhancements of the solutions applied to streamline work and increase organizational performance.

The conclusions from the research imply significant practical recommendations for the managers of the IT sector:

- It is important for them to be aware of the significance of the demographic and individual variables associated with work for the course of the process of KS.
- The evaluation of the adjustment of employees (by taking account of the demographic features and variables associated with work), while also the evaluation of the appropriate use of their potential for the effectiveness of the course of KS should be conducted at the stage of recruitment.
- In the context of the readiness towards KS, particular attention should be paid to the motivation of women in this sphere, considering the afore-mentioned fact that they usually constitute a relatively smaller representative group in the environment of IT employees.

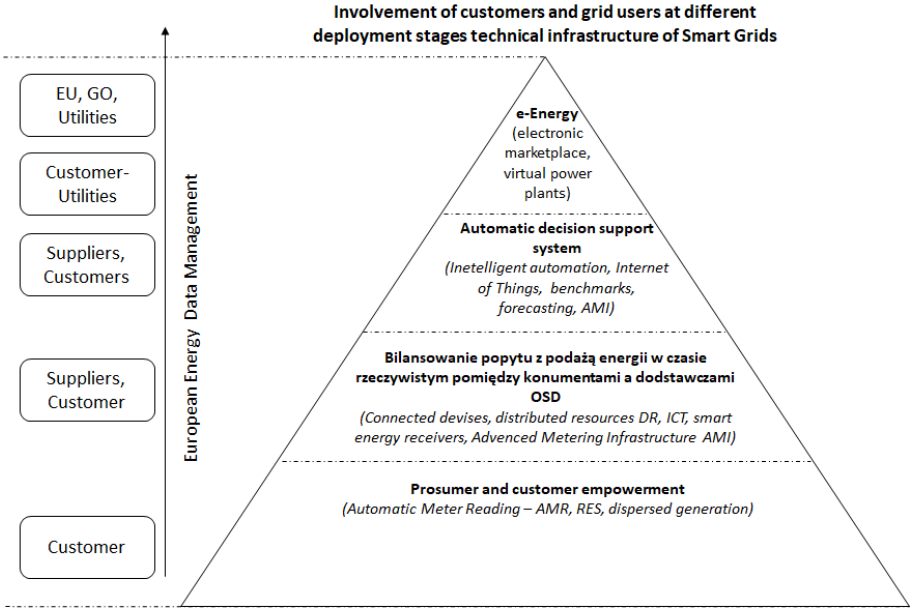
Managing Knowledge Acquired from Smart Meters in a Distributed Advanced Metering Infrastructure

Robert Kuceba
Czestochowa University of Technology, Poland

robert.kuceba@pcz.pl

Abstract: The primary purpose of this article is to present the functional information and knowledge - acquired from smart electricity meter readings, which are a component of the Advanced Metering Infrastructure (AMI). The relations between the management of knowledge acquired from the AMI system and the new empirically identifieddecision-making processes that make the management of electricity value more efficient, both on the side of the supplier but also, which need to be emphasised, on the side of the consumer/household, often the energy prosumer (micro RES production), are indicated in it. In the first part of the article - the theoretical and cognitive part - justification has been given for the subject matter specified in the title of the paper. Attention was drawn to the dynamic digitization and automation of energy metering readings. The size of the AMI market in terms of the growth in the number of smart meters in households, as well as the size of the market, has been quantitatively described. In the context of the dynamic growth of smart electricity meters, the growth of heterogeneous knowledge on households resulting from high-frequency readings was justified, which in fact reflect not only variable energy demand but also the culture of energy demand and use. In the paper its author has structured the insights gained from the AMI infrastructure. In turn, the second - empirical - part attempts to answer two research questions: 1) What information/knowledge in addition to real-time bi-directional energy readings necessary for energy value management can be generated through the use of high-frequency clocking smart meters?; 2) How to use the acquired knowledge, manage the knowledge, acquired from the readings of the distributed AMI (smart electricity meters) infrastructure, in terms of key decision-making processes that make energy value management more effective, both on the supplier side but also on the consumer/household side, frequently the energy prosumer - micro RES production. In order to answer the above two research questions, a questionnaire survey was conducted and a brainstorming, scientific discourse with inference was carried out with a group of business practitioners, including managers of corporations and energy companies - improving their knowledge, and competences in the area of management and entrepreneurship in energy markets, including RES.

Keywords: Smart meters, Advanced Metering Infrastructure AMI, Knowledge management,Ddecision-making processes



1. Introduction

The digitisation of the electricity sector is currently being dynamically implemented on the part of the final consumers of electricity also included in the household group. Directly, these activities are related to the digitisation and automation of energy metering readings, both active and reactive, in integration with the digitisation of electricity bills. This was activated through the use of high-frequency clocking smart meters - usually two-way electricity readings. This has improved communication between electricity end-users (the demand side to date) and DSOs (the supply side to date). According to Allied Market Research, the global smart meter market was valued at USD 21.13 billion in 2019. It is planned that this market could be worth USD 39.2 billion in 2027. The instruments for accelerating the growth of this market segment are financial and non-financial mechanisms, driven by government initiatives in the world's leading economies that are commonly introducing smart meters and upgrading outdated infrastructure. It is important to note that households are a priority for smart metres deployments until 2027. This is also regulated in the European Union. The EU Commission issued the document "*Benchmarking smart metering deployment in the EU-27 with a focus on electricity", jointly drafted by DG ENER and JRC, as COM(2014)356* (European Commission, 2021). The document is a report on smart meter deployments, in EU Member States, based on economic assessments of long-term costs and benefits (CBA - cost benefits analyses), of smart metering of electricity as well as gas. It was assumed that by 2020, almost 72% of European consumers will have a smart electricity meter. Of course, in reality, it can be stated by referring to the indicated scenarios for 2020, that this has been delayed. However, between 2023 and 2027, the diffusion of smart meter deployments is anticipated. In Poland, for example, 80 % of meters are expected to be replaced in 2028 and 100 % by the end of 2030.

2. Implementation of Smart Measurement Infrastructure - Economies of Scale

Smart Meters technologies implemented in Advanced Metering Infrastructure structures are analysed not only from the perspective of the end user - the consumer but also from the perspective of energy suppliers, Distribution System Operators and at the highest level in the context of: National or at the scale of European Electricity Systems (Andreadou, et al, 2016),. According to the European Technology Platform (ETP) (European Technology Platform, 2021), also hierarchically but now in the context of users, four layers can also be

distinguished. The different layers show the activities, the involvement of the different user groups of smart metering networks, taking into account the increasing value of the technical infrastructure (Figure 1).

Source: Elaborated based on European Technology Platform, 2021

Figure 1: Involvement of Consumers and Smart Grid Users in the Next Stages of Technical Infrastructure Deployment

In the first layer (Figure 1) of the end user/consumer of electricity, the infrastructure of their electricity receivers (demand side), is connected to the grid, with the functionality of automatic AMR readings. In order to strengthen the position of customers, new roles are being introduced to them in this layer, in addition to energy use/consumption, also the role of energy generation in distributed generation sources, especially in micro RES (Niedziolka, 2018). This has forced bi-directional energy flows, thus necessitating bi-directional readings in Smart Meters (Dorothy, et al, 2017). In the second layer (Figure 1), the user group includes energy suppliers, the local Distribution System Operators, in addition to consumers, frequently prosumers (Kuceba, et al., 2018) of electricity. In this layer of smart metering networks, by connecting the consumption and generation infrastructure of end users to the electricity grid infrastructure, the continuity and reliability of balancing demand with supply of electricity is ensured, obviously in real time. In this layer, DR distributed generation resources and distributed energy receivers are connected to the grid. In order to automate the management of distributed DR resources, including distributed energy receivers, in the third layer (Figure 1), Automatic Decision Support Systems are intended for consumers and energy suppliers. These systems, are responsible for controlling the technical infrastructure of Smart Meters, often on the basis of explanatory and inference models. Many times, through learning and inference capabilities, these are autocratic systems making self-learned decisions. Full automation is now also provided by the Internet of Things IoT (Abu Bakar, et al, 2019), also enabling remote control of distributed technical infrastructure Smart Grids (Rihan, 2019). The final layer of users, the fourth (Figure 1), concerns electricity suppliers, Distribution System Operators DSOs and also Transmission System Operators TSOs, at scales already macro-regional, e.g., national or EU-wide. The fourth layer is e-Energy, an electronic energy market, created primarily by virtual power plants with distributed generation infrastructure (in particular RES) and groups of distributed electricity consumers/prosumers, in cooperative networks (Kuceba, 2022). In line with the subject matter defined in the title of this article, the fundamental layer of smart metering, frequently bi-directional, is the electricity consumer/prosumer layer. From the point of view of the system approach, the management of the distributed metering structure of smart meters and, at the same time, the management of the distributed community of final consumers, the following basic modules and, at the same time, functionalities, are distinguished, which include, among others: Sumary Bills, Automated Meter Reading AMR, Demand Response, Distribution Automation, Time of Use Pricing, Advanced Metering Infrastructure, Critical Peak Pricing (Andreadou, et al, 2016). The implementation of Smart Meters in distribution networks on the low-voltage side, close to final electricity consumers, providing metering and bi-directional flow of electricity, has contributed to the diffusion of energy prosumers, who are assigned two main roles (Kuceba, et al, 2020): 1) the consumer of electricity (the demand side on the smart meter side) and 2) the producer of electricity (the

supply side on the smart meter side). Measuring and managing the bi-directional flow of electricity makes it possible to balance the non-linear daily demand for electricity with the non-linear supply of electricity generated on the prosumer side, in distributed and dispersed sources with different characteristics: daily and seasonal dispatchability (including non-linear RES). Due to the non-linear dispatchability of RES, apart from these sources of distributed and dispersed generation a fundamental part become (European Commission, 2021): Electricity Storage, Electricity Vehicles and also technologies categorised as Internet of Things IoT, including Smart Appliances and Home Automation Networks (Ahmed Qarabsh, et al, 2020). Real-time metering provides the final system energy balancing of DSOs - energy surpluses and shortfalls just on the prosumer side. The advantages of smart metering on the household side include: 1) remote reading and configuration through communication via the electricity grid or a built-in wireless communication module; 2) continuous monitoring of energy consumption and energy production at prosumer sources; 3) generation of statistics on habits and trends - the culture of electricity use by households; 4) possibility to pay bills in pre-paid or new payment models; 5) easier diagnosis of faults; 6) implemented advanced analytical algorithms (using also machine learning or deep learning), which ensure the mitigation of illegal electricity consumption; 7) optimisation of energy consumption, which translates not only into lower bills, but also has a positive impact on the environment.

When justifying the research topic in relation to the title of the present paper, it is important to emphasise that electricity meters provide high-frequency (usually clocked to take readings taken every 15 minutes) various categories of data, information and also knowledge, such as: actual meter readings of active energy taken from the DSO network (readings in kWh); actual meter readings of active energy introduced into the DSO network (readings in kWh); meter readings of active energy taken from the DSO network in peak and off-peak hours (readings in kWh), interruptions in electricity production and consumption, failures on the prosumer's side of electricity demand and supply; peaks in daily peak load and energy production on the prosumer's side. Generating a large number of readings on the prosumer side with a high clock frequency and, at the same time, taking into account the dynamic growth of smart metering in households over the last three years and the planned growth in 2023-2027, requires distribution system operators DSOs as well as commercial operators COs and commercial-technical operators CTO, to look for systemic solutions to manage big data and also to manage the acquired knowledge resources (Maurer, et al, 2011) (Shanker, et al, 2017). The foundation for the acceleration of any new solutions in this area, while at the same time taking as a prerequisite, are appropriately designed and configured knowledge bases. The aggregation of big data in knowledge bases, the definition of explanatory and inference models ensures the correct implementation of processes for the management of large amounts of data and information and, indirectly, the management of smart metering infrastructures, heterogonous electricity users, especially households, including prosumers (Fadaeenejad, et al, 2014). Thus, this paper attempts to empirically identify the decision-making processes that make knowledge management, the value of electricity, more effective, both on the supplier side but also, it should be emphasised, on the consumer/household side, often the energy prosumer (micro RES production).

3. Methodology

The identification and analysis of the activities of data and information management processes (Bylok, 2021) aggregated from smart meter levels was carried out in two research stages - 1) a questionnaire survey (focus method) conducted in a group of experts from the widely understood electricity industry; and 2) a scientific discourse panel with inference (brainstorming) conducted in a group of experts, business practitioners strictly in the areas of electricity markets, electricity trading and electricity value management. The aim of the research carried out was to answer the main two research questions, research problems, convergent with the topics identified in the article: 1) What information/knowledge, in addition to real-time bi-directional energy readings necessary for energy value management, can be generated through the use of high-frequency clocking smart meters; 2) How to use the acquired knowledge, to manage the knowledge, obtained from the readings of the distributed AMI infrastructure (smart electricity meters), regarding the key decision-making processes that make energy value management more effective, both on the supplier side but also on the consumer/household side, frequently the energy prosumer (micro RES production). In the first research part, a questionnaire survey was conducted among a group of business practitioners, including managers of corporations and energy companies - managers improving their knowledge, and competences in the area of management and entrepreneurship in energy markets, including RES (Kasaei, et al., 2017). The respondents were students of the Executive MBA-ESG programme. In total, the population in the two training groups of the surveyed energy company managers, was N=41. The lead expert was the Author of this publication at the same time - acting as an expert/lecturer leading tutorials in the areas of energy security, energy efficiency, smart grid and smart metering. In the second stage of the research, six domain experts, managers, decision-makers strictly in the area of electricity markets, and in

particular in the field of electricity trading and value management, were selected (purposive selection) from the first group of respondents. The author of this publication was also leading the panel of experts, who is an expert and practitioner in the fields of, among others, Smart Grid, Smart Metering and also virtual power plants, which meant that the population of the group of domain experts was n=7.

4. Results

The first stage of the research attempted to answer the research question: What information/knowledge, in addition to real-time bidirectional energy readings, necessary for electricity value management, can be generated through the use of high-frequency clocking smart meters? Each of the 41 respondents to the survey, using a questionnaire based on the focus method, indicated a maximum of 5 areas of information/knowledge that could be extracted from two-way electricity readings (...). The focus method adopted, limiting to 5 responses, reduced the occurrence of random responses, focusing each respondent on the relevant responses that are automatically perceived, foregrounded. This resulted in 18 relevant pieces of information/knowledge, essential for managing the sustainable value of electricity. The results obtained are summarised in Table 1. The individual information/knowledge generated from the readings from the electricity meters was assigned a percentage and a number of indications. The information and knowledge obtained from the AMI system, as the results of the research carried out, have been summarised according to the descending criterion - from the highest number of indications to the lowest. Table 1 visualises the individual categories of knowledge information identified by the survey respondents in the AMI system.

Table 1: Information and Knowledge Extracted From the AMI System (smart meters)

Information and knowledge extracted from the AMI system (smart meters)		**Number of indications**
1.	Raw metering data obtained from all metering systems of the AMI infrastructure	**92,7% (38)**
2.	Information/knowledge necessary for the generation of daily/seasonal calendar characteristics Pd=f(t), in real time: a) individual on the customer, electricity prosumer side; b) aggregated on the node, transformer, power district side	**78,0% (32)**
3.	Information/knowledge necessary for the generation of daily/seasonal integral characteristics Ed=f(t), in real time: a) individual on the consumer, prosumer side of the electricity system; b) aggregated on the node, transformer, power district side	**73,2% (30)**
4.	Information/knowledge on balancing evening peak loads by transferring loads to off-peak periods	**51,2% (21)**
5.	Information/knowledge about overloading - excessive power input from prosumer sources into the electricity grid	**29,3% (12)**
6.	Information/knowledge of actual charges as a function of daily tariffs or other prepaid payment models	**26,8% (11)**
7.	Information/knowledge about energy consumer preferences and behaviour	**21,9% (9)**
8.	Information/knowledge about the actual energy balance of the prosumer of electricity - feeding IoT applications of the control of smart energy consumers in households, for the actual on-line balancing of demand with supply on the part of the consumer group and also on the part of individual consumers/prosumers	**19,5% (8)**
9.	Information/knowledge on consumption and production at prosumer electricity sources, e.g. in 15-minute, hourly, daily, monthly modes (...)	**19,5% (8)**
7.	Real-time information/knowledge on the quality parameters of distributed electricity from prosumer RES sources, as well as information on the availability of these sources during peak and off-peak demand periods	**14,6% (6)**
10.	Information/knowledge on loads on LV networks , MV/LV (medium/low voltage) transformer stations/switches	**14,6% (6)**
11.	Information/knowledge on schedules (at intervals of e.g. 15 minutes and hours) of operation of prosumer RES sources on MV and LV networks	**12,2% (5)**
12.	Information/diagnostic knowledge about the state of electricity networks, location and causes of faults or failures, on-demand power quality control, detection of cases of illegal energy consumption	**9,8% (4)**

Information and knowledge extracted from the AMI system (smart meters) Number of indications		
13.	Information/knowledge about the utilisation rate of electrical networks, network losses, flow rates	**7,3% (3)**
14.	Information on the electrical parameters of all MV/LV transformer stations/switching points	**7,3% (3)**
15.	Information/knowledge of trading losses	**4.9% (2)**
16.	Information/knowledge on aggregate demand and supply of electricity to ensure optimal operation of SCADA systems	**4.9% (2)**
17.	Information/knowledge on distribution of MV and LV nodes	**4.9% (2)**
18.	Information/knowledge on the location of consumers and distributed prosumer sources feeding into the GIS. Full information on MV and LV networks in terms of topological data and technical parameters of infrastructure elements.	**4.9% (2)**

The results obtained provide a broader perspective on the value of electricity meter readings and, above all, in the context of aggregable knowledge and its value in sustainable electricity management. The information/knowledge extracted from aggregated smart meters can constitute, with an appropriate decomposition, a set of attributes and values that can feed heterogeneous decision-making systems, using algorithmised and also non-algorithmised methods using artificial intelligence (Deng, et al, 2015) (Tounquet, et al., 2019). The compilation of information and knowledge that can be extracted from elementary readings of bi-directional electricity flows in a distributed AMI infrastructure, according to the experts involved in the study, constitutes an aggregated tabular 'Real Consumer Behaviour Knowledge Map', which can be expanded under any heading, with the possibility of adding further information/knowledge items of course.

In the next stage of the research, in line with the assumptions made, an attempt was made to answer the second research question: How to use the acquired knowledge, manage the knowledge, obtained from the readings of the distributed AMI infrastructure (smart electricity meters), in terms of key decision-making processes that make energy value management more effective, both on the supplier side but also on the consumer/household side, frequently the energy prosumer (micro RES production). In accordance with the research methodology adopted, a panel discussion with inference (adopted as: brainstorming) was conducted at this stage, with the participation of domain experts - managers, decision-makers strictly in the area of electricity markets and, in particular, in the field of electricity trading and value management.

On the basis of the brainstorming, scientific discourse with inference, in the group of domain experts, a selection was made of key decision-making processes in which high relevance is attributed to heterogeneous information/knowledge extracted from the AMI system (smart meters). his refers to the information/knowledge summarised in Table 1, as indicated by the first group of respondents surveyed.

The domain experts, identified new decision-making processes, or significantly modified, unambiguously to be emphasised, decision-making processes that can be implemented using knowledge generated from smart meter readings in a distributed AMI structure. Furthermore, a portfolio structure of methods and tools was proposed and an attempt was made to justify its structure. These are methods and tools that can support the identified decision-making processes as well as digitise them (Deng, et al, 2015) (Tounquet, et al, 2019) using, inter alia, artificial intelligence, obviously where the source of knowledge constitute its identified areas (Table 1). Interesting from a cognitive point of view in the use of the information and knowledge identified and grouped in Table 1, was the identification by the experts participating in the study of six decision-making processes that are important in the management of energy demand and supply, especially in non-linear RES, both on the supplier side but also on the consumer/household side.

The order of the summarised decision-making processes is not random, as it was adopted according to the relevance of the knowledge information, which is determined according to the number of indications by respondents in the first stage of the research (Table 1).

The first process identified, which is accelerated by the knowledge gained from the AMI system, is:

The creation of tailored electricity supply portfolios to meet the actual needs of final consumers. This matching is linked to the scheduling and organisation of two-way transmission of electricity and information on its created value, as well as the generation of new services for heterogeneous electricity consumers. The research process

emphasises that the source of knowledge in this decision-making area is the metering data obtained from all the metering systems of the AMI infrastructure, the cumulative metering knowledge on the basis of which the calendar characteristics Pd=f(t) and the integral characteristics Ed=f(t) are generated in real time, with high reading frequencies: a) individually on the side of the consumer, the electricity prosumer; b) aggregated on the side of the node, transformer, electricity region.

The above decision-making process, based on readings in the AMI system, should be methodologically supported, according to the domain experts, by visualisation of current and cumulative (integral) characteristics in real time, analyses of energy load and supply in prosumer sources, at arbitrary time intervals, including analysis of energy production from RES on the prosumer side. Tools supporting these analyses and, indirectly, the decision-making process in the area in question were also assigned. In particular, multivariate statistical analysis systems and the generation of dynamic econometric models, e.g. classes, GARCH, were distinguished. With regard to the creation of tailored electricity supply portfolios to meet the actual needs of final consumers, the need for integration with the internal CRM system/contract registration system (contracts with customer groups) on the part of the commercial operator was identified. Due to the non-linearity of electricity production in prosumer RES sources, it is proposed to carry out appropriate analyses using Business Intelligence tools, e.g. PowerBI, as well as machine learning systems, e.g. GNU R interpreted programming language or IBM SPSS Modeler.

The second decision-making process identified by the expert team that is possible with the aggregation of information/knowledge gained from the AMI system is:

Customer relationship management with the aim of customer segmentation, acceleration of customer confidence through flexible adjustment of tariffs, new payment models to the actual preferences of electricity consumers. Indirectly, this process involves: comparing - at specific time intervals - actual loads with the daily function of tariffs, preparing price offers to encourage the use of electricity consumers during off-peak hours, personal matching of energy consumers/customers to the DSR (Demand Side Response) programme. In the context of the above decision-making process, domain experts distinguish that it can generally be improved on the basis of information/knowledge about balancing evening peak loads by shifting loads to off-peak periods, information/knowledge about the preferences and behaviour of energy consumers, as well as information/knowledge about the consumption and production of prosumer sources of electricity, high-frequency readings, e.g. in 15-minute, hourly, daily, monthly modes. Similarly to the first decision-making process, also in this scope the domain experts attribute tools to support the identified above decision-making process. In particular, they distinguish intelligent systems for matching the prosumer to electricity tariffs and other payment models, e.g. in an R or IBM SPSS Modeler (Learning Machine) environment - due to individual consumer behaviour, non-algorithmised models are proposed.

The third decision-making process identified by the expert team that is possible with the aggregation of information/knowledge obtained from the AMI system is:

Maintaining and ensuring the stability of electricity grids through the management, by the commercial operator, of the key electricity loads of heterogeneous consumers/prosumers. Indirectly, this concerns the generation of schedules (time intervals favourable to the consumer) of energy consumption based on feedback from smart electricity receivers. In this respect, the information/knowledge relates to the actual on-line energy balance of the electricity supply on the prosumer side, with the aim of balancing it by means of a consumer-AMI-integrated - consumer application - Internet of Things (IoT) to control of smart household energy receivers. In technical terms, this involves the integration of stationary/mobile smart meter applications with IoT mobile applications - control of smart energy receivers in households/on the side of heterogeneous electricity consumers (allocation by tariff groups or other payment models introduced). In terms of tools, the experts highlight the importance of implementing integrators, integration and communication hubs of smart meter applications with IoT applications.

The fourth identified area requiring improvement of existing decision-making processes, according to the experts, is:

Network condition diagnosis, fault detection and localisation, on-demand power quality monitoring, detection of illegal energy consumption, diagnosis of network disturbances, expansion of the use of network infrastructure to include distributed smart meter infrastructure, including consideration of prosumer RES penetration. Indirectly, this also includes support for on-demand monitoring of medium-voltage MV and low-voltage LV networks. In this decision-making scope, the key information/knowledge acquired from the AMI system,

concerns: information/knowledge obtained in real time about the quality parameters of distributed electricity from prosumer RES sources, as well as information/knowledge about the availability of these sources during peak and off-peak demand periods, information/knowledge about the loads of MV LV networks , MV/LV transformer stations/junctions, as well as information/diagnostic knowledge about the state of electricity networks, location and causes of faults or failures, on-demand energy quality control, detection of cases of illegal energy consumption. In this case, the analysis of metering data from smart meters in the AMI infrastructure, according to the domain experts, should be carried out using multivariate statistical analyses and dynamic econometric models, e.g. class, GARCH. In this respect, it is important to design a diagnostic model, this time based on models of deep learning libraries, machine learning and automated learning. The aim is to create and select a model that can predict the state of the network (justification of non-algorithmised methods), detect and localise faults, and control power quality. At this stage, the domain experts propose and at the same time justify the use of libraries such as KERAS, xgboost (eXtreme Gradient Boosting), randomForest (random decision forest), H2O and autoML (Automated machine learning libraries) available within the R development environment.

The fifth identified decision-making process which, in the opinion of the domain experts, can certainly be made more effective using information/knowledge gained from the AMI system is:

Real-time monitoring of commercial losses and their elimination/reduction through balancing energy demand with supply on the part of heterogeneous consumers. The relevant information/knowledge in this regard, also summarised in Table 1, includes: information/knowledge on commercial losses, information/knowledge on aggregated electricity demand and supply, ensuring, among other things, optimal operation of SCADA systems, and information/knowledge on the magnitudes of flows at medium-voltage MV and low-voltage LV network nodes. Here, the importance of a real online analysis of the relationship between electricity supply and demand is highlighted. Due to the non-linear nature of this relationship in reality, the use of a machine learning model is proposed - a model for intelligent matching of demand and energy production on the prosumer/line branch/transformer/energy district side. In this area of machine learning, the GNU R- interpreted programming language environment and also optionally the IBM SPSS Modeler system are proposed in the tool context. It was reasoned that the application of machine learning to analyse supply-demand relationships and detect abnormal behaviour can be fully implemented on the basis of historical data using libraries of automated machine learning etc. Libraries such as KERAS, xgboost (eXtreme Gradient Boosting), randomForest (random decision forest), H2O and autoML (Automated machine learning libraries) available within the R development environment can also be used at this stage.

The sixth decision-making process that can be made effective on the basis of the information/knowledge acquired from the AMI system is:

Management of the movement, switching on and off of all appliances, energy receivers, energy sources in the electricity grids covered by smart metering. In this case, the decision-making processes should be fed with all the information/knowledge that is highlighted in the previous five decision-making cases and also with information/knowledge about the location of consumers and distributed prosumer sources feeding into the GIS system (full information about MV and LV networks, in terms of topological data and technical parameters of infrastructure elements).

In this case, it was proposed to implement or expand an IT system of the GIS type, containing information on MV and LV networks in terms of topological data and technical parameters of AMI infrastructure elements, as well as information on current parameters of supply, energy consumption on the part of heterogeneous electricity consumers (breakdown by tariff groups, or other payment models).

5. Conclusion

In this paper, the cognitive focus has been on two main aspects: 1) Identification of the information and knowledge that can be extracted from the bi-directional readings of electricity (high frequency) in AMI systems, necessary to manage the value of energy both on the supplier side and, above all, on the consumer/prosumer side; 2) Identification of key decision-making processes, fed by the identified information/knowledge. Processes that make energy value management effective, both on the supplier side but also on the consumer/household side, frequently the energy prosumer (micro RES production). It was reasoned that the analytics of the large metering data sets acquired in the distributed AMI infrastructure, provide a knowledge stream for, among other things: 1) the creation of tailored electricity supply portfolios, in the context of the real needs of households; 2) the scheduling and organisation of bi-directional electricity transmission and value-created information; 3) the creation of new services for heterogeneous electricity consumers; 4) the management of electricity grid stability

on the part of the Operator; 5) real-time monitoring of commercial and technical losses and their elimination; 6) integration of smart meter applications with IoT applications - on the side of electricity consumers/prosumers - for the ongoing monitoring of electricity consumption and ongoing balancing of demand with energy produced, in households in micro RES. Referring to the future, managing knowledge aggregated in terms of knowledge and information identified in Table 1, has measurable value in the context of energy efficiency, energy security, energy conservation and also in the dimensions of sustainability and social responsibility. Future research directions will focus on defining IF-THEN learning rules that are digital representations of the six decision-making processes identified and highlighted in this paper. Learning rules relevant for machine learning.

Abstract: In this paper, the authors address a new approach to three organizational, functional cultures: knowledge culture, learning culture, and collaboration culture, named together the KLC cultures. Authors claim that the KLC approach in knowledge-driven organizations must be designed and nourished to leverage knowledge and intellectual capital. It is suggested that they are necessary for simultaneous implementation because no one of these functional cultures alone is as beneficial for a company as all of them are together. Moreover, there is a risk that organizations with a learning culture developed without collaboration are stuck at the individual level of learning only; and that a knowledge culture developed without a learning culture jeopardizes the organization to be stuck in a passive way where only old, multiply verified knowledge is accepted. As a result, such companies cannot grow. That extreme situation leads to the rejection of new knowledge that is usually rationalized by the need for business safety security - that is nothing more than a ruse for intellectual laziness or personal barriers of fixed-minded managers. Summing up, based on the empirical evidence (640-cases sample, composed of Polish knowledge workers; SEM method of analysis), this paper delivers empirical evidence that knowledge culture rejects mistakes acceptance component of learning culture and that the learning climate component itself is not sufficient for explicit knowledge sharing. Knowledge sharing, organizational intelligence, and innovativeness are key benefits of the synergy that offers the KLC cultures simultaneous implementation and cultivation. The results expand the former studies by Kucharska and Bedford (2020; 2023) and Kucharska (2021a-b) and expose that KLC cultures and TRUST are needed to develop tacit knowledge sharing clearly is an essential ingredient for organizational intelligence development.

Keywords: Knowledge culture, Learning culture, Collaborative culture, KLC cultures, Knowledge sharing, Tacit knowledge, Explicit knowledge, Collective intelligence, Trust

1. Introduction

Recently Kucharska and Bedford (2023) introduced the KLC cultures synergy idea that the essence is the simultaneous implementation of functional cultures of knowledge, learning, and collaboration for knowledge-driven organizations' growth. Authors claim that these cultures support and strengthen one another to develop favorable conditions for new knowledge creation and utilization that impact the organizational ability to create change (innovativeness) and to adapt collectively to externally induced changes (organizational intelligence), „ The KLC cultures are so powerful together, thanks to their tremendous contribution to tacit knowledge-sharing behaviors that are focal for human and relational capital development.

Understanding company culture's contribution to its performance is particularly critical in today's hyperdynamic knowledge economy. Culture will always dominate strategy (Bedford and Kucharska, 2020), „ However, it can play an even more significant role in the knowledge economy, where knowledge is the primary form of capital and the most critical intellectual production factor. To thrive and survive in the knowledge economy, managers must "see" their company culture's power to shape the company's course and learn to gain and sustain knowledge, learning, and collaboration cultures synergy. Nowadays, hyperdynamic business reality requires intelligent actions. When managers "see" their cultures as assets, they can shape and use them for the company's best (Kucharska and Bedford, 2023), „

This study aims to deliver a piece of empirical evidence supporting the KLC culture's powerful impact on knowledge-driven organization ability to create knowledge (explicit and tacit) that matters for organizational intelligence and innovativeness development.

2. Conceptual Framework

KLC cultures

The focal point to clarify the KLC culture approach to knowledge-driven organizational culture introduced by (Kucharska and Bedford, 2023) is the clarification of the key characteristics of each of them as well as the exposition of their relations.

A culture of knowledge dominates in knowledge-oriented organizations that focus more on static knowledge exploitation (Kucharska and Bedford, 2023; Van Wijk et al., 2012), whereas learning culture dominates in organizations that focus more on dynamic, constantly breaking 'the status qu.' Furthermore, knowledge culture is a base for learning culture. To expose the difference between these cultures the easiest way is to compare the effects of such a different organizational focus. It is easy to predict that if any organization is stuck in the knowledge-orientation stage, then it exists in a reality where static exploitation of knowledge and control dominates, and the new knowledge is rejected. In such organizations, old, proven methods of cultivating acting are more appreciated than new solutions seeking, and any risk is rejected; consequently, mistakes tied to this risk are avoided. Organizations based chiefly on proven knowledge often prefer to "keep things as they are" - and that "safe, well-known routines control-oriented" organizational attitude might block these organizations' development.

In contrast, a learning culture leads to constant, dynamic knowledge acquisition provoked by "intelligence in action" (Erickson and Rothberg, 2012), „ A pervasive and persistent learning culture is essential to the development and growth of learning organizations in the current economic climate of continuous change (Maes and Van Hootegem, 2019; Rass et al., 2023), „ An organizational learning culture can facilitate the creation and sharing of and discourage the hoarding or hiding of tacit knowledge (Kucharska and Rebelo, 2022a-b; Weinzimmer and Esken, 2017), „ By itself, a knowledge culture does not have this effect, though it is a basis for fostering curiosity and exposing knowledge gaps that lead to learning. This finding is consistent with the research of Webster and Pearce (2008), who highlighted the importance of situational learning, which is essential to active learning. Situational learning is aligned with the current context. It is especially relevant today in a dynamic and rapidly changing business environment. Acting in such a dynamic business environment might naturally cause many mistakes. Moreover, the lack of mistakes acceptance component of a learning culture can block learning from them at the organizational level. Therefore, a learning culture without developed mistakes' acceptance component is an illusion of learning culture (Kucharska and Bedford, 2020), „ Based on the all above, the hypotheses are given below:

H1a: Knowledge culture positively influences the learning climate component of learning culture.

H1b: Knowledge culture negatively influences the mistakes acceptance component of learning culture.

A culture of learning is an organization's ability to create, acquire, and exchange knowledge, modify its behaviors and choices, and integrate that new knowledge and insights into its organizational knowledge (Garvin, 1993), „ Moreover, Kucharska and Bedford (2020) empirically proved that this organizational ability depends on two dimensions: learning climate and mistakes acceptance and that the climate component influences the mistakes acceptance component. Therefore, the hypothesis is added as below:

H1c: Learning climate component of learning culture positively influences the mistakes acceptance component

Moreover, if an organization is seen as a group of people coordinated to achieve the aim non of them can achieve alone – then collaborative culture is an essence of any organization's existence (Kucharska and Bedford, 2023), „ Learning requires collaboration. Collaboration supports learning that is a source of new knowledge (Kucharska and Bedford, 2020; Nugroho, 2018), „ Collaboration is then the core competency that enables knowledge organizations to create relational knowledge capital. Based on this, the hypothesis is given below:

H1d: Collaborative culture influences the learning climate component of learning culture positively

H1e: Collaborative culture positively influences the mistakes acceptance component of learning culture

Based on the Kucharska (2017) study, it is empirically proved that knowledge culture and collaborative culture are correlated and that both foster knowledge sharing, especially tacit. Therefore the hypothesis is added:

H1f: Knowledge culture and collaborative culture are correlated

Moreover, Alavi et al. (2005) and Yang (2007) studies indicated that knowledge sharing is motivated by collaborative culture; therefore, the additional hypothesis is formulated as below:

H2: Collaborative culture influence positively the explicit knowledge sharing

Knowledge sharing

Knowledge is recognized today as the most critical company resource that can provide organizations with a sustainable competitive advantage (Barney, 1991), „ Therefore, it's sharing among workmates is equally critical for this competitive advantage creation and implementation. The culture of learning supports knowledge dissemination (tacit and explicit) across the company (Lucas, 2006; Schmitz et al. 2014; Kucharska and Bedford, 2023), „ Therefore, the hypotheses are formulated below:

H3a Mistakes acceptance component of learning culture influences positively explicit knowledge sharing

H3b: Mistakes acceptance component of learning culture positively influences tacit knowledge sharing.

H3c: Learning climate component of learning culture positively influences tacit knowledge sharing.

H3d: Learning climate component of learning culture positively influences explicit knowledge sharing.

Moreover, following Islam et al.'s (2015) statement that knowledge culture supports the flow of knowledge throughout the organization and relying on Kucharska's (2021a) empirical evidence, it is assumed that knowledge culture might motivate knowledge workers to share their newly discovered thoughts and ideas. Thus, the following hypothesis is formulated:

H4: Knowledge culture influences tacit knowledge sharing positively.

All knowledge is rooted in tacit knowledge, as Polanyi (1966) stated. Following him, the hypothesis is given below:

H5: Tacit knowledge sharing fosters explicit knowledge sharing.

Organizational development

Change is a characteristic of the current economy. In the knowledge economy, creating and adapting to change are what organizations and individuals do to exist and create value (Rass et al., 2023), „ Existing in a fast-changing environment requires making change a part of daily organizational routines. How organizations deal with the adaptability need and respond to surrounding change determines their survival and development. For improving innovation and business performance, developing a robust knowledge management (KM) strategy is a pivotal step for many firms today (Lai et al., 2022), „ In line with this, the hypothesis is developed below:

H6 Explicit knowledge sharing fosters market innovations

Knowledge is a vital asset of the current economy because it is essential to company intelligence development (Rothberg and Erickson, 2007), „ Feuerstein et al. (1979) defined intelligence as the ability to adapt to change. Following him, the organizational capacity to adapt to change is seen as its intelligence. Tacit knowledge sharing among workmates fosters adaptability to change (Kucharska and Rebelo, 2022); therefore, hypotheses have been given below:

H7: Explicit knowledge sharing fosters organizational intelligence (change adaptability), „

H8: Tacit knowledge sharing fosters organizational intelligence (change adaptability), „

Organizational adaptability reflects how an organization responds to change by managing stress and uncertainty, exposing flexibility or resilience, and supporting those who tackle problems to face the change (Reupert, 2020), „ Martin et al. (2013, p. 1) defined adaptability as 'appropriate cognitive, behavioral and/or emotional adjustment in the face of uncertainty and novelty.' Change is a characteristic of today's economy that places companies in a permanent learning and development mode related to adjusting and gaining market advantage and creating value through constant innovativeness (Kucharska and Rebelo, 2022), „ Bearing in mind all above, the hypothesis is formulated as follows:

H9: Organizational intelligence (change adaptability) fosters market innovations.

Trust

TRUST impacts knowledge sharing (Kmieciak, 2021; Rutten et al., 2016), „ Trust among co-workers ensures successful collaboration and vice versa; both increase knowledge sharing, team creativity, and performance (Kucharska, 2017), „ At the same time, knowledge sharing supports trust-building among knowledge workers

(Thomas et al., 2009), „ Therefore TRUST, it is included in this study as a control variable (CV), „ CVs imputation enables including extraneous variables that are not the focal point of the thorough research but remain theoretically important (Carlson and Wu, 2012; Nielsen and Raswant, 2018), „ Based on the former studies of Kucharska (2017), Kucharska et al. (2017), and Kucharska and Kowalczyk (2016), TRUST is a critical facilitator needed for tacit knowledge sharing. It is why the hypothesis is added below:

H_{cv}: Trust positively impacts tacit knowledge sharing.

Figure 1 below, based on the all above, summarizes the conceptual framework of the planned empirical research visually.

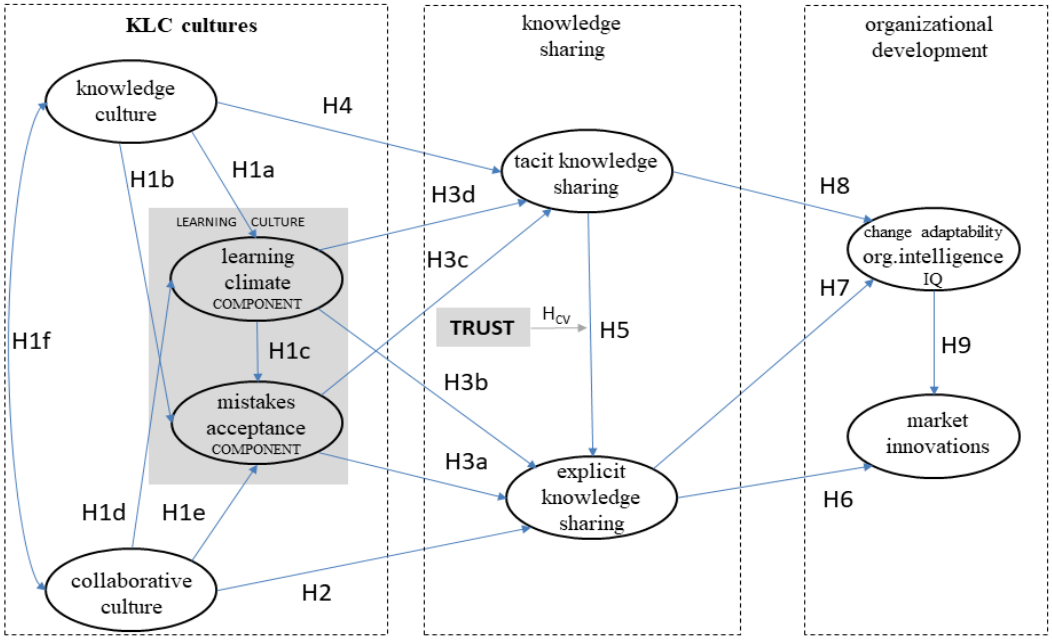

Figure 1: Conceptual Framework

3. Methodology

Sampling procedure: this study was targeted at Polish knowledge workers; therefore, qualified respondents declared that their work's first input and output is knowledge. Moreover, to secure the respondents' familiarity with their organizations' issues, we qualified only those who worked a minimum of one year for their current employer. Data were collected in March 2023 by applying the CAWI method by Biostat® Poland. Sample characteristics: sample is composed of 640 Polish knowledge workers: 306 specialists and 334 managers; 329 women and 311 men representing mostly private (77%) companies from different sectors to illustrate the general view on Poland (dominating sectors: production and knowledge services 19% each), „ Measures: respondents referred to the majority of questions using a 7-point Likert scale. Appendix 1 presents measured constructs scales and their sources. Obtained reliabilities are given in Table 1. Additionally, Appendix 2 presents the Cross-Loadings Matrix. It is because two of the nine used scales (the organizational Trust and the organizational IQ) were invented and validated by authors. The Cross-Loadings Matrix exposes that the used scales do not overlap. Control variable (CV): Trust was input into the model as CV; to do so, the composite variable was created based on the scale measures.

Method of analysis: structural equation modeling (SEM) with the use of SPSS Amos 26 software (Byrne, 2016), „

Sample quality: Kaiser–Meyer–Olkin (KMO) test: .957, the total variance extracted: 75% and Harman one factor test: 44% justify the good quality of the sample.

Table 1: Basic Statistics, Obtained AVE Root Square, and Correlations Between Constructs

	Mean	SD	AVE	CR	Cronbach alpha	T	CC	KC	LCc	LcM	TKS	EKS	IQ	InnE
T	3.59	2.01	.57	.79	.80	**.753**

LcM	3.12	1.7	.80	.94	.94	.437	.651	.398	.608	**.894**				
TKS	3.61	.07	.66	.85	.87	.637	.69	.606	.718	.543	**.813**			
EKS	3.56	1.98	.55	.79	.78	.668	.902	.642	.719	.692	.719	**.742**		
IQ	3.64	1.98	.59	.85	.85	.592	.75	.567	.708	.58	.786	.742	**.765**	
InnE	3.59	1.96	.54	.78	.77	.557	.738	.535	.678	.567	.697	.722	.758	**.732**

Note: n=640 KC-knowledge culture, LCc-learning culture climate component, LCm-Learning culture mistakes acceptance component, CC-collaborative culture, TKS-tacit knowledge sharing, EKS-explicit knowledge sharing, T-trust, IQ- organizational change adaptability, InnE – market (external) innovations

After the positive assessment of the sample and scales reliability, the structural confirmatory factor analysis (CFA) model was developed to ensure that the scales performed appropriately. The evaluation of the model quality was initially conducted based on constructs measurements consistency tests such as the average of variance extracted (AVE), composite reliability (CR), and Cronbach's alpha. AVE exceeded 0.54 for all constructs, which was acceptable (Hair et al., 2017), „ Cronbach's alpha test was used to confirm the consistency of the construct measurement model. The alpha coefficient was greater than 0.77 for all constructs, which was adequate (Hair et al. 2017, pp. 112), „ The CR was greater than 0.78 for all loadings, which was more than the required minimum of 0.7 (Hair et al., 2017), „ The square root of each construct's AVE exceeded the correlations between any pair of distinct constructs except CC-LCc and CC-EKS (bolded in Table 1), „ It means that there is a strong interdependency between collaborative culture, learning climate, and knowledge sharing in Poland. On the one hand, this interdependency may cause little bias; on the other hand, it exposes how focal is collaborative culture for knowledge spreading in Poland.

4. Results Presentation and Discussion

Obtained results exposed (Table 2; Model A and B comparison) that TRUST is next to KLC cultures synergy, a focal company facilitator of knowledge-sharing processes in the knowledge-driven organization. The entire model quality was strengthened thanks to the trust (CV) imputation.

Moreover, results show that knowledge culture supports the learning climate component of a learning culture (H1a), but it is negatively related to the mistakes acceptance component (H1b), and the climate component supports the mistakes acceptance component (H1c) – as was indeed assumed by the KLC cultures approach by (Kucharska and Bedford, 2023), „ On the contrary, collaborative cultures support both components of learning cultures (H1e, H1f), „ That next supports knowledge sharing except for the fact that the hat learning climate itself (H3b) is not sufficient for explicit knowledge sharing. It might be that it is mediated by tacit knowledge sharing or by mistakes acceptance component of the learning culture. These assumptions require further profound verification. Nevertheless, it altogether exposes why knowledge culture itself is not enough for knowledge-driven company development. Knowledge, learning, and collaborative culture (KLC cultures) support one another and together deliver to the organization the expected benefit of smooth knowledge sharing (H2; H3a,c,d; H4; H5), „ Finally, knowledge sharing fosters organizational intelligence (H7; H8) that matters of innovations (H6) creation that is a potent source of the expected competitive advantage.

Table 2 below presents hypotheses verification details supporting this view.

ns-not significant result

Table 2 compares the obtained results for two models: Model A, run with TRUST as CV, and Model B, run without it (Aguinis and Vandenberg, 2014; Becker et al., 2016), „ The model with TRUST fits better with the data. So, it supports the theoretical justification given to input TRUST as a CV to the study. Therefore, all the subsequent analyses and visualizations (Figure 2) are presented for the model with TRUST.

Note: n=640, ML; χ2=1043.45(331) CFI=.941 TLI=.933 RMSEA=.059 Cmin/df=3,15; p<.05 **p<.01 ***p<.001

ns-not significant result

Figure 2: Results

The presented results expand the former studies by Kucharska and Bedford (2020; 2023) and Kucharska (2021a-b) and expose that KLC cultures and TRUST are needed to develop tacit knowledge sharing, which clearly is an essential ingredient for organizational intelligence development.

5. Limitations and Implications

The key limitation of this research is that it bases on data collected in only one country. The second important limitation is the identified strong interdependency between collaborative culture, learning climate, and knowledge sharing in Poland. This interdependency may cause little bias, but at the same time might be it exposes how focal collaborative culture is for knowledge spreading in Poland – to be sure how to interpret it, further studies are needed. Moreover, the presented results expose only direct relations. No mediated or moderated effects are included. So, further studies can explore these relations more in-depth.

6. Practical Implications

Practical implications are direct, KLC cultures facilitated by TRUST drive organizational intelligence. Therefore, KLC cultures are worth to be implemented simultaneously. Moreover, there is a risk that organizations with a learning culture developed without collaboration are stuck at the individual level of learning only; and that a knowledge culture developed without a learning culture jeopardizes the organization to be stuck in a passive way where only old, multiply verified knowledge is accepted. As a result, such companies cannot develop. That extreme situation leads to the rejection of new knowledge that is usually rationalized by the need for business safety security - that is nothing more than a ruse for intellectual laziness or personal barriers of fixed-minded managers. Similarly, knowledge culture itself rejects the mistakes acceptance component of learning culture that makes entire learning problematic. Can we learn without mistakes? Obviously, we cannot. So, knowledge culture itself – without learning and collaboration also jeopardizes organizational development. There is no development without learning. Moreover, the learning climate component of learning culture is not sufficient for explicit knowledge sharing, and collaboration is needed to make learning and sharing happen. So, knowledge sharing, organizational intelligence, and innovativeness are key benefits of the synergy that offers the KLC culture simultaneous implementation and cultivation. TRUST strengthens this effect.

Summing up the practical perspective of the obtained results: those managers who care about developing knowledge-driven organizations in the hyperdynamic conditions as observed today need to build a collective intelligence to do so, they must implement KLC cultures and build TRUST.

7. Conclusion

Knowledge sharing, organizational intelligence, and innovativeness are key benefits of the synergy that offers the KLC cultures simultaneous implementation and management. TRUST strengthens this effect. So, those managers who care about developing knowledge-driven organizations in the hyperdynamic conditions observed today need to build collective intelligence; to do this efficiently, they should implement KLC cultures and build TRUST. The presented results expose that KLC cultures and TRUST are needed to develop tacit knowledge sharing, which clearly is an essential ingredient for organizational intelligence development. Collective intelligence, understood as a network of knowledge workers brilliant minds' that collaborate smoothly, is a severe organizational potency that needs to be activated. KLC cultures' synergy facilitates it significantly.

Acknowledgements

The presented research is a result of the project Tacit Knowledge Sharing Influence on Innovativeness. The Sector Analysis No. UMO-2018/31/D/HS4/02623 financed by the funds of the National Science Center (NCN) Poland.

Appendix 1: Scales and Their Sources

Knowledge culture (Kucharska and Bedford, 2020)	All employees perceive knowledge as valuable resource. We have a common language to support knowledge exchange. We are encouraged to share knowledge, ideas, and thoughts. We care about the quality of knowledge that we share.
Learning culture (Kucharska and Bedford, 2020)	Learning climate component All staff demonstrates a high learning disposition. We are encouraged to engage in personal development. We are encouraged to implement new ideas every day. We are encouraged to engage in seeking new solutions. Mistakes acceptance component People know that mistakes are a learning consequence and tolerate it up to a certain limit. Most people freely declare mistakes. We discuss problems openly without blaming others. Mistakes are tolerated and treated as learning opportunities.
Collaborative culture (Kucharska and Bedford, 2020)	My company supports cooperation between workers. Cooperation among the different duties, teams, and departments was encouraged. Co-workers volunteer their support even without being asked. People support each other.
Tacit knowledge sharing (Kucharska and Erickson, 2023)	I share knowledge learned from my own experience. I have the opportunity to learn from the experiences of others. Colleagues share new ideas with me. Colleagues include me in discussions about the best practices.
Explicit knowledge sharing (authors' own scale)	There is a formal policy encouraging knowledge sharing at my place of work.

	Knowledge is shared among people in my team and division. Other teams and divisions share knowledge with us. We share our knowledge with other teams and divisions.
TRUST (authors' own scale)	I trust people at work. People in my team trust one another. People in my division trust one another. People in my entire organization trust one another.
Change adaptability (org. intelligence - IQ) (Kucharska and Bedford, 2020)	We are flexible to changes. We can adjust ourselves to changes. We adapt to changes easily. We used changes.
External, market innovations (Kucharska and Erickson, 2023)	We provide competitively superior innovations to our clients. Our innovations are perceived positively by our clients. We are better than our competitors at introducing innovations. I am proud of our innovations.

Collaborative Structures in WikiProjects: Wikipedia Users' Activity Case Study

Katarzyna Kukowska
Czestochowa University of Technology, Poland

katarzyna.kukowska@pcz.pl

Abstract: The research presented in the article concerns the development of organizational and cooperation structures from interpersonal interactions in virtual communities sharing knowledge. It is assumed that the activity of communities functioning on the Internet reflects the organization of human communities in the offline space. The main aim of the research was to characterize the structures of cooperation groups that are formed around WikiProjects. The research question was: what is the structure of activity of Wikipedians in WikiProjects in chosen language versions of Wikipedia? The method used in the research is the content analysis method. The author calculated data thanks to the Wikipedia xTools. The numbers of participants involved in WikiProjects were analysed by referring to the Dunbar number concept and the cultural determinants of cooperation, thus referring to the masculinity index (MAS) according to Hofstede. Research has shown that WikiProject members show similarities to the layered community formation proposed by Dunbar. The sizes of groups of active editors are closer to these values. As the WikiProjects group grows, the ratio of declared participants to active participants decreases. The production of value in virtual communities, the ability to work together as a team in physical isolation, is becoming increasingly important. The results of the research may be significant to the knowledge management specialists and virtual communities practitioners.

Keywords: Dunbar's number, Collaboration in WikiProjects, Cultural dimensions, Knowledge management, Virtual communities

1. Introduction

Participation in the creation of a global knowledge exchange system by presenting one's intellectual skills is an attractive alternative activity for many people. Pro-social motives may create a sense of moral obligation to share knowledge for community development. By sharing knowledge with others, people fulfil their own altruistic needs while experiencing pleasure (Yu et al., 2010) and with the IT infrastructure in place, people are willing to share knowledge with others (Ruppel and Harrington, 2001). This is evidenced by the uninterrupted development of the global encyclopaedic project, namely, Wikipedia, for over 20 years. The spontaneous behaviour of individuals in editing activities leads to the formation of collaborative structures. Their form is difficult to predict. The foundations of the Wikimedia Movement, which unites Wikipedians, are freedom of expression, freedom to learn, social activities, and activities related to Wikimedia projects (‘Ruch Wikimedia’, 2021). In the view of the author, the phenomenon of Wikipedia is an interesting subject of research due to the spontaneously emerging structure of cooperation in the spirit of volunteering. Despite the lack of governance structures, the system works. On the one hand, the structure of the project is becoming increasingly hierarchical, but hierarchy is intertwined with horizontal structures (Arazy et al., 2018). It is indicated that its effectiveness in terms of durability and productivity is due to the fact of a kind of independence of the project's activists. The freedom to join and leave, with the effect of a high turnover of members, as has been written about by, among others (Chen et al., 2010) has not shaken the permanence of this structure.

WikiProjects are groups of Wikipedians working in teams to improve Wikipedia. WikiProjects may be dedicated by topic and coordinate a specific type of task (‘WikiProject’). The subject of the research undertaken by the author remains the collaborative structures of WikiProjects, with relation to the number of participants and their correspondence to Dunbar's number, as well as the cultural dimension of collaboration with relation to the Masculinity Index (MAS) according to Hofstede. The conclusions presented in this article are the result of an in-depth research process on WikiProjects that was commenced in 2022. The first stage of the research showed that according to the acquired data, WikiProjects show similarities to the layered community formation proposed by Dunbar (Kukowska, 2022). The second stage of the research involved updating the data and including a new indicator: the number of WikiProject members active in the last three months was extracted. Determining the number of active members with relation to the declared participation more accurately reflects the true picture of community structures and the level of cooperation in general terms.

2. Literature Review

The structural complexity of social systems determines the efficiency of the functioning of groups and individuals in social life. The structuring of groups, their stability and the dynamics of change within them have

certain social consequences. Regardless of the context of the groups' activities, micro-level processes merge into macro-level structures. The forces of attraction and disintegration, the cohesion of groups that consolidate cooperation, while also the formation of boundaries all remain the subject of research by representatives of various sciences (Dunbar and Sosis, 2018; Stadtfeld et al., 2020).

Dunbar in his research demonstrates that the layers that define the closeness of relationships in traditional hunter-gatherer communities of primitive tribes is also reflected in contemporary structures of interaction (Dunbar, 2010; Dunbar, 2014). Moreover, it matters little whether they are set in real or virtual space. Their foundation remains the networks of interaction that bind the links together. Social populations are characterised by a high degree of sustainability, although the size of these populations is of course variable. Every day we spend about 2 hours on social interactions. In addition, we spend nearly 50 minutes on interacting with the 5 closest people. These are usually the people we live with. Another layer is the 15 people with whom we are in direct or mediated contact through digital media and telephony. Those who do not belong to layer 5, receive approx. 20% of our attention. A further 35 people in layer 50 receive an average of 0.4% of our time each day. Nowadays, this can be applied to colleagues who are not part of our support group. For layer 150, one person receives enough attention to fill one actual appointment per year (Gamble et al., 2014). Ties in the subsequent layers vary in terms of their strength and quality (Dunbar, 2012; Skolik and Kukowska, 2022). The growth, or loss of members of a layer over time can lead to its disintegration. The numbers defining layers 50, 150 and 500 are the optimum points around which the population sizes oscillate. The greater the deviation, the greater the risk of disintegration of the community in question. Natural dividing points differentiate organisations in terms of their size, while representing optimal values of cohesion and relative stability over time (Dunbar and Sosis, 2018).

The social nature of human beings triggers the desire to create networks of relationships with qualitatively diverse ties. It seems that the size of the communities in which we operate may condition the tendency to seek mutual similarities. Simply belonging to a social collective can be an important tool for creating bonds. Sharing common traits, e.g., cultural identity, may be enough to induce a sense of closeness with a stranger. In the persistence of the different layers of the collective, homophily plays an important function, which Launay and Dunbar present from the perspective of innate tendencies towards social behaviour and group categorisation. Evolutionarily speaking, we may show a drive towards intimacy with certain communities or groups with which we identify with common labels, such as interests. The exclusivity of the group in question plays an important role in this regard (Launay and Dunbar, 2015).

Dunbar numbers referred to in algebraic analyses of group sizes by Kurokawa (Kurokawa, 2022). Kurokawa and Ihara prove that the evolution of cooperation becomes more likely as the size of groups increases, as long as the goods they produce are public goods. When goods are common goods, the evolution of cooperation is less likely as group size increases (Kurokawa and Ihara, 2017; Kurokawa, 2021). The characteristics of Wikipedia's functioning are part of the afore-mentioned conditions. Furthermore, large-scale collaboration may be explained by the direct reciprocity, which is found in WikiProjects.

The research addressed in the WikiProjects collaboration was conducted, among others, by Forte et al. (2012) based on the English version of Wikipedia. The authors demonstrated the validity of WikiProjects as groups to coordinate work in different forms of support. In addition to their commitment to creating and improving the thematic content posted, WikiProject members also support each other by, for example, providing places to find contributors. Solomon and Wash conducted an analysis of WikiProjects in the context of their development by referring to the concept of critical mass. They proved, among other things, that the collective contribution of small actions in the early stages of establishing a WikiProject is more valuable to its sustainability than the participation of advanced editors. In addition, building a large membership early on has a greater impact on future community activity than accumulating many contributions (Solomon and Wash, 2014).

Qin et al. measured the effectiveness of WikiProjects by the amount of work done by its members. This used comments on WikiProject discussion pages to identify communication networks. Using the social network theory, the authors examined the structural properties of these networks and concluded that the moderate level of connectivity and internal consistency of the communication network could positively influence the efficiency of the project. The same is true for the longer membership period at WikiProjects on average (Qin et al., 2015).

Online communities are subject to the same rules and norms as in the offline world. Thus, the analysis of these social structures provides valuable characterisations of the determinants of organisation in both spaces (Lu et

al., 2014; Vesa et al., 2017; Dunbar, 2021). Studies of virtual communities have shown that the increased turnover of participants may increase interest in these groups. Communities with a high turnover seem to be potentially more attractive and people are more likely to join them. Changes in the composition of members make interactions more dynamic, thus creating the impression of activity and commitment. This recovery catalyses the level of group participation (Dabbish et al., 2012). At the same time, it has been suggested that such communities may be more sustainable than communities with a relatively fixed membership (Farzan et al., 2011).

The issue of group cohesion in the dynamically changing membership of the Wikipedia community was addressed by Benkler. Horizontal structures are characteristic of Wikipedia's structure, but users are partly constrained by the rules adopted by the community. User contributions are controlled by those with greater authority. They are awarded to committed individuals who enjoy the trust of the community. The existence of procedures and inequalities of power allows for greater efficiency, thus maintaining quality and also maintaining consistency. This gives the site a better chance of survival (Benkler, 2006).

Knowledge sharing is influenced by psychological and organisational culture factors Yu et al. (2010). The motivation to work for the public good may therefore be fuelled or extinguished depending on the values embedded in a given culture. Research citing Hofstede's analysis of cultural dimensions in the context of cooperation and collaboration in Wikipedia was undertaken, among others, by Konieczny (2009). The author describes Wikipedia's decision-making processes by identifying the determinants of their control and relating them to the development of power in Wikipedia. Wikipedia's organisational culture is aligned with power distance, avoidance of uncertainty, while also individualism and collectivism. Hara et al. (2010) argued that the cultural dimensions according to Hofstede allow for the interpretation of differences between eastern and western Wikipedia. The polite behaviour of Eastern Wikipedians was explained by a greater respect for the hierarchical structure of society and a preference for teamwork. Western Wikipedia editors showed less power distance. Petrushyna et al. (2014) analysed European and Asian Wikipedias. User edits were compared to analyse differences in knowledge construction. Reference was made to the cultural dimensions according to Hofstede and Schwartz considering power distance, rootedness and egalitarianism of cultures. Samoilenko et al. (2016) used data on the co-occurrence of edits in different language versions of Wikipedia to explore cultural similarities. They concluded that the linguistic versions represent a common point of view when there are linguistic similarities. They explain the similarity of editorial interests by the number of bilingual people and the similarity of languages. It was discovered that cultural similarity as defined by dimensions according to Hofstede also applies to language. Usman and Yennita (2018) compared Italian and Indonesian Wikipedias with each other on the basis of a survey. Differences were shown regarding the relationship between members' interactions and community promotion and knowledge sharing. In the collectivist Indonesian culture, with greater interaction between members, there was more willingness to share knowledge and more promotion of one's own community. The interactions of members of the individualistic Italian culture did not promote community, and community participation did not ultimately lead to knowledge sharing.

Research on the diversity of Wikipedia's language version community due to IDV and MAS was also carried out by the author of this article together with her team. IDV has been shown to correlate with the activity (number of edits per page). In individualistic cultures, activities on Wikipedia are relatively less regulated, and user activity may indicate a greater boldness in editing others' content. In collectivist cultures, less assertiveness and a greater degree of regulation of actions can have an inhibiting effect on knowledge sharing (Kukowska and Skolik, 2021). With regard to the MAS research, a method of content analysis and analysis of the user activity log was adopted as follows: showing accolades, expressing thanks for contributions to Wikipedia content, manifesting one's gender as a Wikipedia user and participating in the Women in Red project. Cultures with a high MAS place high value on achievements and symbols of success, while nurturing relationships and appreciation, concern for individual needs and quality of life are closer to female cultures. According to the study, in cultures with lower MAS, there was more acknowledgement of contributions and cooperation, and gender marking was less important. In cultures with high MAS, decorations and symbols of success were important and more prominent (Karczewska and Kukowska, 2021).

3. Methodology

This study was based on a measurement of WikiProjects membership and user activity frequency. The original 2021/2022 study analysed the number of all enrolled participants in 55 randomised WikiProjects from a selection of 36 language versions of Wikipedia (Kukowska, 2022). The research was developed more

profoundly in late 2022 and early 2023. The criteria for selecting a particular language version in both parts of the study was to have a minimum of 300 active Wikipedians. As a result, the following language versions were selected: English, Arabic, Bengali, Bulgarian, Chinese, Croatian, Czech, Danish, Finnish, French, Greek, Hebrew, Spanish, Dutch, Indonesian, Japanese, Korean, Lithuanian, Malay, German, Norwegian, Persian, Polish, Portuguese, Russian, Romanian, Serbian, Slovak, Slovenian, Swedish, Thai, Turkish, Ukrainian, Hungarian, Vietnamese and Italian. WikiProjects were related to various scientific, cultural and technical issues.

The method used was to analyse the activity records of the number of WikiProjects participants. Participants were counted from WikiProjects pages or their subpages. A similar method of sampling the membership based on lists of enrolled participants on WikiProjects was used in the study of Chen et al. (2010), among others. The study looked at the impact of group diversity on the amount of work done and on drop-outs from WikiProjects. In this study, the tool (gadget) "Who is active?" was used to check the activity of Wikipedians in most language versions. This made it possible to measure the actual number of users involved in individual WikiProjects. The numbers of enrolled and recently active users (i.e., active in the last three months) differed significantly, especially in the large WikiProjects. The analysis of enrolled and active WikiProject users helped to reduce the number of WikiProjects surveyed compared to the first phase of the study. While 55 WikiProjects were studied in the first phase, there were 33 in the second phase.

The first hypothesis was adopted in order to contrast the result with the conclusions obtained from the first stage of the research, in which only declared participation in WikiProjects was considered. The variable of editing activity in the last 3 months was assumed to be a more precise indicator for measurement.

> *H1: WikiProjects as groups of Wikipedians show a similarity to the layering of communities according to Dunbar's 'rule of three' numbers (5, 15, 50, 150, 500). The sizes of groups of active users (editors in the last 3 months) are closer to these sizes than in the case of groups of declared users.*

The optimum number of a staff team, depending on the author, oscillates between three and 25 people, subject to slight modifications. Teams of 5 to 12 people are considered to be most effective (Robbins, 2002), or from 3 to 8 people (Gellert Manfred and Nowak Claus, 2008). Therefore, it is to be expected that small numbers of users will be the most active, regardless of the total number of users enrolled in WikiProjects. This justifies the second hypothesis.

> *H2: The ratio of active users to all WikiProject participants decreases as the number of WikiProjects participants increases.*

As MAS had previously been correlated with the activity of Wikipedians (Pfeil et al., 2006; Karczewska and Kukowska, 2021), it seems reasonable to also correlate it with the activity of WikiProjects participants. It is noteworthy that the focus of activity in Wikipedia is primarily on individual action, close to the cultural dimensions described as masculine.

> *H3: The ratio of active users per language version to the total number of users enrolled in projects correlates with a lower Masculinity Index (MAS).*

To verify the afore-mentioned hypotheses, statements of the following variables were prepared:

- The number of total participants enrolled in the individual WikiProjects in the language versions studied;
- The number of active WikiProjects participants in the last 3 months;
- The number of active WikiProject users as a proportion of the total number of enrolled users per language version;
- The number of WikiProject domains - the number of WikiProjects from the selected knowledge domains from a pool of 33 WikiProjects that occurred in the language version;
- MAS - masculinity versus femininity.

4. Research Results and Discussion

4.1 Size of the WikiProjects Editorial Community vs. Dunbar's Number

The study verified user activity through their participation in WikiProjects. For a better illustration and a certain level of smoothing of the high-variability data, the calculation used in the study involved the average measured for the k (equal to 5, 7, 9 and 11, respectively) of the consecutive user groups. The boundary value

for the test (for two mean values) is equal to 1.64. A very clear change in the number of participants is observed for WikiProjects with group sizes of 14-20 participants (depending on the length k from t∈{-1.80 : 5.88}, for each t p < 0.036), with their dynamics only decreasing around groups of 35. Another clear change starts for projects with 45 participants and slows down around 51 (for the 11-period series 69) participants with an incidental point of 59 participants. The last statistically significant decrease in active WikiProjects users in the studied range (up to 200 participants) includes counts for 112 participants. As k = 11, we still register significant drops in the number of participants at 120-129. However, we also observe statistically significant increases for 39 (t = 2.200; p = 0.014) participants, 52 (t = 2.157; p = 0.015) participants and 106 (t = 2.449; p = 0.007) participants. Each of these groups is significantly higher (in terms of numbers) relative to its neighbours (Fig. 1).

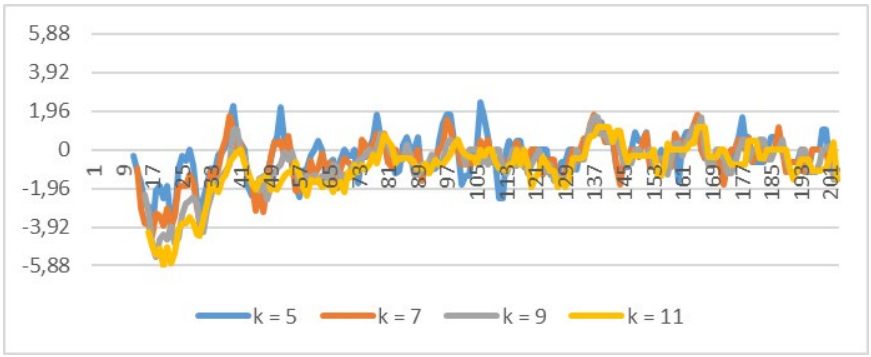

Figure 1: Average Test Values for the Number of WikiProjects with a Given Number of WikiProjects Participants Depending on Their Size

The results show significant changes in the number of WikiProject participants primarily in the layer referred to by Dunbar as the support group, whose numbers include approx. 15 people. These groups form strong bonds and in this group, the individual may receive support in daily activities. The next layer is the so-called good friends, whose numbers are approx. 50 people. In the case of WikiProject participants, the groups and the changes in them number counts between 35 and 45 are visible. The size of the groups of Wikipedians involved in WikiProjects show a similarity to the layering of communities according to Dunbar's number. It may therefore be assumed that H1 has been positively verified.

In H2, it was assumed that the ratio of active users with regard to all WikiProject participants decreases as the number of WikiProjects participants increases. There is a weak, yet statistically significant negative linear correlation (r = -0.097; p = 0.008) between the number of people subscribed to WikiProjects and the percentage of active users. As WikiProjects teams grow, the ratio of those enrolled with regard to active participants decreases.

4.2 Masculinity Index (MAS) of Individual Language Versions and the Activity of WikiProjects Participants

The study assumed that the ratio of active users in each language version with relation to the total number of users enrolled in the projects correlates with lower MAS according to Hofstede (H3). The results did not support (r_s = 0.115; t = 0.677; p = 0.503) this hypothesis (Fig. 2). This may be due to the fact that there is very little representation of women both in the different versions of Wikipedia and in most WikiProjects.

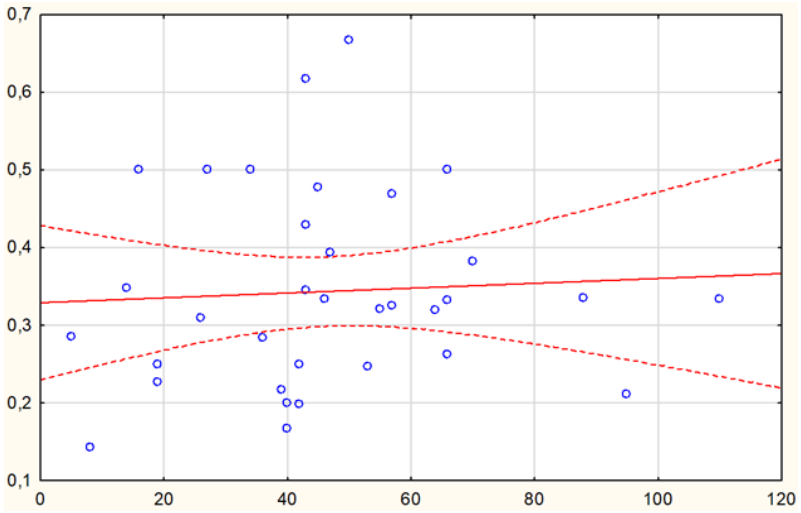

Figure 2: Relationship Between the size of MAS and the ratio of Active WikiProjects Members to Total WikiProjects Subscriptions

WikiProject structures develop in a spontaneous process, with the impetus for their creation coming from topics in various fields. The studied WikiProjects were characterised using Ward's clustering method. This gave control over the resulting number of groups, allowing the most natural clusters of survey elements to be presented (Szajt, 2014). For the 2021-2022 data, it seems clear that there are two main clusters, the first more numerous and the second far less numerous. In the former, a close proximity is observed between medical science, whereas sport in the latter – biographies, flying, films, football aside, as it were. Data from 2022-2023 with the same indicators (WikiProjects in selected language versions) and little change in the number of participants yielded a different result. For the 2022-2023 data it seems reasonable to divide it into three main clusters, the first and second more numerous and the third far less numerous comprising only biographies, flying, films, football (isolated earlier) and anime & manga, while also computer games. In the first focus, the previously observed close proximity between medical science and sport extended to music and musicology. WikiProjects are seemingly grouped together regardless of subject matter. However, in the right-hand side of both graphs (Fig. 3 and 4) are the very popular WikiProjects related to the sphere of mass culture. Biographical topics, on the other hand, cover a large part of Wikipedia and heated disputes often erupt around them. Aviation, on the other hand, gathers disproportionately more hobbyists than other technical and military issues.

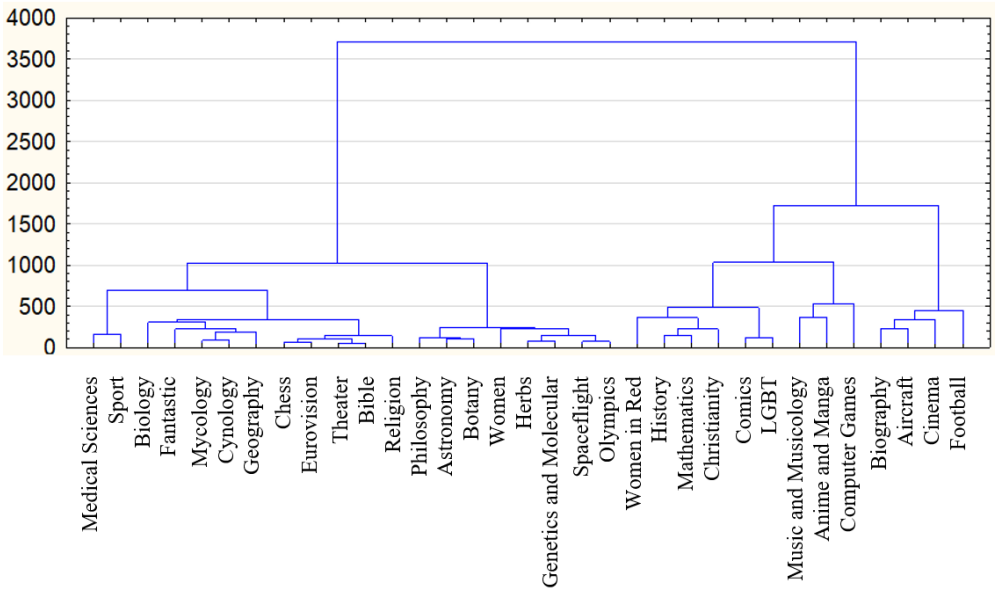

Figure 3: Ward Cluster Analysis Graph (Euclidean distance) for WikiProject in 2021/2022 by Popularity in 34 Language Groups

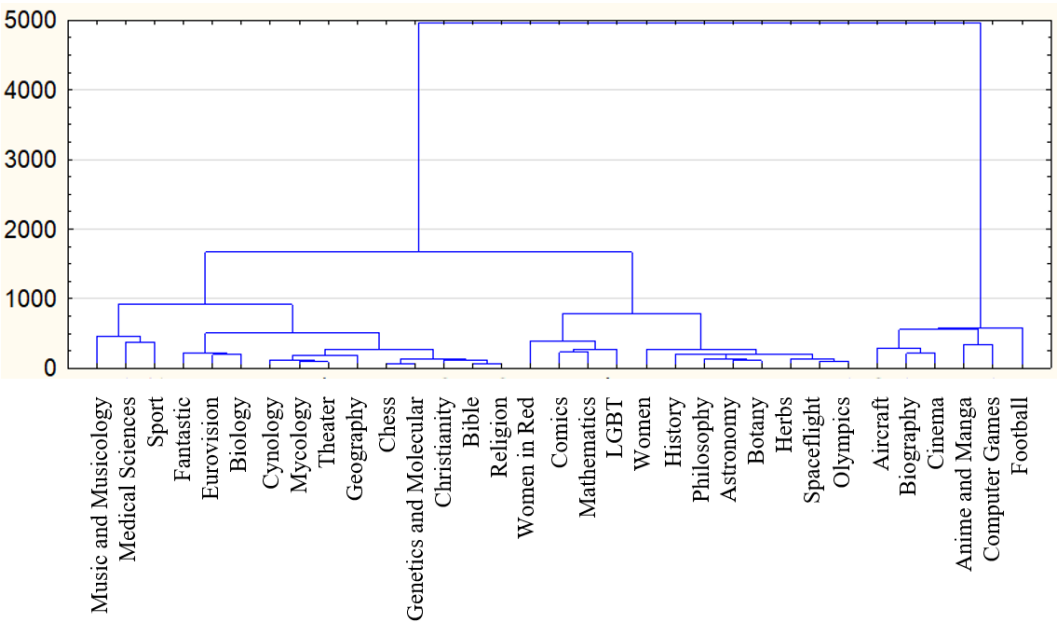

Figure 4: Ward Cluster Analysis Graph (Euclidean distance) for WikiProject in 2022/2023 by Popularity in 34 Language Groups

5. Conclusions

Measuring membership in WikiProjects and measuring the productivity of these communities has been cited as one of the significant difficulties associated with studying WikiProjects (Solomon and Wash, 2014). A practical contribution to the research so far is the presentation of the ratio of declared participation in WikiProjects to actual commitment to work for the improvement of Wikipedia. The "Who is active" tool used in the study simplified the data counts and made it possible to scan this work as a single source. Counting only the declared participation in a given WikiProject in advance was fraught with the falsification of participant activity. The fact that the majority of efforts to make content public are made by a vast minority of individuals was pointed out by Peddibhotla and Subramani (2007) and Raban and Rabin, (2009). The characterisation of online group structures based on the actual activity of their members facilitates a better description of the communities studied. In the future, expanding the research to include more WikiProjects and more language versions of Wikipedia would enable more accurate conclusions.

It seems that with the organisational changes brought about by the global pandemic, the theme of the emergence of spontaneous collaborative structures in online communities has become even more cognitively attractive. The safety and security crisis has changed perceptions of the determinants of online group activity and thus the specifics of their functioning and effectiveness. The production of value in social interactions in the online sphere, the ability to work together as a team in physical isolation, is becoming increasingly important. The conditions surrounding these processes are therefore worth exploring.

6. Limitations

The method used to measure participation in WikiProjects from lists of their participants was not possible in every case. This is because it is not a universal way of declaring participation in WikiProjects. In several cases, the count required searching for participants on directly inaccessible WikiProject subpages. Despite the care taken in mapping the data, the values of which are often small in terms of recently active members, there remains a margin of error that is difficult to estimate. A different issue also highlighted by Morgan et al. (2013) remains the contribution to the WikiProjects of individuals who do not explicitly declare their affiliation.

Abstract: Nowadays, public and private organisations appear increasingly committed to fostering the skills necessary to deal with the challenges of the current scenario. From this perspective, public and private organisations are developing new spaces for learning. The notion of learning space draws its origin and main application in educational institutions. However, it constitutes a distinctive concept for all the organisational contexts in which the creation and management of knowledge and learning dynamics are enabling factors that support innovation and growth dynamics. Although several studies have already discussed the features characterising a learning space or a learning environment, the literature is fragmented and does not provide a comprehensive, fresh view of the learning space, its components, or its impact on learning processes and knowledge dynamics. This is particularly true in management literature. The research results synthesise data and knowledge gathered from the systematic literature review, providing researchers and practitioners with an integrative picture of the definitions of "learning space" and "learning environment" in the management literature and producing a descriptive framework that highlights the relevant dimensions that influence learning processes and knowledge dynamics.

Keywords: Learning environment, Learning space, Knowledge dynamics, Management, Systematic literature review

1. Introduction

Nowadays, public and private organisations appear increasingly committed to fostering the skills necessary to deal with the challenges of the current scenario by enhancing their learning capacity. The current scenario is increasingly complex and characterised by uncertainty and volatility; therefore, organisations need to develop innovation capacity, considered a key driver for survival, competitiveness, and long-term growth and success (Hamidi et al., 2019). Innovation capacity refers to the organisation's ability to develop new ideas, products, services, or processes that foster new value for the organisation, its stakeholders, and the surrounding environment. It involves the ability to recognise and respond to changes in the business environment, as well as the ability to leverage internal and external knowledge and resources to create new opportunities (Yildiz et al., 2021).

A range of factors influence it, and most are related to the processes of learning and knowledge. In fact, for an organisation, learning and knowledge processes and dynamics represent the engine for developing the capabilities for sustainability in the new business age (Nonaka and Takeuchi, 2019; Hamidi et al., 2019).

In such a perspective, several researchers emphasised the importance of learning orientation, knowledge sharing, and the learning environment as critical determinants of innovation capacity (Yildiz et al., 2021).

Individuals with a strong learning orientation are more likely to expose themselves to new knowledge and have a higher capacity to recognise, assimilate, and exploit it. Knowledge management is a driving force for innovation because it allows identifying, collecting, sharing, and applying knowledge and turning knowledge capital into real outcomes. Therefore, effective knowledge management practises, including knowledge sharing, can contribute to the development of innovation capacity. Moreover, a learning environment or learning space refers to the physical, social, and cultural context in which learning occurs. In this vein, according to the literature, in the last few years, new spaces to foster innovation and boost learning and knowledge dynamics have increasingly become key objectives for public and private organisations (Yildiz et al., 2021; Morris, 2020; Hamidi et al., 2019).

The literature suggests that learning spaces are places where knowledge is created, shared, and applied; they may be described as spaces of interaction between individuals, their behaviours, and the external environment.

Despite their growing importance, the literature is fragmented, and there is a gap concerning a comprehensive and holistic view of the distinguishing dimensions of learning spaces (Csizmadia et al., 2022; Cheng, 2015).

In this regard, this study aims to identify dimensions and features that characterise effective learning spaces and may support innovative capacity development.

The research is carried out through a systematic literature review answering the question, "What are the dimensions of a learning space that influence learning and knowledge dynamics?" aimed at providing an integrative picture of the evolution of the concept and definition of "learning space" and "learning environment" in the management literature, producing a descriptive, theoretical framework that supports the identification of the relevant dimensions that should be managed and evaluated. Specifically, it aims to guarantee and enhance the effectiveness of a learning space.

2. Research Methodology

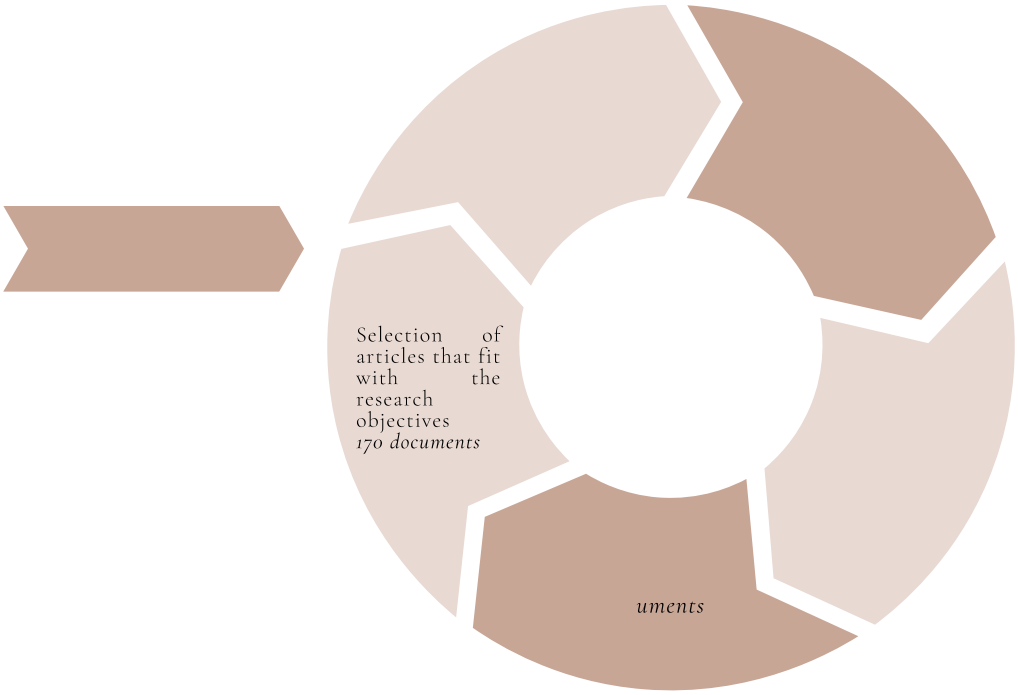

Figure 1: Steps of the Research Process and Number of Selected Papers

The management literature provides a vast amount of data and articles, and analysing them is a challenging task. (Crossan and Apraydin, 2010). One of the responses is to undertake an extensive analysis of the contributions in the literature. The adopted approach proposed by Tranfield et al. (2003) is a scientific and transparent process reported in sufficient detail to permit replication (Tranfield, 2003). With a SLR approach, insights and evidence from the literature have been found, synthesised, and evaluated.

Tranfield et al. (2003) proposed three main phases: i) planning the review; ii) conducting an inspection; and iii) reporting and disseminating.

The first step, concerning the planning phase, was conducted by defining keywords and searching terms to carry out the SLR. The search strings were defined according to the research question, derived from a first scoping review: "What are the dimensions of a learning space that influence learning and knowledge dynamics?". Initially, the research strings chosen were "learning space" AND "dimensions". However, formulating a query considering only these two keywords resulted in being too specific; indeed, given the plurality of terms used interchangeably to refer to learning spaces and dimensions, a broader selection requirement has been adopted to include all the significant studies, adding to the query other terms with "OR". In consequence, the selected research strings were "learning space" OR "learning environment" AND "dimensions" OR "components" OR "characteristics" OR"features". The search strings chosen are wide enough to understand the level of knowledge and contributions in this field and identify the areas to explore. The following steps concern the conduct of the inspection. With the scope of building a holistic and comprehensive understanding of the dimensions of learning

spaces, the approach concerning using multiple databases has been adopted. Specifically, the multiple databases considered were Web of Science (WoS) and Scopus, acknowledged as complete databases for academic papers (Falagas, 2008). The final set of works to be considered has been defined, identifying all relevant articles and removing duplicate papers.

In this case, predetermined criteria were chosen to decide what literature to include or exclude. Filters were applied to include articles already published in journals from 2009 to 2023 to focus on the most recent developments.

The research field of interest was Business, Management, and Accounting. Conference papers, articles not written in English, book chapters, and special issue editorials were excluded. All duplicate papers from different sources were identified and removed.

Titles, abstracts, and keywords of the remaining articles were analysed to include contributions aligned with the aims and focus of the analysis.

In fact, other exclusion criteria are chosen after a first scan of the essential article source information and concern the consistency between the article topics and the research questions. Specifically, contributions in fields disconnected from business, management, and economics were dismissed.

As a result of the research strings, after applying the selection criteria, 373 documents have been selected: 297 results from Scopus and 76 from the Web of Science. The documents were opened into a spreadsheet, and the duplicates were removed.

Then, reading the title, keywords, abstracts of identified papers, and full text, the essential documents for the research's purpose were selected. The notion of learning space has been approached from several perspectives and in diverse dimensions. Thus, the critical articles selected were 170.

3. Analysis of the Results

3.1 Distinctive Dimensions of a Learning Space

The concept of learning space emerges in the educational field within the socio-constructivist paradigm of learning, described as the result of the interaction between individuals and the environment.

Generally, an educational learning space may be recognised as a virtual location or a physical place, such as a classroom, a laboratory, a lecture room, or a workshop, where knowledge is created, shared, and applied (Morris, 2019).

The notion of learning space has its origins and main application in educational institutions. However, in the current scenario, the development of learning spaces or learning environments based on active methodologies and the use of new advanced technologies constitutes a distinctive concept for all the organisational contexts in which the creation and management of knowledge and learning dynamics are enabling factors that support innovation and growth dynamics. A learning space is a multi-dimensional space that includes different factors, characteristics, and dimensions. It can be formal or informal, and it can take place in a variety of settings, depending on the context of the application, such as classrooms, libraries, museums, online platforms, knowledge management systems, innovation laboratories, creativity rooms, co-working spaces, innovative workplaces, educational spaces, and lecture rooms (see, e.g., Nonaka and Takeuchi, 2019; Jung et al., 2018; Gonzalvez et al., 2014).

According to Kuokkanen and Van der Rest (2022), a learning space is not neutral but may significantly impact the learning process and outcomes. Learning spaces enable and facilitate the creation and sharing of knowledge and learning by managing tangible and intangible components. Although several studies have discussed the features of learning spaces, especially in educational contexts, there is still a gap regarding a comprehensive and holistic view of the distinguishing dimensions of learning spaces. This is particularly true in the management literature (Csizmadia et al., 2022; Mueller & Strohmeier, 2010).

In this context, this study aims to identify dimensions and features that characterise effective learning spaces and support and influence successful learning and knowledge activities and dynamics. The connections between all the dimensions of a learning space can be subtle and powerful for learning and knowledge dynamics. In sum, identifying a learning space's key dimensions would help better manage and assess its performance. In such a prospect, the study attempts to answer the following research question: "What are the dimensions of a learning space that influence learning and knowledge dynamics?"

A critical analysis of the extant literature suggests that it is possible to identify some distinguishing dimensions and components of learning spaces. These different dimensions are interrelated and mutually influence each other in defining and characterising a learning space. According to different researchers, the critical infrastructural components and dimensions are: i) the physical environment; ii) technological tools; iii) organisational resources; iv) actors and interactions; v) culture and atmosphere (see, e.g., Bindhu & Manohar, 2015; Csizmadia et al., 2022). Through a systematic literature review, this study analyses the dimensions of learning spaces more in depth, describing the elements and items included in every dimension. Each sub-dimension has a different weight and contributes differently to the development of a learning space. In the following, each sub-dimension will be analysed and discussed.

Table 1: Theoretical Framework: Learning Space Structural Dimensions

	Sub-dimensions	**References**
Physical Setting	*Virtual (e.g., individual space characteristics)* Hybrid *and physical (furniture, lights, colours, decorations, dynamic space, flexibility and adaptability, layout of the class, spaces and arrangements, study spaces, collaboration spaces).*	(Christensen et al., 2023; Jens and Gregg, 2022; Berbegal-Mirabent et al., 2021; Sasson et al., 2021; Dleikan et al., 2020; Sankari et al., 2018; Osorio et al., 2017; Lancaster and Milia, 2015; McLaughlin & Faulkner, 2012; Heiskanen & Heiskanen, 2011).
Technological resources	*Supporting and basic technologies (e.g., platforms, tablets, smartphones, webcams, projectors, digital whiteboards, platforms, headphones, digital watches, etc.)* *Advanced and 4.0 technologies (e.g., artificial intelligence, virtual reality, 3D printers, augmented reality, metaverse, big data, internet of things, additive manufacturing, machine learning, smart factories, etc.)* *Software*	(Abdalina et al., 2022; Ali et al., 2022; Ghani et al., 2022; Lee and Tan, 2022; Lu, 2022; Reyes-Mercado et al., 2022; Hines and Netland, 2022; Upadhyay and Khandelwal, 2022; Safdar et al., 2022; Snieder and Zhu, 2020; Eisenbardt, 2021 Renz and Valdova, 2021; Renz & Vladova, 2021; Akdere et al., 2021; Sasson et al., 2021; Delgado et al., 2020; Hliouli et al., 2020; Latrous & Khadraoui, 2020; Rasheed et al., 2020; Marta, 2019; Borge et al., 2018; Gdanetz et al., 2018; Aouf et al., 2017; Lau, 2015; Mahenge & Mwangoka, 2014; Olsen et al., 2011; Huang et al., 2010; Jurasaite-Harbison, 2009;
Organisational Resources	Methods, processes, and activities Systems of practises and procedures that providers use to support and enrich the learning processes and knowledge dynamics *(e.g., project- or problem-based learning, design thinking, storytelling, collaborative communities, web-based videos, narrated stop-motion animation, modelling, gamification, simulation, flipped classrooms, content-driven processes, etc.)* The topics, themes, concepts, and facts, often grouped into subjects, that are expected to be learned (e.g., economics, entrepreneurship, digitalization, STEM subjects, etc.) Economic resources	(Yan et al., 2022; Nashaat et al., 2022; Mojtahedi et al., 2020; Wannapiroon & Petsangsri, 2020; Zakaria et al., 2019; Xu et al., 2018; Corney, 2018; Song et al., 2018; Filippou et al., 2018; Aggarwal, 2017; Dai & Bal, 2009; Jurasaite-Harbison, 2009; MacNeil et al., 2009)
Actors and interactions	*Knowledge providers (e.g., teachers, professors, researchers, mentors, entrepreneurs, facilitators, etc.)*	(Lee and Tan, 2023; Abuhassna et al., 2022; Ching Lee and Yian Tan, 2022; Müller and Wulf, 2022; Toiviainen et al., 2022; Bianchi & Vignieri,

	Sub-dimensions	References
	Learners (internal or external: e.g., learners, students, organisations, managers, employees, staff, etc.) *Internal* *i. Horizontal (e.g. workgroup, peer relationships)* *ii.Vertical (e.g. scaffolding, supporting relationships, mentoring, leadership, etc.)* *iii.External (e.g. partnerships; coaching)*	2021; Delgrado et al., 2020; van Riesen et al., 2019 Sankari et al., 2018; Lancaster and Milia, 2015; Elmadani et al., 2015; Esichaikul et al., 2013; Mihalca et al., 2011; Jurasaite-Harbison, 200;
Culture and Atmosphere	*Culture and Atmosphere (e.g., open-minded culture, routine culture, flexible mindset, positive environment with* trust, cooperation, safety, risk-taking support, and equity, *formal or informal atmosphere, motivating and engaging environment, creative atmosphere, friendly atmosphere, academic atmosphere, active learning atmosphere, etc.)* KM culture *(the willingness to transfer, create, and share knowledge from tacit to tacit, tacit to explicit, and explicit to explicit)*	(Abuhassna et al., 2022; Csizmadia et al., 2022; Lee and Tan, 2023; Black & Mischel, 2023; Montiel-Ruiz et al., 2023; Gupta & Priyanka, 2023; Lazzari, 2023; Erdoğdu and Akrolu, 2021; Akhmetshin et al., 2019; Burusic, 2019; Maheshwari & Seth, 2019; Jung et al., 2018; Karkoulian et al., 2013).

3.1.1 The infrastructure of a learning space

As already mentioned, learning spaces enable and catalyse knowledge and learning dynamics, supported by tangible and intangible structural dimensions that foster open, honest, and receptive interactions among the stakeholders involved (Delgado et al., 2020). The dimensions are specified in Tab. 1 and further discussed in the following:

3.1.2 Physical setting

Learning spaces emerge as places where learning and knowledge dynamics are activated and supported. The management literature has highlighted the influence that the physical setting has on dynamics, interactions, and processes, as well as on individuals' skill development and behaviour definition. Consequently, attention to detail is essential to positively impacting the learning space's effectiveness.

The physical setting of a learning space refers to the physical and virtual space or spaces in which learning happens (Sankari et al., 2018).

The physical setting includes individual and common spaces. Scholars have discussed some key characteristics of such spaces: furniture, seating arrangements, lighting, temperature, decorations, and acoustics (Sasson et al., 2021). Furniture that facilitates the interactions between actors, tools, and the environment is preferred. At the same time, the quality of the air, luminous colour, and light can help develop a favourable and stimulating learning space (Dleikan et al., 2020; Jens and Gregg, 2022).

Generally, an effective learning space design favours engagement, creativity, and collaboration with a high level of comfort and flexibility. All the design elements characterising the space must merge into a synergistic whole.

Researchers pointed out that learning spaces are oriented and designed towards the learner and the learning and knowledge processes and are characterised by flexibility, functionality, participation, and empowerment in emerging and innovative spaces (Heiskanen & Heiskanen, 2011).

3.1.3 Technological resources

The technological resources dimension contemplates a combination of technological tools and infrastructures that enhance learning and knowledge processes and dynamics. Different technological tools can foster or prevent impacts on the learning process. Consequently, the design and management of a learning space must

be associated with choosing the appropriate tool to exploit their potential and maximise the value added (Delgado et al., 2020).

According to the literature, the technological dimension is considered a key factor in the success of learning spaces, as it enables learners to access a wide range of educational content and resources and to engage in active, experiential, and collaborative activities. They provide individuals with means for representing knowledge in multiple ways (Sasson et al., 2021).

The literature discussed the use of various technological tools, in particular supporting and basic tools, advanced and 4.0 technologies, and software. Examples of basic technological assets and software supporting learning and knowledge dynamics are platforms, computers, mobile phones, tablets, projectors, e-readers, 3D printers, headphones, digital watches, digital whiteboards, etc. (Latrous & Khadraoui, 2020).

More advanced technologies can contribute to the enrichment of learning by enhancing the learning strategy and institutionalising continuous learning and the protocol for sharing and transforming knowledge. Some representative examples pointed out in the literature are: Artificial intelligence, the Internet of Things (IoT), augmented and immersive reality, digital platforms, the metaverse, sensors, algorithms, adaptive learning platforms, and other smart technologies that facilitate interaction and collaboration in the learning process (Abdalina et al., 2022; Diaz Tito et al., 2021).

However, different researchers also acknowledge the limitations of technology, such as the need for effective data processing and the potential for technology to create a sense of isolation and disconnection among learners. In this vein, the individuals involved in a learning space must best integrate the technologies into the functioning mechanisms of the space (Snieder and Zhu, 2020).

3.1.4 Organisational resources

This dimension includes the tangible and intangible resources that support learning processes and knowledge dynamics within a learning space.

Specifically, it includes methodologies, contents, materials, and resources available to support learning. Learning methodologies are systems of practises and procedures that providers of knowledge employ to develop a learning process. Some examples of methodologies may be project- or problem-based learning, design thinking, storytelling, collaborative communities, web-based videos, narrated stop-motion animation, modelling, gamification, simulation, flipped classrooms, content-driven processes, etc. (Filippou et al., 2018; Maheshwari & Seth, 2019).

According to the literature, a key aim for developing new learning spaces is to understand what methodologies support and favour the introduction of technologies.

On the other hand, topics are themes, concepts, and facts, often grouped into subjects, that are expected to be learned (e.g., economics, entrepreneurship, digitalization, STEM subjects, etc.) (Aggarwal, 2017; Akhmetshin et al., 2019).

Schobel & Scholey (2012) identify other important organisational resources: economic resources and, specifically, the financial strategies adopted. The authors argue that learning spaces with well-defined financial strategies are linked to positive outcomes and are well-positioned for success.

3.1.5 Actors and interactions

The success of a learning space strongly depends upon the actors, how they are engaged within the facility, and how they interact with each other.

The nature of the people or users involved in learning spaces is vast. According to the literature, two types of knowledge actors can be identified in a learning space: providers of knowledge and learners. Learners can be an internal or external target; some examples are students, managers, organisations, employees, and staff. They are considered central actors, seen as active developers of their own learning, engaged in authentic learning and knowledge processes. On the other hand, providers are people who support learners, acting as coordinators who facilitate interactions and the exchange and development of knowledge. They assume great relevance and act as facilitators of the learning process. This role may coincide with that of teachers, professors, transformative leaders, innovation managers, researchers, mentors, entrepreneurs, facilitators, organisers, etc. (Stern et al., 2020; Pawlowsky et al., 2020; Nonaka & Takeuchi, 2019; Sankari et al., 2018).

Further studies state the importance of the prior knowledge and skills of the actors involved in obtaining a successful performance. Prior knowledge, which may cover several contents and skills, interacts with other variables to influence learning outcomes and can be further enhanced through a culture oriented to knowledge and the interactions among actors (Mihalca et al., 2011).

The actors' interaction concerns the system of interactions between internal and external actors that take place in the learning environment. According to the literature, the design of the learning space has to promote positive relationships and a sense of belonging (Abuhassna et al., 2022).

The actors' interaction concerns the system of interactions between internal and external actors that take place in the learning environment. According to the literature, the design of the learning space has to promote positive relationships and a sense of belonging to enhance motivation and engagement.

Learners and providers continuously engage with each other and with the learning space. The interactions can be horizontal, vertical, or external. Horizontal and vertical interactions can take various forms, such as verbal communication, written communication, scaffolding, collaboration activities, feedback, and reflection. In a physical setting, interactions may occur through face-to-face discussions and group work, whereas in an online learning environment, interactions may occur through discussion forums, video conferencing, and other digital communication tools.

Concerning external interactions, physical proximity increases communication, face-to-face contact, and knowledge spillovers. In this vein, clusters of organisations with a high level of linkage between them and universities and R&D centres can foster success in learning environments (Toiviainen et al., 2022).

Effective interactions require active participation, mutual respect, and a willingness to engage in constructive dialogue and feedback (Delgrado et al., 2020).

3.1.6 Culture and atmosphere

This dimension identifies the mood, attitudes, expectations, practises, norms, and sensorial qualities distinguishing a learning space. It influences the effectiveness of the space by increasing or preventing motivation, attention, creativity, and the level of involvement of people. A learning space includes constructs concerning the experiences lived by the individuals involved and influenced by their behaviour. The quality of a learning space is strongly influenced by the nature and orientation of the actor's culture. (Pawlowsky et al., 2020) A positive learning environment promotes an open-minded culture, flexibility, and willingness to engage in innovative activities. It provides opportunities for learners to explore new ideas and concepts and to develop critical thinking and problem-solving skills (Burusic, 2019). Together with the actor's culture, the development of a strong knowledge culture is also a key determinant of the learning space's effectiveness. Knowledge culture drives and encourages the coding, transfer, and application of knowledge to promote learning and innovation. (Abuhassna et al., 2022; Csizmadia et al., 2022; Karkoulian et al., 2013).

The atmosphere of a learning space refers to the shared values, beliefs, attitudes, and behaviours of the individuals who participate in the learning process. It includes the norms and expectations that guide interactions among learners and instructors, as well as the creativity, level of collaboration, respect, and inclusivity fostered within the learning space. A positive learning atmosphere is fostered by supportive, friendly, active participation, critical thinking, and constructive feedback. It also values diversity and promotes a sense of community and belonging among learners. The atmosphere can be formal in traditional learning processes or informal in unstructured settings (Jung et al., 2018).

A favourable culture and energy translate into the behaviour of people who appear involved, focused, and engaged in the learning processes and dynamics.

4. Concluding Remarks

Nowadays, public and private organisations appear increasingly committed to fostering the innovation capacity necessary to deal with the challenges of a complex and uncertain scenario. A range of factors influences innovation capacity, and most of them are related to the processes of learning and knowledge. In fact, for an organisation, learning and knowledge processes and dynamics represent the engine for developing the capabilities for sustainability in the new business age. In such a perspective, learning environment, knowledge, and learning dynamics are considered key determinants of innovation capacity; therefore, spaces to foster innovation and boost learning and knowledge dynamics are acquiring increasing importance and becoming key objectives for public and private organisations.

The literature suggests that learning spaces are places where knowledge is created, shared, and applied; they may be described as spaces of interaction between individuals, their behaviours, and the external environment. Although several studies have already discussed the features characterising a learning space or a learning environment, especially in an educational context, the literature to date is fragmented and does not provide a comprehensive, fresh view of a learning space, its infrastructural dimensions, or the impact that has on learning processes and knowledge dynamics. This is particularly true in management literature.

In such a context, based on a systematic review of the literature, this study provides a clear and holistic understanding of the infrastructural dimensions characterising a learning space to support the management and assessment of these spaces in educational and organisational contexts.

Consequently, the systematic literature review has provided a consistent background for developing a theoretical framework.

Learning spaces are characterised by: i) a physical setting; ii) a technological dimension; iii) organisational resources; iv) actors and interactions; v) culture and atmosphere.

The research results synthesise the data and knowledge gathered from the literature review and offer implications and insights both for theory and practice. From a theoretical viewpoint, the paper contributes to the further development of the literature about LS by providing a definition suitable for different levels of application, specifically: "the physical, virtual, and hybrid space, of formal or informal nature, characterised by action and interactions among different actors and their capabilities, which promotes cognitive processes and influences knowledge and learning dynamics through its tangible and intangible components, generating innovation capacity." Then, the study identifies specific variables and dimensions to consider to support innovation dynamics within a public or private organisation.

Moreover, the analysis of the literature reveals the importance given to the management and assessment of learning spaces. In fact, managing and assessing a learning space is necessary to ensure its effectiveness, achieve goals and objectives, and trigger a virtuous cycle of improvement. (Reyes Mercado, 2022; Greasley and Bennet, 2014; Grieves et al., 2005)

Managing a learning space means creating an environment that supports learners' learning and knowledge processes. Specifically, effective management of a learning space involve:

- providing resources and materials that are relevant to the learners,
- creating a safe and welcoming physical space, and
- establishing clear expectations and guidelines for behaviour.

Therefore, several researchers suggest a need for further research on the management and assessment of learning spaces, particularly in terms of defining all the performance dimensions, selecting appropriate technologies, providing training and support for knowledge providers and learners, monitoring usage and engagement, and continuously evaluating and improving the space and the activities organised. The studies emphasise the importance of gathering feedback from learners and knowledge providers to ensure that the learning environment meets the needs of all actors (Reyes-Mercado, 2022; Müller F.A.; Wulf T., 2022; Erdoğdu and Çakıroğlu, 2021; Greasley and Bennet, 2014; Mueller and Strohmeier, 2011). Moreover, from the literature, it emerges that there is a need to focus on learning spaces developed in the digital age, specifically those developed integrating advanced technological tools such as augmented and virtual reality, the metaverse, artificial intelligence, and the internet of things.

Concerning more practical implications, the paper provides managers with a theoretical framework that may support different actors (e.g., universities, organisations, companies, and public administration offices) to make informed decisions and management plans based on key data and knowledge and to develop effective learning spaces supporting virtuous cycles of learning, knowledge management, and innovation.

The Fusion of Talent Management and Knowledge Management: An Odd Couple or Happy Nuptial

Lawrence Abiwu and Isabel Martins
University of KwaZulu-Natal, South Africa

AbiwuL@ukzn.ac.za

Abstract: The purpose of this paper is twofold, firstly, to explore the factors that affect the retention of knowledge workers in South African higher education institutions; secondly, to show how talent management can benefit knowledge management practices. The mixed-methods design was employed to collect and analyse the quantitative and qualitative data. Stratified and purposive sampling techniques were used to select 347 respondents from three South African universities. Questionnaires and interviews were used to collect the data from 277 participants. The Statistical Package for the Social Sciences was used to analyse the quantitative data, while the qualitative data was analysed using NVivo (version 12.0). The quantitative and qualitative findings confirmed that work-life balance, promotion and employer-employee relationship positively impact the retention of knowledge workers in South African higher education institutions. This study provides a deeper understanding of how universities could leverage employee promotion, employer-employee relationship and work-life balance to retain knowledge workers in the competitive business environment. The study demonstrates that factors of talent management such as promotion, employer-employee relationship and work-life balance, are viable tools for retaining knowledge workers to position higher education institutions at the cutting edge. These factors can benefit knowledge management practices. The study expands on the limited research on employee retention strategies, talent management and knowledge management.

Keywords: Employee-employer relationship, Knowledge management, Talent management practices, Talent retention, work-life balance

1. Introduction

Igielski (2017) argues that, in the last decades, there have been changes in the traditional approach to work to a more modern approach, such as computerisation of workstations and distance work. Consequently, employees' skills and competencies have also changed to meet the new expectations of the employers involved in identifying and acquiring knowledge. Muzam (2022) maintains that the world economy has shifted from the traditional production system into a more service-oriented economy known as the knowledge economy. Choong and Leung (2021) and Servoz (2019) advocate that the new economy requires employees with technical know-how in almost every sector. The aforementioned assertions emphasise the importance of knowledge workers. The latter systematically acquire knowledge and have a high level of education and unique skills required to assist the organisation in achieving its goals. From the knowledge-based view (KBV) of the firm standpoint, knowledge resides at an individual level, making its integration a vital function for an organisation (Grant, 1996).

De Sordi, Azevedo, Bianchi and Carandina (2021) point out that knowledge workers use and apply organisational knowledge. Surawski (2019) compared knowledge workers with other workers, including white collars and experts, and concluded that one key feature of knowledge workers is that they work mainly with symbols and transform them into cognitive processes, creating value for the organisation. Muzam (2022) concurs that knowledge workers are autonomous individuals whose work depends on a high level of knowledge and perform complex tasks primarily focusing on problem-solving. However, it has been found that because of the competition for talent, knowledge/talent retention has become a critical issue for many firms and an equally challenging situation for most employers. For instance, Lesenyeho, Barkhuizen and Schutte (2018) assert that nearly half of the academics in South African higher education institutions (HEIs) have considered leaving their jobs. Yimer, Nega and Ganfure (2017) shared similar sentiments, in that academic turnover in South African HEIs has been a major concern as it disrupts the normal functioning of academic enterprises. In a recent study, Barkhuizen, Lesenyeho and Schutte (2020:191) argue that the voluntary turnover intentions of academics in South African HEIs are escalating, which presents significant challenges to HEIs, including “additional costs for the induction and training of new staff, loss of research outputs and organisational productivity, and reduced quality of teaching due to mid-semester replacements of lecturers”. According to Lesenyeho and Schutte (2020), compensation and recognition, as well as institutional practices had significant influence on employees’ intention to quit their jobs. Musakuro and de Klerk (2021) acknowledge that most academics leave South African HEIs for better compensation and career opportunities.

Several scholars have proposed diverse opinions and solutions to address the retention challenge in South African HEIs. For instance, Kanyumba and Lourens (2021) found that retention strategies include compensation and benefits, succession planning, training and development and career development opportunities. Similarly, Lesenyeho and Schutte (2020) suggest that HEIs redevelop talent management (TM) practices such as compensation and recognition, career development and general institutional practices to address the diverse needs of a new generation of academics. The extant literature suggests that most empirical studies on academic retention in South African HEIs focused solely on compensation and benefits, succession planning, training and development and career development opportunities (Kanyumba & Lourens, 2021; Musakuro & de Klerk, 2021; Lesenyeho & Schutte, 2020). However, there is limited empirical research concerning the influence of promotion, work-life balance and employer-employee relationship on academic retention in South African HEIs.

2. Literature Review

2.1 Talent Management

TM is not a novel concept. Nevertheless, it has been obscurely defined because of its complexity (Lockwood, 2006). Vladescu (2012) conceptualises TM as the integrated set of activities used by organisations to attract, retain, and develop the most talented people they need for future purposes. According to Aytaç (2015), TM is a process deemed to attract, develop, place, retain, and integrate highly qualified workforce members while having the potential for high performance per the organisation's long-term strategies to gain a competitive advantage.

McDonnell, Collings, Mellahi and Schuler (2017) point out that TM is gaining more significance as a vital component that creates value for organisations. Al-Dalahmeh (2020) postulates that TM has become a strategic topic for managers in global organisations. Contrary to the above findings, Al-Dalahmeh (2020) argues that although the strategic importance of TM, research in the area is still few, mainly conceptual research. Al-Dalahmeh's (2020) findings are consistent with Gallardo-Gallardo, Thunnissen and Scullion (2020) and van Zyl, Mathafena and Ras (2017), who believed that, although some organisations have implemented diverse TM practices, there are nevertheless many unknown issues of TM (Al-Dalahmeh, 2020; Gallardo-Gallardo et al., 2020) and these need to be investigated. This study attempts to address these issues.

2.2 Knowledge Management

In this competitive era every organisation requires knowledge in order to remain sustainable. According to Sokoh and Okolie (2021), knowledge creation is vital for oorganisational sustainability. The above assertion underpins the importance of knowledge management (KM) and KBV of the firm. The role of knowledge KM in organisations has become increasingly important in the knowledge-based economy. Skryme (1999) conceptualises KM as systematic activities that relate to knowledge and processes of creating, collecting, organising and carrying out in pursuit of organisational goals. Likewise, Sokoh and Okolie (2021) state that KM is concerned with discovering, creating, disseminating and utilising knowledge. Jones and Shideh (2020) discover that the essence of KM is to ensure that information is shared and transmitted to employees within organisations. For de Bem Machado, Secinaro Calandra and Lanzalonga (2022), KM represents the capacity to manage information, such as gathering knowledge, transforming knowledge into new strategies or ideas, and implementing and preserving it. Idrees, Xu, Haider and Tehseen (2023) contend that organisations have increasingly focused on KM techniques as they realised how necessary knowledge is to achieve sustainable competitive advantage.

2.3 Talent Retention Strategies

The estimated cost of employee turnover ranges between 1 to 2.5 times the employee's salary (Lewis & Heckman, 2006). Talent retention involves the science of maintaining employees in their current jobs within the organisation for a longer period (Lewis & Heckman, 2006). Also, Madurani and Pasaribu (2022) acknowledge that talent or knowledge retention involves retaining talent and ordinary employees to remain working with an organisation. In their study, Mabaso, Maja, Kavir, Lekwape, Makhasane and Khumalo (2021) found TM practices such as rewards, work–life balance, performance management system, improved training and development, employee recognition and career progression opportunities influenced talent retention in the consultancy industry. Moreover, Boakye, Arpoh-Baah, Odoom, Afram, Addai and Agyemang (2022) confirm that factors such as remuneration, care and concern from employers, training and development opportunities, an improved promotion system, conducive working environment and increased employee engagement, influenced retention of senior members in Ghanaian private tertiary institutions. This study focused on

retention strategies, such as work-life balance, employer-employee relationship and promotion, because these received little scholarly attention.

2.3.1 Work-life balance and talent retention

The term work-life balance was coined by Lockwood (2003) and has become popular in modern times, especially during the COVID-19 era. Osterman (1995) explains that work-life balance practices consist of institutionalised, structural, and procedural work arrangements and formal and informal practices, that assist people to easily manage both their work and family lives. Singh and Dubey (2016) argue that most employees leave their organisations because they feel that their emotions and passions have not been recognised. Moreover, Shockley, Smith and Knudsen (2017) and Hashim, Azman, Ghani and Sabri (2016) found that a strong link exists between work-life balance and employee retention. Likewise, Panda and Sahoo (2021) established that psychological empowerment partially mediates the relationship between work–life balance and the retention of professionals. Based on the above, the following hypothesis could be formulated:

H_1 There is a statistically significant relationship between work-life balance and talent retention

2.3.2 Employer-employee relationship and talent retention

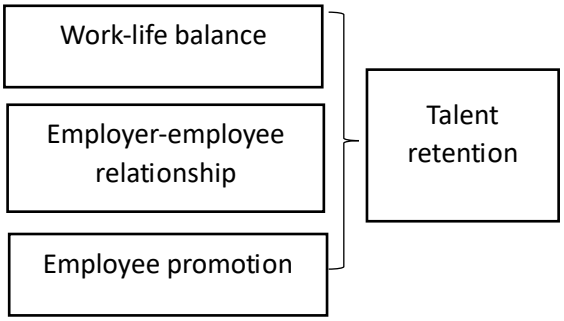
Torrington and Hall (1998) conceptualise the employer-employee relationship as a framework of organisational justice, which comprises organisational culture and management styles and rules, as well as procedures dealing with employee grievances. A good employer-employee relationship is also important because it encourages employees to work better and to achieve increasingly good results (Burns, 2012). Oruh, Mordi, Ajonbadi, Mojeed-Sanni, Nwagbara and Rahman (2020) found that managerialist employment relations had a negative effect on the retention of doctors in Nigeria. Kim, Tam and Kim and Rhee (2017), in their study, discover that organisational justice and organisation-employee relationship quality have a negative association with turnover intention. Based on the above, the following hypothesis could be formulated:

H_2 There is a statistically significant relationship between employer-employee relationship and talent retention

2.3.3 Employee promotion and talent retention

Promotion has been described as the movement of an employee from a lower position to a higher position within the organisational hierarchy (Otoo, Assuming & Agyei, 2018; Dessler, 2008). Promotion often results in a rise in the employee's salary, with a concomitant span of authority and control (Baker, Jensen & Murphy 1994). According to Netswera and Rankhumise (2005), the opportunity for promotion is an important reason for most workers remaining in their job, particularly those young and enthusiastic. Singh (2012) concurs that promotion increases the morale of employees and encourages them to take more interest in their work. Ekabu, Nyagah and Kalai (2018) and Sitati, Were and Waititu (2016) also confirm that that prospects of promotion significantly impacted employee retention within organisations. A study by Bibi, Pangil, Johari and Ahmad (2017) reveals that compensation and promotional opportunities had a significant relationship with employee retention. In their study, Ekabu, Nyagah and Kalai (2018) confirm that promotion prospect has a negative and an inverse relationship with turnover intention. By contrast, Fairris (2004) found that employee promotion is associated with high turnover. The findings by Fairris (2004) are also consistent with Joarder, Sharif and Ahmmed (2011), who discovered that employees' opportunity for promotion has less impact on faculty turnover decisions. Following the above, the hypothesis below could be formulated:

H_3 There is a statistically significant relationship between promotion and talent retention



2.4 Theoretical Framework that Underpins this Study

The KBV of the firm is the most appropriate theoretical lens upon which the study is predicated. The KBV theory maintains that knowledge is the most crucial resource of every organisation (Bontis, 2002; Barney, 1991). The KBV assumes that the most important input of production and primary source of value is knowledge (Grant, 1996). The term 'knowledge' has been conceptualised as a strategic resource that does not lose value as do traditional economic productive factors (land, capital, labour, and entrepreneurship) (Alchian & Demsetz, 1972). The KBV of the firm is further based on the premise that competitive success lies in the ability of the firm to develop new knowledge-based assets that create core competencies. The assumptions of the KBV of the firm are consistent with the aims of talent retention, which stimulates and inspires talented workforce to remain working with the organisation for a longer duration. The KBV of the firm is the most

appropriate theoretical lens because, when applied, it will help HEIs to generate, integrate, share and retain knowledge required to compete in the competitive markets.

2.5 Conceptual Model

The conceptual model upon which the study is predicated is shown in Figure 1.

Source: The Authors

Figure 1: Talent Retention Strategies in Higher Education Institutions

As depicted in Figure 1, work-life balance, employer-employee relationship and employee promotion positively impact talent retention in South African HEIs. This assumption is consistent which previous empirical research, which states that work-life balance (Mabaso *et al*., 2021; Smith & Knudsen, 2017), employer-employee relationship (Oruh et al., 2020) and promotion (Sitati *et al*., 2016) statistically impact talent retention in organisations.

3. Research Methodlogy

The study adopted pragmatism as the research paradigm because it offers an alternative approach integrating positivist and constructivist paradigms into one research, thereby determining how quantitative and qualitative methods are used. Descriptive and exploratory studies were conducted to adequately describe and provide an in-depth understanding of the talent retention strategies in South African HEIs. The mixed-methods research was used to validate the research findings. The study was conducted in three South African HEIs in Durban, Cape Town and Pretoria. The target population for the study was 3613, which included academics, cluster leaders, deans, and professional services. The stratified and purposive sampling techniques were used to select 347 participants for the study. The study variables were measured on a 5-point scale, ranging from strongly agree (5) to strongly disagree (1). The questionnaire comprised 16 items: work-life balance (4 items), promotion (4 items) and employer-employee relationship (7 items). The measuring instrument was validated and fit for this study. Quantitative data quality was determined through reliability and validity, while qualitative quality control was assessed through trustworthiness – credibility, dependability, conformability and transferability. The quantitative data was collected from 265 respondents, whereas the qualitative data was collected from 12 participants. The Statistical Package for the Social Sciences (version 27.0) was used to analyse the quantitative data. Descriptive and inferential statistics were computed to interpret the findings. For instance, Cronbach's alpha coefficient was used to determine the reliability of the measuring instrument, while factor analysis was computed to assess the validity of the measuring instrument. Moreover, Kaiser-Meyer-Olkin Measure and Bartlett's Test were utilised to assess the sample adequacy. Pearson's correlation (*r*) was used to determine the relationship between the dependent (talent retention) and independent variables (employer-employee relationship, promotion and work-life balance). The qualitative data was analysed using NVivo (version 12.0). The thematic analysis was employed to analyse the qualitative data to identify, organise and report the patterns or themes from the dataset.

4. Findings

Cronbach's alpha was computed to determine the reliability of the questionnaire. It helped to determine whether tests and scales adopted in this study are fit for purpose. Traub and Rowley (1991) suggest that the reliability score ranges from 0 to 1, with perfect reliability equalling 1 and no reliability equalling 0. According to the rule of thumb, reliability scores between 0.70 and 0.80 may be acceptable (Downing, 2004). The findings are shown in Table 1 below.

Table 1: Reliability of the Questionnaire - Cronbach Alpha

Variables	Number of Items	Cronbach Alpha
Employer-employee relationship	7	0.92
Promotion	4	0.74
Work-life balance	4	0.80

Table 1 shows that the reliability scores range from 0.74 (for promotion) to 0.92 (for employer-employee relationship), suggesting internal consistency. From the statistical point of view, the findings suggest a reasonable degree of reliability because they met the threshold. Therefore, the research instrument used to collect the data was reliable, and can be adopted by scholars in similar research Table 2 below shows the results of the exploratory factor analysis (EFA).

The EFA is usually applied in social science research (Razak, Ma'amor & Hassan, 2016). EFA aims to provide in-depth relationships among variables in a study. Therefore, EFA was used to evaluate the relationship between latent variables developing theoretical constructs. The EFA, using the principal component extraction method, was computed to reduce the number of factors in the structural model. Items with loadings >0.40 were regarded as highly significant when extracting the factors, making them more interpretable.

Table 2: Validity of the Questionnaire- Pattern Matrix[a]

	Component		
	1	**2**	**3**
EER1	.741		
EER2	.763		
EER3	.809		
EER4	.742		
EER5	.736		
EER6	.742		
EER7	.790		
P1		.699	
P2		.339	
P3		.546	
P4		.493	
QWL1			.635
QWL2			.799
QWL3			.710
QWL4			.588
Eigenvalue	**7.09**	**1.74**	**0.95**
% of variance	**47.26**	**11.57**	**6.30**
Extraction Method: Principal Component Analysis.			
a. 3 components extracted.			

From Table 2, the findings revealed that three factors could be extracted: Factor 1 (Employer-employee relationship), Factor 2 (Promotion) and Factor 3 (Work-life balance). The three factors explained 65.13% of the variance of the questionnaire. Furthermore, the findings showed that all the items in the questionnaire suggested acceptable loadings of > 0.30.

As explained above, the KMO and Bartlett's test measures the sample size adequacy, ranging from 0 to 1, reaching 1 when all the items were perfectly estimated without an error. Table 3 below shows the results of the KMO and Bartlett's test.

Table 3: Meyer-Olkin Measure and Bartlett's Test

Kaiser-Meyer-Olkin Measure of Sampling Adequacy.		**.901**
Bartlett's Test of Sphericity	Approx. Chi-Square	2273.605
	Df	105
	Sig.	.000

From Table 3, the measure of sample adequacy (MSA) score was 0.901 (marvellous). Statistically, the requirements of sampling adequacy were met. Thus, the sample was adequate for the factor analysis. Table 4 shows the descriptive statistics. Descriptive statistics were used to summarise the data in an organised manner, which helped to explain the relationship between variables in the sample. Measures of central tendency such as Mean was used to determine the inter-item consistency of the various constructs that formed part of the study. Using the scale of 1-5, a mean score value of 3.00 and beyond was considered significant, hence acceptable. Moreover, measures of dispersion, including standard deviation (SD) was used to describe the degree to which the data value for the construct is spread around the mean value.

Table 4: Descriptive Statistics

Dimension	**Mean**	**95 % Confidence Interval**		**Std. Dev.**	**Min.**	**Max.**
		Lower Bound	Upper Bound			
Employer-employee relationship	4.42	4.35	4.50	0.64409	1.00	5.00
Work-life balance	4.41	4.34	4.49	0.61909	1.00	5.00
Promotion	4.32	4.25	4.40	4.5000	1.00	5.00

The findings from Table 4 suggest that the items measuring employer-employee relationship (Mean = 4.42), work-life balance (Mean = 4.41) and promotion (Mean = 4.32) have very high mean scores, exceeding 3.00. The findings indicated that all the variables that form part of this study are highly significant. This implies that the respondents perceived employer - employee relations, work-life balance and promotion as TM practices that influence the talent retention in HEIs. Table 5 shows the results of the inferential statistics using Pearson's correlation.

Table 5: Pearson's Correlation

		Talent retention	**Employer-employee relationship**	**Work-life balance**	**Promotion**
Talent retention	Pearson Correlation	1	-	-	-
	Sig. (2-tailed)				
	N	265			
Employer-employee relationship	Pearson Correlation	.909**	1	-	-
	Sig. (2-tailed)	<.001			
	N	265	265		
Work-life balance	Pearson Correlation	.869**	.681**	1	-
	Sig. (2-tailed)	<.001	<.001		
	N	265	265	265	
Promotion	Pearson Correlation	.767**	.492**	.619**	1
	Sig. (2-tailed)	<.001	<.001	<.001	
	N	265	265	265	265
**. Correlation is significant at the 0.01 level (2-tailed).					

Table 5 showed a strong positive relationship between talent retention and the employer-employee relationship (r = 0.909, p < 0.001). Moreover, a strong positive relationship existed between talent retention and work-life balance (r = 0.869, p < 0.001). Furthermore, there was a strong positive relationship between talent retention and promotion (r = 0.767, p < 0.001). The subsequent section presents the qualitative findings. The data analysis suggests that talent retention strategies in South African HEIs included employee promotion, employer-employee relationships, and work-life balance. The following section describes the qualitative findings.

The qualitative data was collected from 12 participants through online interviews during the COVID-19 pandemic. The data was transcribed manually and analysed using NVivo. The study adopted the six qualitative data analysis steps proposed by Braun and Clarke (2006). These include data familiarization, generating codes, searching for themes, reviewing themes, defining themes, and write-up. Thematic analysis was adopted to help identify, organise and report the patterns from the dataset. Following this, mind maps were used as the visual representation to help sort the different codes into themes. Some codes were classified as main themes, whereas others were categorised as sub-themes. The thematic analysis revealed that promotion, employer-employee relationship and work-life balance were the talent retention strategies most employees valued most in higher education institutions. The themes which form the basis of the findings are shown in Figure 2.

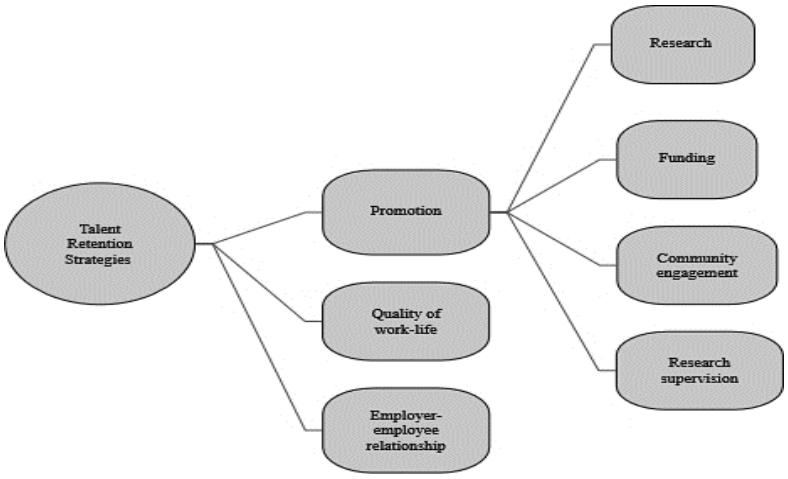


Figure 2: Talent Retention Strategies

4.1 Theme 1: Promotion

Based on the interviews, most (N = 7) participants argued that promotion was an essential TM practice that helped reduce labour turnover in South Africa. The following are some of the participants' quotes related to the findings.

Participant 7:

In academia, promotion is considered an important issue. Promotion, as a TM tool, can influence staff retention either positively or negatively. Institutions that value staff promotion is more likely to retain their human capital (Institution A).

4.2 Theme 2: Work-Life Balance

From the interviews, the majority (N = 9) expressed a similar opinion that quality of work-life balance was a vital TM practice that helped retain talent. The following are some of the quotes that emerged from the interviews.

Participant 1:

A better quality of work-life balance is the key to attracting and retaining qualified and motivated employees in an organisation. To reduce labour turnover, institutions like this have designed and implemented programmes such as flexible work arrangements to improve the quality of work-life for all staff (Institution B).

4.3 Theme 3: Employer-Employee Relationship

From the interviews, most (N = 7) participants believed that, although the employer-employee relationship influenced talent retention, the relationship among staff in South African HEIs was problematic. Some of the participants' views on the findings are stated as follows.

> *Participant 8:*
>
> *I am not sure that the relationship in this institution is a healthy one. We are supposed to be working together as teams, but some people act otherwise. For example, it is difficult for most staff to collaborate to publish papers (Institution A).*

5. Discussion

Barkhuizen et al. (2020, p.191) contend that the voluntary turnover intentions of academics in South African HEIs are escalating, which presents significant challenges to HEIs, including "additional costs for the induction and training of new staff, loss of research outputs and organisational productivity, and reduced quality of teaching due to mid-semester replacements of lecturers." Against this background, the study investigated TM practices influencing talent retention in South African HEIs. Three hypotheses supported the study. Hypothesis 1, indicated a statistically significant relationship between work-life balance and talent retention. Moreover, interviews were conducted to confirm and validate the quantitative results. This hypothesis was tested and achieved via mixed-methods research. The results of the quantitative and qualitative studies confirmed that work-life balance positively impacted talent retention in South African HEIs. The findings are consistent with previous studies (Shockley et al., 2017; Singh & Dubey, 2016), which state that a strong relationship exists between work-life balance and employee retention. According to Singh and Dubey (2016), most employees leave their organisations because they feel that their emotions and passions have not been recognised. In a recent study, Panda and Sahoo (2021) confirmed that psychological empowerment partially mediates the relationship between work–life balance and the retention of professionals. This study confirms that work-life balance leads to a stronger organisational commitment. It has been proven that employees who adhere to work-life balance programmes think more strongly about remaining in the same organisations for a maximum period. According to Panda and Sahoo (2021), 60% of research demonstrated that those employees who can balance professional responsibility with family and personal responsibilities have a greater tendency to remain in a particular organisation. The views of the above authors are also consistent with Kanwar, Singh and Kodwani (2009), who state that work-life balance programmes demonstrate the likelihood of increasing employee morale, reducing absenteeism and retaining employees.

Hypothesis 2, states that a statistically significant relationship occurs between employer-employee relationship and talent retention. This hypothesis was also tested and achieved through mixed methods. The results from the quantitative and qualitative studies agreed that the employer-employee relationship influenced talent retention in South African HEIs. Oruh et al. (2020) found that managerialist employment relations had a negative effect on the retention of doctors in Nigeria. By contrast, Kim et al. (2017) discovered that organisational justice and organisation-employee relationship quality are negatively associated with turnover intention.

Hypothesis 3, states a statistically significant relationship between promotion and talent retention. The results of the quantitative and qualitative studies confirmed that promotion positively impacted talent retention in South African HEIs. The findings are also supported by existing research. Sitati et al. (2016) confirm that promotion prospects significantly impact employee retention within organisations. Moreover, Bibi et al. (2017) confirm that compensation and promotional opportunities had a significant relationship with employee retention. Likewise, a study by Ekabu et al. (2018) reaffirms that promotion prospect has a negative and an inverse relationship with turnover intention. On the contrary, Fairris (2004) argues that employee promotion is associated with high turnover. Joarder et al. (2011) also found that employees' opportunity for promotion has less impact on faculty turnover decisions.

6. Managerial and Theoretical Implications

This study explored TM practices influencing talent retention in South African HEIs. The findings will be important tools for HEIs to retain their intellectual capital or knowledge workers. Theoretically, the findings will help expand knowledge on TM, KM and talent retention in HEIs. Thus, the study will provide better understanding of TM, KM and talent retention in HEIs.

7. Conclusion

Labour turnover in academic institutions worldwide has become a concern for many stakeholders of HEIs. For this reason, the study examined the TM practices that influence talent in South African HEIs. The findings demonstrated that TM practices, such as employer-employee relationship, work-life balance and promotion, positively impacted talent retention in South African HEIs.

8. Limitations and Directions For Future Research

The scope of the study only applied to South African HEIs, limiting the generalisation of the findings because of the differences in an organisational context. Hence, future research should focus on different industries.

Data Availability Statement

The original contributions presented in the study are included in the article. Further inquiries can be directed to the corresponding author.

Ethics Statement

The research protocol (HSSREC/00000852/2019) was approved by the University of KwaZulu-Natal Humanities and Social Sciences Research Ethics Committee.

Author Contributions

All authors mentioned in this manuscript have made a substantial, direct, and intellectual contribution to the work and approved it for publication. This article is published as an extension of the doctoral thesis pertaining to the first author.

Funding

This research received no specific grant from any funding agency in the public, commercial or not-for-profit sectors.

Competing Interests

The authors have declared that no competing interest exists.

How Sharing Pro-Environmental Knowledge Creates Business Management Processes

Małgorzata Łęgowik-Małolepsza
Technical University of Częstochowa, Poland

m.legowik-malolepsza@pcz.plz

Abstract: The study poses a research question: how does sharing pro-environmental knowledge create business management processes? Although pro-environmental knowledge is important for the success of modern enterprises, the literature on the subject does not provide insight into the dynamic processes taking place in the market environment of enterprises, not to mention how pro-environmental knowledge increases the attractiveness of enterprises' offers and allows them to react quickly to changes. Against this background, this study, conducted on a sample of 1,024 enterprises, analyzes the effects of introducing pro-environmental knowledge in the context of creating business management processes. Moreover, this study develops a holistic framework to explain the interactions between pro-environmental knowledge and tailored to the needs and expectations of all employees (Bissing-Olson, Iyer, Fielding, Zacher, 2013). Observations and the proposed framework shed new light on the understanding and acceptance of the creative role of pro-environmental knowledge in company management by company employees.

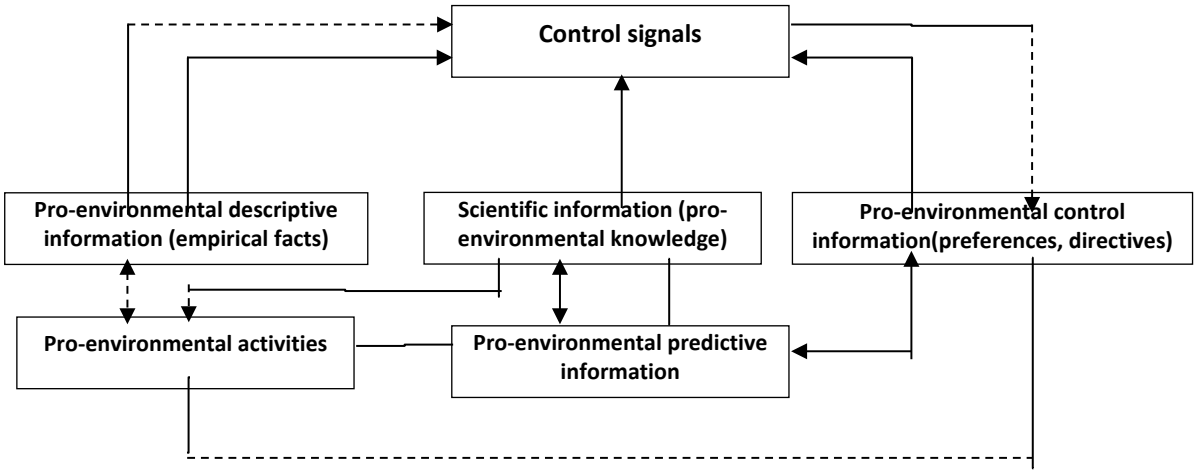
Keywords: Sharing knowledge, Pro-environmental, Business management processes

1. Introduction

The subject-matter related to pro-environmental activities is important not only due to the need to protect natural resources and minimize the negative impact on the natural environment, but also simply becomes fashionable among enterprises. In this paper “pro-environmental” knowledge is understood as ecological awareness regarding limited natural resources, environmental pollution or an increase in the level of consumer waste, which causes not only changes in consumer behaviour, but also the way of doing business by enterprises that see the need to implement pro-environmental activities (Norton, Zacher, Ashkanasy, 2015).

Possessing pro-environmental knowledge and its skillful application provides the opportunity to increase the attractiveness of offers of enterprises and allows for responding quickly to changes in the environment (Otola, 2009). However, to make this possible, it is necessary to implement an effective way of sharing pro-environmental knowledge in enterprises so that pro-environmental activities are understandable and acceptable to the company's employees. Sharing pro-environmental knowledge is also inextricably linked to adjusting pro-environmental activities to the needs and expectations of all employees.

2. Pro-Environmental Knowledge as a set of Information



Due to the role that pro-environmental knowledge plays in the area of business management processes, taking into account the time factor it refers to, the following types of pro-environmental information in an enterprise building knowledge can be listed (Pichert, Katsikopoulos, 2008):

- pro-environmental descriptive information - presenting the real world in the present time, showing its pro-environmental aspects concerning life and work, taking into account the pro-environmental relations between participants of economic processes, pro-environmental methods and techniques applied, technical and economic connections and various pro-environmental phenomena occurring in the real world,
- pro-environmental predictive information – which relates to predicting future pro-environmental phenomena and events, the scope of which is unlimited, it may refer to the spheres of social, economic, and technological life. As part of pro-environmental predictive information, one can distinguish scientific information, pro-environmental knowledge, which is the result of scientific research. It concerns the formulation of innovation related to, e.g., new pro-environmental technologies, production, or management processes and mainly refers to future pro-environmental applications. In the economic system, there is information called control information, through which it is possible to influence the pro-environmental behavior of people and the nature of decisions made by them. Control information consists of:
- pro-environmental information on preferences – this type of information is aimed at pro-environmental tastes of users and is intended to encourage specific behavior. This information concerns the identification of pro-environmental goals and functions as well as the assessment of

value, indicates the advantages and disadvantages of the solution, it is intended to encourage or discourage,

- pro-environmental directive information - which concerns control through various types of pro-environmental orders, prohibitions, instructions, guidelines, signposts, standards, rules, guidelines. In addition, it is to persuade people to make certain pro-environmental decisions.

The relationships between the four types of pro-environmental information listed above in the perspective of business management processes are presented in Figure 1, the interpretation of which shows the links in the course of development between various types of pro-environmental information (solid lines) and the relationships in the course of controlling development (dashed lines). The diagram also shows control signals, i.e., pieces of pro-environmental information "from the real-world system and the institutional environment, which connect them together and determine the degree of compliance of actions taken under the influence of control information with the existing situation."

Source: Own study based on: Wiatrak, 1997.

Figure 1: Types of Pro-Environmental Information and Connections Between Them

In regard to the presented division of pro-environmental information in economic processes, taking into account the time factor, the role of pro-environmental information in solving decision-making problems and making decisions should be emphasized. In the field of enterprise management, the place of pro-environmental information “primarily consists in the reduction in pro-environmental uncertainty, assessment of risk of planned strategic activities and the possibility of the company’s development”. Pro-environmental information plays an important role in building the company's knowledge, and thus the competitive advantage of the company, i.e., in maintaining the company in the market, which can be classified under the following categories (Huang, 2016):

- pro-environmental information as the basis for decisions - regardless of the position taken, a sufficiently detailed information base is necessary for the process of effective decision-making,
- pro-environmental information of strategic importance - pro-environmental information applies to all areas of the company's activity at the same time, it cannot be excluded from any department, therefore it has a global reach within a given company and affects all its management functions,
- ro-environmental information as "added value" - the added value of the product or service increases in proportion to the increase in available pro-environmental information on the stages of creating this product or service,
- pro-environmental information as a commodity - information has become the object of exchange, which takes place in purchase and sale transactions. Various types of business intelligence agencies and consulting companies deal with the sale of information.
- pro-environmental information as the fourth factor of production - information, in addition to labor, land and capital, affects the size of the company's income and costs,
- pro-environmental information as a factor affecting the functioning of society - today it is impossible to imagine life without access to such a huge source of information as the Internet, the impact of which on the functioning of society is indefinable,
- pro-environmental information as meeting the needs and possibilities of management - having a specific resource of information, the management staff have insight into the internal and external

situation of the enterprise, quickly notice emerging needs that can be satisfied by using the possibilities of management.

To sum up, the presented types of pro-environmental information create knowledge in the company. Its identification, dissemination and skillful use allow for gaining a competitive advantage and survive in dynamic market conditions. Streamlining knowledge sharing processes in enterprises shapes the possibilities of creating management processes in these enterprises.

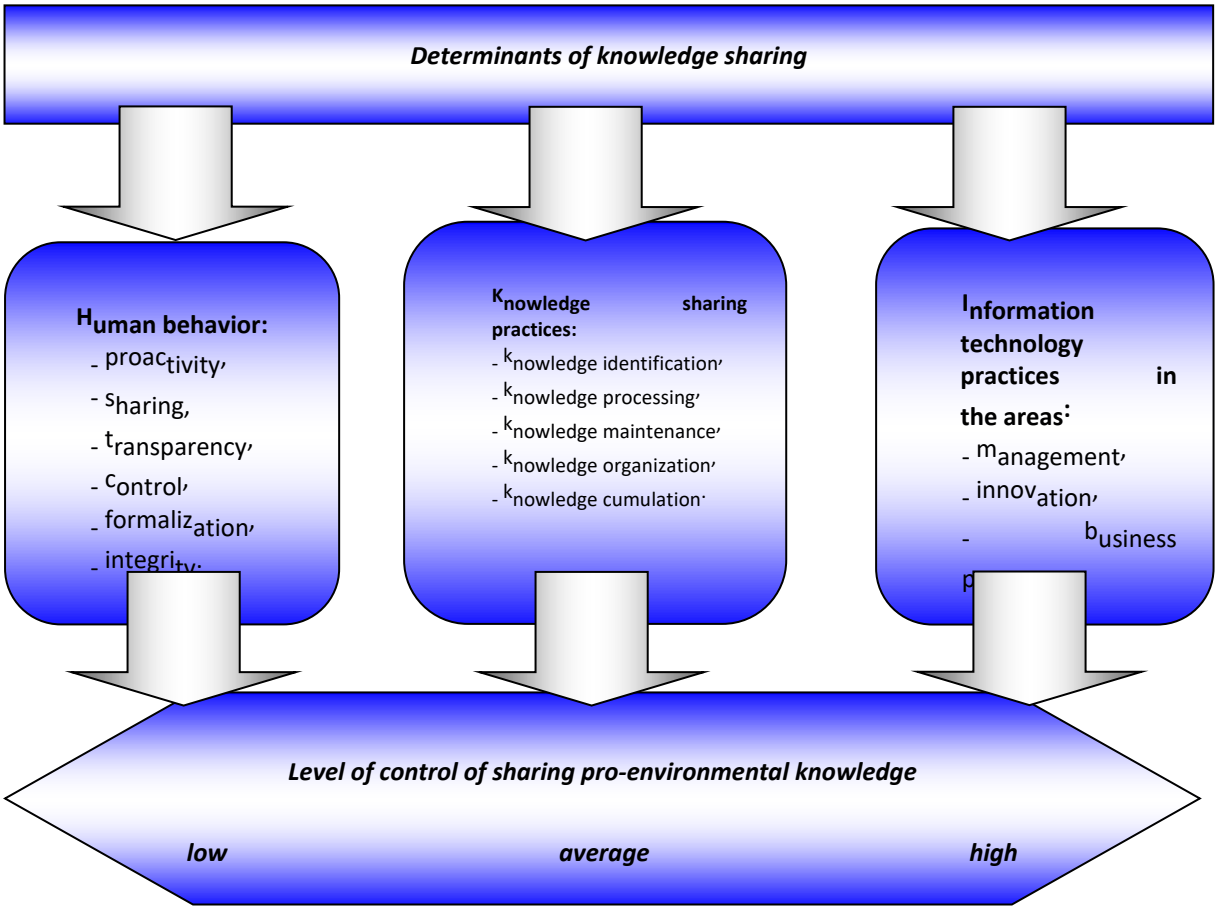
3. Determinants of Knowledge Sharing

When attempting to define the determinants of knowledge sharing, it is worth paying attention to the approach to information management, referred to as the concept of *information orientation* (IO) developed by D.A. Marchand (Marchand, 2000), which deals with the information behavior of employees, the technology applied and knowledge management. As a result of the conducted research, D.A. Marchand indicated the existence of competences affecting the effective use of knowledge and its sharing. Fifteen competencies have been divided into three areas of information management relating to:

- Human behavior - the first group includes 6 out of 15 employee competencies that should be instilled in the behavior of managers. They affect the values they present in relation to the use of knowledge and the following are distinguished here: proactivity, sharing, transparency, control, formalization, integrity.
- Knowledge sharing practices - the next five competences for the effective use of knowledge refer to the use of the company's potential to make the best use of information in the entire enterprise management process. The following competencies are distinguished in this group: knowledge identification, knowledge processing, knowledge maintenance, knowledge organization, knowledge cumulation.
- Information technology practices - the last 4 competencies concern the proper use of the available information infrastructure in the areas of: management, innovation, business processes and operations (Pavalache-Ilie, Cazan, 2018)·

The idea of the method is to show the relationship between the way of knowledge management, behavior of employees towards information and the technology used and the impact on the overall performance of the company (Davenport, Marchand, 2000). This efficiency can be measured by an increase in market share, level of innovativeness or increasing the company's reputation. The information-oriented approach to knowledge sharing integrates all levels of management and applies to all levels of activity (operational, tactical, and strategic). 15 competencies by D.A. Marchand affecting the effective application and sharing of knowledge are presented in Figure 1.

To sum up, the presented continuum of knowledge sharing conditions presenting 15 competencies by D.A. Marchand affecting the effective use of knowledge and sharing it, is a set of determinants of knowledge sharing, which, when implemented in the business activity of the entity, increase its chances of survival in the dynamic market environment of enterprises.



4. Objectives of Sharing Pro-Environmental Knowledge and Enterprise Management

The objectives of sharing pro-environmental knowledge in the enterprise can be considered in relation to three levels: enterprise resources, enterprise functions, management problems.

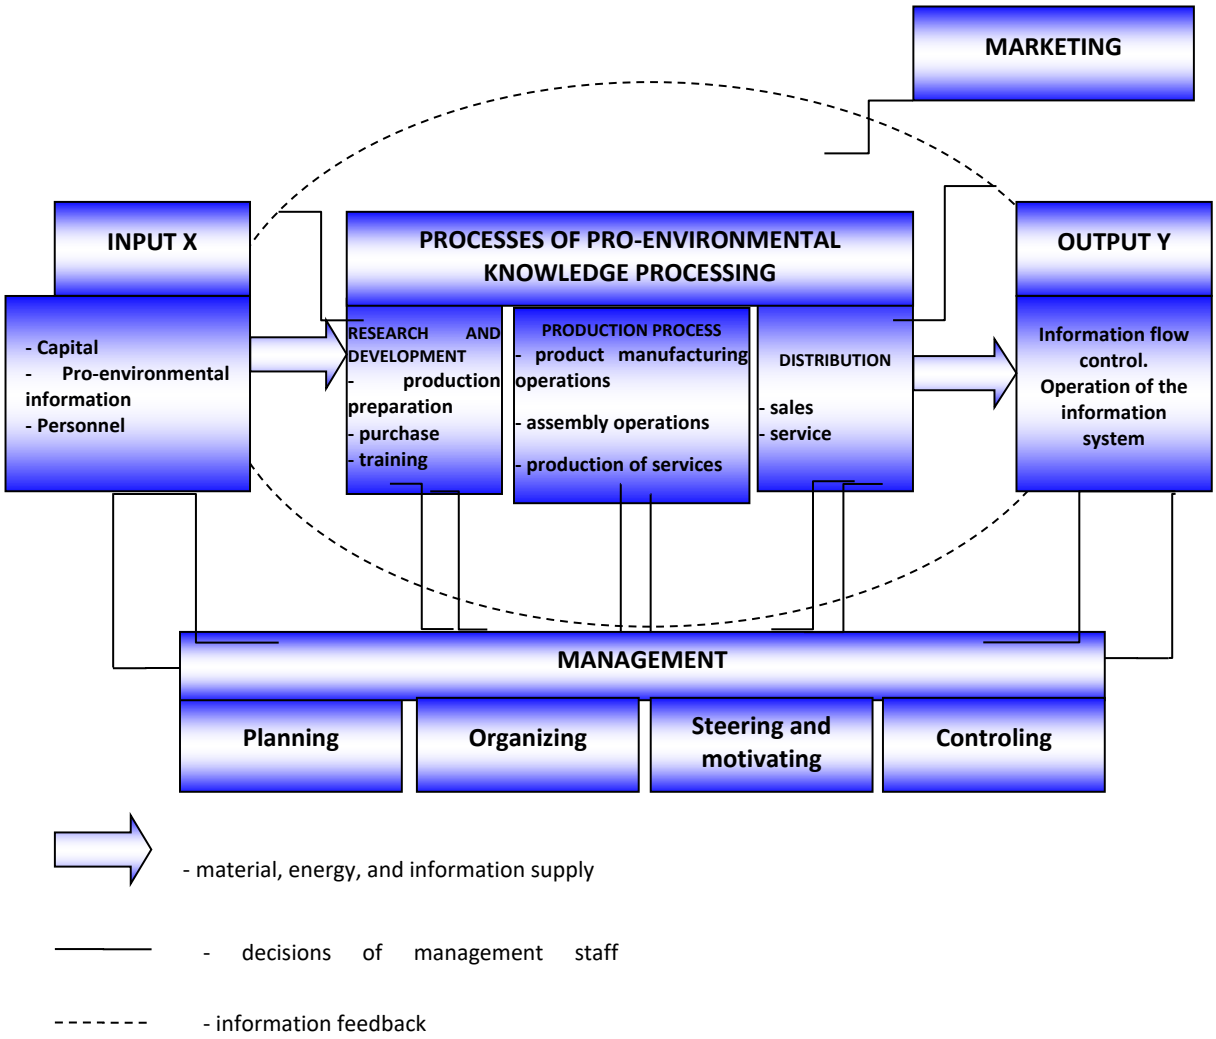
At the level of enterprise resources, sharing pro-environmental knowledge should support processes related to the management of company resources, i.e., human resources, from recruitment, through motivation, to dismissal. Another resource is financial management, including, among others, supporting cash flows. Then, sharing pro-environmental knowledge is to support processes related to the management of fixed and current assets, their acquisition and use, and involvement in the production process. Finally, sharing pro-environmental knowledge is aimed at supporting and streamlining information flows and, consequently, supplying the company and its employees with knowledge. Therefore, the sharing of pro-environmental knowledge is to support the sharing of knowledge and information throughout the value creation chain of the enterprise, by providing pro-environmental knowledge in the appropriate quantity and quality.

From the point of view of the company's function, sharing pro-environmental knowledge refers to the functional areas that exist in the company, it is aimed at supporting processes related to, among others, the area of supply

management, it is to improve the flow of pro-environmental information about suppliers, deliveries, deadlines for their implementation, etc. Another functional area is production management, where the proper sharing of pro-environmental knowledge is to facilitate the planning and control of the production process. Providing pro-environmental knowledge in the right quantity and quality is also necessary for the functioning of other areas, such as distribution and marketing management. In order to achieve the company's goals, it is necessary to share current pro-environmental knowledge in the field of market research, research into tastes and preferences of current and potential buyers, promotion and advertising.

Source: Own study based on: Stoner, Freeman and Gilbert 2001; Griffin, 2000.

Figure 2: Continuum of Knowledge Sharing Conditions



Management issues are a platform where the sharing of pro-environmental knowledge is to serve the ongoing monitoring of performance management. It is to provide pro-environmental knowledge for the calculation of performance indicators, and in the case of obtaining inappropriate parameters of these indicators, to indicate the areas causing these distortions. Analogically to performance management, pro-environmental knowledge management is intended to serve quality management (Dayan, Heisig, Matos, 2017). It is to monitor the level of quality in all possible areas on an ongoing basis and to justify the reasons for deficiencies in this quality if such cases occur.

To sum up, the discussed objectives of sharing pro-environmental knowledge in the company were related to the resources and functions of the company and management problems, but this is not a closed range of application areas of pro-environmental knowledge, but only an outline for further considerations.

5. Pro-Environmental Knowledge in Enterprise Management

When assuming that "information is treated as one of the essential factors due to which the enterprise can shorten the response time to changes in the environment" (Stefanowicz, 2004), special attention should be paid to the flow of pro-environmental information in the implementation of enterprise management processes. The dynamic aspect of managing pro-environmental information flow processes is associated with (...) planning, organizing, and controlling the actual implementation of sequences of activities

that constitute the processes implemented in the company (Pavalache-Ilie, Unianu, 2012). In static terms, process management concerns the management of pro-environmental information resources and "is associated with the issues of information policy, the required level of information quality, information security policy in the context of information technologies" (Molla, Abareshi, Cooper, 2014).

Source: Own study based on: Durlik, 1993.

Figure 3: Model of Pro-Environmental Information Flow in Economic Processes in Enterprise Management

In analogy to the three elementary levels of management, the management of pro-environmental knowledge flow processes can also be considered from the point of view of the same three levels (Klöckner, 2015):

- strategic management of pro-environmental knowledge flow processes - consists in determining how the processes and pro-environmental information flow in the company are to run within 2-3 years. It is also planned how the resources are to be used to improve the company's position in the market and gain a competitive advantage,
- tactical management of pro-environmental knowledge flow processes – its scope includes the management of processes and pro-environmental information resources for up to 1 year. As part of this management, the response to changes in the environment is important, as well as medium-term supervision of flows of pro-environmental information streams and the functioning of the information system,
- operational management of pro-environmental knowledge flow processes - consists in ongoing planning, organization, implementation, and control of the functioning of the enterprise management system in terms of economic processes and access to pro-environmental information used in everyday work (Reeves, Love, Tillmanns, 2012).

The model of the pro-environmental information flow in economic processes in enterprise management is presented in Figure 3. In this model, resources in the form of capital, pro-environmental information and personnel are at the input to economic processes characteristic of enterprises. The processing of pro-environmental knowledge should take place at every stage of the product manufacturing process, i.e., at the stage of research and development, production, and distribution, including marketing activities. At the same time, the processing of pro-environmental knowledge should be implemented in terms of each management function, i.e., as part of planning, organizing, motivating and controlling (Casaló, Escario, 2018). In such a model process of pro-environmental knowledge processing, at the output, there is the ability of control the flow and operation of the pro-environmental information system.

6. The Research Methods

The research was conducted based on critical analysis of literature. Critical literature analysis is a research method that presents existing theoretical and empirical approaches and shows how to prepare research works aimed at expanding existing knowledge or developing a specific research field. Critical analysis of literature should therefore be treated as a synthetic, objective, and reliable summary of a specific theoretical area. In the second part of the study, pro-environmental attitudes in the surveyed enterprises were verified. In this part, the respondents' answers to 4 statements in the field of pro-environmental activities of enterprises were analyzed, which at the same time defined the answer to the research question posed in this study.

7. Verification of Pro-Environmental Attitudes in the Surveyed Enterprises - Research Procedure

The research procedure focuses on the analysis of 4 statements regarding the pro-environmental activities of enterprises, which were asked for using a questionnaire. The analyzed statements are presented below:

1. pro-environmental policy is flexible enough to respond quickly to any change,
2. pro-environmental policy introduced in the company increases the attractiveness of the product/service offer,
3. pro-environmental policy introduced in the company is understandable and acceptable to employees,
4. pro-environmental policy introduced in the company is tailored to the needs and expectations of all employees.

The research was carried out on a sample of 1024 randomly selected enterprises. Verification of pro-environmental attitudes in the surveyed enterprises allows for assessing how sharing pro-environmental knowledge creates business management processes.

Table 1: Verification of Statement No. 1

			Total
pro-environmental policy introduced in our company is flexible enough to respond quickly to any changes	I completely disagree	Number	146
		%	14.3%
	I disagree	Number	160
		%	15.6%
	I neither disagree nor agree	Number	326
		%	31.8%
	I agree	Number	288
		%	28.1%
	I completely agree	Number	104
		%	10.2%
Total		Number	1024
		%	100.0%

Source: Own study.

When relating to the first analyzed statement, 32% of the respondents have no opinion on whether the pro-environmental policy introduced in their company is flexible enough to allow for responding quickly to any change. This means that the sharing of pro- environmental knowledge is not flexible in these enterprises. Moreover, as much as 30% of the respondents unequivocally state that the pro-environmental policy, and thus sharing pro-environmental knowledge, is not flexible in their company. Thus, only 38% of the respondents believe that the pro-environmental policy introduced in their company is flexible enough to allow for responding quickly to any change.

To sum up, the results of the survey show that the pro-environmental policy implemented in enterprises represented by 62% of the respondents is ineffective, inflexible and requires the more effective sharing of pro-environmental knowledge. Therefore, according to 632 respondents, sharing pro-environmental knowledge has a negative impact on the creation of management processes since, in their opinion, sharing pro-environmental knowledge does not allow for responding quickly to any change.

Table 2: Verification of Statement No. 2

			Total
The pro-environmental policy introduced in our company increases the attractiveness of the product/service offer (they are more modern, fashionable...).	I completely disagree	Number	104
		%	10.2%
	I disagree	Number	122
		%	11.9%
	I neither disagree nor agree	Number	266
		%	26.0%
	I agree	Number	307
		%	30.0%
	I completely agree	Number	225
		%	22.0%
Total		Number	1024
		%	100.0%

Source: Own study.

When analyzing the responses of those surveyed to the second statement, it is noticeable that 26% of the respondents cannot adopt a position on whether the pro-environmental policy implemented in their company increases the attractiveness of their product/service offer (they are more modern or trendy), which is a similar result as in the case of the first statement. This implies that every fourth respondent recognizes the problem regarding sharing pro-environmental knowledge. On the other hand, only 22% of the respondents believe that the pro-environmental policy implemented in their company does not increase the attractiveness of their product/service offer, which can be interpreted in such a way that sharing pro-environmental knowledge in these companies is ineffective since it does not increase the attractiveness of their product/service offer. On the other hand, as much as 52% of the respondents declared that the pro-environmental policy implemented in their company increases the attractiveness of their product/service offer.

To sum up, it should be noted that over half of the respondents recognize positive effects of sharing pro-environmental knowledge in the form of increased attractiveness of their product/service offer. Therefore, according to 532 respondents, sharing pro-environmental knowledge has a positive impact on the creation of management processes as, in their opinion, sharing pro-environmental knowledge increases the attractiveness of the product/service offer.

Table 3: Verification of Statement No. 3

			Total
The pro-environmental policy introduced in our company is understandable and acceptable to the employees of the company	I completely disagree	Number	104
		%	10.2%
	I disagree	Number	83
		%	8.1%
	I neither disagree nor agree	Number	305
		%	29.8%
	I agree	Number	389
		%	38.0%
	I completely agree	Number	143
		%	14.0%
Total		Number	1024
		%	100.0%

Source: Own study.

The next analyzed statement was difficult to verify for 30% of the respondents, i.e., 305 respondents could not answer whether the pro-environmental policy introduced in their company is understandable and acceptable to the company's employees, which leads to the conclusion that the knowledge of pro-environmental activities undertaken in these 30% of the companies is not properly disseminated, communicated, and accepted by employees. At the same time, 18% of the respondents unequivocally answered that the pro-environmental policy introduced in their company is incomprehensible and unacceptable to the company's employees, which indicates a problem with sharing pro-environmental knowledge in these companies. On the other hand, 52% of the respondents decided that the pro-environmental policy introduced in their company is understandable and acceptable to the company's employees.

In conclusion, slightly more than half of the respondents believe that sharing pro-environmental knowledge brings a positive effect in the form of understanding and acceptance by employees of the actions taken and the pro-environmental policy implemented in the company. Thus, according to 532 respondents, sharing pro-environmental knowledge has a positive impact on the creation of management processes because, in their opinion, sharing pro-environmental knowledge makes the pro-environmental policy understandable and acceptable to the company's employees.

The last of the analyzed statements was difficult to answer by almost 28% of the respondents, who were unable to determine whether the pro-environmental policy introduced in their company is tailored to the needs and expectations of all employees. This means that the respondents do not have enough knowledge about the pro-environmental activities of enterprises. At the same time, it should be noted that over 20% of the respondents believe that the pro-environmental policy introduced in their company is not tailored to the needs and expectations of all employees. This is information about the lack of effective sharing of pro-environmental knowledge in those enterprises where it is necessary to implement corrective actions. In turn, 52% of the respondents claim that the pro-environmental policy introduced in their company is tailored to the needs and expectations of all employees.

To sum up, slightly more than half of the respondents believe that sharing pro-environmental knowledge brings a positive effect in the form of adjusting the pro-environmental policy in their company to the needs and expectations of all employees. Therefore, according to 533 respondents, sharing pro-environmental knowledge has a positive impact on the creation of management processes since, in their opinion, sharing pro-environmental knowledge makes the pro-environmental policy tailored to the needs and expectations of all employees.

Table 4: Verification of Statement No. 4

			Total
The pro-environmental policy introduced in our company is tailored to the needs and expectations of all employees	I completely disagree	Number	104
		%	10.2%
	I disagree	Number	104
		%	10.2%
	I neither disagree nor agree	Number	283
		%	27.6%
	I agree	Number	350
		%	34.2%
	I completely agree	Number	183
		%	17.9%
Total		Number	1024
		%	100.0%

Source: Own study.

8. Discussion

In relation to the analyzed 4 statements concerning pro-environmental policy, and thus pro-environmental knowledge, a large percentage of indecisive respondents draws attention, which ranged from 26% to 32% in individual questions. The answer "neither disagree nor agree" was chosen by 266 to 326 respondents, which means that they do not have pro-environmental knowledge, which creates enterprise management processes in such a way that the areas for improvement are indicated. In addition, considering the total number of respondents who disagreed with the above statements, it turns out that there were from 187 to 306 of them. These results not only show the problem with sharing pro-environmental knowledge, but also give consideration to whether the applied pro-environmental activities and the applicable pro-environmental policy are effective. To sum up, it should be emphasized that the information obtained based on the 4 above-mentioned statements provides many conclusions, the verification of which implies the need to implement appropriate pro-environmental knowledge management processes in enterprises, so as to increase the number of responses accepting the statements analyzed in this study in the future. For this purpose, it is recommended to implement D.A. Marchand's 15 competencies, influencing the effective application and sharing of knowledge, referred to in this study.

9. Conclusions

The conducted analysis concerning 4 statements showed the gaps in the area of sharing pro-environmental knowledge in enterprises. It turns out that although pro-environmental activities are widely known and applied, it still often happens that:

- pro-environmental policy is not flexible enough to respond quickly to any change (30%),
- pro-environmental policy introduced in the company does not increase the attractiveness of the product/service offer (22%),
- pro-environmental policy introduced in the company is incomprehensible and unacceptable to the company's employees (18%),
- pro-environmental policy introduced in the company does not match the needs and expectations of all employees (22%).

The indicated gaps in terms of sharing pro-environmental knowledge in enterprises create business management processes that emphasize pro-environmental activities. It is recommended to particularly emphasize the flexibility of undertaken pro-environmental activities, which can be achieved by greater focus on new, up-to-date solutions. In addition, it is noted that pro-environmental activities should have a positive impact on the attractiveness of the product/service offer. In turn, the sharing of pro-environmental knowledge should

be so consistently and effectively organized that pro-environmental activities are understandable and acceptable and tailored to the needs and expectations of all employees.

Creating Knowledge of the Competitiveness of Enterprises in the Context of Changes in Management Processes

Sylwia Łęgowik-Świącik
Czestochowa University of Technology, The Faculty of Management, Poland

s.legowik-swiacik@pcz.pl

Abstract: The unpredictable conditions of the competitive environment of modern enterprises force managers to look for new ways of managing enterprises. Furthermore, the diversity of the competitive environment requires the introduction of changes in the management processes of the company, which will enable building a competitive advantage and will allow for its sustainability. Therefore, the study raises the research question: how to create knowledge of the competitiveness of enterprises in the context of changes in management processes. The study presents the concept according to which the introduction of changes in management processes requires the creation of knowledge, which will enable distinguishing the company against its competitors. Therefore, the objective of the study has been the in-depth understanding of the creation of knowledge of the competitiveness of enterprises in the context of changes that can be introduced in management processes. Moreover, the publication deepens the understanding of the relationship between competitiveness factors determining the company's capabilities, its prospects, and the projection of changes in the environment. The research methods applied to accomplish the assumed objective are critical analysis of literature, a survey questionnaire carried out in 2022 and Pearson's correlation analysis. The empirical research was conducted on the basis of data obtained from one hundred enterprises from Poland. The conclusions from the research suggest that managers' attention ought to be focused on identifying the factors of competitiveness of enterprises that enable them to achieve a competitive advantage.

Keywords: Creating knowledge, Enterprise management

1. Introduction

The dynamics of the competitive environment of modern enterprises is a characteristic that constitutes changes in management processes. Therefore, ensuring the sustainability of the company's competitive advantage requires managers not only to have the ability to recognize market opportunities and threats, but also to identify factors that create knowledge of the competitiveness of enterprises, allowing for introducing changes in management processes to create new value. The proper selection of factors creating knowledge of the competitiveness of enterprises should correspond to changes in markets (Fischer, 2011), management trends, and technologies, as they determine the achievement and maintenance of competitive advantages (Bojar, Freitag-Mika 2008). Furthermore, the selection of factors that create knowledge of the competitiveness of enterprises requires the identification of customer needs satisfied by products manufactured, determination of groups of customers whose needs are satisfied, and indication the way to satisfy those needs, as well as determination of functions fulfilled by the enterprise in its activities undertaken with the intention of achieving market objectives.

Due to the fact that it is currently believed that the main challenge faced by management teams of companies is changes in management processes (Hamel, 2007), the research interest in this article focuses on identifying the factors for creating knowledge of the competitiveness of enterprises and the possibilities of introducing changes in management processes to implement the acquired knowledge (Borgatti, Everett, Freeman, 2002). The objective of this article is to fill the gap by deepening the understanding of creating knowledge of the competitiveness of enterprises in the context of changes that can be introduced in management processes (Torres, dos Santos Ferraz, Santos-Rodrigues, Matos, 2016). Additionally, the article develops the subject literature by seeking relationships between the factors for creating knowledge of competitiveness.

The key research question is: how to create knowledge of the competitiveness of enterprises in the context of changes in management processes? Based on the literature review, the factors for creating knowledge of the competitiveness of enterprises were identified, taking into account changes in management processes. To achieve the adopted objective and answer the formulated research question, the structure of the article consists of three main parts. In the first part of the article, the competitiveness of enterprises in terms of changes in management processes is presented. The second part of the article is the presentation of the research methodology used to achieve the research objective. In the third part, the results of the empirical research are presented and discussed, depicting some theoretical conclusions along with practical implications.

2. Competitiveness of Enterprises and Changes in Management Processes

Creating the competitiveness of companies enables distinguishing the company against its competitors and allows for sustainable functioning in variable market conditions. This means that the competitiveness of enterprises has strategic importance in the management process, as a properly developed strategy should enable the creation of a competitive advantage in the market, perceived as the company's operations that include all of its functional areas together with the entire value chain (Porter, 2003). Building a strategy based on the potential of competitiveness can be a source of a competitive advantage for the company if it considers the utilization of key resources and skills (Soo, Devinney, 2002).

Referring to management theory, it is important to emphasize that the concept of the competitiveness of companies has many definitions. In the subject literature, the competitiveness of enterprises combines certain product characteristics (packaging, advertising, delivery conditions) and key resources (financial, human, material, intellectual), (Nikolova, Rodionov, Afanaseyeva, 2017). The competitiveness of the company depends on its opportunities, as well as other enterprises competing in the market (Prahalad, Krishnan, 2008). In the context of the competitiveness of enterprises (Cyfert Krzakiewicz 2016), the company's reputation is very important, which results from the brand, as well as knowledge acquired from relationships with customers and knowledge resulting from research in terms of services and products provided (Brandenburger, Nalebuff 1996). Companies seeking to stand out from competitors search for new sources of revenue, rationalize cost structure and improve products manufactured through changes in production technologies and accessibility for customers (Bumane, 2018). Competitiveness can be analyzed in terms of a company, product, industry, region, or country (Cherep, 2014).

The basis for obtaining benefits from the gained competitive advantage is the ability to generate increased value-added, associated with the transformation of the traditional value chain (Porter, 2000). M.E. Porter, the creator of the value chain, emphasized that it is an inherent part of the theory of competitive advantage (Porter 1979). He stated that the value chain is a general conceptual framework that allows for the consideration of any actions relevant to the company's activity from a strategic perspective. The concept of the value chain enables conducting the analysis of operating costs and evaluation of their significance in terms of the possibility of differentiation (Porter, 1990). M.E. Porter is known as the creator of the positioning school, but he also appreciated the importance of the resource-based school, writing that "actions are the essence of the company's functioning and determine the character of necessary resources and skills, and the selection of strategy determines whether individual resources and skills will be valuable for the company or not" (Porter, 2000). The concept of building a competitive advantage by M.E. Porter combines, on the one hand, the positioning theory of the strategic management school with the resource-based theory on the other hand (McGahan, Porter, 1997). The basis for building a competitive advantage is the crucial role of valuable actions and the value chain. According to M.E. Porter, the concept of building a competitive advantage harmoniously combines both theories because resources and competencies are the elements of concrete actions that are not detached from costs or value generated for the customer (Porter, Kramer, 2006).

A tool enabling changes in management processes in the conditions of market competition of enterprises is the business model. It presents the logic of the company's operations in a specific field, including a set of elements, factors, and relationships between them (Afuah, A. 2004). The business model can be treated as an advanced, contemporary form of the organizational model of enterprise management, which plays a key role in achieving the primary objective of every enterprise, which is to increase the value offered to the customer, which is to ensure that the company remains competitive (Afuah, Tucci, 2003) . The business model articulates the value proposition, identifies market segments, defines value chain structures, calculates cost structures and potential revenue sources, describes the company's position in the value chain connecting the supplier (Stępień, 2022), the company, and customers, and formulates the competitive strategy that allows for retaining profits (Chesbrough, Rosenbloom 2002). To sum up, it should be noted that the definitions referred to are the result of the scientific discourse conducted by researchers in the field of management (Kramer, Porter 2011). Attempting to synthesize a multidimensional approach to creating knowledge of the competitiveness of enterprises in variable market conditions (Chluska, 2022), it can be indicated that the factors constituting changes in enterprise management processes emerge from the presented definitions, and these are:

- new sources of revenue (Osterwalder, Pigneur, 2010),
- cost structure rationalization (Morris, Schindehutte, Allen, 2005),
- changes in the set of key resources (Hamel, 2002),

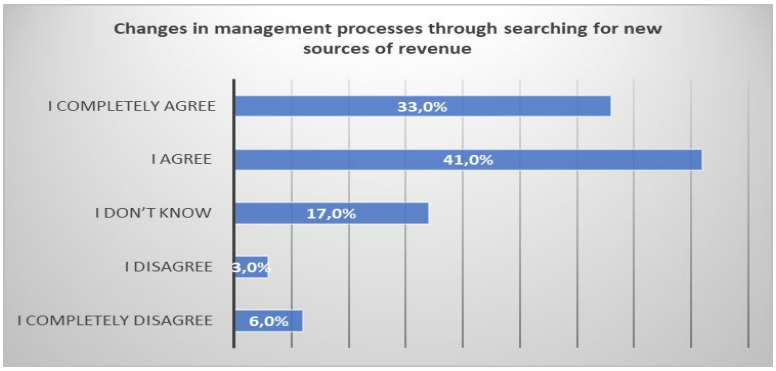
- changes in customer relationships (Osterwalder, Pigneur, 2002),
- changes in the area of services provided (Casadesus-Masanell, Ricart, 2011).

The presented factors for creating knowledge of the competitiveness of enterprises, considered in the context of changes in management processes, constitute a spectrum of functions that new knowledge is to provide. Proposing the factors for creating knowledge of competitiveness serves as a starting point for conducting empirical research and becomes a conventional, abstract carrier of innovation about creating knowledge of the competitiveness of companies.

3. Research Methodology

The study of the phenomenon of creating knowledge of the competitiveness of enterprises in the context of changes possible to introduce in management processes, an extract of which is presented here, was conducted in 2022 as part of the author's own research. In the first stage of the study, based on the analysis of the literature, the most important conclusions of which are presented in the previous part of the article, the factors for creating knowledge of the competitiveness of companies were identified, taking into account changes in management processes. Based on this, a survey questionnaire was prepared to deepen the understanding of creating knowledge of the competitiveness of enterprises in the context of changes that can be introduced in management processes.

The second main part of the study was conducted using the CATI method (Hair, 2014) on a sample of 100 Polish companies running business in the Silesian Voivodeship. The choice of the region was determined by the fact of constant changes in its economic profile. The Silesian voivodeship is undergoing intensive transformation from a region once dominated by the mining industry to an area related to services and creative industries (Department of Regional Development 2022). Moreover, the requirement to achieve the objectives related to achieving climate neutrality goals causes that companies operating in the Silesian voivodeship choose a business activity model directed to innovation development and knowledge management. The population of the surveyed companies consists of micro, small and medium-sized private sector service companies with a European territorial scope of activity. The selection of the population was based on the assumption that micro, small and medium-sized private sector service companies undergo strong competition and cannot benefit from economies of scale, therefore they should create knowledge of competitiveness and introduce changes in management processes. The initial population accepted for the study included approximately 300 companies (micro, small, and medium-sized), and during the study, it was possible to reach 100 respondents from such companies.

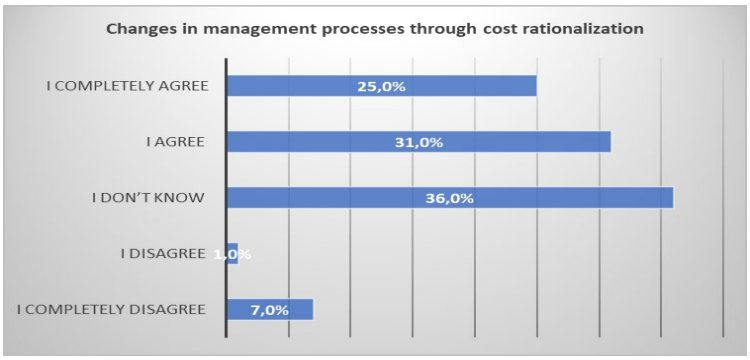


The research was conducted using a survey questionnaire. The respondents were the senior managers of the surveyed companies. The research tool was verified for reliability. The survey questionnaire used in the study covered five main issues of creating knowledge of the competitiveness of the surveyed companies in the context of changes in management processes: seeking new sources of revenue, cost structure rationalization, changes in the set of key resources, changes in customer relationships, and changes in the area of services provided. The statements describing the theoretically identified factors for creating knowledge of the competitiveness of the surveyed companies were rated by the respondents on a Likert scale, from 1 to 5, where the response of 1 indicated "I completely disagree" and 5 indicated "I completely agree" (Vogel, Koutsombogera, Costello, 2020).

To analyze the relationship between the factors for creating knowledge of the competitiveness of the surveyed companies, the linear Pearson correlation was applied in the second part of the study The ranges of the strength and direction of the linear relationship in the conducted analysis were as follows: from 0 to 0.4 - weak relationship, from 0.4 to 0.6 - moderate relationship, from 0.6 to 0.9 - strong relationship, from 0.9 to 1.0 - very strong relationship (Suchecki, 2013). In the statistical analysis, the significance level of $p = 0.05$ was assumed. The analyses were performed using SPSS software.

This article focuses on deepening the understanding of creating knowledge of the competitiveness of enterprises in the context of changes possible to introduce in management processes. Therefore, in the subsequent part of the article, the attention will be focused on the identification of factors for the competitiveness of enterprises and the relationships between these factors, which should contribute to achieving a competitive advantage through the projection of changes in management processes.

4. Results of the conducted Empirical Research

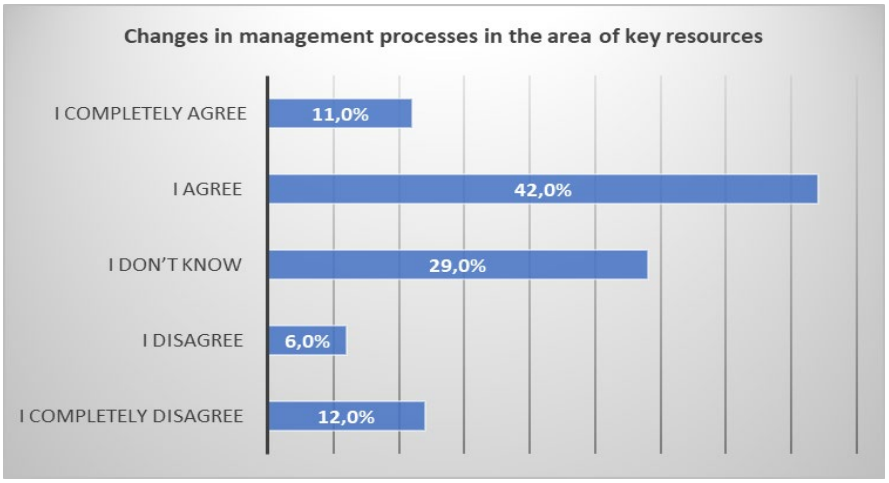


In the first stage of the research procedure, the factors for creating knowledge of competitiveness were identified and evaluated in the opinion of the respondents. Among the factors for creating knowledge of the competitiveness of the surveyed companies, the following were distinguished: searching for new sources of revenue, cost structure rationalization, changes in the set of key resources, changes in customer relationships, and changes in the area of services provided. Figure 1 shows new sources of revenue as the factors for creating knowledge of the competitiveness of the surveyed companies.

Source: Own study.

Figure 1: Searching for new Sources of Revenue as a Factor for Creating Knowledge of the Competitiveness of Enterprises

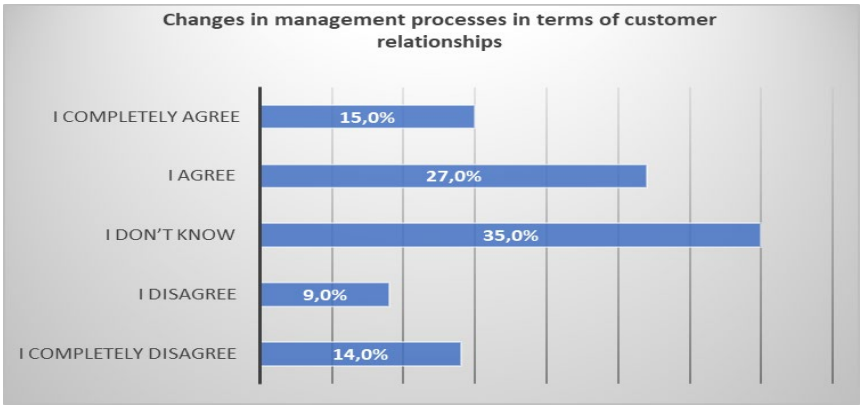
According to Figure 1, as much as 74% of the respondents declared that they completely agreed or agreed with the statement that their company introduces changes in management processes to seek new sources of revenue. Therefore, it can be concluded that the surveyed companies aim at expanding their knowledge of new sources of revenue of the conducted activity through offering new products and services, which may result in increased competitiveness. In turn, 17% of the respondents declared that they did not know whether their company searched for new sources of revenue, which may indicate the lack of the respondents' interest in expanding their offer. Additionally, 9% of the respondents completely disagreed or disagreed that their company searched for new sources of revenue. The presented research indicates that the vast majority of the respondents are interested in seeking new sources of revenue in their activities, which suggests that this is an important factor for creating knowledge of the competitiveness of the surveyed companies. Figure 2 presents cost structure rationalization as the factor for creating knowledge of the competitiveness of the surveyed companies.



Source: Own study.

Figure 2: Cost rationalization as a Factor for Creating Knowledge of the Competitiveness Of Enterprise

According to the obtained research presented in Figure 2, 56% of the respondents declared that, in their companies, there were introduced changes in management processes through cost structure rationalization. This may suggest that these companies strive to reduce costs by identifying the areas of potential changes. In turn, 36% of the respondents do not have knowledge of cost structure rationalization in their company. Additionally, 8% of the respondents completely disagree or disagree that cost rationalization occurs in their company. The obtained results suggest that introducing changes in management processes in terms of cost structure rationalization is an important factor for creating knowledge of the competitiveness of the surveyed companies for the majority of the respondents. It informs how cost reduction affects the financial result and

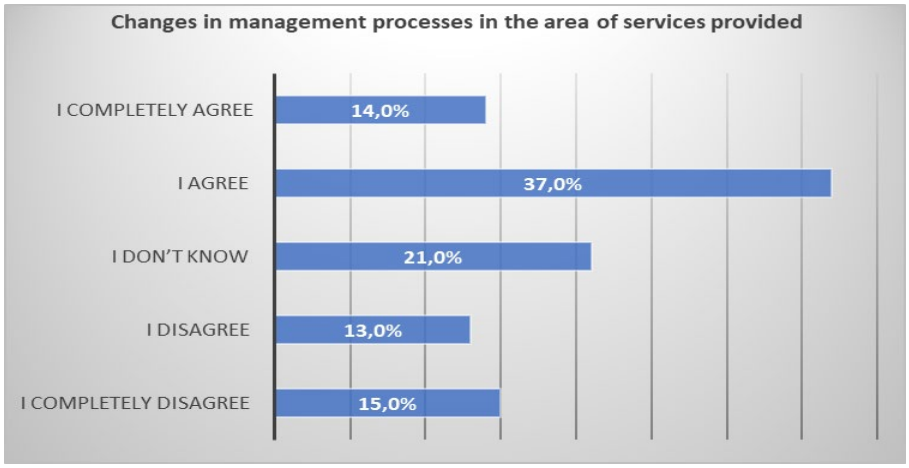


efficiency of the conducted activity. Figure 3 presents key resources as a factor for creating knowledge of the competitiveness of the surveyed companies.

Source: Own study.

Figure 3: The set of key Resources as a Factor for Creating Knowledge of the Competitiveness of Enterprises

Based on Figure 3, it can be concluded that 53% of the respondents declared that they completely agreed or agreed with the statement that their companies introduced changes in management processes in the set of key resources. In the surveyed companies, operating in the competitive environment, it is important to carefully utilize the resources possessed. Therefore, making changes to the set of key resources is an important factor for creating knowledge of the competitiveness of the surveyed companies. In turn, 29% of the respondents stated that they did not know whether changes were made to the set of key resources. Additionally, 18% of the respondents declared that they completely disagreed or disagreed with the above statement, which may indicate that, in these companies, no changes are made to the set of key resources in search for an increase in competitiveness. Figure 4 presents changes in customer relationships as a factor for creating knowledge of the competitiveness of the surveyed companies.



Source: Own study

Figure 4: Customer Relationships as a Factor for Creating Knowledge of the Competitiveness of Enterprises

Based on the research results presented in Figure 4, it can be concluded that 42% of the respondents declared that they completely agreed or agreed with the statement that their company implemented changes in management processes in terms of customer relationships. This may indicate that, in these companies, changes in the area of customer relationships, may translate into gaining and maintaining a competitive advantage in the market, making changes in this area an important factor for creating knowledge of the competitiveness of the surveyed enterprises. It should be noted that 35% of the respondents declared "I don't know", so it is possible that the respondents are not focused on changes in customer relationships. In turn, 23% of the respondents disagreed or completely disagreed with the statement that, in their companies, there were changes in customer relationships. This may be due to the stability of customer relationships, without

the need for changes in the relationships. Figure 5 presents changes in the area of services provided as a factor for creating knowledge of the competitiveness of the surveyed enterprises.

Source: Own study.

Figure 5: Changes in the area of Services Provided as a Factor for Creating Knowledge of the Competitiveness of Enterprises

The results presented in Figure 5 indicate that 51% of the respondents declared that they completely agreed or agreed with the statement that their company implemented changes in management processes in the area of services provided. This may mean that these companies modify their services by introducing a wider package of additional services within the basic service, which positively affects their level of competitiveness, thus constituting a factor for creating knowledge of competitiveness. From the opinions of 21% of the respondents, it can be concluded that they do not know whether changes in the area of services provided are made in their company, which may indicate that this group of the respondents lacks knowledge on this subject. In turn, 28% of the respondents declared that were no changes in the area of service provision in their company.

In the second stage of the research procedure, the relationships between the factors for creating knowledge of the competitiveness of the surveyed enterprises were examined. This should contribute to a deeper understanding of the creation of knowledge of competitiveness in the context of changes that can be introduced in management processes. When examining the factors for creating knowledge of the competitiveness of the surveyed enterprises, the strength and direction of the linear relationship between the input variables were examined in the second part of the research procedure. The investigated relationships were additionally confirmed by a significance test (at the level of $\alpha = 0.05$).

As shown in Figure 6, in the case of the companies examined, there is a strong positive relationship between introducing changes in management processes through changes in customer relationships and changes in the area of provided services (0.74). The surveyed companies make changes in customer relationships by introducing a package of additional services enabling an improvement in their competitiveness. Additionally, positive changes in customer relationships may bring favorable effects in the form of loyal customers and acquiring new ones. Furthermore, introducing changes in the area of services provided should contribute to an increase in the company's revenues, which can translate into a higher financial result.

Cost structure rationalization	0.50

Changes in the set of key resources	0.44	0.53		
Changes in customer relationships	0.43	0.35	0.63	
Changes in the area of service provided	0.45	0.35	0.66	0.74
	New sources of revenue	Cost structure rationalization	Changes in the set of key resources	Changes in customer relationships

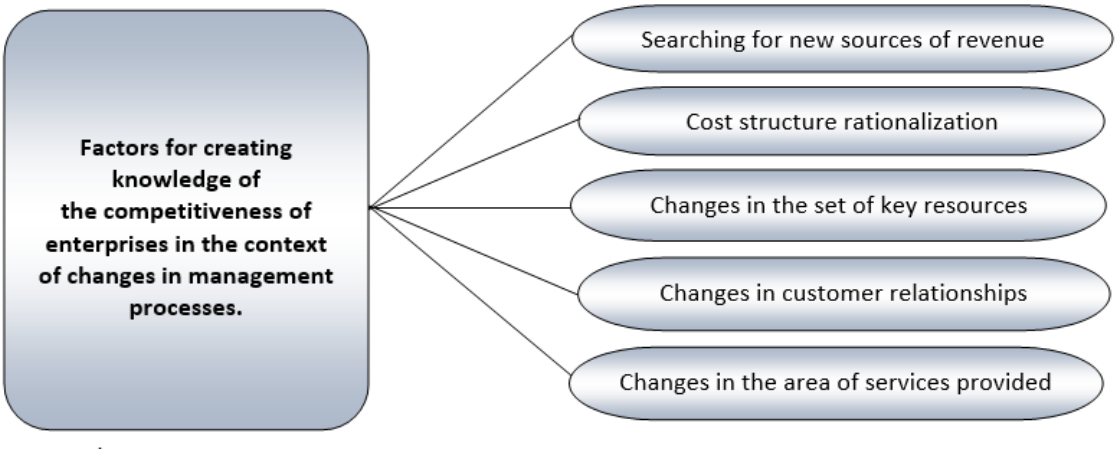
Source: Own study.

Figure 6: Matrix of the Correlation of Factors for Creating Knowledge of the Competitiveness of Enterprises

When examining the relationships between introducing changes in management processes through changes in the set of key resources and in the area of services provided, a strong positive relationship (0.66) is observed. Companies, which introduce changes in the set of key resources, are more attractive to potential customers. Additionally, companies that make changes in the area of services provided stand out in the market, which has a positive effect on the process of building the competitiveness of the surveyed companies. Customers are more willing to use the services of companies which offer them a wider range of services compared to their competitors. The results of the research obtained using the Pearson correlation matrix show that, in the case of the surveyed companies, there is a strong positive relationship between introducing changes in management processes through implementing changes in the set of key resources and introducing changes in customer relationships (0.63). This may mean that the examined companies are interested in knowledge of the competitiveness of enterprises and introduce changes in the set of key resources to improve customer relationships. This is another action that makes the examined companies more attractive to their customers. A moderate positive relationship is observed between introducing changes in management processes through changes in the set of key resources and changes in cost structure rationalization (0.53). It follows that the examined companies are interested in changes in the set of key resources so as to enable the rationalization of operating costs, which is favorable for building a competitive advantage.

In the case of the surveyed companies, there is a moderate positive relationship between changes in management processes in terms of cost structure rationalization and seeking new sources of revenue (0.50). This may mean that the examined companies, when rationalizing costs, are oriented to new customers who will generate new sources of revenue, which are a chance to increase the competitiveness of enterprises.

Based on the results presented in Figure 7, it can be concluded that, in the case of the studied companies, there is a moderate positive relationship between introducing changes in management processes through seeking new sources of revenue and changes in the area of services provided (0.45), changes in the set of key resources (0.44), and changes in customer relationships (0.43). The source of new revenue for companies operating in the competitive market can be changes introduced in the area of services provided, implemented through changing the configuration of the key resources, which should translate into the emergence of relationships with new customers.



On the basis of the obtained results, it can be stated that there is a weak positive relationship between introducing changes in management processes through cost structure rationalization and changes in customer relationships (0.35) and changes in the area of services provided. This may mean that the studied companies rationalize cost structure, but the quality of customer relationships and provided services is crucial in the process of gaining and maintaining a competitive advantage, which is mainly reflected in the achieved sales revenue and not in cost reduction.

Summing up the results of the research procedure regarding the study of relationships between the factors for creating knowledge of the competitiveness of enterprises, it should be pinpointed that all the relationships

show a positive correlation. This may be due to the fact that the surveyed companies are aware of the potential of knowledge they possess and use opportunities to build their competitiveness.

5. Discussion

The knowledge of the factors that trigger changes in management processes determines the building of the competitiveness of the surveyed companies. Seeking new sources of revenue, cost structure rationalization, and changes in the set of key resources, provided services, and customer relationships (Figure 7) are the factors that trigger changes in management processes due to changes in the environment of the examined companies. Their task is to coordinate actions focused on recognizing customer preferences, acquiring, and retaining them, which allows for building competitiveness by the studied companies. This means that the examined entities build a competitive advantage by considering changes aimed at rapid adaptation to new conditions and are willing to notice positive aspects in their business activities, which contribute to their competitiveness.

Source: Own study.

Figure 7: Summary of Factors Creating Knowledge of the Competitiveness of Companies in the Context of Changes in Management Processes

It is worth noting that the strong positive relationship between changes in the area of services provided and changes in the set of key resources, as well as introducing changes in customer relationships, is a response to the question of how to create knowledge of the competitiveness of companies in the context of changes in management processes. This confirms the previously adopted assumption of the occurrence of the relationship between the examined variables. Furthermore, in the case of the set of key resources and changes in customer relationships, the observed relationships may indicate an increase in awareness among the management staff of the studied companies regarding the potential which is associated with possessing knowledge.

In this context, some new aspects of "meta" factors in management processes emerge, such as: focus on employees, implementation of models for exploiting internal and external sources of knowledge, and flexibility and agility of response to changes in the environment. By creating knowledge about competitiveness in the context of changes in management processes, enterprises should redefine their relations with employees. Employees should not be reduced to the level of the company's resources, since they bring not only knowledge, but also experience, both to and from customers. Moreover, as part of Future-of-Work, relations with employees in the long term become a generator of the company's competitive advantage, built through their work potential and knowledge. This leads to the conclusion that the further direction of research should aim at explaining what role the staff will play in value creation processes in the situation of rapid development of Artificial Intelligence. Research in the field of management science should take into account interrelationships between the acquisition and use of employee knowledge and its processing and transformation by AI into valuable results.

To sum up the above considerations, it can be assumed that the identification of factors that create knowledge of the competitiveness of the studied companies in the context of changes in management processes enables gaining and maintaining a competitive advantage.

6. Conclusions and Summary

When concluding the considerations presented in this paper, it is worth emphasizing that the factors for creating knowledge of the competitiveness of companies should secure the sustainability of a competitive advantage. However, the identification of factors that create knowledge of competitiveness requires taking into account current and future sources of revenue, which are generated due to key resources offered to customers, as well as a competitive approach to the market, which, combined with appropriate cost structure, provides new value to the customer. The considerations presented in this study allow for confirming the assumption of the research objective related to the in-depth understanding of creating knowledge of the competitiveness of companies in the context of changes possible to introduce in management processes. The conducted literature review and empirical research results allowed the formulation of the following conclusions:

- the object of the analysis in terms of creating knowledge of the competitiveness of companies is the identification of factors that determine the introduction of changes in management processes to increase a competitive advantage.
- understanding the factors for creating knowledge of the competitiveness of enterprises becomes a manifestation of strategic behavior of companies, enabling them the achievement and maintenance of a competitive advantage.

This paper supports the current view that there is no single universal model for creating knowledge of the competitiveness of companies. Moreover, the multifaceted nature of the issue of creating knowledge of the competitiveness of enterprises and interdisciplinary character of the considerations create the premises for shaping the factors for creating knowledge of the competitiveness of companies in generating new knowledge necessary for decision-making by the management staff of modern enterprises.

The further direction of research in this area should take into account the new perspectives of enterprise management processes under Future-of-Work, by redefining relations with employees in the context of the development of Artificial Intelligence

Knowledge Management in Enhancing Organizational Flexibility in Manufacturing Enterprises

Anna Lemańska-Majdzik
Czestochowa University of Technology, Poland

a.lemanska-majdzik@pcz.pl

Abstract: In today's market conditions, enterprises operate in times of uncertainty, constant pressure from competition, increasing quality requirements, and rapidly changing technologies. The speed and intensity of changes mean that enterprises are forced to look for the most effective flexible actions to meet market conditions. The dynamic capabilities of enterprises are reflected in the dimensions of flexibility, which have different speeds and are conditioned in different ways, e.g., through the level of knowledge management in the enterprise. The article is based on the review of international literature using the science mapping method in the area of knowledge management and organizational flexibility, as well as the results of the research conducted on a group of manufacturing companies. The aim of the article is to indicate the level of knowledge management in manufacturing enterprises and its impact on selected dimensions of flexibility in the areas of organizational activity. The study is based on the results of the research on a group of 355 Polish enterprises, which was carried out in 2022. The author's questionnaire was used during the study. The results of the study were the basis for the analysis, which indicated the level of knowledge management and the level of organizational flexibility in manufacturing enterprises. The analysis also made it possible to indicate whether there are dependencies between the level of knowledge management and the level of flexibility in the organizational dimensions of companies' operations. The novelty of the article is the indication of recommendations for the increase in the level of knowledge management in order to enhance the flexible actions necessary in an extremely turbulent organizational environment.

Keywords: Management, Knowledge management, Organizational flexibility, Manufacturing enterprises, Poland

1. Introduction

In the face of the rapidly changing industrial environment and competitive pressure, companies have had to develop their ability to respond and adapt better to the dynamic business environment (Cheng, 2007). Therefore, the flexibility, and thus organizational capacity of the enterprise to use resources, strengthening their internal competencies in terms of developing diverse strategies and actions that enable the achievement of organizational goals, turns out to be essential. Organizational flexibility is a dynamic capacity, since the organization is able to renew and recreate resources, rapidly and efficiently integrating and configuring them in response to the dynamics of the environment (Yousaf & Majid, 2018). Furthermore, Shukor et al (2020) recognize organizational flexibility as a dynamic capacity, as it is important to cope with complexity, minimize uncertainty, and support management in complex and turbulent environments. In such an environment, knowledge management is the most important strategic resource and therefore is considered crucial for improving the company's performance (Carrasco-Hernández & Jiménez-Jiménez, 2016). However, knowledge management processes and the extremely dynamic environment require new ways of operating of the organization, in particular the departure from the rigid framework of functioning and the transition to flexibility in many organizational dimensions.

The objective of the article is to examine the level of knowledge management in companies and its impact on selected dimensions of organizational flexibility in the areas of business activity. The reasoning is based on the results of the research conducted in 2022 on a group of Polish manufacturing companies. The article contributes to science by combining the level of knowledge management with selected dimensions of flexibility building organizational flexibility in extremely turbulent conditions. In addition, the scientific contribution of this article consists in the demonstration of the analysis of bibliometric data related to the identified procedures in two areas, namely, knowledge management and organizational flexibility in a turbulent business environment.

2. Literature Review

2.1 Procedure

To achieve the planned main objective, the review of literature concerning the subject matter was conducted using the science mapping method in the VOSviewer software. The method used in this research is to conduct bibliometric analysis to produce a network visualization of keyword maps for the queries (Visser, van Eck & Waltman, 2021; van Eck, et al, 2010). The review of literature performed is based on the structure of data obtained from the original queries, as well as the scope and results of the database. The queries used in this study enabled the exploration of the Scopus database, which is commonly used in scientometrics to examine

the progress and evaluate various fields of science (Van Eck & Waltman, 2010). The conducted review of literature allows for data analysis using mapping tools and enables the formulation of the research problem.

The review of literature was conducted using keyword coexistence analysis, which was used to group reflecting research into organizational flexibility and knowledge management. The criteria for searching records in the database included searching by subject (title, abstract, keywords), the accepted word phrases "flexibility" OR "organizational flexibility" OR "flexibility of organization" AND "knowledge management" OR "management of knowledge". As a result, 1262 documents were obtained, which included scientific articles in journals in the field of "Business, Management and Accounting" and "Environmental Science" in English with no time limit. The further analysis of abstracts and modification of keywords not meeting the criteria (the first 20 most frequently repeated keywords) allowed for the identification of three main clusters (Fig. 1). Cluster 1 "Knowledge management" (red), Cluster 2 "Flexibility" (blue), Cluster 3 "Competitions" (green). The conducted bibliometric analysis allowed the formulation of the research problem in the form of the research question: What are the relationships between the level of knowledge management in the company and its organizational flexibility?

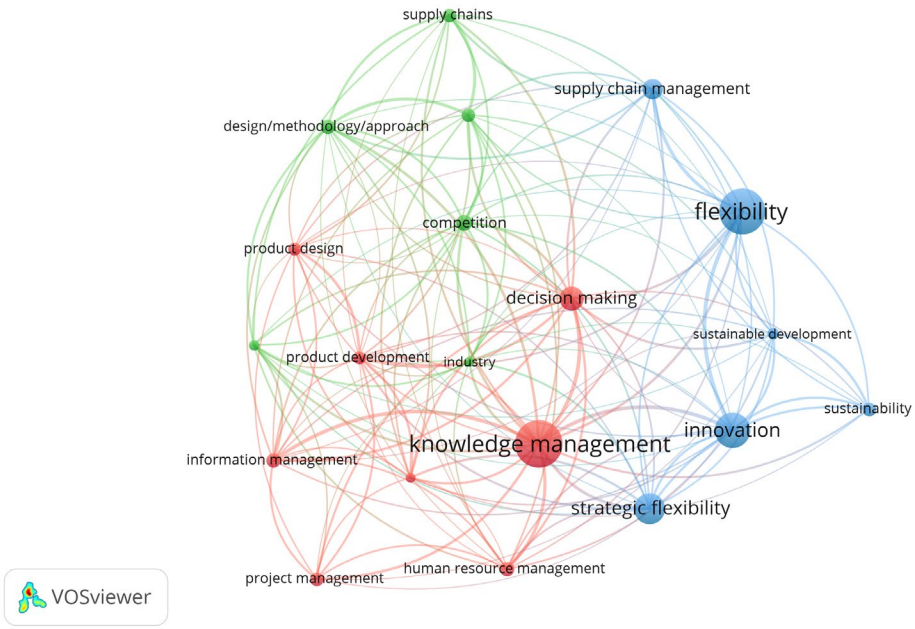

Figure 1: Bibliometric map of Keyword Coexistence Results from Scopus

2.2 Knowledge Management

Knowledge is the key resource of the organization constituting the source of sustainable differentiation, and thus competitive advantage. Knowledge in the enterprise combines capabilities and dynamic capacities, as well as information and technological practices, allowing the company to predict the nature and potential of changes in the organizational environment more accurately and determine the adequacy of both strategic and tactical operations (Wiklund & Shepherd, 2003). From the point of view of the organization, knowledge is not a resource collected solely in individual units that make up the organization, but is embedded in procedures, processes, or organizational structures, and social relationships created with stakeholders (Okręglicka, 2022). Organizations with a higher level of knowledge management capability are more likely to increase competitiveness by collecting, organizing, and transforming knowledge to achieve their organizational goals (Shujahat et al, 2019). The method, speed, and efficiency of using knowledge in management are the most important factors ensuring and maintaining the competitive advantage of the organization, and the inability to use it determines the obstacles to achieving and creating the competitiveness of the company, as well as its development (Omerzel & Gulev, 2011). According to Gao, Chai and Liu (2018), knowledge management can provide enterprises with the tools and techniques they need to overcome the overwhelming information they encounter and enable them to improve learning effectiveness and increase their competitive advantage. Moreover, the existing research suggests that a dynamic organizational capacity plays a crucial role in achieving organizational and business performance through knowledge management, including its detection, sharing, and reconfiguration (Antunes &

Pinheiro, 2020); and the capabilities in this area related to dynamic operations of enterprises in the business environment have a direct and indirect positive impact on the company's results (Lin & Wu, 2014; Li et al, 2020).

2.3 Organizational Flexibility

Flexibility, as a characteristic of the company, is desired by all organizations as it is an important factor determining its functioning. Organizational flexibility is primarily perceived as the ability that enables the organization to exist in the context of variable business conditions (Verdú & Gómez-Gras, 2009; Morgan et al, 2019). Therefore, the flexibility of operations means that entrepreneurs flexibly modify plans or decisions in a constant manner, adapting to changing circumstances of the company's functioning (Brettel, Mauer & Engelen, 2012). Unfavorable business environments currently require organizational flexibility from companies, i.e., the company's dynamic abilities to keep up with changes in the market and to respond rapidly to unpredictable and unexpected market conditions (Santos-Vijande, López-Sánchez & Trespalacios, 2012; Peng, Liu & Lin, 2015; Chatterjee et al, 2023). If significant changes occur in the organization's environment, the organization should respond to them to a greater extent. Changes introduced in the organization within the framework of flexibility may lead to a temporary change in the level of activity, which in turn may lead to the ultimate activity of the organization (Sharma, Sushil & Jain, 2010) and ensure a competitive advantage (Weaven et al, 2021). Sushil (2001) draws attention to the reflection of mutual relationships between flexibility in individual functional areas and the organization's flexibility as a whole. The flexible response of companies to unexpected changes in the environment, which are currently becoming common, is critical in the case of the impact on their organizational reactions. They require organizational discipline, consisting in adherence to principles when creating organizational structures and processes. On the other hand, organizational agility should be allowed, which can be expressed through creativity, improvisation, and adaptability of the organization (Volberda, 1997; Harrald, 2006).

The review of literature provides evidence that organizational flexibility is crucial for creating value in operational, production, and technological strategies, as well as for developing competitiveness (Lyu et al, 2022; Bhupendra & Sangle, 2022) and innovativeness of enterprises (Abubakar et al, 2019). Therefore, it is important to perceive flexibility from the perspective of its dimensions (Dreyer & Grønhaug, 2004; Zhou, Wu, 2010; Khin, Ahmad & Ramayah, 2012). Combining partial flexibilities thus gives a synergy effect, and in the case of organizational flexibility, this synergy effect can be determined as the surplus of benefits resulting from the flexibility of individual levels of the organization compared to the flexibility of the entire organization (Kasiewicz, 2009), whereby the flexibility of individual elements of the organization affects the flexibility of the entire enterprise. Therefore, according to the observations of Sushil (2001), De Toni and S. Tonchia (2005), and Eapen (2009), it can be assumed that organizational flexibility consists of partial flexibilities and is of a mixed nature. Perceiving the flexibility of the enterprise through the logic of partial flexibilities has its advantages, which, among others, affect the precise capture of the degree (level) of the company's flexibility, resulting from the functions, processes, resources, and dimensions of the organization (Moroz, 2013, p. 55).

Based on the above arguments and observations of the business environment, the main hypothesis was formulated, which is: Hypothesis 1: A higher level of knowledge management in the organization influences an increase in the level of organizational flexibility of the enterprise.

3. Methodology

The main objective of the article is to examine the level of knowledge management in enterprises and its impact on selected dimensions of organizational flexibility in the areas of business activities. In order to test the main hypothesis, the pilot studies were conducted in 2021, and then data were collected from a sample of 355 Polish manufacturing companies. The main research was conducted in 2022.

The research process was carried out in stages, i.e., firstly, the review of literature was conducted, which allowed for the identification of the research problem and the formulation of the research hypothesis. During the literature review, some scientometrics techniques were used. The science mapping method was applied, including cluster analysis for the needs of bibliometric analysis (Van Eck, Waltman 2021). The VOSviewer software and data analysis tools available in the SCOPUS database were used for the analysis.

The survey questionnaire was subsequently developed. The questionnaire consisted of closed-ended questions in the groups of individual research areas on a 5-point Likert scale (Sheng, Zhou & Li, 2011; Peng & Luo, 2000),

where 1 indicated "definitely not" and 5 "definitely yes". This is a managerial approach, in which this tool is most often used in social science research.

During the further analysis, the level of knowledge management (KM) was examined based on the classification by Carrasco-Hernández and Jiménez-Jiménez (2016), in which five sub-variables were identified consisting of items allowing for the diagnosis of the studied area. On the other hand, the level of organizational flexibility of enterprises was diagnosed based on the approach by Yeniaras, Di Benedetto and Dayan (2021), who distinguished four dimensions of flexibility that make up overall organizational flexibility, i.e., operational (OF), financial (FF), structural (SF) and technological (TF), which were constructed with relevant items.

Subsequently, based on the convenient sample selection, the enterprises participating in the research were identified. Then, the incomplete and incorrectly completed questionnaires were rejected, and the collected data were analyzed to accomplish the research objective. Finally, in the group of the surveyed enterprises, manufacturing companies were identified, over 60% of which had been operating for over 10 years, including 43% of micro enterprises, 25% of small enterprises, 18% of medium-sized enterprises, and 14% of large enterprises operating in southern Poland.

4. Results

Firstly, during the analysis of the research results, the constructed research tool was subjected to reliability tests (Table 1). The reliability estimation method using the Cronbach's alpha coefficient was used (Taber, 2018; Christmann & Van Aelst, 2006). The conducted analysis showed that, for the organizational flexibility scale in its individual dimensions, the reliability was 0.812 in total, thus it was good reliability, whereas, for the knowledge management scale in its individual components, it was 0.933 in total, thus it was excellent reliability. It turns out that the research scales constructed in the tool meet the criteria and their use in quantitative research is justified according to the adopted classification by George and Mallery (2016, p. 240).

Table 1: Reliability and Validity

Variables	**Cronbach's α**
Knowledge management	0.933
KM1	0.792
KM2	0.845
KM3	0.816
KM4	0.769
KM5	0.881
Organizational flexibility	0.812
OF	0.669
FF	0.769
SF	0.565
TF	0.801

Subsequently, the level of KM and organizational flexibility in Polish manufacturing companies in total was examined, as well as broken down by size of employment. The European classification of enterprises (number of employees) was adopted, i.e., micro, small, medium-sized and large companies (EU Commission Regulation No 651/2014). The data analysis showed that the average level of knowledge management in all companies was 3.516 on a 5-point Likert scale, and this level deviates from the average value by +/-0.849 points. The median value for the level of knowledge management indicates that at least 50% of the respondents rated KM at the level of 3.625 or less on a 5-point scale. At the same time, it can be seen (Fig. 2) that, in micro-enterprises, the level of KM is the lowest, whereas, in large enterprises, it is the highest. It is worth adding that the value of the chi-square statistic (Chi squared test=245.3945; df=19; p-value=0.00000) indicates a statistically significant relationship between the variables, i.e., the level of knowledge management and the size of employment in enterprises.

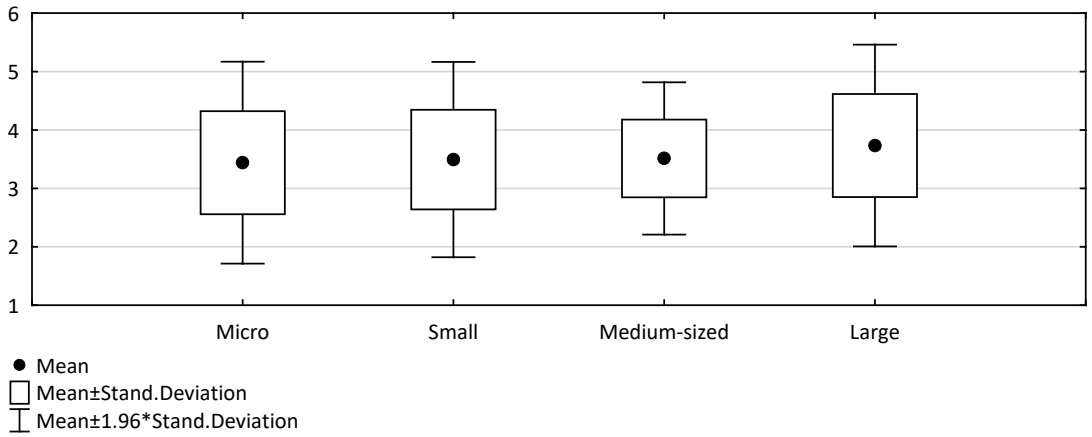

Figure 2: The Level of KM in the Manufacturing Company (n=355)

The further data analysis showed that the average level of organizational flexibility in Polish manufacturing companies was 3.735 on a 5-point Likert scale, and this level deviates from the average value by +/-0.699 points. At the same time, the median value for the level of organizational flexibility indicates that at least 25% of the respondents rated organizational flexibility at the level of 3.364 or lower on a 5-point scale. Interestingly (Fig. 3), small enterprises declare the highest level of organizational flexibility, and this level is the lowest in micro-enterprises, and the differences in the distinguished groups of companies are small and no statistical relationship.

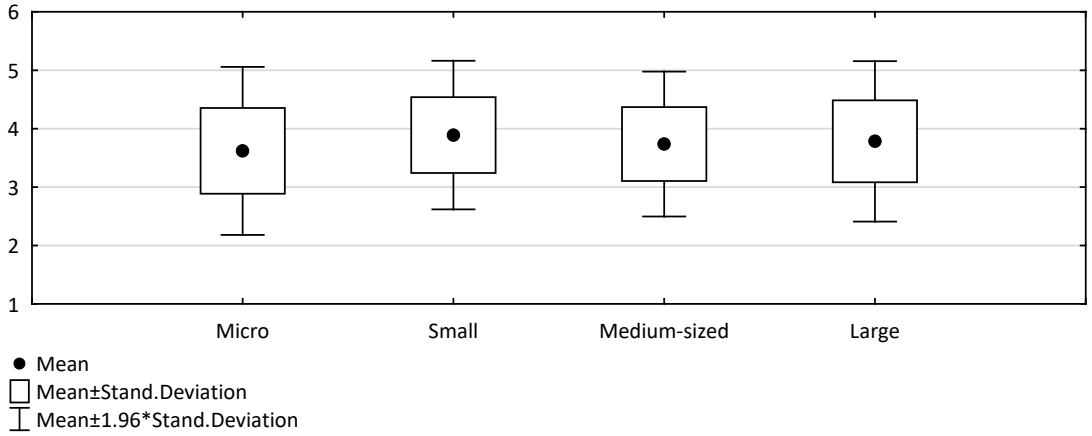

Figure 3: The Level of Organizational Flexibility in the Manufacturing Company (n=355)

In the next step, it was examined whether there was a linear relationship between the variables, for which the Kendall's tau-b correlation coefficient was used (Table 2). Initially, the correlations between the level of KM and individual dimensions of organizational flexibility (OF, FF, SF, TF) were identified, as well as between KM and the overall level of flexibility. The analysis showed that the correlations between the variables are statistically significant for $p<0.05$ and can be described as moderately positive, ranging from $t=0.306$ to $t=0.483$.

Table 2: Correlation Analysis (n=355)

Dimensions of organizational flexibility	Management of knowledge (t)
OF	0.306*
FF	0.349*
SF	0.341*
TF	0.416*
Total organizational flexibility	0.483*

*Kendall's tau correlation (p-value<0.05)

5. Discussion

The obtained results confirm the research by Carrasco-Hernandez and Jimenez-Jimenez (2016), which shows that knowledge management is important and positively related to organizational flexibility, and thus the higher the level of knowledge management the higher the level of organizational flexibility demonstrated by the studied companies. As indicated by the research by Tippins and Sohi (2003), in an extremely turbulent environment scenario, knowledge is considered the most important strategic resource in the organization, and therefore the knowledge management process is considered critical to improving the performance of the organization. However, organizational performance is not possible without the flexibility of dynamic actions. Organizational performance and flexibility together drive the development of enterprises in turbulent business environments, but this hypothesis cannot always be confirmed in a stable environment (Phillips, Chang & Su, 2018). Therefore, organizational efficiency, perceived as the flexibility of action, affects the performance of the organization in terms of delivering products and/or services, operations of related organizations, and plays a significant role in relation to customers and business partners (Stokes, Schneider & Lyons, 2010; Yusuf et al, 2014). The review of literature also shows the research results indicating a positive impact of knowledge management on the results of enterprises (Holsapple & Jones, 2005). Organizational flexibility regarded in this way includes the mix of formal and informal mechanisms that may arise within or outside the organization. Management practices can affect employee actions, strategic behavior, and the company's results and may include the use of financial control systems, recruitment and engagement of resource managers, implementation of human resource practices, decentralization of power, and increased management engagement (Dekker et al, 2013).

6. Conclusions and Future Research Directions and Limitations

To sum up, the conducted analysis based on the research results showed that the level of knowledge management in manufacturing companies depends on their size and is linked to their organizational flexibility. This applies to all dimensions of organizational flexibility studied, and thus operational, financial, structural, and technological flexibility. Furthermore, the higher the level of management in manufacturing companies the higher the organizational flexibility, which determines the functioning of companies in extremely difficult business environment conditions. Moreover, the research results indicate the direction of dynamic actions in the field of knowledge management, which enhance the flexibility of enterprises, among others, through acquiring knowledge from the environment and from the organization members, distributing information and its interpretation, as well as organizational memory.

The conducted research is not free from limitations. Firstly, it results from the COVID-19 pandemic, which disrupted the activities and production processes of companies and their functioning in extremely turbulent and unpredictable economic conditions. Secondly, the war beyond Poland's borders distorted the needs and expectations of both companies and their customers, and the need for flexible actions was not always adjusted to the resource capabilities of enterprises. Thirdly, the study was conducted on a selected group of companies, and a wider research group selection would reveal a wider range of organizational needs and interactions. In the future, the author plans to continue the analysis by expanding it to a model and factor analysis, as well as to broaden the research to companies from different sectors of the economy operating in a different business environment.

7. Theoretical and Practical Implications

The study has several implications for practitioners. Recommendations in the area of operations for strengthening the organizational flexibility of manufacturing enterprises, which becomes the basis for functioning in an extremely variable business environment, should focus on activities that influence an increase in the level of knowledge management. Undoubtedly, the ability to acquire knowledge from the environment, as well as internal knowledge, should be intensified. The interpretation of acquired knowledge and its distribution among the organization members is of great importance. Companies should focus on strengthening teamwork, where members know and share a common goal. Organizational memory, which consists in proper management of databases available to the enterprise, is also important. Strengthening these areas of activity under knowledge management will allow for an increase in the level of organizational flexibility in various dimensions, and the synergy effect will enable strengthening the overall level of organizational flexibility of enterprises.

Strengthening Organisational Resilience Through Knowledge Management: The Santa Catarina´s Civil Defence Case

Carlos Eduardo de Lima[1], Denilson Sell[1] and Regina Panceri[2]
[1]State University of Santa Catarina, Florianopolis, Brazil
[2]Santa Catarina´s Civil Defence, Florianopolis, Brazil

cadulima@gmail.com
denilsonsell@gmail.com
reginapanceri@gmail.com

Abstract: The constant changes in the political, social, and economic scenarios, as well as recent major crises and natural disasters that have affected Santa Catarina, Brazil, and the world, have increased the demand for organisations to provide more resilient responses. Civil Defence organisations are no exception, and they must prioritise the identification and management of critical knowledge to enhance their organisational resilience. In light of this, a case study was carried out in Santa Catarina´s Civil Defence (SCCD), a public government organisation that plays a critical role in the territorial resilience of SC state. The study aimed to evaluate SCCD's organisational resilience and develop a continuous improvement plan based on critical knowledge. To achieve this, the Resilience Analysis Grid (RAG) was used as a tool to characterise the SCCD's resilience potential. The analysis showed that the organisation has an appropriate level of resilience potential. However, to identify ways to enhance this potential, it was necessary to analyse critical knowledge for monitoring, anticipating and responding to unexpected events, as well as exploring how SCCD promotes learning in the face of new situations. To do so, a framework was used to analyse critical knowledge to organisational resilience capabilities. This framework was used to present an improvement plan for the organisation's resilience potential, based on the use of techniques and methods for knowledge management. The plan recommended several practical steps that could be taken to enhance the resilience of the SCCD, including the creation of a knowledge management system, the development of training programmes, and the identification and management of critical knowledge. In conclusion, the study highlighted the importance of critical knowledge in enhancing organisational resilience and demonstrated that a continuous improvement plan based on critical knowledge could lead to significant improvements in the resilience of organisations like the SCCD. By following the study's recommendations, organisations can become better equipped to respond to future challenges and maintain their resilience in the face of change and uncertainty.

Keywords: Organisational resilience, Critical knowledge, Knowledge management, Risk and disaster management, Civil defence

1. Introduction

Climate change and the increasing frequency of natural disasters have highlighted the need for organisations, particularly those involved in disaster management, to enhance their resilience capabilities. This is especially crucial for public defence organisations like the Santa Catarina Civil Defence (SCCD) in Brazil, which play a critical role in ensuring the safety and resilience of communities in the face of various risks and disasters.

Santa Catarina, being the second most affected state in Brazil by natural disasters, has experienced significant financial losses amounting to billions of reais. In light of these challenges, it is imperative for SCCD to strengthen its resilience potential and improve its capacity to respond swiftly and effectively to unexpected events. However, traditional approaches and methods are no longer sufficient to address the complex and unpredictable nature of disasters.

In response to this need, this study aims to investigate how knowledge management can contribute to strengthening the organisational resilience of SCCD. By focusing on the identification and management of critical knowledge, the study seeks to enhance SCCD's ability to anticipate, monitor, respond to, and learn from unexpected events. To achieve this, a case study approach was employed, with SCCD serving as the research subject due to its significant role in the territorial resilience of Santa Catarina.

The research objectives include evaluating SCCD's current organisational resilience and developing a comprehensive improvement plan based on critical knowledge management techniques. The study employs the Resilience Analysis Grid (RAG), a tool developed by Hollnagel (2010), to assess SCCD's resilience potential across four core dimensions: response, anticipation, monitoring, and learning. Additionally, Fraga's (2019) framework for analyzing critical knowledge resources is used to identify areas where knowledge management practices can be implemented to enhance SCCD's resilience capabilities.

The findings of this research have practical implications for public defence organisations like SCCD, as well as for the broader field of disaster management. By adopting effective knowledge management strategies,

organisations can improve their resilience potential, enhance their ability to protect communities, and respond more effectively to future challenges and uncertainties. Furthermore, this study contributes to the scientific understanding of how knowledge management can be leveraged to strengthen organisational resilience in the context of risk and disaster management.

To further validate and expand upon the findings of this study, future research could apply the proposed framework and methodologies to other public defence organisations. This would allow for a more comprehensive evaluation and comparison of resilience potential across different contexts, leading to the development of tailored knowledge management strategies to enhance organisational resilience in diverse risk and disaster management scenarios.

2. Theoretical Foundation

2.1 Fundamentals of Organisational Resilience

According to Fraga, Varvakis and Sell (2019), given the complexity of organisations and their intensive knowledge processes, research in multidisciplinary areas that seek to understand better these environments, such as the area of organisational resilience, is necessary.

Lee, Vargo and Seville (2013) state that the ability of organisations to continue to operate and provide goods, services, and jobs is fundamental to the ability of communities to be resilient. “However, the task of building more resilient organisations is complicated by the inability to translate the concept of resilience into tangible work constructions for organisations” (McManus et al., 2007).

When resilience became part of safety discussions, it was defined as "the intrinsic capacity of an organisation (system) to maintain or recover a dynamically stable state that allows it to continue operations after a major accident and/or in the presence of continuous stress" (Hollnagel, 2006). However, Beauchamp et al (2019) highlight that like the concept of human well-being, resilience is complex and multidimensional, often linked to desirable impacts on development.

Resilience is a multifaceted concept with overlapping dimensions, including robustness, fault tolerance, flexibility, survivability, and agility. Definitions and interpretations vary across fields, but all agree that resilience is critical for thriving in the face of adversity. (Hosseini, Barker and Ramirez-Marquez, 2016). Currently, several disciplinary perspectives operate in many domains of application of the resilience concept. These different perspectives have led to the construction of numerous organisational resilience models.

McManus et al. (2007) states that organisational resilience requires three main qualities: self-awareness, effective vulnerability management, and adaptability to new and unforeseen circumstances. The concept of resilience as a measurable property of a system or organisation is emphasized by Hollnagel and Nemeth (2021). According to Hollnagel (2010), resilience is something that an organisation does, rather than something that it possesses. In this sense, Hollnagel (2010) proposes the RAG tool for assessing the degree of resilience of an organisation based on four main abilities, including the ability to respond, anticipate, monitor, and learn (Figure 1).

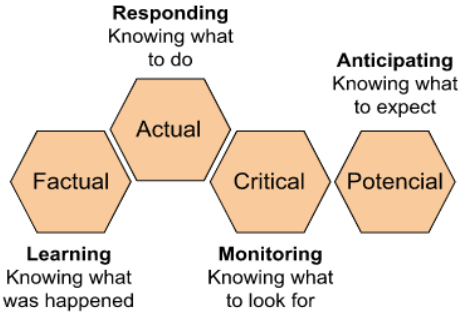

Figure 1: The four Core Capabilities of Organisational Resilience. Source: Hollnagel (2010).

Fraga (2019) states that, to be resilient, an organisation needs to be capable of working on these four basic and essential practical abilities and highlight that an organisation's ability to recover and adapt to unexpected events is a measurable quality of resilience (Hollnagel, 2010; Fraga, 2019; Hollnagel and Nemeth, 2021).

2.2 Knowledge as a Critical Factor for Resilience Potential

Knowledge is the combination of information with experience, context, interpretation, and reflection, which is applied in relevant decisions and actions. In this sense, Choo (2003) emphasizes the integration of meaning creation, knowledge construction and decision-making processes in organisations with a knowledge focus.

Fraga (2019) highlights that organisations need to be aware of their knowledge assets to achieve precise and objective management. However, the growing volume of raw data makes managing these assets an even greater challenge. Therefore, the use of tools to transform them into useful information is essential.

As emphasized by Nonaka and Takeuchi (1998), Hollnagel (2006), and Fraga (2019), knowledge is a critical factor in increasing organisational resilience. To achieve this, Neaga (2010) proposes the use of knowledge accelerators to develop resilience in uncertain and complex environments, while Albuquerque (2020) highlights the importance of a tool for all phases of organisational resilience.

Van de Walle (2014) observes that public sector organisations tend to rely on traditional recipes of organisational reform that result in new types of formalism. However, making knowledge accessible is essential to ensure sustainability and transfer of knowledge to all. Knowledge management is therefore fundamental for organisations working with risk and disaster management, as demonstrated by CEPED/UFSC (2016), which presented a systemic approach to civil protection and defence actions, represented in the operation cycle (Figure 2).

Figure 2: Cycle of civil defence´s operation. Source: CEPED/UFSC (2016) translated by authors.

Hollnagel and Woods (2006) argue that to achieve resilient performance, constant updates of knowledge, skills and resources must be available to all members of an organisation. Thus, Fraga (2019) proposes a framework for analysing critical knowledge resources related to resilience capabilities, adapting the Critical Knowledge Factors (CKF) model developed by the Paris Knowledge Management Club in 2000 to include knowledge criticality factors (Figure 3).

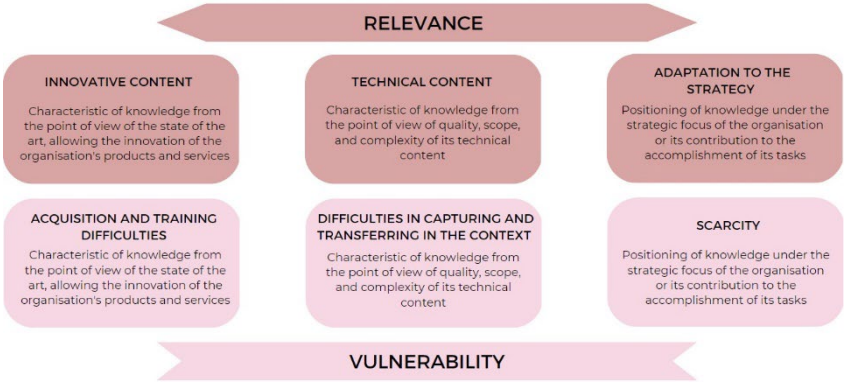

Figure 3: Factors of Knowledge Criticality. Source: Fraga (2019) Adapted by Authors

Therefore, based on the literature review, the theoretical analysis units were adapted and complemented with RDM elements (prevention and mitigation, preparedness, response, and recovery) in order to highlight the importance of knowledge as a catalyst for organisational resilience. Organisations must understand knowledge as something critical to monitor, anticipate, respond to, and learn from (Fraga, 2019) and overcome the challenge of identifying tacit or complex knowledge to apply it in their strategies and tasks.

3. Method

This research used the concept of resilience of Hollnagel (2010) as the ability of an organisation to recover and adapt to unexpected events through its capacities to respond, to monitor, to anticipate, and to learn. Furthermore, the study assumed, following Fraga (2019) and Nemeth and Hollnagel (2022), that the quality of resilience can be measured and improved.

In that regard, Fraga's (2019) framework (Figure 4) is positioned as a practical tool for identifying and analysing critical knowledge from the perspective of resilience capabilities, with the objective of enabling specific actions related to knowledge management that can contribute to organisational learning and performance. Consequently, the framework was selected as a tool for this research, with adaptations made to suit the phases of RDM. The framework of Fraga (2019) consists of four phases, each of which includes further subdivided stages that may be adapted to account for differences in the studied organisation and researcher position.

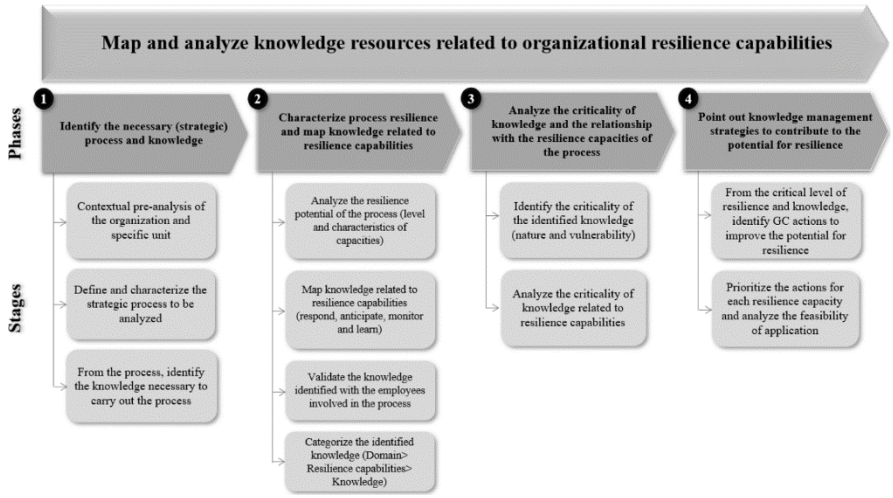

Figure 4: Analysis Framework for Knowledge Resources Critical to Resilience Capabilities. Source: Fraga (2019)

In this study, data was collected using forms, spreadsheets, individual interviews, and group meetings, following the steps described by Fraga (2019). The participants included two internal coordinators (Monitoring and Alert and a Regional Coordinator), one external coordinator (meteorology), three managers (operations, hydrology, and training and education), and four expert advisors (two geologists and two hydrologists). This allowed for a comprehensive understanding of organisational context, knowledge-intensive processes, and identification of key knowledge assets and gaps. The main phases and stages of the data collection process are presented in Figure 4, and the results of the study's application will be discussed in the following sections.

4. Analysis of Organisational Resilience of SCCD

In this section, the steps used to analyse the resilience potential of SCCD, according to the guidelines of Fraga's (2019) framework, as well as the results obtained at each stage of application of the tool, will be presented.

4.1 Phase 1 - Identification and Required Knowledge

The first phase aimed to identify the process and knowledge that would be analyzed. To do so, it was subdivided into three distinct stages carried out with the support of the following data collection instruments as demonstrated in Figure 5.

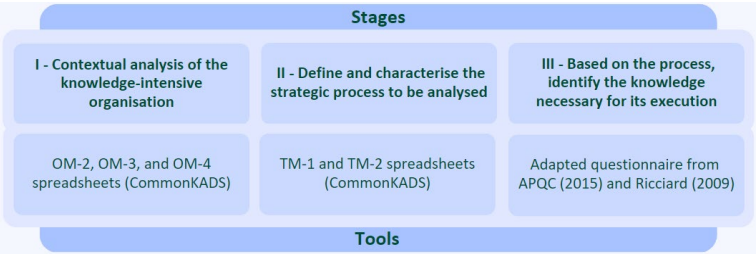

Figure 5: Data Collection Instruments for Phase 1. Source: Fraga (2019) Adapted by Authors

Based on documentation review and the researcher's experience over the last 4 years at the institution, the "Risk Assessment Process" was suggested and approved by the area responsible for it and, after the application of Phase 1, the results shown in Figures 6 and 7 were obtained.

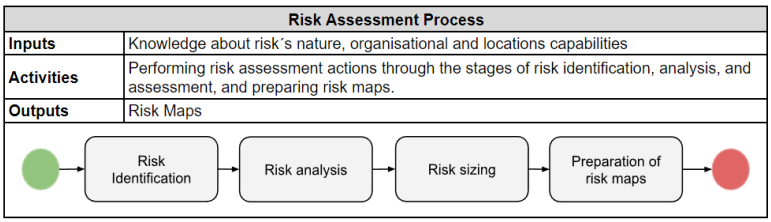

Figure 6: Representation and Characterization of the Process. Source: Authors

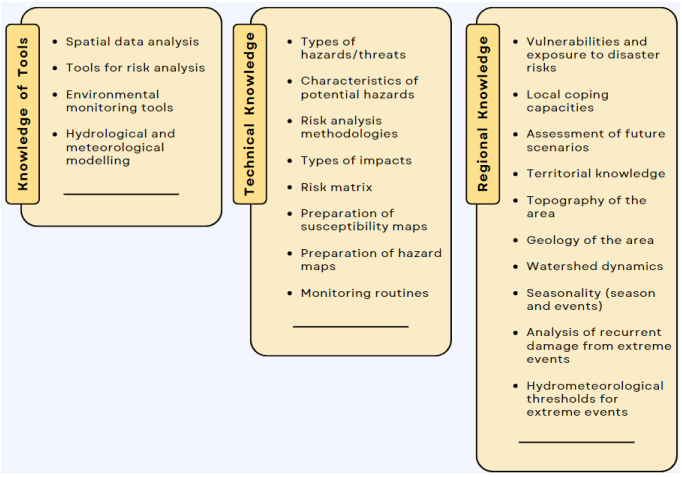

Figure 7: Table of Knowledge Required to Perform the Process. Source: Authors

4.2 Phase 2 - Characterization and Related Knowledge

The second phase aims to characterise the resilience of the process (by identifying related risks and analysing its potential for resilience) and map knowledge related to resilience capabilities (respond, anticipate, monitor, and learn). To do so, it was divided into three distinct stages, which were carried out with the support of the data collection instruments demonstrated in Figure 8.

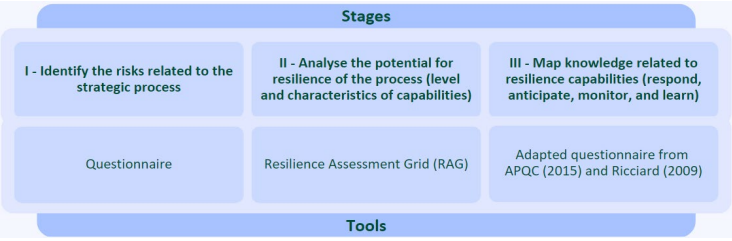

Figure 8: Data Collection Instruments for phase 2. Source: Fraga (2019) Adapted by Authors

After Phase 2 was implemented, the SCCD achieved a score of 2.79 for potential organisational resilience, which is considered acceptable based on the methodology used. This result was uniformly perceived by all interviewees, increasing the accuracy of the outcome. Moreover, individual scores were assigned to each

resilience capacity, with scores of 2.83 for anticipation, 3.00 for response, 2.83 for monitoring, and 2.50 for learning. Besides, figure 9 illustrates the list of risks related to the process.

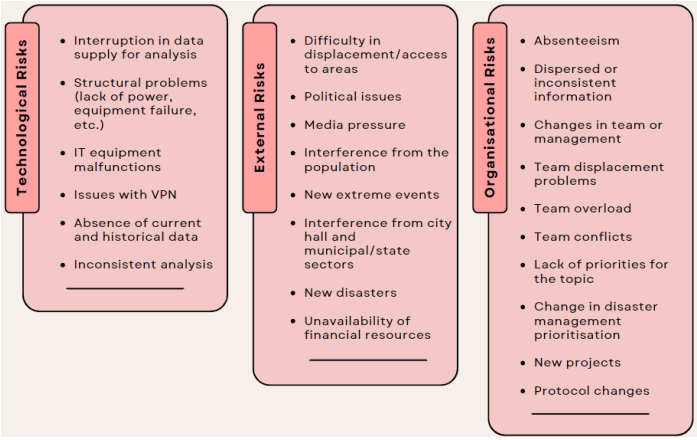

Figure 9: Risks Related to the Process. Source: Authors

In this phase, knowledge was also mapped, and in the next subsection, the analyses of the knowledge related to each resilience capability will be presented. In the following subsection, this knowledge was presented with an evaluation of criticality according to the criticality criteria used in the methodology.

4.3 Phase 3 - Criticality Analysis

In the third phase, the criticality of the previously mapped knowledge was identified according to the criteria presented in Fraga's framework, and an analysis of the importance of the knowledge was conducted based on the ratings given by the interviewees. To do so, it was subdivided into 2 distinct steps, which were carried out with the support of the following data collection instruments as demonstrated in Figure 10.

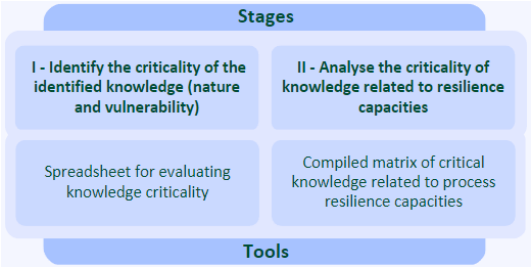

Figure 10: Data Collection Instruments for Phase 3. Source: Fraga (2019) Adapted by Authors

To perform data collection in the first stage of this phase, spreadsheets for risk assessment were used with the knowledge mapped in the previous phase. To guide the interviewees, following Fraga (2019), a Likert scale with 3 levels (1 - Low, 2 - Medium, 3 - High) was defined to grade the criticality factors of knowledge regarding their nature and vulnerability related to each of the mapped knowledge for each of the 4 resilience capabilities.

In the second stage of this phase, to analyse the criticality of the knowledge, the coefficients are calculated per criticality factor based on the median of the ratings assigned by criteria for each knowledge. With the completion of Stages I and II of the third phase of the framework, it was possible to calculate the coefficients of the criticality factor (presented in Figure 3) for each knowledge related to each resilience capacity, based on the median of the responses from the 10 interviewees.

The average of the resulting critical factors for each knowledge was calculated in order to obtain a unified score for each critical factor of the knowledge related to resilience capacities. In total, 16 knowledge related to the capacity to anticipate, 9 related to the capacity to respond, 11 related to the capacity to monitor, and 10 related to the capacity to learn were identified. After that, some inferences and revisions were made in the recorded interviews in order to identify the main knowledge to be prioritised. With this analysis, it was possible to draw specific conclusions about the knowledge related to each resilience capacity, as well as general conclusions considering all the knowledge from the different capacities together.

The first conclusion was the identification of knowledge with the highest averages, considering all six critical factors for each capability: AK9 for anticipating (knowledge of communication techniques), RK5 for responding

(knowledge of meteorological and hydrological operational processes), MK11 for monitoring (knowledge of monitoring tools), and LKs 1 and 9 for learning (knowledge of the history of risks and updating of hydrometeorological thresholds for extreme events).

These knowledges stood out not only for their high averages but also because their innovative content, technical content, and alignment with the strategy were the main contributors to these results. Another important inference was that some knowledge from the capacities presented direct relationships with each other, allowing generalisation of specific knowledge (Table 1).

Table 1: Critical Knowledge to be Prioritised

Critical General Knowledge	Abilities	Specific Knowledge
Processes Anticipating	Anticipating	AK3 - Internal process flows
	Responding	RK9 - Internal process flows
	Monitoring	MK4 - Institutional processes
	Learning	LK6 - Continuous process improvement techniques
Monitoring tools	Anticipating	AK7 - Monitoring tools
	Monitoring	MK11 - Monitoring tools
Internal competencies	Anticipating	AK2 - Competencies of other internal areas
	Responding	RK6 - Institutional operational procedures
Communication techniques	Anticipating	AK9 - Communication techniques
	Responding	RK10 - Communication
Techniques for analysing historical data	Learning	LK1 - Risk history
		LK3 - Ability to interpret and qualify historical data
		LK9 - Ability to update hydrometeorological thresholds for extreme events
	Monitoring	MK3 - Ability to interpret monitored data and its indicators

Source: Authors.

4.4 Phase 4 - Knowledge Management Strategies for Organisational Resilience

Phases 1, 2, and 3 of the framework had been applied earlier and the subsequent phase, phase 4, aimed to mitigate risks of failures in asset execution and improve asset resilience. This phase consisted of two distinct stages, which utilised analysis instruments depicted in figure 11. The primary objective of phase 4 was to implement KM actions specific to the risk assessment process to enhance the asset's resilience.

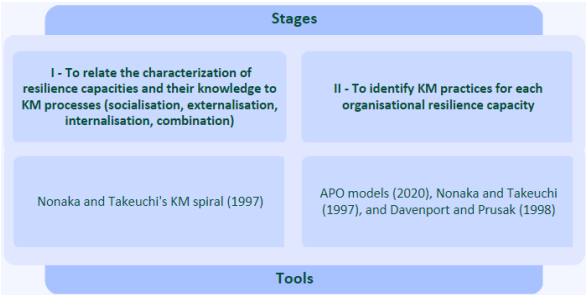

Figure 11: Data Collection Instruments for Phase 4. Source: Fraga (2019) Adapted by Authors

By mapping and prioritising critical general knowledge, along with characterising their respective resilience capacities (anticipate, respond, monitor, and learn), it became possible to identify and define some KM practices, according to the typification proposed by Nonaka and Takeuchi (1997) (socialisation, externalisation, internalisation, combination).

After analysing the previous data, as well as the results presented, it was possible to survey KM practices (such as mentoring programs, communities of practice, training, capacity-building, etc.). The intersection of these practices with issues to be solved to address knowledge deficiencies related to each of the resilience capacities of the "Risk Identification, Analysis, and Sizing" process resulted in the data presented in table 2.

Table 2: Matrix of Actions for Managing Critical Knowledge Related to Resilience Capacities

Ability to anticipate			
Issues to be addressed	Related knowledge	KM process	KM practices
Poor alignment with organisational strategy	AK2, AK3, AK9	Externalisation	Creation of discussion forums
Communication failures	AK9	Socialisation	Mentoring program, creation of discussion forums
Deficient dissemination of tacit knowledge	AK7	Socialisation	Communities of practice
Ability to respond			
Issues to be addressed	**Related knowledge**	**KM process**	**KM practices**
Dispersed or inconsistent information	RK6, RK9, RK10	Combination	KM through intranet
Limited knowledge about organisational processes	RK6, RK9	Socialisation	Space for sharing information and experiences
Complexity of knowledge	RK10	Internalisation	Mentoring program, trainings and capacity-building initiatives
Ability to monitor			
Issues to be addressed	**Related knowledge**	**KM process**	**KM practices**
Knowledge about monitoring tools	MK3, MK11	Socialisation	Communities of practice
Lack of documentation on the tools	MK4, MK11	Combination	KM through intranet
Ability to use data for analysis	MK3, MK11	Internalisation	Trainings and capacity-building
Ability to learn			
Issues to be addressed	**Related knowledge**	**KM process**	**KM practices**
Absence of current and historical data	LK1, LK3	Combination	Use of artificial intelligence tools
Diffuse knowledge	LK3	Socialisation	Communities of practice
Complexity of knowledge	LK3, LK9	Internalisation	Trainings and capacity-building

5. Conclusions

This research has provided valuable insights into the role of knowledge management in enhancing the resilience potential of public defence organisations, as exemplified by the Santa Catarina Civil Defence (SCCD) in Brazil. By focusing on critical knowledge and implementing targeted strategies, this study has demonstrated the measurable cognitive value of knowledge management in improving organisational resilience.

The findings of this research offer practical implications for SCCD and other similar organisations involved in risk and disaster management. The identified knowledge management strategies, such as communities of practice, mentoring programs, and discussion forums, provide tangible approaches to address knowledge deficiencies and enhance organisational alignment, communication, and technical expertise. By implementing these strategies, organisations can strengthen their ability to anticipate, respond to, monitor, and learn from

unexpected events, ultimately improving their resilience and their capacity to protect the communities they serve.

Importantly, the framework and methodologies used in this study can be adapted and applied to other public defence organisations facing similar challenges. By employing the Resilience Analysis Grid (RAG) and the framework for analysing critical knowledge resources, organisations can assess their resilience potential, identify knowledge gaps, and develop tailored improvement plans. This adaptability and scalability of the research methodology increases its utility and value for a wide range of organisations operating in diverse risk and disaster management contexts.

The nature of the results obtained in this study holds significant utilitarian value. By enhancing their organisational resilience through effective knowledge management, public defence organisations can save lives, reduce financial losses, and mitigate the long-term impacts of disasters on communities. The practical implications of this research extend beyond academic discourse and can be directly applied to improve the preparedness and response capabilities of organisations involved in risk and disaster management.

Further research could build upon this study by applying the proposed framework and methodologies to other public defence organisations, validating and expanding upon the findings presented here. Future studies could also explore the long-term impact of implementing knowledge management strategies on organisational resilience and the effectiveness of these strategies in different risk and disaster management scenarios.

In summary, this research has highlighted the measurable cognitive value of knowledge management in enhancing organisational resilience. By leveraging knowledge management strategies and adopting the proposed improvement plan, organisations like SCCD can better anticipate, respond to, monitor, and learn from unexpected events, ensuring the safety and well-being of the communities they serve. The applied approach has effectively guided the identification and implementation of appropriate methods and techniques that address the specific needs of SCCD. Besides, the outcomes of this research offer practical insights that can be adapted, mapped, and utilised by other organisations involved in risk and disaster management, ultimately contributing to the broader goal of building resilient communities and mitigating the impacts of disasters.

Abstract: The application of knowledge management strategies, such as knowledge codification and personalization strategy, influences business performance because appropriate knowledge management strategies align with firms' strategies and support knowledge management activities. However, the findings of previous empirical studies regarding the relationship between knowledge codification strategy versus knowledge personalization strategy and business performance are inconclusive. This study aims to adopt a meta-analysis approach to investigate the relationships between knowledge codification strategy versus knowledge personalization strategy and business performance. It reveals that the knowledge codification strategy was positively related to the overall business and financial performance, while the knowledge personalization strategy was positively associated with overall business performance. To the best of the authors' knowledge, this is the first meta-analysis research that clarifies the knowledge management strategy—business performance relationship.

Keywords: Knowledge codification strategy, Knowledge personalization strategy, Business performance, Meta-analysis, National culture

1. Introduction

Knowledge management (KM) initiatives are difficult to be implemented without an appropriate management strategy (Liu, Farzad, et al., 2022; Oluikpe, 2012). Hansen et al. (1999) proposed two KM strategies, namely, knowledge codification and personalization (Sánchez et al., 2015). A knowledge codification strategy focuses on the capturing, codification, and retention of explicit knowledge with the support of technologies (Choi & Lee, 2012), whereas a knowledge personalization strategy is concerned with enhancing tacit knowledge communication through people's social networks interaction (Oluikpe, 2012).

The different choices of KM strategies, such as knowledge codification and personalization, influence the firm performance because clearly defined KM strategies align with business strategies (Liu et al., 2020) and support KM activities (Liu et al., 2022a). For example, the knowledge codification strategy emphasizes sharing, transferring, and storage of explicit knowledge. Organizations can easily use the codified knowledge they need; thus, the efficiency of knowledge application is improving, leading to better business performance. On the other hand, the knowledge personalization strategy complements the knowledge codification strategy by supporting employees to share, transfer and apply tacit knowledge. The tacit knowledge is extremely challenging to be transformed into documents. Once firms successfully establish methods for tacit knowledge sharing and application, firms can enhance their capability to receive more competitive advantages.

Previous review studies (Farooq, 2022; Inkinen, 2016) on KM and performance made no attempt to evaluate the effectiveness of the KM strategy (knowledge codification strategy and knowledge personalization strategy) on the business performance of firms. The effect size of the knowledge codification strategy—business performance relationships and the knowledge personalization strategy—business performance relationships remain unclear. A comprehensive understanding of the relationships between KM strategy and business performance is still obscure due to conflicted findings of previous studies. Thus, it is interesting to systematically examine previous KM strategies and performance studies through a meta-analysis, aiming to offer new insight into the KM strategies—business performance relationships.

2. Literature Review and Research Questions

The majority of empirical studies on KM strategy and business performance adhered to the categorization of knowledge strategy by Hansen et al. (1999), but based on this classification, there are some conflicting findings from these empirical studies. According to Ling (2013), the knowledge codification strategy had a positive or negative effect on moderating the intellectual capital—business performance relationships depending on the dimensions of intellectual capital, whereas Liao (2011) discovered a significant negative association between knowledge codification strategy and overall business performance. Interestingly, Bavarsad et al. (2015) found that the knowledge codification strategy did not have any influence on the firm's internal performance. On the contrary, several studies have shown a positive correlation between knowledge codification strategy and the financial performance of firms (Chen & Huang, 2014; Cohen & Olsen, 2015; Payal et al., 2016). In addition, Hasan et al. (2015), Shehata (2015) and Shahzad et al. (2016) concluded that the knowledge codification strategy had a positive impact on the firm's overall business performance. A significant positive relationship between the knowledge codification strategy and the non-financial performance of the firm was revealed by Cohen and Olsen (2015), while Kim et al. (2014) believed that the validation of the effectiveness of knowledge codification on non-financial performance depended on the availability of high maturity information systems and intensity of environmental knowledge. Despite there are possible reasons to explain these contradicted findings, however, such findings fail to provide a clear theoretical understanding of the knowledge codification—business performance relationship, therefore, the first research question is as follows: What is the relationship between knowledge codification strategy and business performance?

Likewise, earlier studies on the relationship between knowledge personalization strategy and business performance remain ambiguous. Ling (2013) and Payal et al. (2016) found that the relationship between the knowledge personalization strategy and the financial performance of firms was insignificant or even negative (Hartono et al., 2018). It has also been claimed that the relationship between knowledge personalization strategy and overall business performance is insignificant (Shahzad et al., 2016). However, it was argued that the relationship between the knowledge personalization strategy and financial performance (Chen & Huang, 2014) and the knowledge personalization strategy—overall business performance relationship was positive (Hasan et al., 2015). Due to such mixed findings, the second research question is as follows: What is the relationship between knowledge personalization strategy and business performance?

National culture is the collective code of the minds of a nation's people in a way that differentiates them from others (Hofstede, 2001). Hofstede et al. (2010) propose a framework including six dimensions —power distance (PD), individualism versus collectivism (IC), masculinity versus femininity (MF), uncertainty avoidance (UA), long-term orientated versus short-term orientated (LS) culture, and indulgence-oriented versus restraint-oriented (IR) culture —to evaluate the differences that exist between national cultures. All these six dimensions affect KM practices and activities (Liu, Tsui, et al., 2022). In addition, national culture, as an important moderator, is frequently applied in organizational research (Tsui et al., 2016).

Recently, many meta-analytic studies, adopting national culture as a moderator to inspect the influences of national culture on the knowledge-friendly organizational culture—performance relationship (Liu et al., 2021), the KM leadership—performance relationship (Liu et al., 2022c), the KM technology—performance relationship (Liu et al., 2023), and the organizational learning—performance relationship (Liu et al., 2022b). However, the moderating effects of national culture on the relationship between KM strategies and business performance remain unknown. Therefore, the third research question is as follows: Does national culture moderate the knowledge codification strategy versus knowledge personalization strategy—business performance relationships?

3. Methodology

3.1 Meta-Analysis

Meta-analysis offers a statistical examination based on many empirical findings from previous individual studies to integrate the empirical evidence (Hartung et al., 2008; Hempel, 2020) by amending errors and bias of the quantitative studies (Schmidt & Hunter, 2015) which is widely used in many fields, such as in educational, social, and medical sciences (Cheung, 2015). This research tries to investigate the relationship between KM strategies (knowledge codification strategy and knowledge personalization strategy) and business performance across empirical scholarly works; thus, the meta-analysis method was adopted to integrate the findings of the earlier studies. Group analysis for categorical moderators (Noel & Todd, 2012) was also applied to examine whether national culture is related to the effect sizes. The statistical analysis was carried out by using CMA3.0.

3.2 Coding of Variables

3.2.1 Primary variables

Business performance

Followed by Liu et al. (2021), the business performance was mainly measured in three different dimensions as follows. The first category used financial indicators, such as return on equity (ROE), return on investment (ROI), cash flow, sales growth, profitability, and market share to measure financial performance. The financial performance was coded as 'F'. The second category emphasized non-financial measurement which was coded as 'NF'. The second category included the following influencing factors such as the satisfaction of stakeholders, time to market, cost reduction, organizational reputation, personnel development, research and development, etc. The last category combined both financial and non-financial indicators which were coded as 'OBP' to evaluate overall business performance in this research.

3.2.2 Moderators

National cultures

Six dimensions of Hofstede et al.'s (2010) national culture framework, namely, power distance (PD), individualism vs. collectivism (IC), masculinity vs. femininity (MF), uncertainty avoidance (UA), long-term orientation vs. short-term orientation (LS), and indulgence vs. restrained (IR) culture were coded based on the regions where the data of the selected research was collected. We followed the approach of Gang Liu et al. (2021) to divide these dimensions of national culture mentioned above into two groups to evaluate the moderating effects of national culture on the KM strategy—business performance relationships (More details can be found on page 113 of Liu (2021)).

3.3 Search Strategy and Results

This research adopted the Scopus database to search relative research papers since more knowledge management journals are indexed in this database compared with the Web of Science. Additionally, the paper selection criteria are crucial to implementing meta-analysis (Cooper, 1998). *Knowledge management* and *performance* were selected to locate the papers if these keywords appear in the article's title, abstract, or keywords from 1975 to 2018 in this study. In accordance with the criteria above, 32,496 papers were retrieved and 31,526 were English-written articles. Limited to the studied topics, 24,663 remaining articles were examined by the contents of the abstracts and keywords. After excluding the unexpected papers, such as irrelevant papers, non-empirical papers, papers without reporting correlation coefficients, and inappropriate papers on measurement, finally, fourteen studies regarding the relationship between the knowledge codification strategy and business performance, eleven studies scrutinized the relationship between the knowledge personalization strategy and business performance were used in this study.

4. Results

It is apparent that the knowledge codification strategy had a positive relationship with overall business performance (r= 0.305, 95% CI: 0.132, 0.460, Z-value= 3.390, p= 0.001 < 0.01) and financial performance (r= 0.274, 95% CI: 0.174, 0.369Z-value= 5.210, p < 0.001) In addition, the knowledge codification strategy—overall business performance relationship was affected by different degrees of indulgence ($Q_{between}$: 28.538; df(Q):1; p-value: 0.000***< 0.001) of national culture. Furthermore, comparisons between collectivism and individualism ($Q_{between}$: 3.568; df(Q):1; p-value: 0.059*< 0.1) on the knowledge codification strategy—financial performance relationship were significantly different according to the categorical moderator test.

The empirical finding indicated that the knowledge personalization strategy was correlated with overall business performance (r= 0.208, 95% CI: 0.036, 0.368, Z-value= 2.362, p= 0.018< 0.1). No significant differences were found between national culture in influencing knowledge personalization strategy and overall business performance. Unfortunately, due to the limited number of research samples, studies on the relationship between knowledge codification strategy and non-financial performance, knowledge personalization strategy and financial performance, and knowledge personalization strategy and non-financial performance were not evaluated.

5. Discussion

The results of this study show that there was a significant positive correlation between the knowledge codification strategy and overall business performance. The finding agrees with the previous studies (Hasan et

al., 2015; Shahzad et al., 2016; Shehata, 2015). A positive correlation was also found between the knowledge codification strategy and financial performance. The findings corroborate with the ideas of others (Chen & Huang, 2014; Cohen & Olsen, 2015; Payal et al., 2016), who suggested that there is a linkage between the codification strategy and financial performance. Strong evidence showing the knowledge personalization strategy had a positive association with overall business performance when there was a significantly positive overall effect size. Similarly, this result matches those observed in earlier studies (Hasan et al., 2015; Shahzad et al., 2016) as well.

The study concluded that appropriate knowledge management strategies are an essential predictor of business performance since organizations can fill knowledge gaps through well-defined knowledge management strategies. First, it was analyzed that knowledge codification strategy was positively correlated with overall business performance and financial performance. For instance, if an organization's knowledge relies heavily on being stored in the brains of its employees, then, codification strategy is of vital importance in this case, especially, when the employee turnover rate is high or when leaders who were born after World War Ⅱ (baby boomers) are retiring from the organization. With this strategy, the organization can still utilize this codified knowledge when employees leave, which indicates that the more knowledge codified, the less the influence on organizational performance induced by knowledge loss. Second, there was a pronounced positive relationship between knowledge personalization and overall business performance. The knowledge personalization strategy emphasizes knowledge exchange, knowledge sharing, and transfer between employees within an organization. Employees have access to relevant knowledge within the organization's employee network about the problems they encounter in their work. Such effective knowledge transfer and application can be easily transformed into organizational value and lead to better organizational performance for the organization. However, since the number of studies on the knowledge codification strategy—non-financial performance relationship, the knowledge personalization strategy—financial performance relationship, and the personalization strategy—non-financial performance relationship is quite small, no specific effect sizes of these relationships have been provided at present, future research should continue to examine these relationships in depth. This study analyzed the effect of national culture on the knowledge codification strategy—overall business performance relationship and the knowledge codification strategy—financial performance relationship, based on the analysis, first, it concluded that the knowledge codification strategy—overall business performance relationship was stronger in restrained culture. One factual explanation for this finding is that in restrained culture, people are more likely to rely on books or other forms of codified knowledge, as used in classroom learning, and they do not interact well with others, especially, those who try to avoid interacting with strangers, and such behavior hinders their access to tacit knowledge. Second, it was found that the knowledge codification strategy—financial performance relationship was strengthened in collective societies. This result may be explained by the fact that people who work or live in collective societies are more likely to feel responsible for the development of the group, and therefore, they are keener to codifying and sharing knowledge with fellow members within the group, whereas people who work or live in individualistic societies are somewhat more independent and do not need and are less likely to codify knowledge for others. In addition, the empirical evidence could not validly specify the impacts of national culture on the knowledge personalization strategy—business performance relationship due to ambiguous comparisons of this study in terms of the knowledge personalization strategy—overall business performance relationship and an inadequate sample size of the studies regarding the knowledge personalization strategy—financial performance relationship and the knowledge personalization strategy—non-financial performance relationship.

6. Conclusion

6.1 Theoretical Contributions

This is the first comprehensive meta-analytic study that comprehensively investigated and clarified the KM strategies—firm performance relationships. It contributes to KM theory by providing a clear interpretation of the magnitudes of the relationship between the knowledge codification strategy and overall business performance, the relationship between the knowledge codification strategy—financial performance, and the relationship between the knowledge personalization strategy and overall business performance based on 1,084 subjects in six studies, 740 subjects in five studies, and 994 subjects in five studies, respectively. Our knowledge from previous studies, such as Inkinen (2016) and Farooq (2022) on the strategic KM—business performance issues, has been supplemented and expanded. The generalizability of these findings is more persuasive than in individual studies.

This is one of few studies that address national culture when investigating KM strategies and business performance simultaneously, and as such, this work makes a valuable contribution to both KM theory and international business research. It creates new knowledge and new research directions on the role of national culture in influencing KM strategies by demonstrating that the knowledge codification strategy—overall business performance relationship was strengthened in a restrained culture and the knowledge codification strategy—financial performance relationship was strengthened in collective societies by using meta-analysis.

6.2 Managerial Implications

This study helps scholars and practitioners to better understand the knowledge-based theory from the perspective of the strategic application of KM and provides feasible recommendations at the level of management implications. This combination of findings provides some support for the conceptual premise that managers need to select appropriate KM strategies that meet their business development needs as their organizations evolve. For example, the knowledge codification strategy should be prioritized if the employee turnover rate is high in an organization, whereas the knowledge personalization strategy should be deployed when employees greatly depend on others' tacit knowledge to accomplish their tasks. Such two complementary strategies, knowledge codification strategy and knowledge personalization strategy provide managers with strategic management approaches that can be combined. Therefore, managers should also assess their internal business requirements and external contexts.

These findings are of vital importance to managers as our research findings provide further instructive support for them. Managers should be aware that in addition to internal obstructions, external factors, such as national culture, might boost or impede KM activities. Those managers working in multinational companies should understand that the benefits of KM may be realized in very different ways in different cultural contexts and external circumstances. For instance, emphasizing on collective knowledge codification strategy might be less effective in individualistic societies but more likely to be easily accepted in collective societies. Furthermore, the knowledge codification strategy might be not undesirable if the knowledge codification process is tedious in indulgence-oriented societies, but it might be not a concern in restrained cultures where leisure is less valued.

6.3 Limitations and Future Research

First, the papers obtained in English written from 1975 to 2018 from the Scopus database in this study might suffer from a language bias and database bias, although such biases were considered limited, according to Livingston et al. (2008). Second, another limitation that could have affected the moderating effects of national culture on KM practices—performance relationships was the binary classification of national culture based on Hofstede's national culture scores. Differences in the national culture adjustment test might be related to the national culture group assignment, as some values close to the threshold were classified into two different groups. Third, the knowledge codification—non-financial performance relationship, the knowledge personalization—financial performance relationship, and the personalization—non-financial performance relationship still remain unclear due to the limited sample size. More studies regarding KM strategies and performance can be conducted in the future. In addition, this study only focused on knowledge codification verse personalization strategy, further research can examine knowledge exploration verse exploitation strategy—performance relationships. Finally, different types of performance, such as innovative performance, sustainable performance, team performance, and employee performance can be used to take further research on KM—performance relationships by using the meta-analysis.

Note

1 No publication bias was found after testing the sample through the fail-safe N test.

2. Details of the dataset can be obtained from the first author.

Spiritual Knowledge Management: Practical Wisdom and Faith-at-Work Brought to Life

Elaine Long
The Chicago School of Professional Psychology, USA

Elainelong2029@gmail.com

Abstract: Integrating knowledge management, faith-at-work, and phronetic workplace domains, this paper presents phronesis, or practical wisdom, and faith-at-work (FAW) based on theoretical principles of moral actions and character virtues and real-life examples of FAW practices such as thoughts, behaviors, and feelings, bringing to life the practically-wise company. Answering a call to investigate phronesis in the workplace to understand how the individual level of practical wisdom spreads throughout the company achieving a practically-wise company this paper refines one segment of Long's (2022) research findings in Faith at Work: People, Places, Practices, and Tools from the spiritual knowledge management (SKM) domain perspective. These FAW experiences equate to spiritual knowledge and spiritual intelligence in motion while supporting human resource development strategies for employee flourishment. The methodology is empirical phenomenology presupposing theory for the relevant phenomena. The Long (2022) study adds a deeper understanding that sharpens and supports SKM by extracting specific findings and implications of the integration of practical wisdom, moral actions, character virtues, and FAW practices - intersections that enlighten organizations to create desirable value.

Keywords: Faith-at-work, Phronesis, Spiritual knowledge management, Practical wisdom

1. Introduction

The integration of practical wisdom (phronesis), knowledge management – specifically spiritual knowledge and intelligence, and workplace spirituality or faith-at-work principles can help business psychologists, industrial/organizational, and knowledge management scholar-practitioners to better understand the holistic flourishing of the mind, body, and spirit for individuals at work and the collective organization. The chosen aim of this paper is to "shift to a discussion on how best to create climates for this holistic flourishing, whether or not this is called organizational spirituality" (Poole, 2009; p. 587) while addressing the concern that "development of phronesis in the workplace ought to be investigated to enable an understanding of how the individual level of practical wisdom spreads throughout the company to the achievement of a practically wise company" (Rocha & Pinheiro, 2021b; p. 131). The integrated thinking from these domains, using real-life examples from Long's (2022) empirical study leads to a practically-wise, spiritual knowledge management model. Sections four and five, methodology and theoretical backgrounds, provide context for sections six through eight, findings, discussion, and conclusion.

2. Methodology

Long's (2022) FAW empirical research methodology provides a backdrop for relating practical wisdom to workplace spirituality. The phenomenological study provided a theoretical and practical understanding of workplace spirituality (WPS) as faith-at-work (FAW) to explore a deeper awareness of the experience in the lives of employees and managers considering various faith-at-work organizational frameworks (Miller & Ewest, 2015) and individual practices, tools, and characteristics. One problem, noted by Long (2022), is that

> *much research in organizational and management development either neglects or is inconsistent with what defines and impacts the spirituality experience (Mohamed et al., 2004; Pandey & Gupta, 2008) …since 1990, a range of literature reviews, quantitative analyses, and theory development has existed in the WPS field, but relatively few phenomenological studies combine the individual unit of analysis (i.e., employees' and managers' perceptions) in the context of the organizational frameworks. (p. 18)*

To address this, "methodology included post-modern and life story concepts to investigate two common areas of phenomenological study, i.e., what are the experiences and the contexts of those experiences, with both the participant's actions and the researcher's interpretation" (Long, 2022, p.81). The two research questions were based on workplace spirituality's ideal ontology (the nature of reality, and what kind of being *is* the human being, of FAW, is conceptual with intersubjectivity and multiple realities) and relative epistemology (the relationship between the inquirer and the known, is subjective with unique outcomes as the data): (1) How do people experience work in relation to their spiritual and faith beliefs, and (2) How are the respondents' environment, practices, tools, and characteristics part of their experience? In this study "constructivist and interpretative approaches are both applicable to the inductive and exploratory nature of

this WPS research study and address the two common areas of phenomenological study, i.e., what are the experiences and what are the contexts of those experiences" (Long, 2022, p.84).

To enhance research triangulation and data collection and analysis richness, in addition to semi-structured interviews, the manager and employee participants completed a 5-day journal and provided photographs of their FAW tools or practices in their workspaces. The number of photographs, days journaled, and interview hours of all sources were 46, 56, and 15.23 hours, respectively. These prompted and captured real-time perspectives of their lived spiritual phenomenon. A targeted sample of 50% female/male, management/non-management, for-profit/non-profit industries, and a wide representation of spirituality/faith affiliations were met.

Three phases of coding and analysis based on Moustakas' (1994) structures assembled the larger phenomenological meanings and made sense of the parts hermeneutically while bracketing but not reducing the researcher's heuristic. Pseudonyms protected the confidentiality of the eleven coded participants. Analysis of 3450 codes was not based solely on description codes (14%) but used personal values (32%), processes (23%), and felt emotions (13%). The InVivo (11%) and Themeing-the-data (7%) codes were used for member-checking narrative summaries. The coding, analysis, and findings resulted in a series of six mega-experience elements or themes of (1) tri-identity, (2) spiritual discernment, (3) wholistic spiritual exercises, (4) dynamic processes, (5) creating the right FAW environment, and (6) Faith in the Work (FitW) and W(holy)-ness, classified to a total of 24 sub and micro-experience elements or categories. Summaries of the findings by each research question also give context to the themes because some FAW experience elements are common to all the respondents, some represent similarities among a few, and others are unique to one yet have a powerful impact on a deeper understanding of the spiritual phenomenon. Managers and employees' beliefs, values, and practices revealed not only 24 experience elements but also 14 potential organizational environmental frameworks. The FAW findings that show practical wisdom, moral actions, character virtues, and practices that support scholar-practitioners in understanding and developing practically wise organizations are highlighted in this paper's findings and discussion sections.

3. Theoretical Backgrounds

The following theoretical foundations are briefly mentioned providing context and background. First, FAW embraces the forms of belief and filters through which one constructs meaning and purpose in the world (Miller, 2007) including that, "spirituality is the ongoing transformation of a human being in an engaged and responsible relationship with oneself, the other, the world, and God" (Dienberg & Warode, 2018, p. 815 as cited by Long, 2022, p. 25). FAW incorporates "there is clearly nothing in the definition of religion that necessitates membership in an organized religion. One's religion, then, is one's 'set of beliefs concerning the cause, nature, and purpose of the universe" (Dent, 2019, p. 76). In addition, "spirituality at work is not bounded by formal religious practice, but because the spirit is a sacred power, it is drawn from religions (Bell & Taylor (2001) cited by Long, 2022, p. 48). Thus, the FAW axiom used here accommodates formal and defined expressions of belief as found in religious constructs plus informal and less-defined expressions of belief as found in spirituality (Miller & Ewest, 2015) and concurs with (Lynn et al., (2009) that the workplace spirituality literature has helped to bring one's whole self to work, but needs to take more seriously that religious belief is part of the whole for many individuals. The key takeaway is to be able to live one's experience of faith in the workplace.

Secondly, this paper follows others' lead to look at workplace spirituality, aka FAW as a form of organizational wisdom (Rocha & Pinheiro, (2021a) and why it matters to knowledge management (KM) scholar-practitioners. The KM literature enumerates how organizations create, access, control, modify and keep logical, empirical, and rational knowledge to improve performance towards objective and material aspects of work. However, KM is a triple helix, involving spiritual, emotional, and rational aspects. Omitting or minimizing the spiritual orientation lacks depth and meaning for individuals and organizations (Bolisani & Bratianu, 2018; Bratianu, 2015; Farnese et al., 2019; Gull & Doh, 2004). Spiritual knowledge (SK), then, is the third helix, an intangible asset, that provides possible answers to life values, aspirations, motivations, and ethical principles even while one is at work, requiring conceptual and practical understanding.

As part of responsible knowledge management, Rocha et al. (2022) chronicle descriptions, evolution, and potential applications of practical wisdom, or phronesis in management research. Costello (2019) notes phronesis in the formation of managers and professionals and describes it with subtexts of intelligence and sound judgment from Aristotle in the Nicomachean Ethics as one of three approaches to knowledge distinguished from episteme and techne. "Whereas episteme concerns theoretical know-why and techne

denotes technical know-how, phronesis emphasizes practical knowledge and practical ethics" (Costello, 2019, p. 217). Phronesis is at the individual or the collective level, involving personal, moral, emotional, social, and religious aspects (Rocha et al, 2022). Specifically notable is that practical wisdom is "consider[ed] the all-important virtue of the mind" (Hughes, 2013, p.52, as cited by Rocha & Pinheiro, 2021b:137); it is also classified and included in the concept of moral virtues where virtue is described as a disposition that reliably does the right actions, makes the right choices, and has the right feelings (Hills, 2015). Thus, "practical wisdom is not distinguished from moral virtues" (Rocha & Pinheiro, 2021b, p.137). Biddle (2010) adds that "while a moral value is an object (or thing) by means of which one promotes one's life, a moral virtue is an action (or choice) by means of which one does so" (p.75) and one "must bear in mind not only our material needs but also our spiritual needs" (p.97) in assessing the propriety of an action.

Thirdly, collective phronesis is the sum of people's loftier independent and dispersed phronesis, and the synthesizing efforts to bring together by management pieces of the collective wisdom within and across organizations (Kodama, 2021). Finally, practically-wise organizations do more than just act morally or include a process of reflecting and making decisions, but apply all knowledge (including spiritual) to solve problems practically, efficiently, and effectively to do the least harm possible (Rocha & Pinheiro, (2021b).

4. Findings - Practical Wisdom Foundations of FAW

An integration between practical wisdom, SKM, and workplace spirituality, aka FAW idiosyncrasies, similarities, and commonalities from Long's (2022) empirical findings follows. Long's (2022) findings that focus on the FAW dynamic processes sub-element 4.2 "fruits" (moral actions) of how one treats others, sub-element 4.3 moral virtues and characteristics, and FAW practices are the most critical ones to this paper. All following examples are based on the coded findings, not the participant demographics. "The reflective inquiry process that was used highlights notions belonging to everyone's life exploring the phenomena in a heuristic or interpretative manner (Van Manen, 2016). The subsequent findings and conclusions of the people's stories and experiences go beyond purely reductive explanations of WPS phenomena and the verbatim exemplary quotes are used liberally throughout to fully illustrate the FAW experiences" (Long, 2022, p.110).

4.1 FAW Experience - Sub-Element 4.2: "Fruits" (Moral Actions) of How One Treats Others

Practical wisdom can be viewed as moral virtues (Rocha & Pinheiro, 2021b) and moral virtues as moral actions (Biddle, 2010); and "an action either promotes a person's life and long-term happiness or it does not. If it does, it is virtuous; if it does not, it is not" (Biddle, 2010, p.82). In practice, the spiritual particulars at work as FAW experience elements of virtuous moral actions add a constructive resource for scholar-practitioners.

All the employees and managers in Long's (2022) study determined that FAW is moral actions described as "how you treat others" and involve a variety of dynamic habits, qualities, and deeds. Through intensive coding, the types of moral actions or the "fruits (something that inevitably appears on a healthy tree) of how one treats others are charity, joy, peace, patience, kindness, goodness, gentleness, commitment, and continency or self-control. Tangible examples of employees' and managers' "fruits" or moral actions are found in Table 1.

Table 1: Real-life Examples of FAW Fruits/Moral Actions of How One Treats Others

Moral Action	Description	Pseudonym - Quote from Long (2022)
Charity	The love of God and fellow men expressed in concrete actions.	Kia – "All of the tasks that we have to do should be really moving toward those values of fairness and equity, and, caring, caring for, caring for people."
Joy	State of being undisturbed by the negative things in life.	Griffin – "At the core is service, serving others' needs, and the joy that comes out of serving others is priceless."
Peace	Tranquillity in our soul that comes from relying on God. Rather than getting caught up in anxiety for the future.	Theodore – "Without making time to pray, I may not act peacefully or be charitable when someone is being difficult."
Patience	Ability to bear the imperfections of other people, through our own needs as well.	Miriam – "It's really important to allow people to be who they are, regardless of what their faith is or isn't. So that's just about tolerance of any kind, right?"

Moral Action	Description	Pseudonym - Quote from Long (2022)
Kindness	Willingness to give to others above and beyond what we owe them.	Eve – "And so for me, that's how I exhibit my faith, by trying to treat people with kindness."
Goodness	Avoidance of evil and the embrace of what's right, even at the expense of one's earthly fame and fortune.	Theodore – "In Greek Orthodox practice, evil thoughts are the little things that start to enter your mind that start to direct you towards a failing of some kind. Acedia is one of the most dangerous of the eight evil thoughts…sometimes, even doing 'a good' is not, it is not 'a good' when it is not 'your good'…you must stay focused."
Gentleness	To be mild in behavior is to be forgiving rather than angry, gracious rather than vengeful.	Eve – "It's in the Bible, how many times you're supposed to forgive. He says, 70 times seven times like you're saying like you continue to forgive…Bible reminds me there is no end to being patient."
Commitment	Living life per God's will at all times.	Jacob – "When the wind is not blowing through the sail and not getting us moving, everything just feels stagnant, and it's easy to lose track and just forget the calling that God has put upon us. I find that when things are out of your control, you just really have to kind of look to the One that is in control."
Continence	Self-control is the exercise of moderation in all things.	Joyce - "My faith is emotional control; My faith is behavioral control."

4.2 FAW Experience Sub-Element 4.3: Theological, Moral Virtues, and Character Strengths

In Long (2022), the employees and managers employed the theological virtue of hope, and moral virtues supported by character strengths of prudence, justice, and temperance as part of their FAW experiences. Rocha and Pinheiro (2021b) suggest that to become a person of practical wisdom one needs character virtues and a notion that spiritual characteristics could be an antecedent to wisdom. The FAW: PPPT real-life experiences support these suggestions. Within the dynamic spiritual development and the fruits/moral actions of how one treats others FAW experience elements are the specific characteristics of temperance including prudence, justice including fairness, transcendence including hope, and spirituality. See Table 2. These real-life examples clarify what character virtues (VIA Institute on Character, 2018) of practical wisdom look like at work.

Table 2: Real-Life Examples of FAW Character Virtues

Characteristic	Definition	Pseudonym - Quote from Long (2022)
Temperance: Prudence	Being careful about one's choices; not taking undue risks	Joyce – "I always feel like the Holy Spirit's jumping in and going, warning, warning, warning, you know, always protecting me."
Justice: Fairness	Treating all people, the same according to notions of fairness and justice; giving everyone a fair chance	Kia – "I stand for the truth… not just for rules because they are the rules, there's a reason and a value behind them…fairness, justice, and equity. I see this calling as a driving force of the work that I do, I have to advocate for fair treatment."
Transcendence: Hope	Optimism, future-mindedness, expecting the best in the future, and working to achieve it	Eve – "Regardless of your situation or position even you can still be somebody who, you know, brings life, gives life, gives hope versus you know taking it away from people, and that's kind of my focus when I come into the day while I'm at this job."
Transcendence: Spirituality	Faith and purpose, coherent beliefs about higher purpose, meaning of the universe; meaning of life that shape	Amrit – "Faith wisdoms given to you, father's influence, and values; pass on to your children…it's [faith] largely engrained inside, and it is deeply set inside…. People prefer to leave

Characteristic	Definition	Pseudonym - Quote from Long (2022)
	conduct and provide comfort.	organizations if it conflicts with their value system or faith."

These character virtues help scholar-practitioners identify the phronimos, the one who uses the 'eye of the soul' honed by experience and made possible by good moral character—to act virtuously and prescribe right action to others revealing that "moral expertise is practical wisdom rather than theoretical wisdom" (Khan, 2005, p.39). Purporting there is a need for these characteristics in a phronetic workplace, "one could surmise that the phronimos can sum up a situation, weigh up various factors, and work out what to do to promote or achieve his objectives" (Costello, 2019, p.217). Yet, as FAW's real-life experiences in the next section depict, a variety of practices - thoughts, behaviors, and feelings – cognizant of moral virtues, actions, and character, can further describe phronimos in a phronetic workplace.

4.3 FAW Practices (Thoughts, Behaviors, Feelings)

Descriptions of FAW practices (which are SK or SQ in motion in the SKM domain) were in-depth and specific due to triangulation in Long's (2022) methodology addressing a research call to reduce abstraction around FAW practices (Dyck, 2014). The detailed interview questions were supplemented by five days of journalling about spiritual experiences such as, what did you do? what did you think? what did you feel? what did you believe? and how is spirit or faith present or absent at work today? as well as by the photographs of their workplace spirituality tools, environment, practices, etc. An average of eight, regular FAW practices were implemented by each employee or manager. To dignify the commonalities, similarities, and idiosyncrasies of the FAW practices, see samples of the FAW thoughts, behaviors, and feelings in Tables 3, 4, and 5.

Table 3: Sample of FAW Practices (Thoughts) by Employee/Manager Quotes

Employee/ Manager	Thoughts
Miriam	VIRTUES: … the study of Mussar I think is really instrumental in what I bring not only to work and to my clients, but just, the work on what I try to do for myself. The application of Tzedakah [Hebrew for justice], of this virtue, is really up to you, as long as you also balance using Mussar training and the other virtues.
Amrit	GOD'S GRACE: With my colleagues, faith is at two levels. One, I am spiritually awake…My faith is still there, and two, I am more connected with my colleagues when I am good to them, and in return, they also reciprocate. Supportive friends and colleagues are just a grace God has given you.
Eve	JESUS-LIKE: Jesus is a role model, be like Jesus. Things that I've learned, like the virtues, I have, I try to exhibit within the workplace, such as patience and love, are helping and supporting others.
Adeline	DIVINE ENERGY: Creative writing, not academic writing, expresses emotion, oneself, and the Beyond. Beyond is a… Divine Energy, the guiding force in the universe, God, the souls of people, also angels or småfolk, something like the equivalent of fairies.
Theodore	ETERNAL LIFE: Christian eternal life is an ongoing goal. Christ saves and we make efforts for the grace of Christ to be fully effective in us. In Eastern Orthodox everyone is called to be monastic; most are called to be in the world, not of the world.
Jacob	COVENT LOVE COMMANDMENTS: In Matthew 22:37-40, Jesus talks about the two Greatest Commandments Love God with all your heart, soul, and mind. And elsewhere in the Old Testament, we see that same concept presented to include heart, soul, mind, and body. So, so, essentially, love God, wholesomely. I need no other foundation than the eternally consistent promises of God. Hesed (חֶסֶד) is a Hebrew word that we translate as faithful love or loving-kindness. This is Covenant love and the love God displays through the promises he keeps.

Table 4: Sample of FAW Practices (Behaviors) by Employee/Manager Quotes

Employee/ Manager	Behaviors
Joyce	PRAYING: Praying every day because it's very important to me. I do that faithfully. I listen to Him tell me which would be the best way to go. I do a morning practice, next. I say three times, I believe, in reverence to my belief in the Trinity, and prayers for others. Praise God, never take things for granted, honor Lord Jesus and do no harm, and recognize the Holy Spirit constantly. End my morning practice with, thank you, my Father, Lord Jesus, and Holy Spirit for giving me this day to honor You, and listen some more.
Kia	GRATITUDE: …on my lunch hour; tapping, praying, wishing with the holy medals; it's a "thank goodness".
Monty	REFLECTING: Reflecting, meditating, and listening. The only tool that I used for workplace spirituality today was my playlist which has been consisting of Israeli and Jewish songs.
Amrit	BEING WITH NATURE: Being with natural and spiritual elements is how I connect at work. I recommend we go outside for meetings… the natural light, space, and view of the mountains are spiritual; remove obstacles to thinking clearly and allow you to be yourself at work.
Eve	EMBODYING FAITH: Embodying faith by being patient …no swearing… understand where people are coming from, …trying to connect with them. Handle differences with respect.
Griffin	SPIRITUAL WALKING: We started as a business meeting with three, now it's an ecumenical Bible study with eight men. Our relationships carry over from the corporate world to consulting to help with our spiritual walks today. We have trust… faith discussions and pray for each other.
Pat	SHARING: Listening to others' concerns without persuading them to become an atheist, being a supportive good friend, and not being responsible for others' views. When I opened up, he opened up too; sharing worldviews and our closeness includes sharing resources.
Jacob	MIND-BODY-SPIRIT EXERCISING: Being my whole self at work, including my spirituality, is being consistent with my core values. Inconsistency in one area affects others in the body, spirit, and mind diagram. My mind-emotion affects me spiritually… and in exercising. Spirit to mind to body, or in reverse. Spiritual practices... helps me navigate the day.

Table 5: Sample of FAW Practices (Feelings) by Employee/Manager Quotes

Employee/ Manager	Feelings
Joyce	THANKFUL: I feel thankful every day for what God has given me. I am thankful for giving me the opportunity to serve him throughout the day.
Eve	PEACEFUL: I desire giving and receiving understanding. My spiritual and mental health are connected so I follow my beliefs during challenges and this consistency with beliefs is peaceful.
Pat	CONNECTED: It was surprising to talk about religion at work and to learn about my co-worker's religious views and practices. It made me feel closer and a deeper connection and brought us closer by hearing about his religion and sharing that I am an atheist. Maintain faith without oppression.
Theodore	JOYOUS-SORROW: Spiritual practices at work include feelings of joy and sorrow. My faith includes opposite intentions such as joyous sorrow. Rejoice that Jesus Christ died and rose again for our sins and sorrow for our shortcomings. This gives hope that that although we're generally goof-ups, Christ is going to lead us out of that. The " gift of tears" is forgiveness for our sinful nature and for those who don't know the joy of God, Jesus, and the Holy Spirit. I feel joyful when others overcome challenges and are happy.

This sampling of practices, as mentioned, is spiritual knowledge and intelligence in motion, and represents the phronimos in a phronetic workplace. Next, the human flourishing model in Long's (2022) study is presented supporting the notion of the practically-wise organization as a virtuous learning organization (Rocha & Pinheiro, 2021b) that accesses collective phronesis, along with the integration of FAW and phronetic constructs

5. Discussion

5.1 Integrated Phronetic-Spirituality Workplace

The employees' and managers' FAW practices (thoughts, behaviors, and feelings) in Long (2022) are evidence of Rocha and Pinheiro's (2021b) viewpoint that spirituality supports the phronetic workplace in terms of the three dimensions of meaningful work, opportunities for the inner life, and sense of community and belonging. First, a synthesis of the FAW thoughts was, "[God's covenant] love empowers implementation and development of virtues for a wider scope than oneself; to calmly, purposefully serve others and self to work and live safely in, and not of, the world for eternal goals" (Long, 2022, p. 163). This relates to "once the phronetic workplace is part of a practically wise company, its members feel that their work is meaningful to them, society, and future generations" (Rocha & Pinheiro, 2021b, pp. 149–150). Secondly, a synthesis of the FAW behaviors was, "daily, constant self-awareness and improvements for eternal goals are consistent with their mind-body-spirit values…. praying for others…open discussions…studying and understanding scriptures, Saints, Christ… meditating, listening, believing, giving thanks, reflecting, removing obstacles to being your true self…spiritual elements and inspirational songs" (Long, 2022, pp. 163–164). This parallels the "opportunities for individual and collective spiritual evolution, achieving a transcendental way of living and conquering one purpose…opportunities to learn continuously… other methods… space and time for reflection, meditation, and prayer" – having an inner life within a phronetic workplace (Rocha & Pinheiro, 2021b, p. 151). Thirdly, a synthesis of the FAW feelings was "people feel releasing, uplifting, hope, forgiveness, a deep understanding that is surprising and important, sometimes a dichotomy of joyful sorrow and a gift of tears, deeper relationships with people and beyond people because of God, allowing one to maintain faithfulness without feeling oppressed" (Long, 2022, p.164). These resemble the sense of community and belonging in a phronetic workplace where "members' idiocrasies are both respect[ed] and celebrate[d]. Members' differences are favorable to the workplace, and every form to search for inner growth is valid" (Rocha & Pinheiro, 2021b, p. 150), linking the FAW and phronetic workplace constructs.

5.2 Spiritual Knowledge Management, Human Flourishing, and a Practically-Wise Strategy

Next, Rocha & Pinheiro (2021a) suggest organizational spirituality is an organizational identity that is the result of its values, practices, and discourse, composed of workplace and individual managers' and employees' spirituality; influenced by the environment, organizational culture, and knowledge management (p.248). The individual's moral actions, character virtues, and faith practices mentioned here, plus the individual's workplace culture and context not detailed in this paper but in Long's (2022) full study, assemble a similar approach that creates an organizational strategy for human flourishing. Long (2022) introduces a conceptual human flourishing (HF) model proposing that as individual FAW practices and characteristics which are spiritual knowledge (SK) and intelligence (SQ) in motion develop, they may be part of organizational values that through their interdependence of the physical and non-physical meanings and purpose lead to an organizational culture that is developed and transformed by knowledge management processes that allow changes to happen. When changes including spiritual knowledge management are allowed, a hermeneutical loop, like a virtuous learning organization in a practically-wise organization, creates a climate for flourishing. See Figure 1.

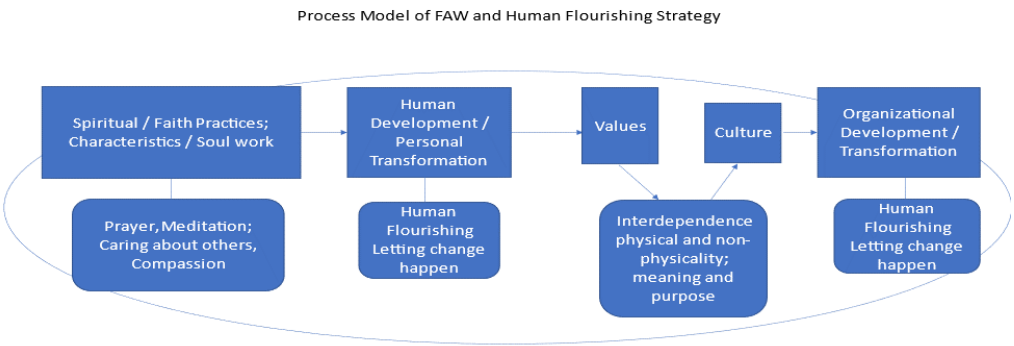

Figure 1: Model of FAW and Human Flourishing

The HF model embraces and allows for the respectful pluralistic use of various types of spiritual knowledge to access and expand spiritual intelligence supporting "how important the ambiance is for developing spirituality" (Rocha & Pinheiro, 2021b, p. 154). In practically-wise companies, workplace spirituality must be "highly developed and an advanced shared context for learning, interaction, and engagement" is crucial for spreading individual phronesis to collective phronesis; plus, "the meaning and purpose are the glue of collective knowledge and spirituality in the workplace" (p. 155). Also, Rocha & Pinheiro (2021b) propose that individual phronesis (practical wisdom) expands to workplace organizational phronesis through enhancing workplace spirituality. In the HF model, access to individual SQ practices and tools builds the collective SQ by acknowledging the glue of collective knowledge and creates value for a practically-wise company. Hence, again, SKM, practical wisdom, and FAW constructs intersect where "a high level of spirituality assists in the unfolding of practical wisdom… mainly in its role in finding the fulfillment and flourishing of one's life" (Rocha & Pinheiro, 2021b, p. 149).

6. Conclusion

The contributions are both theoretical extensions of the literature and practical organizational applications intended for scholar-practitioners.

6.1 Integrated Phronetic-Spirituality Workplace

The first discussion, and respective prior findings, extend the literature with non-abstractions clarifying how the constructs, FAW, and phronetic workplaces, connect and exemplify moral actions, character virtues, and spiritual thoughts, behaviors, and feelings from both theistic and humanistic spheres.

6.2 Practical Contributions Related to Human Flourishing

The second discussion supports a new model of linkages between the FAW experiences involving a variety of spiritual and faith-at-work practices, such as prayer and meditation, embracing FAW characteristics such as caring about others or compassion, where "soul work" develops and engages opportunities for individual phronesis, and a practically-wise organization lets these changes happen, for non-materialistic reasons and the common good, in turn, becomes organizational phronesis, with innovation and shared values creation, resulting in human flourishing. "The implementation of a continuous FAW and HF strategy would reinforce the FAW experiences and continuous FAW experiences would reinforce the HF strategy in a hermeneutical circle" (Long, 2022, p. 191).

Finally, creative inquiry through verbal, written, and visual phenomenological methodology brought to life greater awareness of, extended, and contributes to the literature and practical applications of spiritual knowledge management, practical wisdom, and FAW.

Acknowledgements

My gratitude to Drs. R. Rocha, G.W. Hay, and D.J. Dean for their insightful comments and encouragement.

Strategies for Knowledge Management Readiness at an Engineering Consulting Organization in South Africa

Edigar Mahuni and Madeleine Fombad
Department of Information Science, University of South Africa, Soth Africa

echavhunduka@gmail.com
fombamc@unisa.ac.za

Abstract: *Aim.* This article investigates knowledge management readiness at an engineering consulting firm in South Africa known as Zutari (Pty) Ltd, or Zutari, and suggest a strategy to achieve readiness in engineering firms. Engineering consulting firms are knowledge-intensive firms that offer specialised services in the provision of independent expert knowledge in the fields of engineering, science and other related areas in the public and private sectors, infrastructure, and construction sectors Although knowledge management is widely acknowledged as a strategic enabler in engineering consulting firms, most initiatives fail, making a knowledge management readiness assessment essential before implementation. *Methodology.*

The target population was Zutari's permanently employed technical professionals. Stratified and systematic sampling methods were applied to select a sample of 285 technical professionals. A questionnaire was used to gather quantitative data. The assessment model of Aydin and Tasci (2005) was used to assign readiness levels for the critical success factors under investigation. *Findings.* The findings reveal that the level of knowledge management awareness among Sutaria staff is quite high, even though knowledge management is practised informally. A knowledge management readiness strategy is suggested to get Sutaria to the expected level of readiness. Knowledge management is widely acknowledged as a strategic enabler by employees in Zutari, with information technology currently the only critical success factor at the expected level of readiness. *Conclusion***.** A knowledge management strategy is suggested to assist Sutaria in achieving the expected level of readiness. Further research could test the effectiveness of the readiness strategy in different contexts using mixed methods research. This research will add new knowledge to the body of knowledge in the engineering consulting sector and help firms planning to implement knowledge management. Implication. Not many studies have been conducted to test the organisational readiness for knowledge management in engineering consulting firms. This article adds to the body of knowledge in this field.

Keywords: Knowledge management readiness, Engineering consulting, Knowledge, Knowledge management, Knowledge processes

1. Introduction

Knowledge management in engineering consulting firms will leverage knowledge and best practices, providing prompt response to customer requests, avoiding reinventing the wheel and curbing the loss of knowledge when experts leave the company (Rubin & Powers 2017; Majorize & Buckley 2019; Bishop 2009; Parsons 2017; Pope 2019).Engineering consulting firms are knowledge-intensive firms that employ knowledge workers such as engineers, architects and design thinkers who provide professional consultancy to clients by assisting them in identifying and analysing problems and recommending and implementing solutions (Robinho 2015; Mazorodze and Buckley 2019; Kou 2019). Due to the large amounts of knowledge, generated most of these firms struggle to leverage the knowledge scattered across the organisation or to locate experts to assign to new projects (Mesher, Abdul-Malak, Mazorodze and Buckley 2019). A knowledge management readiness assessment will serve as a guide in planning and implementing knowledge management initiatives, thus minimising risks (Mohd Zin and Egba 2010). Mohd Zin and Egba (2010) define knowledge management readiness as the degree to which the employees in an organisation, the knowledge management processes, and information technology are ready to take advantage of the benefits accruing from knowledge management implementation.

Zutari is among the 580 engineering consulting firms in South Africa with a membership at Consulting Engineers South Africa with vast amounts of tacit and explicit knowledge. This firm has a long-standing history in the engineering consulting field dating back 90 years (Zutari 2021). It became an independent company in 2020 following the demerger of the African business and Aurecon Australia, a global international engineering and infrastructure advisory company (Aurecon Africa 2020). It has 16 offices in South Africa and 13 in other African countries with the head office is in Pretoria. Zutari has 1900 employees: 1600 are technical professionals and 300 are support staff. This firm works with clients to co-create solutions in asset management and digitisation, power generation, storage, transmissions and distribution, environment and climate resilience and many other areas (Zutari 2021). However, most of the workers in this firm work in silos; this affects the production of timely, high-quality project proposals and bids, as revealed by the Chief Executive Officer of Zutari in his address to staff at the beginning of 2021. Considering its geographically dispersed locations on the continent and its potential to become a benchmark for other companies in the engineering consulting sector in South Africa, this study sought

to ascertain Zutari's readiness for implementing knowledge management. The research outcome will help Zutari and other engineering consulting firms prepare for knowledge management implementation.

2. Problem Statement

Knowledge management in engineering consulting firms can lead to improved client satisfaction and decision-making, enhanced work quality and improved overall job performance and satisfaction, thus keeping these firms competitive (Rubin and Powers 2017; Alaudin et al. 2019). Knowledge management at Zutari is still elementary as the organisational structure and delegation of authority are yet to be defined. The question that seeks to be answered are: What is the current state of knowledge management readiness at Zutari? How can the knowledge management readiness strategies at Zutari be enhanced?

3. Knowledge in Engineering Firms

knowledge is defined by Nonaka and Takeuchi (1995:58) as a justified true belief and dynamic human process of justifying personal belief toward the 'truth'. The different typologies of knowledge highlighted in the literature may be classified into two major subcategories as tacit and explicit knowledge. The number of engineering consulting firms investing in knowledge management globally is increasing. Organisations without structured knowledge management may be wasting resources considering that an employee may spend 16% of their weekly 40 hours of work looking for information, and 44% of the time failing to find the information (Rubin & Powers 2017).In global engineering firms, employees are spread across geographically dispersed locations, making it difficult to access the tacit knowledge and to connect employees for collaboration, creation, and knowledge sharing (Barnard and Rothe 2003, Learning Uncut 2019). Despite the benefits of knowledge management by engineering consulting firms, the uncertainty on implementing a viable and cost-effective knowledge management initiative presents a barrier to knowledge management implementation in engineering consulting firms. A knowledge management readiness assessment is necessary to determine the level of readiness for implementing knowledge management; it minimises risks as it serves as a guide to leaders in planning and implementing knowledge management initiatives (Mohd Zin & Egbu 2010).

4. Organisational Readiness for Knowledge Management

Organisational knowledge management readiness is its ability to adopt knowledge management successfully and use it to benefit the organisation (Mohammadi et al. (2009). A readiness assessment will reveal the needs of the organisation, its strengths and weaknesses, any opportunities, threats, and risks regarding knowledge management implementation. Knowledge management readiness requires effective investment in the implementation of critical success factors (Davenport, De Long and Beers 1998; Hasanali 2002; Wong 2005). The common themes that determine readiness are people, structure, processes, infrastructure, technology, culture, content, community, and computing (Lee & Choi 2003; Razi, Karim and Mohamed 2017; Andrawina et al. 2018; Guribie and Tengan 2019; Kaburuan 2019) as noted in Table 1 below. It is clear from Table 1 that and the reviewed literature on knowledge management readiness that people, process, IT, organisational structure and culture are recurring factors.

Table 1: A Summary of Recurring Elements by Different Scholars in their Measurement Frameworks

People are the source of knowledge and critical to knowledge management. They play one of manager's employees' and use their skills or to share personal knowledge (Obaide 2004; Pradana et al. 2015; Andrawina et al. 2018). Botha (2007) refers to them as repositories of knowledge since tacit knowledge resides in people's heads. People provide leadership and sponsorship, support knowledge sharing processes, manage and measure knowledge flows, and content is the knowledge what is managed. It is widely accepted that organisational culture plays an important role in knowledge management implementation in engineering consulting firms (Mohd Zin and Egbu 2010; Maraura 2015; Enshassi, Falouji, AlKilani, and Sundermeieri 2016). Cultural readiness is the extent to which an organisational culture promotes the adoption of knowledge management processes among the employees (Hasanali 2002). The variables suggested in the literature for measuring cultural readiness for knowledge management are collaboration, trust, learning, business strategy, management support and reward. The organisational structure influences knowledge management success. An organisational structure defines how an organisation is divided to manage and support knowledge management (Andrawina et al. 2018). Razi and Karim (2010) classify organisational structures as decentralised and informal. Nonaka and Takeuchi (1995) argue that the rigid horizontal and vertical divisions in hierarchical organisational structures distort knowledge. Mohd Zin and Egbu (2010) encourage organisations to adopt organisational structures that promote teamwork, project-based work and multi-skilled employees that encourage coordination among peers. Knowledge management theorists also recommend flexible and non-hierarchical organisational structures for knowledge management implementation.

IT is critical to knowledge management success and has been used by some scholars to assess IT readiness (Lee and Choi 2003, Razi and Karim 2010; Razi et al. 2017, Shahidi et al. 2015; Kaburuan 2019). A reliable technological infrastructure connects the people to the knowledge processes. Knowledge management also involves different interdependent knowledge processes such as creation, storage, retrieval, transfer and application, defined differently by different authors. Gonzalez and Martins (2017) highlight acquisition, storage, distribution and use. Hansen, Nohria and Tierney (1999) identify two basic strategies for managing knowledge as codification and personification. Codification focuses on capturing explicit knowledge in electronic format and availing it for retrieval. Personification focuses mainly on interpersonal knowledge transfers through personal interaction on communities of practice (CoPs) and enterprise socialisation spaces. A knowledge management strategy should be centred on people in the organisation, not technology (Becerra-Fernandez and Sabherwal 2010). The knowledge management strategy should align with the business strategy of each organisation (Guribie and Tengan 2019).

5. Theoretical Frameworks

The readiness model of Razi et al. (2017) was adopted in this study for identifying critical success factors, the Aydin and Tasci (2005) model to assign a knowledge management readiness level to each variable. Razi et al. (2017) identifies knowledge creation processes, organisational culture, organisational structure, IT, individual perception, and organisational members' behavioural intention in the knowledge management readiness assessment framework. The readiness assessment model of Aydin and Tasci (2005) was used to assign a knowledge management readiness level to each variable, critical success factor and the overall organisational knowledge management readiness level using the calculated mean values. This model enables easy coding and assessment; the alternatives are coded 1, 2, 3, 4 and 5, as in a 5-point Likert-type scale. The 3.41 mean score is the expected level of readiness. It is obtained by identifying the critical level using the formula: 4 intervals/5 categories = 0.8. The divisions of 0.8 demarcate the intervals. Other mean scores are either less or higher than the expected level of readiness. Lower scores indicate that they are not ready and require some work. Higher scores indicate readiness but require some work still. Based on this analysis, the levels of readiness are depicted in Figure 1.

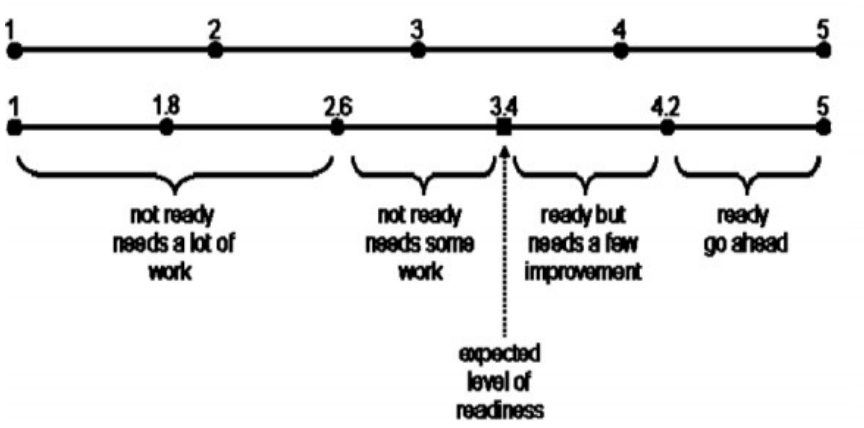

Figure 1: Readiness Assessment Model (Aydin & Tasci 2005)

6. Research Methodology

A quantitative research approach and a case study research design using Zutari as a unique case were adopted in this study. Questionnaires were used to collect data. The accessible population consisted of 1 443 technical experts

working on a permanent basis. A proportionate stratified sampling of the departments was made. Hayes's formula (2021) was used to determine the proportionate stratified random samples of the units as (sample size/population size). For a stratum size of 167, the sample size is calculated as (285/1443) *167 to obtain 33. This was followed by systematic random sampling using the formula of Taherdoost (2017). Using the target population of 1 443, with a confidence level (Z) of 94%, percentage occurrence of a state (P) of 50% and the maximum error (E) of 5%, the sample size (n) was 285 employees.

The study was guided by the following objectives:

- Assess the level of knowledge management readiness for implementing a knowledge management initiative.
- Suggest a knowledge management readiness strategy to guide Zutari in implementing a successful knowledge management initiative.

7. Knowledge Management Readiness by Variable

The variable means shown in Table 2 below were assigned a readiness level using the readiness model of Aydin and Tasci (2005) in Figure 1 above.

Table 2: Knowledge Management Readiness by Variable

Critical success factor	Variable	Mean	Readiness
People	Knowledge of knowledge management	3.1	Not ready, needs some work
	Perceived usefulness	3.7	Ready, needs a few improvements
	Socialisation	3.1	Not ready, needs some work
	Externalisation	3.2	Not ready, needs some work
	Combination	3.4	Expected level of readiness
	Internalisation	3.1	Not ready, needs some work
Process	Knowledge creation	3.3	Not ready, needs some work
	Knowledge identification	3.1	Not ready, needs some work
	Knowledge storage	3.2	Not ready, needs some work
	Knowledge sharing	3.2	Not ready, needs some work

Critical success factor	Variable	Mean	Readiness
IT	IT support	3.2	Not ready, needs some work
	ICT use	3.4	Expected level of readiness
	ICT	3.5	Ready, needs a few improvements
Organisational structure	Distribution of authority and control	3.4	Expected level of readiness
	Flexibility	3.0	Not ready, needs some work
Organisational culture	Collaboration	3.2	Not ready, needs some work
	Trust	3.4	Expected level of readiness
	Learning	3.3	Not ready, needs some work
	Strategy	3.1	Not ready, needs some work
	Top management support	3.1	Not ready, needs some work
	Reward and recognition	2.5	Not ready, needs some work

The average value of the mean values of each variable was used to calculate the mean for the corresponding critical success factor. Each critical success factor mean value is assigned a readiness level in Table 3 below.

Table 3: Critical Success Factor and Overall Organisational Mean and Readiness

CSFs	Mean	Readiness level
People	3.9	Ready needs a few improvements
Process	3.2	Not ready needs some work
IT	3.4	Expected level of readiness
Organisational structure	3.2	Not ready needs some work
Organisational culture	3.1	Not ready needs some work
Overall organisational mean	3.3	Not ready needs some work

The overall readiness score for the people dimension is 3.9, which shows that Zutari strongly values its people as they are the source of knowledge and create, acquire, and share knowledge; this is in line with Obaide (2004)'s recommendations to invest in people. The use of people-centred techniques, such as succession planning, mentoring, tutoring, discussions, technical forums, real-time document collaboration tools and lessons-learnt sessions have been encouraged (Carrillo 2004 and Bishop 2009). . The overall readiness score for process as a critical success factor was 3.2, indicating that Zutari's processes are elementary. Knowledge is created in the organisation through learning, research, and development, problem-solving, creativity and innovation. Tacit knowledge is shared through formal and informal socialisation such as mentorship, meetings, CoPs and brainstorming sessions. Creating an organisational culture and structure conducive to knowledge sharing and nurturing the attitude of seeking help among staff helps to improve tacit knowledge sharing (Obaide 2004; Collison and Parcell 2009).

ICT had the highest mean score of 3.5 and ICT support had the lowest mean score of 3.2. ICT use had a mean of 3.4, equivalent to the expected level of readiness. The overall readiness score for the IT critical success factor was 3.4, which equates to the expected readiness level. IT should not be an end; it should complement a pre-existing knowledge-sharing culture as recommended by Frost (2014). Knowledge management is more than the mere application of IT (Ragab and Arisha 2013; Kuo 2019); there should be a balance between people, process and technology (Bishop 2009; Kuo 2019). The overall readiness level for organisational structure was 3.2. Zutari has a flexible, flat and decentralised organisational structure that facilitates development, acquisition and sharing, and shortens the lines of communication between employees and their management. Zutari employs functional groupings that allow knowledge development and interchange of ideas between experts in the same discipline. The organisational structure has a bearing on the culture as it supports networking and knowledge sharing among the employees. The overall readiness level for organisational culture was 3.1, which indicates that it still needs some effort to get it to the expected level of readiness. Strategy and management support had a mean score of 3.1, reward and recognition 2.5, collaboration 3.2 and learning 3.3, indicating that they all

require some work to get them to the expected level of readiness. Reward and recognition had the lowest mean score of 2.5. Though there is evidence that reward and recognition do take place, it is unclear to most staff. Reward and recognition of those willing to learn, teach and share is a strategic tool to promote knowledge sharing (Becerra-Fernandez and Sabherwal 2010), and must be done visibly for all to see. Examples of informal rewards recommended in the literature include nominating a knowledge management employee of the month and peer recognition is considered a strong motivation with a more sustainable impact when compared to financial rewards (Collison and and Parcell 2004).

8. Knowledge Management Readiness Strategy for Zutari

There is a need to define a strategy for knowledge management implementation at Zutari. The strategic focus areas are: incorporate knowledge management as a business objective, conduct knowledge management awareness campaigns, put in place the necessary infrastructure to support the knowledge management processes and ensure regular monitoring by conducting progress reviews. Each sub-strategy is discussed in chronological order in subsequent paragraphs, starting with the first stage, as presented in Figure 2 below.

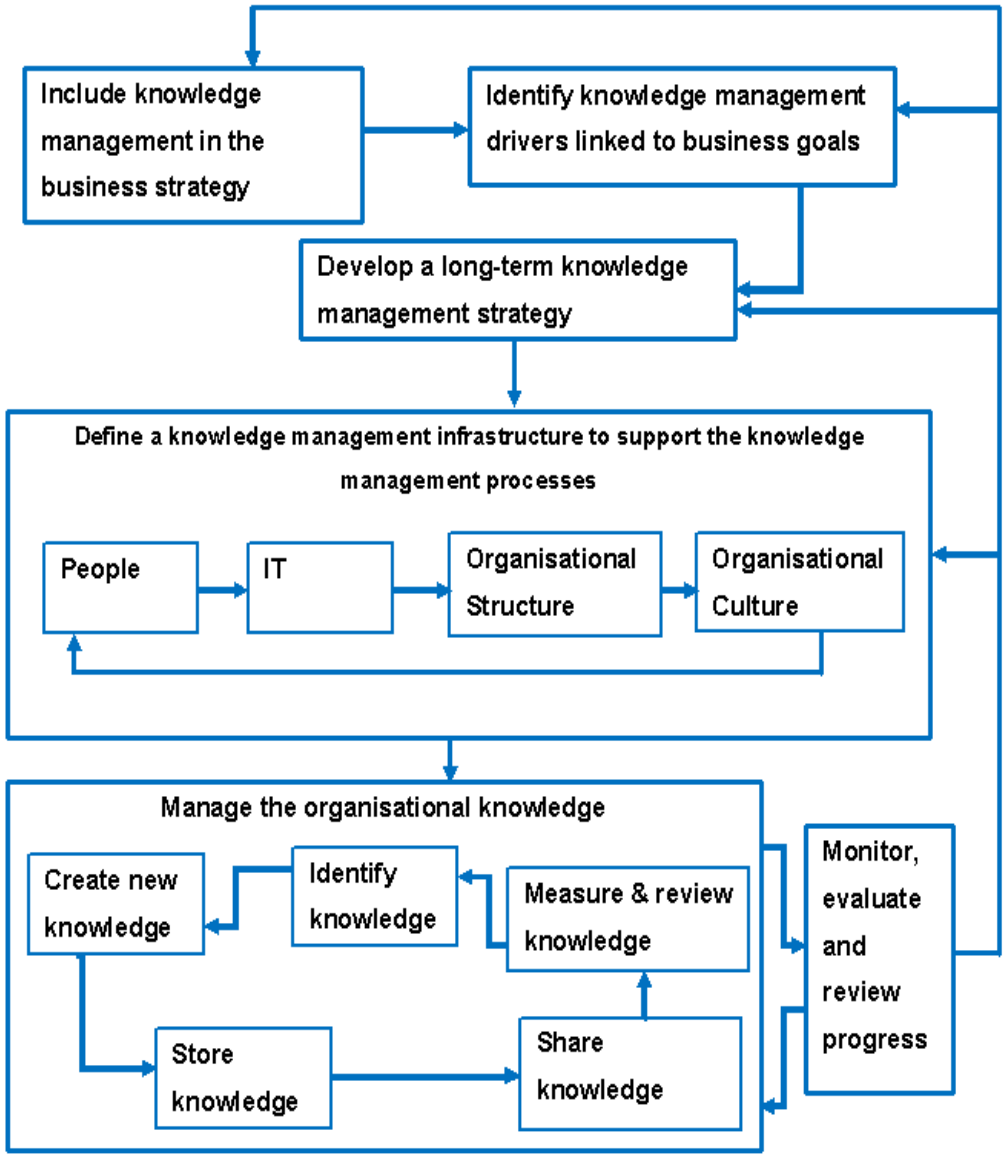

Figure 2: Strategy to Guide Knowledge Management Implementation in Zutari

The research findings reveal that Zutari has an information management standard instead, pointing to the possible existence of confusion between knowledge management and information management. A knowledge

management strategy should be developed that entails identifying and defining knowledge management roles and responsibilities and setting up a knowledge management team. A knowledge management strategy is the overall organisational approach to aligning all its knowledge with its business strategy's knowledge requirements (Mohd Zin and Egbu 2010).

Knowledge management infrastructure is a critical success factor for knowledge management implementation. A balanced knowledge management infrastructure facilitates knowledge identification, creation, storage, sharing and its measuring and reviewing for improvement. The framework of Razi et al. (2017) adopted for this study focuses on the importance of people, process, technology, organisational structure and culture. People influence organisational knowledge management readiness in terms of knowledge creation, leadership, sponsorship, management support, skills, participation and involvement (Harper 2019). Obaide (2004) suggests developing and nurturing employee knowledge management skills. Zutari should develop knowledgeable employees by implementing programmes that facilitate active learning and offering training in areas where knowledge is needed, as recommended by Farnese et al. (2019).

IT timeously connects the people who require the right content (Harper 2019). Although the research findings reveal that Zutari's IT is ready for knowledge management implementation, with a readiness score of 3.4, Zutari should however stay alert given that technology evolves rapidly. IT should be continuously reviewed and kept current. Zutari should continue to provide adequate training for all ICT tools and technologies for effective knowledge management.

The readiness score for organisational structure was 3.2, indicating that Zutari's organisational structure is not ready and needs some work to get it to the expected level of readiness. The firm should promote formal and informal networks and cross-functional teams to increase knowledge sharing. Nurturing CoPs or social networks to enhance knowledge sharing (Wenger, McDermott and Snyder 2002). In terms of organisational culture, it was 3.2 indicating that Zutari not ready for knowledge management implementation. Nenungwi and Garaba (2022) identify organisational culture as a determinant of administrative norms and values, beliefs, and work ethics that either encourage or hinder learning and knowledge sharing.

The readiness level score of knowledge management processes revealed that Zutari's is not ready for the implementation of knowledge management. Zutari should employ knowledge creation processes, among which are learning and development, problem-solving, innovation and creativity, socialisation, externalisation, combination and internalisation (Gonzalez and Martins 2017). Zutari significantly invests in its employees' development through formal and informal training programmes, workshops, conferences, coaching and mentorships. This experience can be formalised and documented as best practices, user manuals, procedures, check lists and reports that can be stored and shared over time to enhance performance and support innovation (Farnese et al. 2019). Zutari should develop programmes that promote externalisation of tacit knowledge such as mentoring, apprenticeship and demonstrations, and a strong knowledge-sharing culture to preserve the core knowledge.

Knowledge becomes passive if it is not reviewed or modified. Guribie and Tengan (2019) recommend ongoing monitoring and review to assess knowledge management maturity. Given that Zutari operates in a volatile technological and global competitive environment, it should implement knowledge review processes to evaluate and replenish knowledge components, help the business adapt to environmental stimuli, solve current organisational problems, and address the current applicability and risk of knowledge. If not reviewed, a large part of the knowledge repository may be forgotten or ignored.

9. Conclusion

The study sought to determine the knowledge management readiness of Zutari and suggest a strategy for implementing knowledge management. The findings revealed that Zutari is not ready for knowledge management implementation. It requires the development of a knowledge management readiness strategy to help it achieve the expected level of readiness. The research outcomes of this study will be generalised to engineering consulting firms in South Africa and Africa Other engineering firms grappling with knowledge management are set to benefit from adopting and using this strategy. Engineering and consulting firms will learn how to conduct a knowledge management readiness assessment and avoid the pitfalls in knowledge management. Further research could test the effectiveness of the readiness strategy in different contexts using mixed methods research to improve to strengthen reliability and internal validity.

Impact of Organisational Culture and Employee Commitment on Knowledge Workers in an Insurance Company

Portia Makgalo and Ophillia Ledimo
Department of Industrial and Organisational Psychology, University of South Africa, South Africa

manetom@unisa.ac.za

Abstract: The purpose of this paper is to provide an empirical understanding on how the constructs organisational culture and employee commitment affect knowledge workers in an insurance organisation. In the knowledge based economy, organisational culture and employee commitment play a critical role in an organisation's sustainability. There is no one size fits all when it comes to the impact of organisational culture on organisational commitment for effective retention of knowledge workers. The relationship is based on the nature or type of the business, the environment where the business operates and employees thereof. Management of knowledge workers relies on ensuring that the culture adopted by an organisation assist to improve employee commitment, thereby retain knowledge workers. An empirical study using a quantitative design was conducted in insurance company and data was collected using survey questionnaires. Non-Probability sampling was applied where a sample size of 318 was selected from a population of +/-600 employees. The SPSS 2017 (version 25) was used for descriptive and inferential data analysis. Research results indicate that organisational culture affect affective employee commitment of knowledge workers. These findings can assist management of knowledge workers to analyse and developing organisational culture that assist in improving employee commitment, thereby retain knowledge workers. The study carried out offer executive management specific guidelines in implementing initiatives for knowledge workers retention in the knowledge-based economy.

Keywords: Organisational culture, Employee commitment, Knowledge workers

1. Background of the Study

In knowledge economy, organisational culture and organisational commitment are major requirements. Knowledge-based economies have the potential to stimulate economic growth, provide higher wages and greater employment opportunities, ultimately enhance a country's global competitiveness. Batugal (2019) notes that organisational culture provides the "glue" which holds the employees together, stimulates their commitment to a common mission, and galvanises their creativity and energy. Culture develops over a lengthy period and acquires significantly deeper meaning. Creating organisational culture that values and respects each member of the organisation is effective in producing higher levels of commitment. Employees as knowledge workers are the lifeline of any business. It is important to create a well-balanced environment in which knowledge workers and management can work knowing that they are all on the same page when it comes to work ethics, business processes, and best practices (Ebert & Griffin, 2017).

Knowledge workers play a critical role in the knowledge economy of South Africa because they apply theoretical and analytical knowledge, acquired through formal training, to develop products and services. According to Statistics South Africa (STATSSA) (2016), the number of knowledge employees in the financial intermediation, insurance, real estate and business services industries amounted to a total of over 2 million. This compares with the country's total labour force of 9 million in the same period. Hence the full labour force in the insurance industry accounted for 21.8% of the country's knowledge workforce. The industry contributed around 15% to the local GDP in 2013, making the country's insurance penetration the second highest in the world (PricewaterhouseCoopers [PWC], 2016). Again in 2018, these industries were strong supporters of the overall GDP growth. Despite the high number of knowledge employees in the insurance industry in South Africa as well as the role that this industry plays in the country's economy, the researchers found that there are limited studies in this area.

1.1 Research Question and Hypothesis

In consideration of the background above, the objective of this study was to fill the research gap by investigating the impact of organisational culture on employee commitment of knowledge workers in an insurance company.

The study was guided by the following main research question: What is the impact of organisational culture on employee commitment of knowledge workers in an insurance company?

The following hypotheses were formulated to address the research question:

(H_0): Organisational culture has no significant impact on employee commitment of knowledge workers in an insurance company.

(H_1): Organisational culture has a significant impact on employee commitment of knowledge workers in an insurance company.

2. Literature Review

2.1 Knowledge Worker Characteristics

In the current climate of turbulent changes, organisations have begun to realise that knowledge workers represent their most valuable asset. A knowledge worker can be defined through the characteristics of their work activities, which are focused on thinking, problem-solving, collaborating and networking (van den Berga, Appel-Meulenbroeka, Kempermana & Sotthewes, 2020). These skills and knowledge are acquired through formal training, such as college or professional certification. Knowledge workers use analytical, theoretical or otherwise high-level knowledge to develop or offer services or products, usually online (Ricard, 2020). Insurance organisations are knowledge intensive sector in nature. Achoki, Swansi, Pondi and Luntugan (2022) indicate that in knowledge-intensive sectors where insurance companies operate tacit knowledge is of great value because such knowledge improves the decision-making process, quality of work, customer services, organisational learning, and accuracy of tasks. A knowledge worker "thinks" for a living instead of performing physical tasks by handling complex mechanisms autonomously, focusing on quality over quantity and working relatively independently (Ricard, 2020). In this study, the researchers consider employees in an insurance organisation as knowledge workers based on their work characteristic and organisational sector that are knowledge based.

2.2 Organisational Culture in Knowledge Based Economy

Every organisation has its own culture and it highlights the need for a healthy and beneficial environment in the knowledge based economy. A healthy organisational culture values each knowledge worker in the organisation regardless of their job description, which results in employees working as a team to meet the organisations and their own personal needs. However, with an unhealthy culture, employees act as individuals, performing their duties to meet own needs, such as pay cheque or health benefits (Lencioni, 2014).

Even though culture has been the focal area of studies in anthropology, sociology, organisational theories and management, the connotation it had was not always the same. Different concepts, assumptions and interests made these connotations dissimilar. Diverse opinions predominantly affected the description of the theoretical base of culture in terms of its composition, impact and applications (Taneja & Saxena, 2014, p. 69 - 72). Culture, while at the one end is described as the set of values and beliefs, on the other is described as a set of symbols, ceremonies and myths that communicate the underlying values and beliefs of the organisation to its employees (Taneja & Saxena, 2014). Although no consensus exists, culture has most often become a heuristic term used to help anthropologists discuss the symbols, meanings, institutions, systems and behaviours of people, rather than a well-defined theoretical project (Vélez-Ibáñez & Heyman, 2017).

Linked to the above definitions, Schein (2010, p40) defines organisational culture as “a pattern of shared basic assumptions learned by a group as it solved its problems of external adaptation and internal integration, which has worked well enough to be considered valid and, therefore, to be taught to new members as the correct way to perceive, think and feel in relation to those problems”.

Previous studies indicated that employees who are happy with the organisation’s culture are willing to make significant strides in their endeavours to meet organisational objectives (Mitic, Vukonjanski, Terek, Gligorovic, & Zoric, 2016). The above definitions of organisational culture affirm that culture is a main tool in knowledge workers retention.

2.3 Organisational Commitment in the Knowledge Based Economy

What makes knowledge workers stay within one organisation for their entire career? What makes an individual attached to an organisation? What are common factors to those knowledge workers who feel they would not like to change organisations? All these questions should be analysed on a continuous basis when examining organisational commitment. Satisfied and motivated employees are a critical factor that separates successful organisations from the alternative (Millar, Chen & Waller, 2017). Ensuring continuous and desirable work outcomes of knowledge workers leads to a positive impact on the organisational commitment of employees. Employees with higher scores of commitment are expected to be more motivated and performing at the highest levels (Berberoglu & Secim, 2015). When it comes to the organisation’s gains, commitment can visibly help raise performance and attendance levels, while simultaneously resulting in lower staff turnover. “Commitment raises an employees’ levels of productivity and results” (Armstrong, 2016, p7); hence it is required in the knowledge based economy to give an organisation competitive advantage. Meyer and Allen (1991) organised commitment

into three components: affective, normative, and continuance commitment, each with related consequences. In other words, the employees stay in the organisation because they want to (affective commitment), because they need to (continuance commitment) or because they feel they ought to (normative commitment).

Organisations should foster affective commitment, such as enhancing the employees' morale to make them proud to be part of the organisation. Organisations working on increasing employee commitment should satisfy some influencers (Wainwright, 2019). Given that knowledge workers are well acquainted with the organisational culture, they will commit to the cause of the organisation (Alvesson, 2013). In line with the above, studies have also shown how uniquely, and significantly organisational culture and commitment can add to the success and competitiveness of organisations in a knowledge based economy (Shahid & Azhar, 2013). Hence continuous research on this topic is important.

3. Research Design

Descriptive research design using the quantitative approach was applied in this study.

3.1 Research Participants and Sampling Process

Non-probability sampling was applied to achieve a sample size of 318 employees from about 600 total knowledge workers (53% of total number of permanent employees) in an insurance company. These knowledge workers are based in the company's 80+ offices in the nine provinces of South Africa, including the organisation's Head Office. The sampling approach to catered for the heterogeneous nature of knowledge workers in the different branches. The sample was made of subgroups characterised as indicated in the frequency Table below:

Table 1: Sample Frequency Table (N = 318)

Variable	Category	Frequency	Representation%
Age	<25 years	0	0%
	25 – 34 years	168	52.8%
	35 – 44 years	93	29.2%
	45 – 54 years	57	17.9%
	55 – 65 years	0	0%
Gender	Male	91	28.6%
	Female	227	71.4%
Tenure period	<5 Years	50	15.7%
	5 – 15 Years	171	53.8%
	>15 Years	97	30.5%
Qualifications	No matric	3	0.9%
	Matric	155	48.7%
	Diploma	71	22.3%
	University degree	89	28%
Occupation level	Non-management	261	82.1%
	Junior Management	24	7.5%
	Middle Management	33	10.4%
Income (gross p.m)	< R 10,000	82	25.8%
	R 10,000 – R 19,000	131	41.2%
	R 19,001 – R 29,000	59	18.6%
	R 29,001 – R 40,000	31	9.7%
	> R 40,000	15	4.7%

3.2 Measuring Instruments of the Study

Biographical questionnaire was developed to establish a profile of the sample group concerning age, gender, qualifications, service period, occupation and income. Organisational Culture Questionnaire (OCQ) was utilised to measure organisational culture developed by Harrison and Stokes (1992). "The questionnaire is intended to measure four dimensions of organisational culture, namely achievement, power, role, and support cultures" (Harrison 1993, p. 1). The OCQ consists of 60 items (15 items for each dimension). Respondents rated statements based on their observations of the different cultural dimensions in their organisation, by responding to a scale ranging from 1 to 4, where 1 is "least dominant view", and 4 is "most dominant view".

Employee commitment was measured using the Organisational Commitment Scale (OCS) developed by Allen and Meyer (1991). The OCS is a self-scoring instrument which comprises a five-point Likert scale with 24 items or statements, which participants responded to on a scale ranging from 1 to 5, where 1 is strongly disagree and 5 is strongly agree. The 24 items are divided into three dimensions with eight statements per dimension, namely affective, continuance and normative commitment dimensions (Meyer & Allen 1997, p. 121). Both OCS and OCQ instruments are self-explanatory, and no supervision was necessary. The questionnaires were completed online by respondents individually, voluntarily and anonymously. The construct related to organisational culture was divided into two sub-constructs, existing culture (EC) and preferred culture (PC). Therefore, three constructs were considered in this study (i.e. existing organisational culture, preferred organisational culture and organisational commitment).

3.3 Ethical Considerations

Permission to conduct research was obtained from the College of Economics and Management Sciences at the University of South Africa (UNISA). The organisation understudy as well as the Research Ethics Committee of UNISA's Department of Industrial and Organisational Psychology granted the researchers ethical clearance. The research activities adhered to the UNISA research policy guidelines.

3.4 Data Collection Analysis

Data collection was conducted using the Lime Survey programme and structured questionnaires used as instruments to collect primary data. Information received from sampling was then interpreted to determine that the population was representative as indicated in Table 2.

Table 2: Response Rate

Employee response rate	
Population	600
Sample	318
Total responses received	437
Incomplete / invalid responses	119
Complete / valid responses	318
Response rate (based on valid responses)	53%

3.5 Statistical Analysis

Research approach adopted in the study was quantitative analysis based on descriptive statistics followed by inferential statistics using the Statistical Package for the Social Sciences 2017 version 25. Analysis of data included the application of Pearson Correlation Coefficient and Regression analysis. The internal consistency of the measuring instruments was determined using the Cronbach's Alpha.

4. Research Results

Discussions and tables below present the descriptive and inferential statistics of the constructs of Organisational Culture Questionnaire (OCQ) and Organisational Commitment Scale (OCS).

4.1 Descriptive Statistics

All the dimensions of the measuring instruments as shown in Table 3. Overall, the two measures obtained scores above 0.80 using the Cronbach's Alpha results, suggesting that the questionnaire is a reliable measure. The

results revealed a high level of internal consistency across the scale and the items of the OCQ – (EC & PC) and OCS variables.

Table 3: Summary of the OCQ (EC & PC) and OCS Reliability (N=318)

Reliability Statistics of OCS-EC		Reliability Statistics of OCS-PC		Reliability Statistics of OCS-S	
Cronbach's Alpha	No. of Items	Cronbach's Alpha	No. of Items	Cronbach's Alpha	No. of Items
0.887	15	0.803	15	0.877	24

The Harrison and Stokes' (1992) OCQ research measuring instrument has already been tested in the South African population and the questions therein were proven to be suitable. Similarly, studies on the reliability of the Meyer and Allen (1997) OCS questionnaire indicate it is a reliable measuring instrument for assessing organisational commitment. Meyer and Allen (1997, p 120) found the internal consistencies of the OCS dimensions "varying between 0.85 for affective, 0.79 for continuance and 0.73 for normative".

4.2 Mean Scores of OCQ (EC & PC) and OCS

Table 4: Summary of the Means and Standard Deviations for the OCQ (EC)

Dimension	N	Minimum	Maximum	Mean	Standard Deviation
Existing Power Culture	318	1	4	2.63	1.27
Existing Role Culture	318	1	4	2.95	2.14
Existing Achievement Culture	318	1	4	2.77	1.61
Total				2.78	

According to Table 4, the mean scores range from 2.63 to 2.95 on OCQ - EC. The highest score was on the existing role culture (mean = 2.95), which is much closer to 3, indicating that the perceived dominant culture in this organisation is role culture. This indicates that knowledge workers of this organisation perceive the current culture as one that provides stability, justice and efficient performance (Harrison, 1993). Achievement culture was the next highest score with a mean score of 2.77. Power culture was the least preferred at 2.63. Standard deviations of the dimensions range from 1.27 to 2.14, which explains the variability in the respondent.

Table 5: Summary of the Means and Standard Deviations for the OCQ (PC)

Dimension	N	Minimum	Maximum	Mean	Standard Deviation
Preferred Power Culture	318	1	4	3.01	1.14
Preferred Role culture	318	1	4	2.83	1.84
Preferred Achievement Culture	318	1	4	2.87	2.07
Total				2.90	

Mean scores ranged from 2.83 to 3.01 on OCQ - PC. The dominant preferred culture in this organisation is the power culture with a mean of 3.01. This means that knowledge workers prefer leadership that is strong in terms of direction, decisiveness and determination" (Wiseman, Ngirande & Setati, 2017, pp. 244-245). Achievement culture was the next dominant, with a mean score of 2.87. In this culture, influence is based more on expert power than on position or personal power, but the influence is more widely dispersed. It measures how organisational culture is based on competence (Harrison, 1993). Closely aligned to achievement culture in terms of the mean score is role culture which is the least dominant with a mean score of 2.83 (Harrison, 1993). Support culture did not meet the required reliability criteria on both OCQ (EC & PC) and was excluded. The standard deviations of the dimensions ranged from 1.14 to 2.07.

Table 6: Summary of the Means and Standard Deviations for the OCS

Dimension	N	Minimum	Maximum	Mean	Standard Deviation
Affective commitment	318	1	5	3.50	1.20

Dimension	N	Minimum	Maximum	Mean	Standard Deviation
Continuance commitment	318	1	5	3.25	1.27
Normative commitment	318	1	5	3.39	1.21
Total				3.38	

Presented above in Table 6 are the mean scores indicate that the knowledge workers of the insurance company are generally committed to the organisation for various reasons, with mean scores ranging from 3.25 to 3.50 The highest score is on affective commitment at 3.50, indicating that the knowledge workers stay with the organisation because they feel a strong sense of belonging to the organisation. Normative commitment was the next highest with mean score of 3.39 commitment, which shows that the knowledge workers have sense of obligation to stay with the organisation. Employees stay in the organisation because they believe they ought to. These employees display both loyalty and moral aspects in the sense that they stay even if things are not good for them because it is the right thing to do (Allen & Meyer, 1996). Continuance commitment indicate a positive mean at 3.25; which indicates the knowledge workers' commitment based on costs associated with leaving the organisation. Employees with this kind of commitment stay employed in the organisation because they need to. Fear of loss can extend beyond financial concerns and include concerns such as the loss of friendships that the employees have developed whilst working for the organisation (Allen & Meyer, 1996). The standard deviations of the dimensions ranged from 1.20 to 1.27.

4.3 Inferential Statistics

Inferential statistics were used to make inferences or estimates about data collected. Multiple regression analysis and Anova results are reported to determine significance and substantiate the model and correlation coefficients. To investigate the impact between the variables under study, correlational statistics for the variables were obtained. These correlations were obtained to test the hypotheses, which are:

(H0): There is no significant impact between organisational culture and employee commitment of knowledge workers.

(H1): There is a significant impact between organisational culture and employee commitment of knowledge workers.

The inferential analysis results of organisational culture and two commitment dimensions, namely continuance and normative were excluded in this paper because there are no significant findings. Table 7 and 8 display, the results of the regression analysis investigating the impact of organisational culture-existing culture on affective commitment. The regression results indicate that the full model is statistically significant at 1% and 5% levels of significance (R = 0.132 with a p-value of 0.000, p-value < 0.01), indicating that 13.2% of the total variation in "affective commitment" is explained by the organisational culture - existing culture.

Table 7: Organisational Culture-Existing Culture and Affective Commitment

ANOVA[a]	R Square	F	Sig.	Durbin-Watson	Sig.
Regression	.132	15.854	0.000[b]	2.009	0.000

a. Dependent Variable; *affective commitment*

b. Predictors: (Constant), power culture, role culture and achievement culture-existing culture.

Table 8: Regression Analysis (model 1): Organisational Culture-Existing Culture and Affective Commitment

Model		Unstandardized Coefficients		Standardized Coefficients	t	Sig.
		B	Std. Error	Beta		
1	(Constant)	1.196E-17	.053		.000	1.000
	Power culture	.265	.043	.285	5.418	.000
	Role culture	.154	.053	.174	3.304	.001
	Achievement culture	.131	.049	.142	2.700	.007

a. Dependent Variable; *affective commitment*

b. Predictors: (Constant), power culture, role culture and achievement culture-existing culture.

Table 7 and 8 show that all three factors, namely power culture, role culture and achievement existing culture have a significant contribution in the affective commitment model. There is a positive relationship between power culture, role culture and achievement culture and affective commitment. The higher the degree of the organisational existing culture, the higher the affective commitment. Researchers were guided by these statistics to accept or reject the hypotheses. The statistics determine significant impact between variables and their dimensions. Pearson's correlations were used to determine the level of significance. These correlations determine whether the null hypothesis is true or false. Hypothesis (H1) was accepted partially based on a 5% level of significance and therefore the null hypothesis (H0) was rejected. This is consistent with the findings by Masouleh and Allahyari (2017) who confirmed the relationship between organisational culture and commitment in their case study.

5. Discussion and interpretation

This section discusses the results of this study.

Table 9: Summary of Results

1	What is the impact of existing organisational culture on employee commitment of knowledge workers?	Existing organisational culture has a positive impact on affective and continuance commitment. This means that when the level of organisational culture increases, the level of affective and continuance commitment increases significantly. However, existing organisational culture has a negative impact on normative commitment, indicating that when the level of existing organisational culture decreases, the level of normative commitment decreases.
2	What is the impact of preferred organisational culture on employee commitment of knowledge workers?	Preferred organisational culture has a negative impact on employee commitment, which means that when the level of preferred organisational culture decreases, the level of commitment decreases.
3	What is the empirical impact of organisational culture on employee commitment of knowledge workers?	The impact of preferred organisational culture on commitment is insignificant. However, the impact of existing organisational culture on employee commitment is significant.

5.1 Existing Organisational Culture v/s Preferred Culture

From a culture perspective, the empirical study results indicated that the dominant existing culture is perceived to be the role orientated culture. However, the dominant preferred culture is the power culture. The study findings are consistent with previous studies in literature such as Nazir, Qun, Hui, and Shafi, (2018) whose study indicated that organisational culture has no significant impact on affective commitment. Contrary to this, research findings by Azar and Avanki (2016) found a positive relationship between organisational culture and affective commitment at the 0.05 level of significance. The descriptive summary of organisational culture for both the existing and preferred cultures, for most of the items, the mean value is between 2 and 3 (leaning more towards 3) which means that the knowledge workers tend to agree on the statement on the questionnaire on a greater scale than 2.

5.2 Organisational Commitment

With regards to commitment, the findings revealed that knowledge workers are affectively committed to the organisation. For most of the items the mean value was between 3 and 4 (most of the values are closer to 4) which means that the respondents tend to agree on the statement. This is a demonstration that the respondents are affectively committed to the organisation. Affective commitment expresses the emotional attachment of the knowledge workers to their organisation, their desire to see the organisation succeed in its goals, and a feeling of pride at being part of that organisation. In other words, knowledge workers stay in the organisation because they want to, as defined by Meyer and Allen (1991; 1997), and also indicated in studies by Pinho, Silva, Oliveira, Oliveira, and Barbos (2020), Presbitero, Newman, Le, Jiang, and Zheng, (2019) as well as Amofa and Ansah (2017, p.18). The standard deviations of the dimensions ranged from 1.20 to 1.27. The dimension with the highest score is continuance commitment, with a total mean score of 1.27. This means that as much as the

employees have affection to the organisation, there is somewhat a sense of obligation around the sense of belonging, i.e. knowledge workers also feel that they ought to stay with the organisation.

5.3 Empirical Relationship Between Organisational Culture and Commitment

From the research findings, it can be concluded that (H_1) is partially accepted. Organisational culture has an impact on the affective employee commitment of knowledge workers in an insurance company. This is evident with the impact of existing culture on affective employee commitment being positive. Similarly, the study by Presbitero et al. (2019) found organisational culture to have an influence on affective organisational commitment. Studies by Aranki, Suifan, and Sweis, (2019); Batugal (2019) as well as Zhou (2017) have also consistently found that there is a relationship between organisational culture and commitment. Therefore, the null hypothesis of this study (H_0) is rejected as it state that organisational culture has no significant impact on employee commitment of knowledge workers in an insurance company. The hypothesis (H_1) is partially accepted in this study. This implies that organisational culture has a significant impact on affective employee commitment of knowledge workers in an insurance company. This supports the studies of Aranki et al. (2019), Wiseman et al. (2017) and Mitic et al. (2016) who confirmed that organisational culture has an impact on organisational commitment. It was further discovered that existing organisational culture has a significant effect on affective and normative commitment followed by continuance commitment. This implies that employees are emotionally attached to the insurance organisation as a result of the organisational culture in their organisation; this is consistent with the findings by Masouleh and Allahyari (2017). In their study in the Ghanian Banking Industry, Amofa and Ansah (2017) also observed that organisational culture has greater influence on affective commitment; followed by continuance commitment while normative commitment had the least impact. The researchers conclude that there is adequate evidence of 5% significance level to infer that organisational culture has an impact on affective employee commitment of knowledge workers in an insurance company.

6. Limitations of this Study Literature Review and Empirical Study

Despite the high number of knowledge workers in the insurance industry in South Africa as well as the role that this industry plays in the country's knowledge-based economy, the researchers has learnt that there are limited studies in this area. There are still many gaps that require further investigations to fully understand the impact of organisational culture on employee commitment to guide future studies. Pinho et al. (2020) and Demo, Fogaça and Costa (2018) note that studies relating this theme to other variables of organisational behaviour are necessary. Jiang (2016) concurs that there are few studies that relate to HR practices with different constructs, particularly commitment. In terms of the empirical study using the OCQ and OCS, the following limitations were found: The study is based in one insurance organisation and therefore limited. Consideration should be given to similar studies in other insurance organisations. The sample could be too small to rely on the results without further investigations. The biographical questionnaire includes income brackets, which some employees may not have preferred to share, thereby leading to incomplete/invalid questionnaires. Quantitative methods were used for this research. According to Nazir et al. (2018), quantitative data can only be utilized to conclude what the relationship between two different variables is, but this type of data cannot describe why such relationships exist or do not exist. In this study, supplementary qualitative data or the mixed method approach could have been helpful to determine why power culture is preferred as well as why existing organisational culture has a negative impact on normative commitment.

6.1 Recommendations for the Organisation Under Study, Insurance Companies, IOP Practitioners and Future Research

Role culture seems to be dominant on existing culture whilst power culture is dominant in terms of preferred culture. Knowledge management practices requires organisational culture that has a positive effect on employee commitment. The findings of this study can be the basis for the leadership of the organisation to create or enhance a culture which will enhance the preferred power culture by the knowledge workers. Ritonga, Ibrahim, and Bahri (2019) add that leadership styles in such conditions are meaningful in knowledge development, sharing and conservation in the knowledge-based economy. The organisation under study should revise their strategy to pave the way for the culture preferred by its knowledge workers. Strengths of power culture and affective commitment should be highlighted, emphasised, maintained and celebrated by the knowledge workers and the organisation; in order to gain competitive advantage in realising knowledge-based economy goals.

Given the results above, it is evident that organisational culture has an impact on employee commitment of knowledge workers. Based on these findings, organisations are advised to diagnose their cultures and determine how it affects knowledge workers' commitment for retention purposes. Better understanding of existing and

preferred organisation's culture may lead to the development of ideal culture in a knowledge-based economy. Van Rooij and Fine (2018) note that cultures are notoriously difficult to change, and lofty promises of changed cultural values and practices can generate more corporate dissonance when real change does not occur. It is therefore important to caution against promises of an easy fix. Subsequently, it is recommended that other organisations should develop cultures that are consistent with the interest of their knowledge workers to gain their commitment and retain them for maximum periods (Olaigbe, Unachukwu, & Oyewole, 2018).

Based on the limitations of this study, future research should look at obtaining larger samples to represent the entire population in the industry. Insurance industry is a constantly developing environment which may have a huge impact culture change. Therefore, future research should continue investigating the impact of organisational culture and employee commitment of knowledge workers. Based on the finding that there is a dearth of knowledge on this topic as well as the large number of knowledge workers in the financial and insurance industry, it is evident that there is a need for further studies on the topic at hand.

7. Conclusion

The main objective of this study was to investigate the impact of organisational culture on employee commitment of knowledge workers in an insurance company for retention purposes. Two hypotheses were selected and tested; data was collected from knowledge workers in an insurance organisation in South Africa. It is therefore concluded that organisational culture has a significant impact on employee commitment of knowledge workers.

Knowledge Management Practices and the Evolution of Healthcare Organizations Based on a Certification Program

Patsy Balconi Mandelli , Cinthya Zanuzzi, Lia Caetano Bastos and Gregório Varvakis
Universidade Federal de Santa Catarina, Florianópolis, Brazil

patsymandelli@gmail.com

Abstract: Quality certification programs are internationally recognized processes for externally assessing and improving quality, resolution, and sustainability in healthcare organizations. In these organizations, knowledge is a strategic intangible asset. Concurrently, knowledge management (KM), through its practices and tools, promotes the use of organizational knowledge, and can help transform knowledge into action in the dynamic, systemic, competitive, and demanding environment faced by such organizations. In this context, this study aims to analyze the association between strategic KM practices and the evolution of certified health organizations by measuring the evolution of quality descriptors implemented during participation in the certification program. The research adopts a quantitative approach, with a descriptive-exploratory nature, and follows a cross-sectional design. Presented here are concepts relative to the theme and constructs that support the analysis proposed in this study. For data collection, two instruments were used. The first is related to the evolution of companies participating in a certification program, and the second is a questionnaire designed to identify knowledge management practices developed within the companies. The study was developed in 24 healthcare companies in Brazil that participated in a certification program. The results identify an association between KM practices and the level of evolution of certified healthcare organizations. The companies have in common the incentive to share knowledge in the workplace, as well as providing continuous training opportunities. There is an observed need for organizations to effectively communicate their strategic objectives and develop financial incentives and career development based on knowledge. The results confirm the relationship between KM practices and the evolution of healthcare organizations.

Keywords: Healthcare organization, Physiotherapy services, Certification/accreditation, Quality assurance, Knowledge management practices

1. Introduction

Healthcare organizations offer differentiated services that demand singular answers to constant unexpected events, and that face challenges to provide assistance that delivers safety to the end user, resoluteness and generation of value, a competitive advantage, sustainability, and growth for companies (Nicklin, Engel and Stewart, 2021; Bernardino, 2017).

The COVID pandemic abruptly showed us the importance of health care systems, their complexity and the need for adapting and reorganizing the system as a whole – end users, service providers, financiers, clients, governments, academic institutions and so on (Zimlichman *et al*., 2021).

Sustainable societies need to consider the connection between knowledge management (KM) and healthcare to be a critical issue for social development with safety for the patient (Karamitri, Kitsios and Talias, 2020). The authors affirm that the sustainability of healthcare organizations depend on the efficient use of knowledge assets and resources. It is necessary to investigate how knowledge permeates the structures of a healthcare organization, identifying possible knowledge sharing predictors that may support the KM strategy of a healthcare company (Nicklin et al., 2017).

Quality certifications are internationally recognized external evaluation programs based on the premise that adhering to preestablished standards and compliance will produce better quality healthcare services in an increasingly safer environment. They are also a way to publicly recognize that a healthcare organization meets national standards of quality (Pomey, 2004).

Michell, Graham and Nicklin (2020), understand that the certification is a tool for translating implementation knowledge or intervention, which aims to improve and increase assimilation of evidence within healthcare organizations while emphasizing knowledge to promote action.

According to Darroch (2005), KM would act as a coordination mechanism within organizations, allowing resources to be efficiently used, promoting interaction, and fomenting improved organizational capacity. It is seen as a coordination mechanism that allows resources to be converted into abilities (Nelson; Winter, 1982). These coordination mechanisms are supported by KM practices, oriented to adequately manage knowledge, aiming at its efficient use and in line with organizational objectives and tasks (Kianto and Andreeva, 2014; Cen, 2004; Dávila et al., 2014).

In view of this context, this study will use concepts of quality certification, knowledge management and its practices, while aiming to identify the association of KM practices with the level of evolution of certified healthcare organizations, within a certification program.

2. Theoretical Foundation

2.1 Certification

Pomey et al. (2010), define certification as a rigorous process of external evaluation which comprehends a self-evaluation, as well as external evaluations according to a certain set of standards. The authors believe that certification processes help introduce organizational changes that improve the quality and safety of service. These changes vary according to organizational context, and the process of certification is a highly effective tool to: 1. accelerate integration and foment a spirit of cooperation within healthcare organizations; 2. help introduce continuous quality improvement programs for recently certified organizations or those not yet certified; 3. create new leadership for quality improvement initiatives; 4. increase social capital, giving collaborators the opportunity to develop relationships, and 5. promote connection among healthcare organizations and other areas.

Guaranteeing updated processes that allow for patient safety is related to quality management in organizations that are based on future-oriented strategies, geared towards society, dynamic and human-centered, especially when performing procedures that decrease risk and waste, and boost the management of continuous improvement in a dynamic, fast, accelerated and often unknown environment (Braithwaite et al., 2020; Greenfield and Braithwaite, 2008; Nicklin, 2015; Nicklin, Engel and Stewart, 2021; Nonaka and Takeuchi, 2021; Zimlichman et al., 2021). According to Novaes (2015), certification programs represent a method that facilitates the development of standards for continuous improvement of patient care and organizational performance.

Within the context of healthcare organizations that provide services, quality certification programs are a vehicle to disseminate learning, effectiveness, and efficiency, to present evidence of their processes and, with that, enable the translation of knowledge within the organizational environment (Nicklin, Engel and Stewart, 2021). Mitchell, Graham and Nickiln (2020) state that, even though quality certification programs are widely recognized, especially for improving organizational performance, researchers provoke the assumption that the true value of a certification process lies in its contribution to safety and quality of healthcare as a means to stimulate and support knowledge for action, a key value for certification which has not yet been articulated. “[…] it is a form of knowledge translation (KT) or implementation intervention that aims to improve and increase the input of evidence in healthcare organizations". (Mitchell, Grahan and Nicklin, 2020, p. 445).

2.2 Knowledge Management

For Peter Drucker (1993, p. 42), the knowledge which we consider knowledge is proven in action. This refers to knowledge as efficient information towards action, and information with a focus on results. These are described as results which are outside the person, in society and in the economy, or in the advancement of knowledge itself. Each individual converts ability into something that can be taught or learned. The changes from one piece of knowledge to another can create a new society; based on knowledge and on the people of knowledge, this would give them power.

In the same year, Wiig (1993) states that many organizations are becoming more and more concerned with organizational knowledge, and the use of knowledge to create and make quality products, deliver quality services, and maximize the efficiency of internal operations. Further, Nonaka and Takeuchi (1994) describe organizational knowledge as the capacity of organizations to create knowledge, disseminate it throughout the organization, and incorporate it into products and processes.

It is understood that knowledge does not remain static within constantly changing economies, as in present times. It is a valuable asset that must be identified, evaluated, acquired, transferred, stored, used, and maintained, remaining available for decision-making (Nonaka and Takeuchi, 1991; Pemberton and Stonehouse, 2000; Downes, 2014).

Consequently, knowledge management presents itself as a process through which an organization perceives and generates value through its intellectual and knowledge assets, and is considered to be a new, influential and visible approach to the art and science of management in recent decades (Uriarte, 2008; Inkinen, Kianto and Vanhala, 2015).

2.3 Knowledge Management Practices

In 2003, the Organization for Economic Co-operation and Development (OECD) pointed out that the implementation of knowledge management (KM) practices would be a crucial phase in which organizations could promote change and integration within a knowledge-based economy. The Comité Européen de Normalisation (CEN, 2004), sustains that KM practices support and constitute a link between the processes of the KM cycle and the strategic objectives of an organization, precisely because authors consider that absorbing elements of knowledge and combining them is an important management challenge within healthcare organizations (Akdere, 2009; Faraji-Khiavi, Ghobadian and Moradi-Joo, 2015). In a systematic review of the literature on KM practices and organizational performance, Inkinen (2016) presents as a contribution of the study that the results increase the understanding of the efficient and effective management of knowledge resources for organizational benefit. They also point out that organizations must be attentive to attributes of leadership and organizational arrangements to achieve company performance through KM.

This present study considers KM practices to be intentional activities or routines, formal or informal, geared towards adequately managing knowledge. It is also based on its efficient use aligned with task-related objectives that support knowledge management, allowing companies to add value from their knowledge-based assets (Andreeva and Kianto, 2012; Dávila et al., 2014; Kianto and Andreeva, 2014; Inkinem, Kianto and Vanhala, 2015).

We chose the concept of certification presented by Nicklin et al. (2014), as a process of external evaluation used to evaluate and improve quality, efficiency, and efficacy of healthcare organizations, therefore producing higher quality health services in a safe environment. Healthcare organizations that provide physiotherapy services and which belong to the National Federation of Physiotherapy Associations and Companies (FENAFISIO) are the object of this study. Such organizations participate in the FENAFISIO Quality Certification Program, have the Quality Certification Seal, and were consequently subjected to external audits at two different times, diagnosis and audit, at an interval of 6 to 8 months. For this study, we adopted the point of view of Inkinen, Kianto and Vanhala (2015), in which KM practices are a set of management activities that allow companies to add value from their knowledge-based assets, grouping KM practices in ten dimensions, according to Table 1.

Table 1: Dimensions and Aspects of KM Practices

Dimensions	Aspects
Strategic management of knowledge	Knowledge as a key input for the development of the organization's strategies
Organizational design	Contemplates the decisions made regarding division of work and responsibilities
Communication and information technology (CIT)	The means to access knowledge in the organization
Knowledge-based recruiting	Directs attention to candidates´ skills and abilities
Knowledge-based training and development	Includes courses and seminars for professional development
Knowledge-based performance evaluation	Employee ability to create, use and disseminate knowledge
Knowledge-based compensation	Involves tangible and intangible motivation; career progression; work recognition
Supervision work	Encompasses key management activities; crucial factors in the performance of organizational culture
Knowledge protection	Use of patents, agreements, legislation, or confidentiality
Learning mechanisms	Increased organizational learning through practice and experience

Source: Inkinen, Kianto and Vanhala (2015).

The choice of this list of KM practices is justified using relevant studies in Brazil (Macau, Brito and Duarte, 2016; Dávila, Andreeva and Varvakis, 2019; Dorow et al., 2019; Anjos, 2020). However, this study intends to evaluate nine dimensions of practices: strategic knowledge management, organizational design, communication and information technology, recruiting, training and development, performance evaluation, knowledge-based compensation, supervision and learning mechanisms. We have excluded the knowledge protection dimension since the healthcare organizations participating in this study do not develop patents.

In order to reach the central objective of this study, it is necessary to know the evolution of the quality descriptors that were evaluated, as well as the presence of strategic KM practices in these organizations. In this manner, we present the methodology used to support this study.

3. Methodology

The research is of an empirical and applied nature, aiming to generate knowledge for practical application. It is an exploratory, explanatory, and descriptive research (Gil, 2009). Regarding the means, the research utilizes the survey method as it deals with primary data from a sample. Through a quantitative approach and analysis, it seeks to draw conclusions corresponding to the collected data (Gil, 2009).

The population is composed of data from 24 (twenty-four) healthcare organizations distributed throughout 9 (nine) states in Brazil, which belong to the quality certification program of the National Federation of Physiotherapy Associations and Companies, FENAFISIO. This federation is composed of healthcare organizations that provide outpatient, hospital, and home-care physiotherapy services. The analyzed data are part of the quality descriptors verification Check List, verified for adequacy and compliance with the 43 quality descriptors evaluated in the program between December 2018 and December 2022. The analyzed data regarding strategic practices of knowledge management were answered by the managers of the organizations through Google Forms after having been certified, that is, having finalized the process of certification. The respondents indicate how much they agree with the 29 questions related to strategic practices ok KM.

The stages of the research are presented in Table 2.

For this study, two measurement instruments were applied, assuming that this study involves the theory about the relationships between a set of variables relevant to the phenomenon under investigation, and that the measurement instruments attribute value to a certain object or event, considering that the phenomenon of interest is inferred from an indicator with which it is correlated (Pedhazur and Schmelkin, 1991).

The first instrument is the actual document from the certification program we studied, that is, the Verification List of quality descriptors. Each of the 43 quality descriptors evaluated can be found on the checklist and is measured on a conformity scale of 1 to 5. These 43 descriptors are subdivided into 3 (three) groups, which are: Infrastructure (physical infrastructure and administrative infrastructure), Provision of Services and Satisfaction (internal client and external client). The organizations participating in the program are analyzed at two different moments of external evaluation: diagnosis and audit. This includes an interval of approximately 6 months between the two. This document is part of the FENAFISIO program for quality certification called Seal of Certification of Quality, and it is a confidential document based on the "Constructivist model for measuring the quality of physiotherapy services from the manager's perspective" (Mandelli, 2015). The evaluated checklist items are presented on the verification list of quality descriptors on Table 2.

Table 2: Verification List of Quality Descriptors

Infrastructure	Physical structure	Noise, lighting, ventilation, temperature, size, privacy, organization, cleanliness, ergonomic space, internal accessibility, external accessibility, quantity of equipment and calibration
	Administrative structure	Management model, financial management, customer service, integration and training program, standardization of administrative and assistance processes.
Customer service	Professional domain	Scheduling, service time, number of patients per hour, degree of specialization, performance, external improvement, therapist-patient bond, risk

		management, compliance with regulatory bodies, use of PPE, clinical protocols, medical records
	Efficiency and efficacy	Treatment plan, treatment time, objectives achieved, adherence to protocols.
Satisfaction	Professional satisfaction	Fee flexibility, continuing education program, compensation, career plan.
	Client satisfaction	Ability to involve the patient in decisions, listening skills, record of complaints, satisfaction questionnaire.

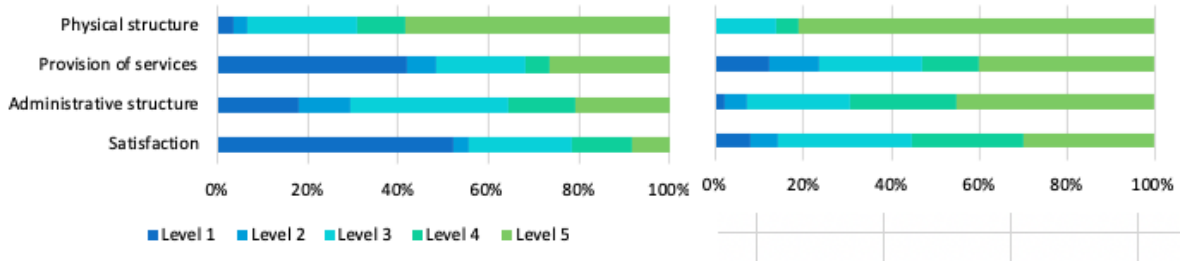
Source: Mandelli (2015).

The second instrument, the strategic practices of KM questionnaire, obtained from Inkinen, Vanhala and Kianto (2015), considered 9 (nine) dimensions of KM practices. All the answers are scored on a 5-point *Likert* scale, where 1 means completely disagree, and 5 means completely agree. The 9 (nine) dimensions are: strategic knowledge management, organizational design, communication and information technology, knowledge-based recruitment, knowledge-based training and development, performance evaluation, knowledge-based compensation, supervision work and learning mechanisms. Based on these dimensions, 29 practices were contemplated. The questionnaire was sent to all certified organizations in the quality certification program, and 24 (twenty-four) responses were received, the same number of organizations analyzed with research instrument 1, respectively.

4. Results and Discussion

Of the 24 organizations analyzed, 5 offer physiotherapy services in hospitals and 19 offer outpatient physiotherapy services (physiotherapy clinics). At first, we observed the evolution results of these healthcare organizations based on the evolution of the quality descriptors represented by the Verification list of quality descriptors (Research instrument 1). Subsequently, these analyses were descriptively associated with the presence of strategic practices of KM within these organizations (Research instrument 2).

The collected data was processed by means of metric tests, run on SPSS 21 software, and presented in descriptive manner.



The metrics (before x after) are first presented, which synthesize and compare the average and deviation of the scores according to a group of descriptors, at the time of diagnosis and audit, and the analysis allows for differentiating groups with greater and lesser evolution between both periods (situational diagnosis and final audit). We consider that the average provides a notion of central tendency of the responses obtained from each group. The deviation provides a notion of dispersal, of how homogeneous (the greater the number, the more heterogeneous) are the responses from each group. The variation (%) indicates, in terms of percentile, how much the average and deviation of the items of each group increased (+) or decreased (-) from the diagnosis to the audit.

Group 2	Diagnosis		Audit		Variation (%)	
	Average	Deviation	Average	Deviation	Average	Deviation
Physical structure	4,17	1,24	4,67	0,50	12,0	-60,1
Administrative structure	3,09	1,82	4,05	1,08	31,0	-40,8
Provision of services	2,68	2,76	3,57	2,01	33,3	-26,9
Satisfaction	2,22	1,98	3,63	1,43	63,6	-27,8

Source: Developed by the authors (2023).

Figure 1: Descriptive Measures of Item Evaluated by Groups in the Diagnosis and Audit

We can see in Figure 2 the synthesis and comparison of the distribution of answers obtained from the items of each group, according to scale levels, at the time of diagnosis and audit. The analysis allows for perceiving the evolution of response distribution between both periods. This presentation format also shows how well each group is evaluated. Levels 1 to 5 correspond to the possible answer categories of evaluated items, from 1 (worst) to 5 (best), and the colored bars indicate the percentage of answers at each level.

Source: Developed by the authors (2023).

Figure 2: Distribution (%) of Answers Per Groups in the Diagnosis and per Scale Level in the Audit

In this manner, the evolution of the verified items was considered to be statistically significant. The satisfaction group presents the greatest evolution of descriptors in relation to the other groups. Customer service and satisfaction are the groups that have descriptors related to the human resources area, such as training and development, performance evaluation, continued education, communication with internal and external clients, as well as client involvement in the decision-making process of their treatment. This present study aims to corroborate with other authors, confirming that certification programs facilitate organizational performance through the lens of improving the evaluated processes in these programs.

The information related to strategic practices of KM is the result of the application of research instrument 2 (two), a KM strategic practices questionnaire, which aims to identify the presence of strategic practices of KM within these organizations.

Firstly, it is important to describe the profile of the respondents. The sample is composed of 24 (Twenty-four) managers, 51.4% of whom are exclusively managers. The remaining respondents are managers and physiotherapists, a characteristic often found in the healthcare organizations that make up FENAFISIO, where the manager also acts as physiotherapist, and vice-versa. The organizations from the sample have been offering physiotherapy services for an average of 21 (twenty-one) years, have an average of 50 (fifty) employees, and their respondents have been working for these organizations for an average of 15 years. Further, all the organizations have gone through the process of quality certification in the last 2 (two) years.

As for the results based on the respondents´ perception of existing practices in the actual organizations, we highlight the investigated dimensions that yielded responses above 80%. These were: knowledge-based supervision work and training and development. Tables 3 and 4 exhibit the specific questions for each of the dimensions and the percentage of responses.

Table 3: Dimension Supervision Work vs. Percentage of Respondents on the Likert Scale Score

Respondents´ perception	score 5	score 4	score 3	score 2	score 1
Encouraging employees to share knowledge in the workplace	91%	8.6%	0	0	0
Encouraging employees to question existing knowledge	80%	11.4%	5.7%	2.9%	0
Supervisors value employees' ideas and point of view by taking them into account	91.4%	8.6%	0	0	0
Supervisors promote discussion in an equitable manner in the workplace	82.9%	14.3%	0	0	0
Share knowledge openly and equitably	91.4%	8.6%	0	0	0
Supervisors allow mistakes to occur and see them as a learning opportunity	54.3%	40%	5.7%	0	0

Respondents´ perception	score 5	score 4	score 3	score 2	score 1
Supervisors continually update their own knowledge	71.4%	22.9%	5.7%	0	0

Source: Developed by the authors (2023).

We observed a considerable presence of KM practices related to the dimension of work supervision. Knowledge management practices that represent this dimension are the managerial practices that Inkinen, Kianto and Vanhala (2015) link to how these organizations establish their organizational culture, which, in turn, communicates with authors that relate supervision work as a crucial factor in the development of organizational culture. This affirms the direct impact on how an organization deals with knowledge management. However, we observed a lesser perception of improvement opportunities derived from mistakes. Inkinen (2016), cites supervision work as a dimension that encompasses key management activities, a critical factor in organizational culture performance.

Table 4: Dimension Knowledge-Based Training and Development vs. Percentage of Respondents on the Likert Scale Score

Respondents´ perception	score 5	score 4	score 3	score 2	score 1
Employees have the opportunity to deepen and expand their knowledge	88.6 %	11.4%	0	0	0
The company offers training that provides employees with knowledge that is up to date	82.9 %	5.7%	8.6%	2.9%	0
Employees have the opportunity to develop skills through training tailored to their specific needs	79.4 %	8.8%	11.8%	0	0
Professional development needs are discussed with employees on a regular basis	60%	34.3%	5.7%	0	0

Source: Developed by the authors (2023).

The intensity of KM practices also appears significantly in the dimension of training and development, which is related to human resource management. This dimension refers to practices that involve the implementation of courses and seminars for employee training and performance. These findings confirm the studies by Dorow (2019) regarding the importance of knowledge sharing in knowledge-intensive healthcare organizations.

Our results corroborate the findings of Inkinen (2016) concerning human-oriented practices as significant factors for company performance. Human resource-oriented activities are related to knowledge-based human resource management and leadership in KM.

The other dimensions of KM practices emerged sporadically in the responses, with little significance in the dimensions of strategic knowledge management and knowledge-based compensation. The literature defines strategic knowledge management as the activities of strategic planning, implementation, and updating related to the knowledge-based assets of the company (Kianto et al., 2014). These activities can enhance organizational performance through mechanisms that allow the organization to focus on activities that add the most value to the company, which is important as intangible assets are sources of competitive advantage (Inkinen, Kianto and Vanhala, 2015; Conner and Prahalad, 1996; Grant, 1996). Aligning strategic knowledge management across various aspects of the organization ensures the utilization of organizational knowledge for action, generating value for healthcare organizations.

Our results support the study by Novaes (2015) that quality certification programs facilitate the development of standards for continuous improvement in patient care and organizational performance. However, when analyzing the presence of knowledge management practices, we observe a relatively incipient and empirical

implementation. This confirms the argument that sustainable societies need to consider the connection between knowledge management and healthcare as a critical issue for social development with patient safety and sustainability for healthcare organizations, as these organizations are also considered to rely on the effective use of knowledge assets and resources (Karamitri, Kitsios and Talias, 2020; Braithwaite et al., 2020).

According to the results obtained in the study, the healthcare organizations participating in the certification program indeed demonstrate significant improvements in the evaluated quality descriptors, particularly in the service delivery and satisfaction groups. When associating these findings with KM practices, we observe an intensity of practices in the dimensions of supervision work and knowledge-based training and development, aligning with the findings of Karamitri, Kitsios and Talias (2020). These authors highlight the existence of KM practices for translating knowledge into action in healthcare organizations regarding specific knowledge sharing issues. However, it is evident that in the other dimensions, the presence of KM practices is incipient, as stated by Silva et al. (2016).

Our study further reinforces the findings of recent research by Karamali (2020) and Hinchcliff (2021), highlighting the need for a greater understanding and formalization of the organizational impact with the presence of KM practices concurrent with the implementation of a quality certification program.

5. Final Considerations

This research aimed to comprehend the presence of KM practices alongside the development of certified healthcare organizations within a certification program in Brazil. It explores the potential for certification programs to generate organizational value through knowledge-based management.

It is evident that the groups of quality descriptors related to human resource management demonstrate significant advancements. Specifically, these dimensions encompass the incorporation of KM practices, such as knowledge-based supervision and training and development.

Our research contributes to bridging the identified gap in the literature regarding the association between KM practices and certification programs. These programs have been employed as management tools, providing support and facilitating the implementation of KM.

Considering the significance of KM practices for healthcare service providers and the nascent discussion within Brazil and within a certification program, the necessity for further studies to deepen the understanding of KM practices associated with organizational development has come to light. Such studies would support organizational performance and development, fostering sustainability and value creation for these organizations.

The obtained results substantiate the importance of incorporating specific quality descriptors for knowledge management within certification programs. This inclusion enables the creation, utilization, and dissemination of knowledge for actionable outcomes within healthcare organizations.

However, the research faces limitations concerning the sample size, specifically the number of participating organizations and respondents. These limitations impede the generalization of the findings. Thus, future studies are suggested to investigate a larger number of organizations, as well as the presence of KM practices in certified organizations. These additional studies can contribute to a comprehensive understanding of how quality management supports KM and jointly generates value and sustainability for healthcare organizations.

Mitigating the Disruptive Consequences of Knowledge Loss in Organizational Settings: Knowledge Loss Clusters and Potential Organizational Interventions

Stefania Mariano
Department of Management, School of Business Administration, American University of Sharjah, UAE

smariano@aus.edu

Abstract: This paper reviews the management and organization studies literature underpinning the construct of knowledge loss. It proposes that five clusters of knowledge loss influence the capacity of organizations to retain their valuable organizational knowledge. Such clusters include hanging, fading, disengaging, dissolving, and vanishing. To overcome the disruptive consequences of knowledge loss, this paper proposes five potential organizational interventions including reminding, refreshing, re-acquiring, re-building, and re-inventing. This paper discusses the implications for theory and managerial practice in the context of the knowledge management literature and provides directions to future research.

Keywords: Organizational knowledge, Organizational forgetting, Knowledge loss, Knowledge management, Organizational interventions, Literature review

1. Introduction

Organizations are constantly working on the proper retention of organizational knowledge, either in the form of storage facilities, or as workforce retention programs. Losing valuable organizational knowledge is indeed costly in terms of wasted time, money, or key resources (Mariano et al., 2020).

Despite the disruptive consequences of losing valuable organizational knowledge, knowledge loss still needs to be fully understood. For instance, the magnitude of disruptions caused by knowledge loss is still unclear. In the scholarly literature, there has been a tendency to treat different instances of knowledge loss univocally, with some exceptions (Martin de Holan and Phillips, 2004). However, a more in-depth examination of the existing scholarly literature shows that this tendency may be detrimental. Addressing the consequences of the most experienced organizational member's departure may be more challenging than retrieving a codified procedure from an archive that has become temporarily unavailable. These two examples relate to dissimilar clusters of knowledge loss that require separate interventions to prevent unsolicited disruptions.

This paper builds on an in-depth examination of the scholarly literature and proposes that different clusters of knowledge loss may indeed exist in organizations, suggesting potential managerial interventions. In this paper, knowledge loss is defined "the accidental disappearance of existing organizational knowledge" (Mariano et al., 2020, p. 191). This paper answers the following research questions: What are the clusters of knowledge loss? Which managerial interventions can reduce the disruptive consequences of knowledge loss?

This paper classifies different instances of knowledge loss in five clusters—i.e., hanging, fading, disengaging, dissolving, and vanishing—and suggests five potential interventions—i.e., reminding, refreshing, re-acquiring, re-building, and re-inventing—to help overcome the disruptive consequences of knowledge loss in organizational settings.

By proposing these five clusters of knowledge loss and their related organizational interventions, this paper contributes to current theory and managerial practice in several ways. First, it provides a more granular description of knowledge loss. Second, it proposes specific organizational interventions that may assist managerial practice with positive consequences on improved productivity and quality (Darr et al., 1995); maintenance of stocks of organizational knowledge (Boone et al., 2008) and knowledge retention mechanisms (Levy, 2011; Schmitt et al., 2011). Finally, this paper helps direct future empirical studies investigating the different impacts of knowledge loss on organizational practices (Mariano et al., 2020).

2. What is Knowledge Loss?

Knowledge loss has become a topic of scholarly and managerial interest since the early 1990s when it was originally discussed in the context of learning curves and organizational forgetting conversations (e.g., Argote, 2013; Blackler et al., 1999). Compared to unlearning (e.g., Cegarra-Navarro and Wensley, 2019)—which is the intentional removal of organizational knowledge to make room for new ways of doing things—knowledge loss

has been conceptualized as an unsolicited phenomenon with disruptive consequences on organizational productivity, efficiency and performance.

Over the last decades, scholars have documented knowledge loss in studies of organizational members' behaviors (Martin de Holan and Phillips, 2004); investigations of storage facilities (Argote, 2013); or have consider it an unsought consequence of organizational restructurings, mergers, or acquisitions (Anand et al., 2012). Grounded in such an extensive scholarly literature, this paper provides a synthesis for theory and managerial practice, grouping the potential causes of knowledge loss into five clusters. This paper also proposes five potential interventions to ease the disruptive consequences of knowledge loss.

3. Clusters of Knowledge Loss

3.1 Hanging

When organizational members become repositories of key organizational knowledge, the likelihood of disruptions associated to their unwanted behavior may increase (Massingham, 2018; Cattani et al., 2012). Hanging describes these potential disruptions and represents a first cluster of knowledge loss. If proper retention mechanisms are omitted, this valuable individual knowledge may be lost. This may be the case of knowledge that has not been used daily, which tends to disappear more easily (Fernandez and Sune, 2009). Indeed, passage of time and infrequent use have been proposed to be potential causes of knowledge loss at the individual level (Argote, 2013). Similarly, the extent to which knowledge is perceived as valuable is likely to influence its usage. Research has found that knowledge not directly connected to the relevant day-to-day tasks tends to disappear more quickly than core knowledge used on a regular basis (Mariano and Casey, 2016). If passage of time, infrequent use, or low perceived value influence the extent to which knowledge is used, hanging may surface. Hanging may be particularly detrimental when multiple individuals contribute to organizational processes and, therefore, the loss of one contribution may have a critical impact on the overall performance at a more aggregated level. For instance, there may be periodic submissions happening at given points in time and there may be considerable work to be performed to meet deadlines. If deadlines are missed, there may be interruptions in the amount of work performed by other individuals at higher levels in the hierarchical structure. Therefore, if the individual knowledge is lost, this may result in potential issues at a more collective level. Proper preventive mechanisms may have to be staged and periodically used to prevent collective disruptions.

3.2 Fading

Fading describes a second cluster related to knowledge retained in storage facilities such as records, archives, collective electronic infrastructure, and databases. Scholars have praised the role of shared databases to preserve information quality and facilitate knowledge transfer across organizational members (Boone et al., 2008; Agrawal and Muthulingam, 2015). Some have proposed that knowledge embedded in technology and storage facilities is less prone to depreciation or loss than knowledge embedded in routines or organizational members, promoting more technologically sophisticated organizational forms (Argote, 2013).

However, the disbandment of storage facilities such as when they break-up or cease to function; or their deterioration—a symptom of reduced quality, strength, passage of time or fall in disuse—are likely to determine the loss of crucial organizational knowledge. For instance, the removal of a repository can affect organizational memory, especially when the repository is highly centralized (Fernandez and Sune, 2009). Similarly, improper "clear desk" policies may produce documentation inaccessible to organizational members (Blackler et al., 1999). At times, technical or physical constraints (Easterby-Smith and Lyles, 2011) may prevent a proper access to storage facilities, records, or databases, although it may be temporal. Similarly, codification processes that make knowledge explicit but more abstract and generalizable could generate the loss of situated and heuristic knowledge available previously (Treleaven and Sykes, 2005).

Since organizational knowledge may dissipate in the long term—in terms of content as well as the rationale behind it (Easterby-Smith and Lyles, 2011)—deliberate and properly planned maintenance strategies are crucial. Having storage facilities is a necessary but not sufficient condition for organizational knowledge to be available and up to date. Keeping a repository functioning and updated is challenging. Similarly, if knowledge is hard to be found in the storage facilities, the system is less likely to be used (Franco and Mariano, 2007). Proper maintenance mechanisms have to be implemented to prevent the accidental loss of explicit organizational knowledge.

3.3 Disengaging

When organizational members move to other roles, departments, subsidiaries, or geographical locations, potential detrimental consequences may occur to organizational knowledge. Such detrimental consequences may include poor data handover (Shankar et al., 2013); reduced knowledge accessibility and coordination (Shaw et al., 2005); disruptions to knowledge flows (Ward and Wooler, 2010); disappearances of important contacts (Ward and Wooler, 2010); and misplaced, lost nodes, or broken links in networks of relationships (Shaw et al., 2005).

Disengaging describes those instances and represents a third cluster of knowledge loss. In such instances, knowledge may be lost but there is still a chance to retrieve it from the network of relationships. Research has found that gatekeepers, brokers, central nodes and, at times, peripheral network nodes contribute to the preservation of organizational knowledge (Argote, 2013; David and Brachet, 2011). A key aspect would be to make individual expertise known at a more collective level and facilitate internal interactions. Acquaintance and socialization strategies, especially in labor intensive organizations, become crucial (Boone et al., 2008). Similarly, a proper assessment of the roles and positions of organizational members may help reduce accidental knowledge losses. Certain forms of social networks that favor an optimal mix between strong and weak ties may also reduce knowledge loss if organizational members move (Droege and Hoobler, 2003; Schmitt et al., 2011). Additional strategies such intergenerational learning practices (Bratianu and Leon, 2015), architectural knowledge, coordination among units, and development of existing capabilities to be transformed in effective organizational routines (Daghfous et al., 2013) could potentially mitigate knowledge loss and increase organizational knowledge retention.

3.4 Dissolving

Dissolving describes a fourth cluster of knowledge loss. In this specific instance, knowledge is permanently lost. It may be the case of departing organizational members, including internal replacement, quitting, or retirement of employees (Parise et al., 2006)—such as aging workforce (Calo, 2008), or replaced management teams (Ciuk and Kostera, 2010). When organizational members leave without a proper knowledge management strategy in place, organizations are likely to experience decreased revenues (Schmitt et al., 2011) and productivity (Massingham, 2018); disruptions to firm's credibility (Joe et al., 2013); customers mistrust (Massingham, 2018); and increased needs to orient and train newcomers (Droege and Hoobler, 2003). Knowledge loss due to turnover (Eckardt et al., 2014) includes the parting of subject matter expertise (Martin de Holan and Phillips, 2004; Eugene Jennex, 2014; Schmitt et al., 2011; Sumbal et al., 2018) and governance knowledge (Joe et al., 2013; Mariano et al., 2018); knowledge about business relationships and social networks (Easterby-Smith and Lyles, 2011); knowledge of business systems, processes or value chains (Joe et al., 2013); and institutional memory (Scalzo, 2006; Massingham, 2008; Haunschild et al., 2015). Indeed, when key organizational members leave, the subsequent knowledge downsize caused by their departures may challenge the capacity to rebuild the lost organizational memory. Depending on who leaves and what knowledge departs with them, knowledge loss may have a qualitatively different impact. Turnover-related disruptions have highlighted the crucial importance of knowledge transfer strategies such as centralized knowledge management systems, demographic inventories (Calo, 2008), knowledge risk profiles, increased collaboration levels and stronger network ties (Droege and Hoobler, 2003; Daghfous et al., 2013; Schmitt et al., 2011), knowledge overlapping procedures, and job and career redesign.

3.5 Vanishing

Vanishing describes a fifth cluster related to the complex combinations of collective and physical spaces where organizational activities take place. It may be the case when mergers, acquisitions, of restructuring impose radical changes that have a disruptive influence on the amount and quality of knowledge possessed at the organizational level, creating knowledge asymmetries (Anand et al., 2012), and loss of know-how. Mergers or outsourcing have been found to create knowledge asymmetries and produce hidden costs of outbound knowledge flows. At times, they may have contributed to the loss of technological know-how (Conti, 2014) or legal knowledge (Reitzig and Wagner, 2010). For instance, leakages of technological know-how have been proposed to be asymmetric with respect to a firm's research and development strategy, with higher losses of valuable organizational knowledge in the case of riskier projects (Conti, 2014). More trusted partners have been proposed to let organizations acquire more knowledge, lose less valuable knowledge, and increase the overall level of alliance satisfaction (Norman, 2004).

4. Mitigating the Disruptive Consequences of Knowledge Loss

This paper proposes the following five potential interventions to help mitigate knowledge loss i.e., reminding, refreshing, re-acquiring, re-building, re-inventing.

4.1 Reminding

Reminding is a first intervention that is proposed to relate to the first cluster of knowledge loss i.e., hanging. It relates to individual knowledge. Reminding is proposed to be performed before (ex-ante) the accidental loss of knowledge may create disruptions at a more collective level. Strategies include prompt mechanisms to avoid knowledge loss due to passage of time or infrequent use of knowledge such as the use of how-to lists to accomplish a routine task; self-training mechanisms to re-acquire knowledge loss due to infrequent use; or the introduction of automated or less automated reminders to be sent periodically to provide the necessary information to accomplish certain tasks. For instance, an automatic gentle reminder that urges to provide certain documented forms of knowledge at given points in time e.g., "please remember to provide your elaborations by (include a certain date)", accompanied with instructions on how to get the task done or individuals to contact in case of specific questions or concerns. Useful managerial assessment questions could include: Can this knowledge be conveniently codified for future uses? Who is in charge of collecting this knowledge? At what point in time is this knowledge going to be requested? Can an automated mechanism prevent potential knowledge loss-related disruptions?

4.2 Refreshing

Refreshing is a second intervention that is proposed to relate to the second cluster of knowledge loss i.e., fading. It relates to organizational knowledge embedded in storage facilities. Refreshing is proposed to be performed concurrently to keep the storage facilities fully functional. Strategies include the facilitation of both access and maintenance of the storage facilities. For instance, facilitating the access to electronic repositories, archives, documents to find explicit knowledge; introducing a dedicated person or system (e.g., automated chatbot) to provide pointers/links; and introducing mechanisms to facilitate and incentivize the sharing or tacit knowledge at a more collective level, since the act of documenting has been proposed to be a valuable strategy to keep key organizational knowledge in place (Levy, 2011). Useful managerial assessment questions could include: How can this knowledge be maintained and retrieved? What retrieval mechanisms can facilitate the location of this knowledge? Will there be a person in charge of maintaining this knowledge? What incentives can ensure the correct and timely update of the storage facility?

4.3 Re-acquiring

Re-acquiring is a third intervention that is proposed to relate to the third cluster of knowledge loss i.e., disengaging. It relates to knowledge found in the individuals' networks of relationships. Re-acquiring is proposed to be performed concurrently to keep or strengthen the networks of relationships to find valuable knowledge that otherwise would be lost. This may be particularly useful during restructuring (Kleiner et al., 2011). Thus, the major aim of re-acquiring would be to facilitate the access to key nodes and links in available networks of relationships, including gatekeepers, brokers, central nodes and, at times, peripheral nodes. Strategies include the facilitation of virtual or less virtual networking sites; datasets of expertise or demographic inventories (Calo, 2008); or the development of relationships that may help increase knowledge exchange to answer questions such as "could you please tell me how we used to do that?" especially at an intergenerational level (Bratianu and Leon, 2015) to facilitate coordination within and across units. Additionally, it may be worth sending periodical updates related to network nodes that clarify where useful knowledge can now be found e.g., "Please note that Person X is now available for clarifications" or "Please note that the position has been assigned to Person Y who will be in charge to answer your questions". Useful managerial assessment questions could include: How can the extended network of relationships be used to retrieve organizational knowledge that has now become unavailable? What pointers or referrals can be implemented to facilitate knowledge retrieval? How can a dataset of expertise be implemented? How can virtual and less virtual networking sites aid the location and retrieval of knowledge?

4.4 Re-building

Re-building is a fourth intervention that is proposed to relate to the fourth cluster of knowledge loss i.e., dissolving. Re-building is proposed to be performed ex-post, through reflection attempts and performance of actions to restore the lost knowledge, with the overall aim to strengthen the capacity to re-build the knowledge that had dissipated. Common clues to this type of knowledge loss include comments such as "we

used to know how to do this but not anymore". Another clue may regard the temporary shift of roles. This may be the case in small businesses when the owner often has to take charge of a position that has become temporarily vacant and for which a replacement has yet to be found. When the organization realizes that knowledge may have been dissolved, actions to rebuild this knowledge, and to prevent similar disruptions need to be taken. These actions include the re-building of tacit, explicit, or relational knowledge, depending on the knowledge type that has been dissolved, including the overlapping of knowledge to have it always available at multiple locations, for instance implementing a master pool strategy to ensure that multiple individuals possess the needed knowledge. Useful managerial assessment questions could include: Is there a chance to restore the lost knowledge? Who can help re-build the lost knowledge? What actions can be initiated to recover from the lost knowledge on a short as well as long term basis? How a distributed knowledge system can be developed to prevent the loss of knowledge?

4.5 Re-inventing

Finally, re-inventing is the fifth intervention that is proposed to relate to the last cluster of knowledge loss i.e., vanishing. Re-inventing is proposed to be performed when knowledge has been permanently lost, often unknowingly. The major aim is to facilitate the recreation or optimization of knowledge and related processes to favor knowledge reinstate. It may be particularly important to look for clues that signal this cluster of knowledge loss after restructuring, mergers, or acquisitions. In these instances, there may be a tendency to re-invent the wheel because of lost know-how (Conti, 2014), knowledge asymmetries (Anand et al., 2012), or loss of technological and legal knowledge (Reitzig and Wagner, 2010). If knowledge loss occurs, there may need to be a conscious intention to identify it to prevent future knowledge loss. Useful managerial assessment questions could include: Has the organization experienced a reduced level of productivity after the restructuring? Could this reduced level of productivity be associated with lost knowledge? What organizational areas have been disrupted the most and who was involved with them? Have knowledge asymmetries advantaged our partners and disadvantaged our organizations? How can this be prevented?

For a summary, see Table 1 and Figure 1.

Table 1: Five Clusters of Knowledge Loss and Potential Organizational Interventions

Cluster	Disruptions	Organizational Interventions and Timeline	Mitigation Mechanisms	Assessment Questions
Hanging	Chain of task interruptions Collective outcomes disruptions	Reminding (ex-ante)	Prompt mechanisms to avoid knowledge loss due to passage of time, infrequent use, or low perceived value e.g., how-to lists, self-training, reminders	Can this knowledge be conveniently codified for future uses? Who is in charge of collecting this knowledge? At what point in time is this knowledge going to be requested? Can an automated mechanism prevent potential knowledge loss-related disruptions?
Fading	Disbandment (i.e., break up or cease to function), deteriorations, fall in disuse Loss of a centralized repository Clear desk policies and inaccessible documents Technical or physical constraints Loss of situated and heuristic knowledge during codification processes	Refreshing (concurrent)	Properly maintained IT Documentation eliciting explicit knowledge storage, access, and retrieval	How can this knowledge be maintained and retrieved? What retrieval mechanisms can facilitate the location of this knowledge? Will there be a person in charge of maintaining this knowledge? What incentives can ensure the correct and timely update of the storage facility?
Disengaging	Knowledge accessibility, coordination, and flow	Re-acquiring	Shared close relationships and	How can the extended network of relationships be used to

Cluster	Disruptions	Organizational Interventions and Timeline	Mitigation Mechanisms	Assessment Questions
	Broken links, misplaced or lost nodes Disappearances of important contacts Poor data handover	(concurrent)	workspaces Increased level of socialization and acquaintance in labor intensive organizations Assessment of role and position: Gatekeepers, brokers, central nodes, and peripheral nodes Favored forms of network structure with optimal mix between strong and weak ties Intergenerational learning Architectural knowledge and coordination among units Development of existing capabilities to transform into routines	retrieve organizational knowledge that has now become unavailable? What pointers or referrals can be implemented to facilitate knowledge retrieval? How can a dataset of expertise be implemented? How can virtual and less virtual networking sites aid the location and retrieval of knowledge?
Dissolving	Newcomers training needs Interferences in knowledge transfer Loss of subject matter expertise, business relationships, network knowledge, institutional memory including know-how, business systems, processes, and value chains knowledge Loss of governance knowledge Decreased revenues, productivity, credibility Increased customers mistrust	Re-building (ex-post)	Centralized knowledge management systems Demographic inventories Knowledge risk profiles and assessment Job and career redesigns Increased collaboration and stronger network ties Knowledge overlapping	Is there a chance to restore the lost knowledge? Who can help re-build the lost knowledge? What actions can be initiated to recover from the lost knowledge on a short as well as long term basis? How a distributed knowledge system can be developed to prevent the loss of knowledge?
Vanishing	Accidental loss due to re-structuring, mergers, or outsourcing Knowledge asymmetries in inter-organizational alliances Hidden costs of outbound knowledge flows Loss of technological/legal knowledge Leakages of technological know-how with higher knowledge losses in riskier projects	Re-inventing (ex-post)	Trusted partnerships Recreation/optimization attempts to facilitate knowledge reinstatement	Has the organization experienced a reduced level of productivity after the restructuring? Could this reduced level of productivity be associated with lost knowledge? What organizational areas have been disrupted the most and who was involved with them? Have knowledge asymmetries advantaged our partners and disadvantaged our organizations? How can this be prevented?

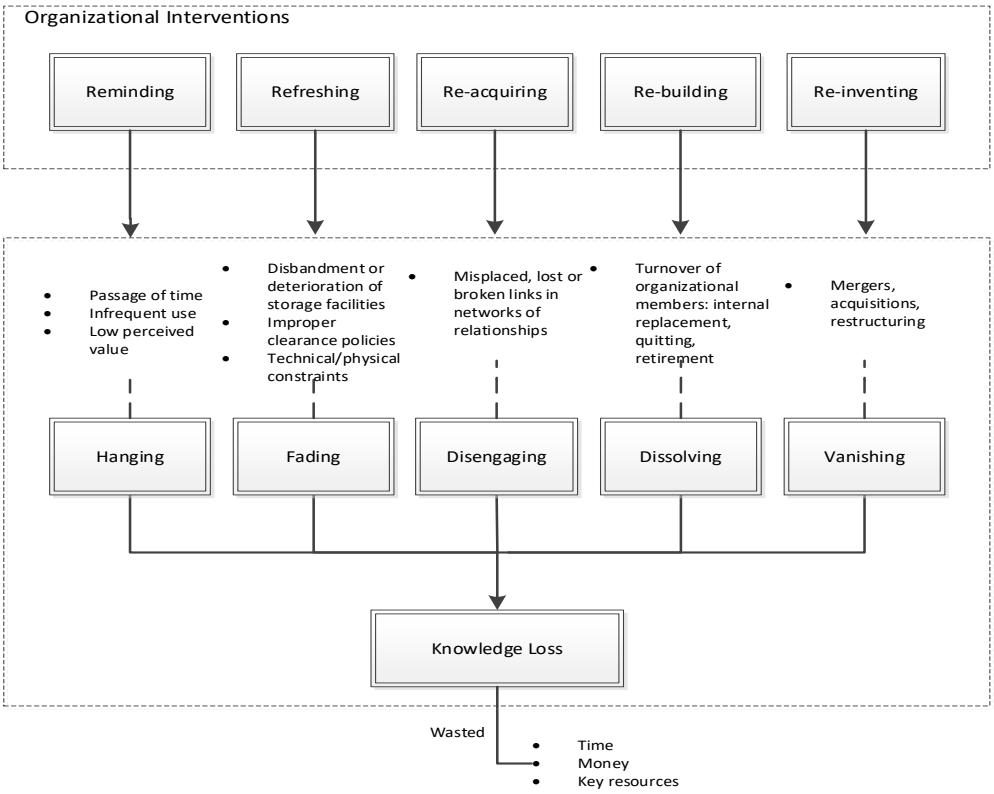

Figure 1: A Synthesis

5. Implications for Theory and Practice

This paper contributes to theory in several ways. First, it expands current understanding by proposing a classification of five different clusters of knowledge loss i.e., hanging, fading, disengaging, dissolving, and vanishing. These clusters of knowledge loss were grounded in the relevant literature on knowledge loss, and showed how changes to individuals and their relationships, storage facilities or the organizational structural dimensions could have an influence on the accidental departure of organizational knowledge. While a great deal of scholarly work has extensively investigated the key role of organizational learning and has linked it to organizational performance, only a few studies have provided more granular descriptions of the disruptive consequences of knowledge loss, proposing organizational dysfunctions such as avoidance, resistance, struggle, alteration, and conversion processes (Mariano and Casey, 2016). This paper adds to these studies and proposes that five clusters of knowledge loss may have different impact on an organization's possessed knowledge, depending on passage of time and infrequent use (Fernandez and Sune, 2009), low perceived value of knowledge (Mariano and Casey, 2016); failures in storage facilities (Franco and Mariano, 2007) or network of relationships (Shaw et al., 2005); or because of changes to an organization's structural dimension (Mariano and Casey, 2016).

Second, this paper proposes five potential organizational interventions to overcome the disruptive consequences of knowledge loss. These interventions include reminding, refreshing, re-acquiring, re-building, and re-inventing. These interventions are proposed to be applied ex-ante, concurrently, and ex-post, to anticipate potential knowledge loss disruptions, correct them along the way, or adjust collectively possessed knowledge after some organizational instances may have reduced it or completely lost it.

Third, this paper provides a new theoretical perspective and novel assumptions that may be tested by future empirical studies, especially those investigating organizations that are going through restructurings, significant changes to workforce, or introduction/disbandment of storage facilities (Levallet and Chan, 2019).

Managers who want to reduce the disruptive consequences of knowledge loss could consider specific points in time to positively enforce, assist, or support certain interventions that may help prevent or overcome knowledge loss. The proposed classification and potential organizational interventions provide managers with a roadmap to better understand knowledge loss as well as the possible ways to decrease its disruptive consequences.

6. Future Research Directions

Future research could empirically investigate the impact of each cluster of knowledge loss (or their combination) on organizational outcomes or organizational change processes.

Another area of investigation could examine the circumstances under which the rigidity of an organization's structure could affect the unintentional departure of organizational knowledge.

Furthermore, future research could investigate the temporal dimension of knowledge loss clusters. How does passage of time influence knowledge loss clusters? What are the conditions under which knowledge loss caused by passage of time produce organizational tensions and unsolicited organizational change?

Organizations that are experiencing high turnover rates or significant changes to workforce, and organizations that are going through restructurings or introduction/disbandment of storage facilities and information technology systems (Levallet and Chan, 2019) would represent ideal settings to conduct empirical examinations.

Abstract: Knowledge management creates value for organizations, allowing them to be more innovative, productive, and competitive if that knowledge is used appropriately. Through this management, vital information is created and disseminated systematically and efficiently, and at the same time, knowledge learning is adopted, transformed, shared, and applied. This research analyzes decision-making for knowledge management in a mature low-tech sector, such as Tequila in Mexico. At the same time, it generates a predictive model of knowledge management that allows innovation in this sector by combining knowledge of modern technologies and ancestral knowledge in manufacturing the product, along with providing support to public policymakers and decision-makers to support small producers and rural communities. The methodological strategy used is an expert system through fuzzy logic, starting from a data set based on the patterns found in a Bayes network. The results show that the most relevant variables in decision-making for knowledge management in the Tequila sector are modern technologies, ancestral knowledge, and the Denomination of Origin. Under the above, it could be inferred that the ancestral knowledge variable is the most influential in achieving high values in managing knowledge management -the output variable preserving the value of a product with a designation of origin.

Keywords: Bayes network,Decision making, Knowledge management, Fuzzy logic model, Machine learning, Tequila sector, México, Low tech

1. Introduction

Knowledge management is a strategic element in the innovation and competitiveness of organizations, for which learning capacity is a critical factor in achieving it. The agribusiness sector is no exception; they must implement knowledge management practices to achieve this. That sector is characterized by small family businesses with a low propensity to generate knowledge and innovation (Vesperi et al., 2021).

According to Gaziulusoy et al. (2013), Pelizza (2020), and Vesperi et al. (2021), agribusiness, being traditional and low-tech companies, are in a situation in which they need to find and implement new ways of innovation, to create, provide and generate value to face current challenges and be more competitive. However, this sector cannot generate new knowledge independently; therefore, it must go beyond its limits (Gaziulusoy et al., 2013; Pelizza, 2020). In this way, knowledge is acquired through or in conjunction with various actors (Chesbrough, 2006) with which they are linked. According to the above, agribusinesses would benefit from the exchange of knowledge with partners, research centers, and universities (Vesperí et al., 2021),

The Tequila sector in Mexico is a traditional and low-tech agribusiness in which knowledge management is crucial to innovation and competitive advantages. That sector has established itself as one of the main agro-industries in Mexico by producing one of the most emblematic alcoholic beverages worldwide and with the denomination of origin (Macías, 2001; Gallardo, 2019; Terán-Bustamante et al., 2022). Currently, this industry represents today more than 25,000 producers in 5 States, and 181 municipalities, a production of more than 2,611 thousand tons of agave that represents 651.4 million liters per year (CRT, 2023); 292 companies certified with Denomination of Origin (CRT, 2023), 1,831 registered trademarks (1,582 national and 376 abroad) (CRT, 2023), employment for more than 70 thousand families (IIEG, 2022).

According to the above, the Tequila industry represents a tremendous economic value for Mexico while having the potential to contribute to rural development and small producers. However, this sector has not benefited the local population or the environment of the drink's origin region. Four factors are argued to explain poor performance: performance:

- The power of the large Tequila-producing companies and the pressure exerted by transnational companies to recognize the contributions of the region of origin and small agave growers (Bowen, 2012; Terán-Bustamante et al., 2022).

- Availability and supply of raw materials suffer from cyclical crises that fluctuate over the years and considerably affect both production levels and costs (Herrera et al., 2018; Terán-Bustamante et al., 2022).
- Connection with the land of origin – geographical indicator (Bowen, 2012) and ancestral knowledge (Terán-Bustamante et al., 2022).
- Management of ancestral knowledge with modern technologies that preserve the benefits of the Denomination of Origin (DO) and explore the knowledge for the natural conservation of the Agaváceas and Nolináceas (Golubov, 2007) for the sustainability of this sector.

Therefore, it is necessary to create an environment that favors disseminating knowledge among companies, communities, producers, and other organizations such as universities and research centers to use knowledge as a strategic resource (Núñez, 2015).

In general, knowledge in organizations needs a structure that facilitates its use effectively. On the other hand, the knowledge generated and appropriated through innovation processes, the acquisition of technology, work with suppliers and customers, interactions with competitors, and the business environment present difficulties to be integrated into the daily actions and activities of the organization. For this reason, it is necessary to develop mechanisms that allow all people to have the full potential of knowledge dispersed in the organization.

Derived from the previous problem, the questions that guide the present research are, What are the critical factors for adequate decision-making in the Tequila Industry in Mexico for optimal knowledge management? Using a knowledge management model, how can the tequila sector make better decisions that benefit all producers and rural communities?

This paper aims to provide knowledge to decision-makers in the public and private sectors to funnel public policies that support rural communities and smallholders. At the same time, generate knowledge by providing a knowledge management model in a low-tech industry such as Tequila, where innovation is developed.

The present work is organized into three sections. The first section addresses the theoretical framework, the main concepts of scientific knowledge, ancestral knowledge, and knowledge management and its relationship with innovation. A very brief characterization of the Tequila sector in Mexico is also made. The second section presents the analysis methodology and model construction based on Bayesian Networks (BNs). The methodological strategy used is an expert system through fuzzy logic, starting from a set of data based on the patterns found in a Bayes network. Finally, the third section presents the results, discussion, and conclusions.

2. Theoretical Framework

2.1 Knowledge Management: Conceptualization and Importance

Knowledge management aims to generate, share, and use explicit (codified) knowledge and know-how existing in a given space to respond to the needs of individuals and communities in their development (ILO, 2023).

Therefore, knowledge management has become the primary key to creating value, so knowledge has been considered a strategic source in organizations.

Value creation is mainly related to activities that concern the human capital of the company, which are aimed at creating new skills through research, learning, or knowledge acquisition. This generation of new knowledge must be linked to its conversion into innovations that provide commercial value (Solleiro and Castañón, 2004 and 2016; Terán-Bustamante et al., 2022).

That involves creating and deploying knowledge management strategies that integrate five fundamental actions: understanding knowledge needs and opportunities; building sector-relevant knowledge; organizing and distributing knowledge; creating conditions for the application of knowledge, and exploiting knowledge, The creation of conditions for the application of knowledge is an action focused on the generation of sustainable competitive advantages (Xue, 2017).

In addition to strategies, it is necessary to consider the barriers to knowledge management; for Doz, Cuomo, and Wrazel (2007), there are four barriers to the integration of knowledge into business activities, which correspond to diversity of knowledge, dispersion of knowledge, the complexity of knowledge and ownership of

knowledge. That implies understanding the dimensions of each one to generate actions that allow overcoming them and thus ensure effective management of the knowledge and experiences available to the organization.

It is worth mentioning that because it is intangible, knowledge is characterized by being complex to understand, share and take root among the sectors of the organization. Using knowledge effectively and consistently is crucial to gaining a competitive advantage. Investing in KM ensures the use of all available knowledge in an organization (Rabeea et al., 2019; Wu and Wang, 2006; Martins et al., 2019).

The Tequila and the value generated by its appellation of origin and knowledge management.

Tequila became the first Denomination of Origin (DO) of Mexico in 1974, which means that it has an intellectual protection model that generates value as a product whose quality and characteristics come exclusively from the geographical environment and from natural and human factors of the place where it is produced (Official Gazette of the Federation (DOF, 2018).

Tequila is considered a symbol of Mexicans for its historical, sentimental, and national value (Olmedo-Carranza, 2010). The value lies in the intrinsic and extrinsic qualities that give it worthy representativeness and motivate to safeguard agave, preserve tequila art, and include Tequila as a gastronomic product of origin and tradition in social, cultural, and economic activity, such as tourism (Schlüter, 2008).

Therefore, the DO of this distillate is a tool for territorial valorization and tourism promotion (Gómez-Cuevas et al., 2020), which has managed, together with the Tequila Regulatory Council (CRT), to control and endorse compliance with the Mexican standard in its production, guaranteeing the consumer its origin and quality (Official Gazette of the Federation,

DOF, (2018).). The Tequila Denomination of Origin (DOT) extends to more countries; today, 44 nations recognize the DOT (mipatente, 2023).

In this context, the value of Tequila has a legacy for the community, as it gives it a sense of belonging that manifests its work, dedication, and part of its essence, in addition to the time it took to create and consolidate the drink (Gómez, 2018). In addition to the above, the denomination of origin that contributes to the product's value positions the Tequila brand and helps preserve and enhance cultural and natural heritage. Industrial and tourist competitiveness would differ (IIEG, 2021). (IIEG, 2022).

3. Methodology

This research was based on a work that modeled the knowledge of experts in the production of Tequila through a Bayes Network (Terán-Bustamante et al., 2022). Next, a data set was obtained from the patterns found in the proposed Bayes network. On the data set, the classification was carried out with the Knowledge Management variable as the objective variable, and it made several experiments to classify the data set. In them, we apply three algorithms for classification Support Vector Machines (SVM), Neural Networks (NN), and Naive Bayes (NB). The metric used to choose the best model was a recall, where we obtained the values 0.573, 0.682, and 0.991 for NB, NN, and SVM, respectively.

In this way, we found that the most relevant variables for the classification process are Ancestral Knowledge, Competitive and Technological intelligence, Customer needs detection, Cultivation of raw materials Agave, Designation of origin based on ReliefF metric (ReliefF measures the ability of an attribute to distinguish between classes on similar data instances).

To have elements to validate the integrity of the results, we apply two methods, the Multiple Criteria decision-making method, and fuzzy logic. The general operation of each of them is described below.

First, it has applied Multiple-criteria decision-making to determine the most relevant factors to achieve the best scenario for Knowledge Management. It is one of the primary decision-making problems which aims to determine the best alternative by considering more than one criterion in the selection process.

We apply the Analytic Hierarchy Process (AHP). AHP is a multi-criteria decision-making method that was proposed in the 1970s by Saaty (Saaty, 2008). It is used to derive ratio scales from both discrete and continuous paired comparisons. These comparisons may be taken from actual measurements or a fundamental scale that reflects the relative strength of preferences and feelings. It has been used extensively for analyzing and structuring complex decision problems. It is a general theory of measurement. AHP is recognized as a valuable method to handle issues with several criteria (Fattoruso, 2023).

The AHP consists of four steps: Identify the decision, options, and criteria; Compare in pairs. It Calculates the importance weight of each criterion; Identifies the best choice by calculating something called utility. In other words, applying the methodology consists of establishing the importance of weights associated with the criteria in defining the overall goal. That is done by comparing the criteria pairwise.

AHP's popularity stems from its simplicity, flexibility, intuitive appeal, and ability to mix quantitative and qualitative criteria in the same framework. AHP has been applied to various decision problems focused on decision-making (Asonitis, 2010).

The first stage of the AHP method consists of establishing the hierarchy of the decision problem by defining the objective; next, the criteria and sub-criteria are specified, then a hierarchical model is elaborated based on element comparison matrices and the use of matrix algebra elements; Finally, once the hierarchical structure of the problem has been built, the elements are assessed, for which the decision maker evaluates the criteria through paired comparisons and considers the different alternatives concerning each criterion, the AHP It allows these comparisons to be made based on both quantitative and qualitative factors, since for them the scale proposed by Thomas Saaty is used, in this way the decision maker can express his preferences between two elements through numerical values. In summary, 1) it offers a numerical ranking according to the classification of alternatives. 2) Allows the use of criteria and sub-criteria. 3) Enables the use of qualitative information. 4) Allows the use of quantitative data. It allows working with a multidisciplinary team.

Next, we use Fuzzy Logic to find the best scenario to achieve Knowledge Management. Considering the selected variables, a model based on Fuzzy Logic (FL) was built, which has a remarkable characteristic that allows building models based on the experience of experts that, like any process where there is human intervention, has value scales that do not they are necessarily exact. There are qualifications for the variables where the scale can be Good, Fair, or Deficient with intermediate values between them, such as Very Good, Good, Almost Good, Fair, Almost Fair, Deficient, or Very Deficient, etc.

In this way, the most relevant variables for the classification were fed, being able to infer the results when mapping the input variables given an output. The process involves membership functions, fuzzy logic operators, and if-then rules. This way, a model involving five input and one output variable was built (Figure 1).

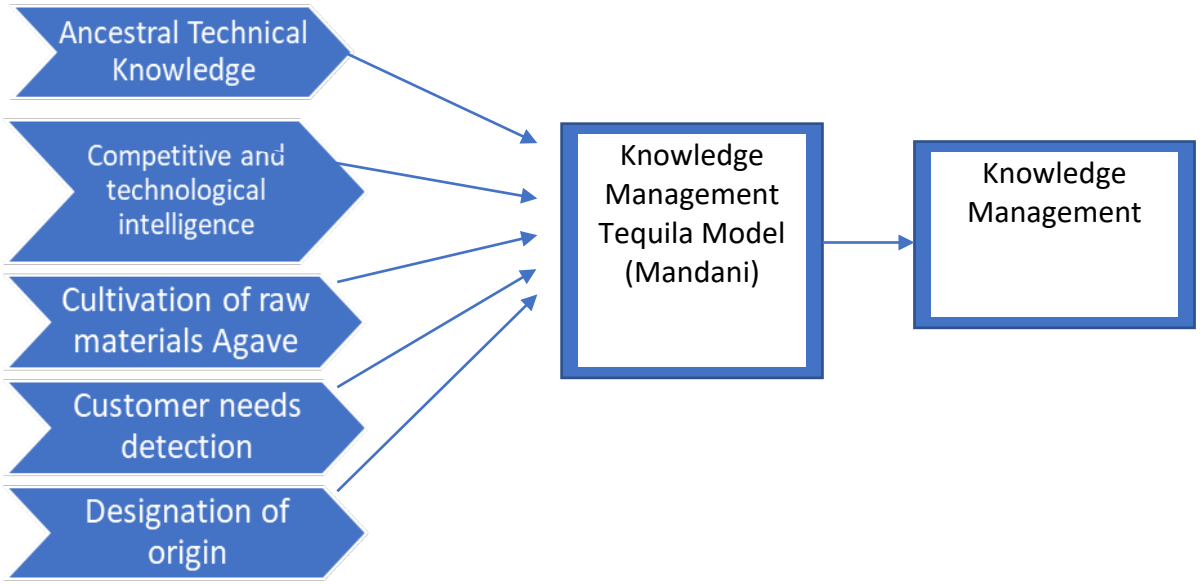

Figure 1: Fuzzy Model

The most straightforward membership functions are formed using straight lines. Of these, the simplest is the triangular membership function, a collection of three points that form a triangle, which has the advantage of simplicity. There are other types of membership functions, such as trapezoidal. A membership function (MF) is a curve that defines how each point in the input space maps to a membership degree between 0 and 1.

Furthermore, fuzzy sets describe vague concepts that admit the possibility of partial membership in them. A membership function associated with a given fuzzy set maps an input value to its appropriate membership value.

Fuzzy logical reasoning operates based on standard Boolean logic. Fuzzy sets and fuzzy operators are the fundamental elements that allow us to build complete sentences. These are the conditional statements, the if-then rules permuted to make valuable inferences. Inferences from a fuzzy rule assign a complete fuzzy set to the output. If the antecedent is only partially true, then the output fuzzy set is truncated according to the implication method. The set of rules competes. The output of each rule is a fuzzy set. However, what is wanted is that the output of an entire collection of rules is a single number (Figure.2).

The input to the defuzzification process is a fuzzy set, and the output is a single number. Given a fuzzy set that spans a range of output values, it is required to return a number, thus going from a fuzzy set to a crisp output.

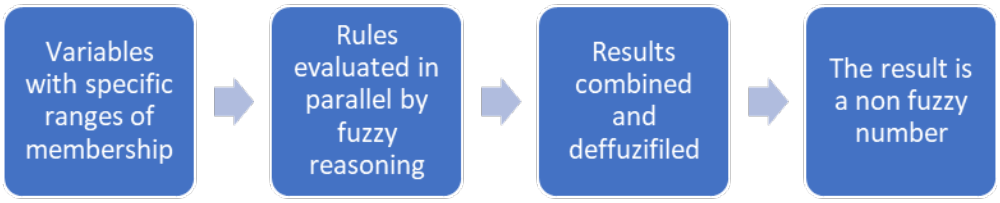

Figure 2: Fuzzy Logic Process

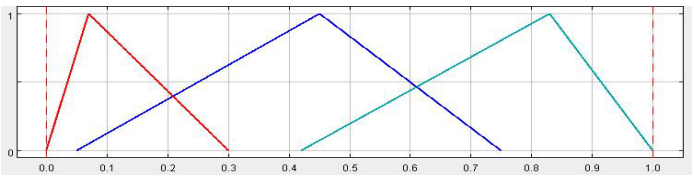
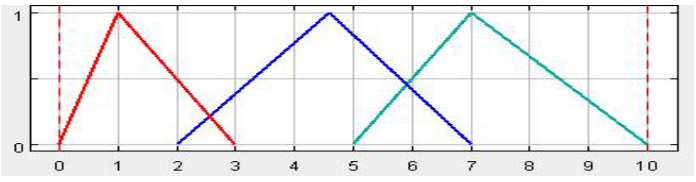
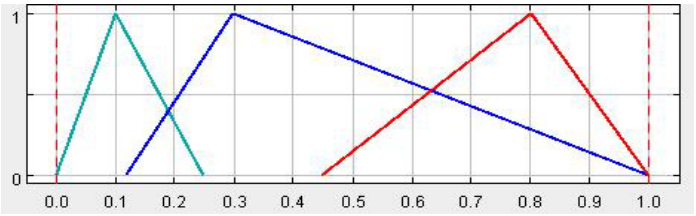
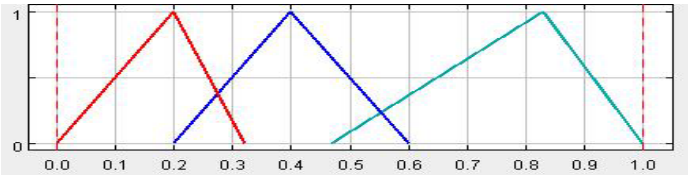
Fuzzy inference systems have been successfully applied in various fields. Due to its multidisciplinary nature, the fuzzy inference system is known as a fuzzy rule-based system, fuzzy expert system, fuzzy model, and fuzzy logic controller, among others.

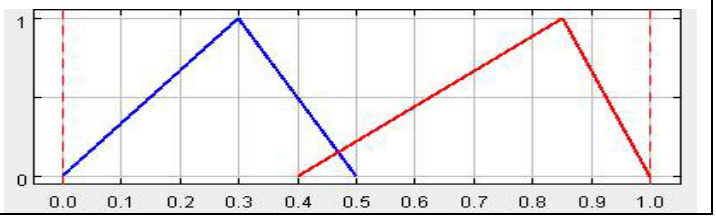




The membership functions are based on the Innovation and Technological Management Model results in the Tequila Sector in Mexico (Terán-Bustamante et al., 2022). Memberships are expressed in terms of probabilities in a Bayes Network Model.







The Fuzzy Logic system was constructed using a Mamdani inference system to obtain the logical implications of the ten rules and five input variables used to build the model (Table 1).

The assigned ranges for the membership functions were given considering the previously assigned crisp values. In this way, sets of fuzzy values were built for each of the parameters assigned to each variable.

A triangular membership function was applied for its efficiency and simplicity. This is explained by employing the graph located in the "membership parameters" column. On the "x" axis, the values that each variable can take are indicated through lines identified with a color code.

Table 1: Fuzzy Logic System Description

Input Variables	Range	Membership Functions	Membership parameters
Ancestral Technical Knowledge	[0,1]	Optimum (Green) Regular (Blue) Deficient (Red)	
Competitive and technological intelligence	[0,1]	Optimum (Green) Regular (Blue) Deficient (Red)	

Input Variables	Range	Membership Functions	Membership parameters
Customer needs detection	[0,1]	Optimum (Res) Regular (Blue) Deficient (Green)	
Cultivation of raw materials Agave	[0,1]	Optimum (Green) Regular (Blue) Deficient (Red)	
Designation of origin	[0,1]	No (Blue) Yes (Red)	

We constructed a set of 10 inference rules that, without trying to be exhaustive, express the possible relations among the input variables based on the knowledge expert (Table 2). Rules must meet some basic standards of completeness, consistency, interaction, and robustness. Completeness: The rules must comply with all possible combinations of inputs so that there are no gaps in which no action is taken. Consistency: Two actions cannot coexist in the same situation, which would produce a contradiction. Interaction: Corresponds to the weight of a rule among the rest; for this, the effect of the rules on the control action must be analyzed. Robustness: It measures the controller's reaction to input disturbances.

The defuzzification step transforms the aggregated fuzzy set into one crisp number using the centroid method. This method returns the area's center of gravity projection under the membership function. Thus, the defuzzification is realized by a decision-making algorithm that selects the best crisp value based on a fuzzy set. The interpretation of these values is the probable value the output variable will have under the inference rules.

Table 2: Inference Rules

Inference Rules	Ancestral	Cultivation	Customer	Origin	Knowledge Management
1	Optimum	Optimum	Optimum	No	0.05
2	Optimum	Optimum	Regular	Yes	0.85
3	Optimum	Regular	Regular	Yes	0.85
4	Optimum	Regular	Deficient	Yes	0.7
5	Regular	Regular	Deficient	No	0.01
6	Regular	Deficient	Regular	Yes	0 75
7	Deficient	Deficient	Deficient	Yes	0.55
8	Deficient	Regular	Regular	Yes	0.56
9	Regular	Optimum	Optimum	No	0.32
10	Regular	Regular	Optimum	No	0.3

Based on the expert's knowledge, the values achieved from the defuzzification process are expressed as a numerical value in the range [0,1] for the output variable (KM).

4. Results, Discussion, and Conclusions

Applying AHP has made it possible to find the optimal values for the combinations of Ancestral Knowledge, Cultivation of Raw materials, Customer needs detection, and Origin denomination factors.

The steps followed to determine the best combination of factors to arrive at the optimal value of KM according to AHP are the determination of comparison criteria, calculation of the weighting for each of the variables, and validation through the value of the ratio of the consistency index, the configuration of the alternative's comparison matrix—finally, the determination of the best combination of factors for Knowledge Management.

The importance of variables comparison was registered in a Criteria Comparison Matrix (Table 3), where the values represent the relative importance based on a range from 3 to 9 according to the Saaty scale. It is based on the opinion of experts on Tequila production as to the importance of the variables about each other.

Table 3: Criteria Comparison Matrix

	Ancestral Technical Knowledge	Cultivation of raw materials Agave	Customer needs detection	Designation of origin
Ancestral Technical Knowledge	1	3	5	5
Cultivation of raw materials Agave	0.333333333	1	3	3
Customer needs detection	0.2	0.333333333	1	3
Designation of origin	0.2	0.333333333	0.333333333	1

Based on the information in the Criteria Comparison Matrix, the weights corresponding to each variable were obtained (Table 4). In this way, the most important variable is Ancestral Technical Knowledge.

Table 4: Calculated Weights for Each Variable

Variable	Weight (Wi)
Ancestral Technical Knowledge	0.54
Cultivation of raw materials Agave	0.24
Customer needs detection	0.14
Designation of origin	0.08

The value assigned for the consistency index is 4, corresponding to the number of variables. In consequence, the Consistency Index Ratio is 0.099. This value is less than 0.10, which validates the calculations made.

Next, the alternative comparison matrices for each variable were elaborated based on the values obtained through the results obtained in the previous work in which the values assigned to each variable in the Bayes Networks were reported (Terán-Bustamante et al., 2022) (Table. 5).

Table 5: Assigned Values to Each Variable

Ancestral Technical Knowledge	Cultivation of raw materials Agave	Customer needs detection	Designation of origin
OPTIMUM	OPTIMUM	OPTIMUM	NO
OPTIMUM	OPTIMUM	REGULAR	YES
OPTIMUM	REGULAR	REGULAR	YES
OPTIMUM	REGULAR	DEFICIENT	YES
REGULAR	REGULAR	DEFICIENT	NO
REGULAR	DEFICIENT	REGULAR	NO
DEFICIENT	DEFICIENT	DEFICIENT	NO
DEFICIENT	REGULAR	REGULAR	YES
REGULAR	OPTIMUM	OPTIMUM	NO
REGULAR	REGULAR	OPTIMUM	NO

The results obtained based on AHP methodology indicate that the combination of values assigned to each variable read by row is shown in Table 6. Where the prioritization value indicates the better combination of values. Combination 1 and combination 2 are the best scenarios to achieve Knowledge Management.

Table 6: Prioritization Results

	Ancestral Technical Knowledge	Cultivation Of Raw Materials	Customer Needs Detection	Designation Of Origin	Prioritization	%
Comb1	0.15	0.18	0.18	0.06	0.15	**15%**
Comb2	0.15	0.16	0.08	0.13	0.15	**15%**
Comb3	0.17	0.08	0.08	0.13	0.13	13%
Comb4	0.17	0.08	0.03	0.13	0.13	13%
Comb5	0.07	0.09	0.03	0.04	0.07	7%
Comb6	0.08	0.05	0.10	0.13	0.08	8%
Comb7	0.03	0.04	0.03	0.13	0.04	4%
Comb8	0.03	0.08	0.09	0.13	0.06	6%
Comb9	0.08	0.18	0.18	0.05	0.11	11%
Comb10	0.09	0.08	0.20	0.04	0.09	9%
Weight (Wi)	0.54	0.24	0.08	0.14	1.00	100%

Next, the procedures corresponding to Fuzzy Logic are applied, and the corresponding results are reported.

Once the Fuzzy Logic Model was applied, the results of the combinations in the fuzzy values of the variables were obtained based on the inference rules fed to the model.

One way to graphically explain the results obtained is through surface plots. Where the influence that each variable has on the objective variable is presented in a three-dimensional graph, where the variables are located on the "x" and "y" axes and the "z" axis, the objective variable is represented.

Based on the inference rules, it is observed that the highest value reached for the objective variable (Knowledge Management) are numbers 2 and 3. In this way, the value achieved by the Knowledge Management variable is explained through the most relevant variables for the classification. For rule 2, the values for the variables Ancestral Technical Knowledge, Cultivation of raw materials, Customer needs detection, and Designation of Origin was optimum, optimum, regular, and yes, respectively. In the same way,

in rule 3, the values for the same variables were Optimum, regular, regular, and yes. In both cases, 80% was obtained for the objective variable. That makes it explicit that different combinations of the fuzzy values in the input variables allow us to achieve satisfactory results in the output variable.

Some of the most relevant results are presented below, utilizing surface plots to explain the influence of pairs of variables.

Then, the influence that the variables have on the output variable indicates that the values in the range [0,1] for the Customer needs detection variable and [0.4,1] for the Ancestral Knowledge variable allow obtaining values close to 85 in the variable output Knowledge Management (KM) (Figure 3).

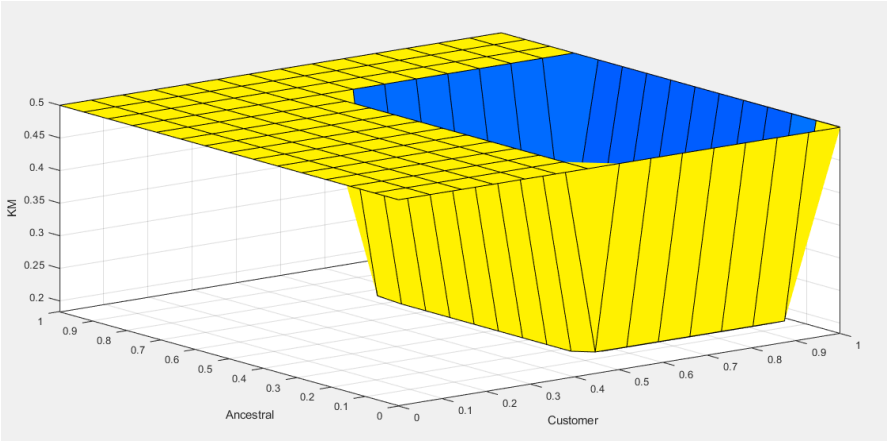


Figure 3: Surface Graph Customers Need Detection vs. Cultivation of raw Materials

For the surface plot corresponding to the Cultivation of raw materials vs. ancestral knowledge variables, it is observed that even if the values for the Cultivation of Raw-Materials variable have values in the range [0,1]. In contrast, the Ancestral Knowledge variable has values in a range of medium to high [0.4,1] to achieve high values in the KM variable (Figure 4).

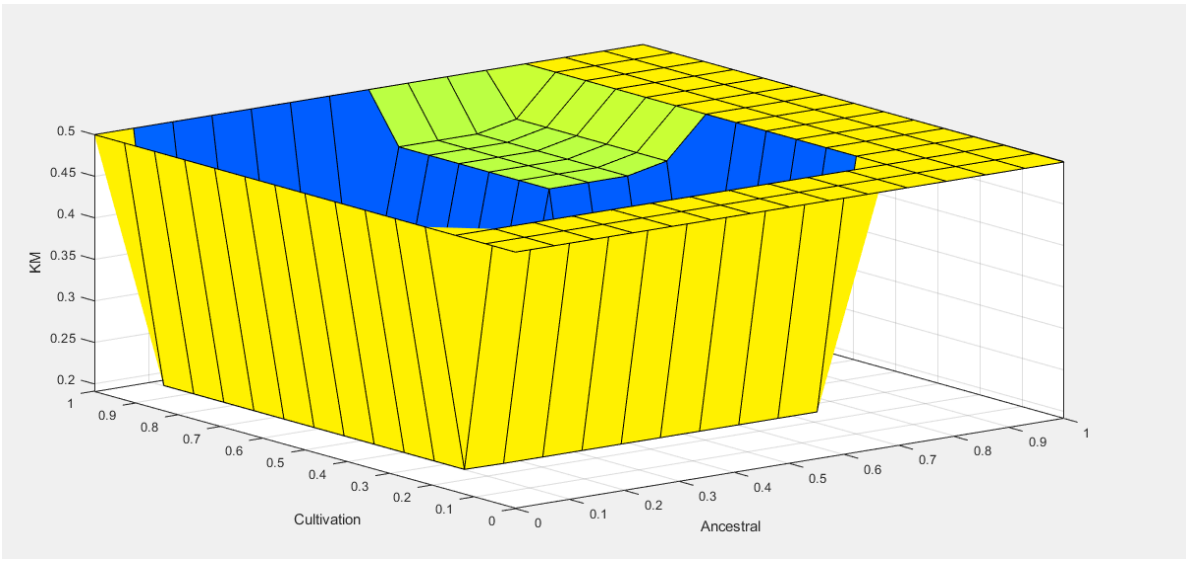

Figure 4: Surface Graph for Cultivation Raw Materials vs. Ancestral Knowledge Variables

Thus, given the characteristics of the complete system, the range of the values for variable Designation of Origin [0.5,1] allows variable KM to reach 85 if the Ancestral Knowledge range of values is in the [0.4,1] range (Figure 5.).

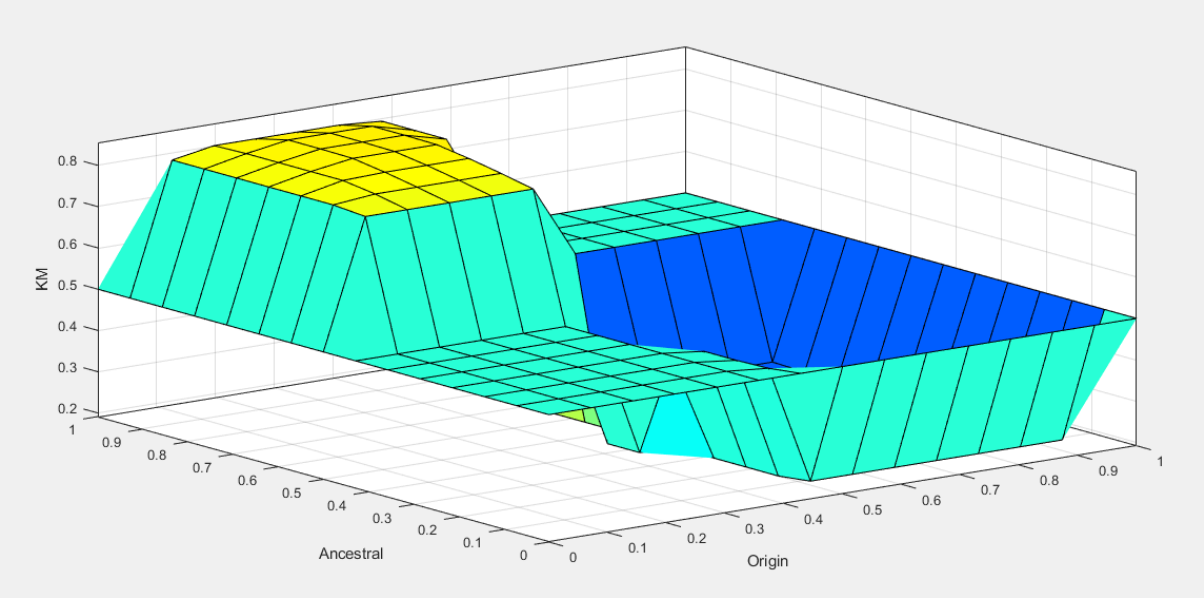

Figure 5: Surface Graph for Designation of Origin vs. Ancestral Knowledge Variables

Based on the results obtained, it is shown that it is possible to achieve satisfactory results in the output variable from the fuzzy sets established as a range for the input variables, considering that humans generally express their knowledge on scales that point values cannot represent.

In summary, the inferences from the system of five input variables and ten inference rules allow us to infer that the Ancestral knowledge variable is the most influential in attaining high values in the Knowledge Management output variable.

5. Conclusions

As can be seen, the Tequila sector has a great tradition in Mexico; it is a fundamental part of the national economy and various regions of the country. The knowledge generated from ancestral values is greatly valued in elaborating this distillate. Thus, it is essential to consider the necessary actions for decision-making for knowledge management in the Tequila sector and generate a model that allows innovation. Knowledge management – through the developer model – is a facilitating system that combines individual and collectible experiences and knowledge, as well as ancestral and technological, to achieve competitive advantages.

It is considering knowledge management as a tool that allows both companies and various sectors of a country to increase their capacity to respond to challenges, changes, crises, and the diverse circumstances of the present and future, with a positive effect on its value when it implies an adequate circulation of ideas and information.

Having a model that allows better decisions, optimal or non-optimal management of knowledge management and its various factors, through the causality of the variables, will enable us to improve decision-making when selecting the factors that better influence to achieve Knowledge Management.

The participation of the State plays the unquestionable role of knowledge and innovation for the development of the economy and society, but also from the specificities of agribusiness. n accordance with the above, the agricultural and scientific policies implemented by the State and the participation of various institutions, such as universities and research centers, which operate in the agribusiness environment, play a crucial role in the sustainability and quality of life of the community's people. For their part, institutes and universities allow and facilitate the link between the various actors while making the best use of the research potential to achieve it (Farrukh et al., 2017; Piotr, 2019).

In summary, an adequate knowledge management strategy in the Tequila sector in Mexico facilitates the appropriation and integration of knowledge from various sources, stimulates the creation of new knowledge and innovative action, and contributes to the generation of competitive advantages and sustainability over time both to the sector and to the various rural communities involved. At the same time, it allows decision-makers and public policymakers to generate programs that will enable the sustainability of this sector.

Abstract: Boycott involves abstention from buying specific products or brands for political, ethical, or ecological reasons. Boycott is usually framed as an expression of political consumerism and has been on the rise. Companies that suffer a boycott may endure severe consequences including long-term damaged brand image and harmed reputation. However, there is still an incomplete picture of the socio-political and demographic profile of boycotters. Most characterizations of political consumers are based on research that combines boycotters and buycotters under a single construct of political consumers, and yet these consumers are driven by different motivations. The objective of this exploratory study is to provide a general characterization of European political consumers that engage in boycotting. The data used was collected between the 25th of May, 2022 and the18th of September, 2022, and was retrieved from the 10th edition (2022) of the European Social Survey. The study employs binary logistic regression to assess the association between boycotting and various potential factors listed in extant literature. Results indicate that boycotting behaviour is affected by age and other life-cycle variables, gender, education, institutional trust, the degree of satisfaction with the political system and the government, the level of trust in information and communication technology, reported self-happiness and self-general health perceptions. In general, the parameters of the models suggest that European consumers that engage in boycotting behaviour tend to be female, young, well-educated, trust on national political institutions and make intensive use of digital media. The conclusions of the empirical study are discussed and interpreted in light of current theories of consumer behaviour that highlight the post-modern, fragmented and globalized characteristics of current western societies. The results of this study enrich the literature on consumer boycotts and confirm the predicting power of various socio-demographic, psychological and attitudinal variables. Avenues for future research are identified together with consideration of the study limitations.

Keywords: Political consumerism, Anti-consumption, Boycotting, Europe, European social survey

1. Introduction

Anti-consumption behaviour has received a fair amount of scholarly attention. The term spans across a wide variety of manifestations, including boycotting, brand avoidance, ethical consuming, voluntary simplification, brand rejection, consumer resistance, consumer rebellion and retaliating (Ozanne & Ballantine, 2010; Chatzidakis & Lee, 2012; Leipämaa-Leskinen et al., 2016). Consumers define their self-identity and their social references through what they choose to consume and also what they choose not to consume (Sandikci & Ekici, 2009). Distastes and dislikes manifest the undesired self, or a facet of the negative self that the consumer may be afraid of becoming (Hogg and Banister, 2001). According to Chatzidakis and Lee (2012), with overconsumption becoming the norm in Western societies, acts of consumption no longer possess the same unique symbolic value. In this context, acts against consumption, against the norms, are now understood to be powerful symbolic acts through which consumers may better express themselves.

This research focus on a specific form of anti-consumption manifestation that is consumer boycott and which involves voluntary abstention from buying specific products for political, ethical, or ecological reasons (Ferrer-Fons and Fraile, 2014). Consumer boycotts are usually framed under political consumerism, a concept that alludes to consumers recurring to market transactions as an instrument of protesting or rewarding desirable institutional behaviours (Koos, 2012; Gotlieb & Cheema, 2017). Targeted companies that suffer a boycott may

endure severe consequences that go beyond immediate reduced sales and profits, and include long-term implications on brand image and harmed reputation (Rim et al., 2020; Wang et al., 2021).

Although available data indicates that boycotts are becoming more prevalent (Seyfi et al., 2021; Tuominen et al., 2022) there is still an incomplete picture of the socio-political and demographic profile of boycotters (Endres & Panagopoulos, 2017; Schwalb et al., 2022). As noted by Kelm and Dohle (2018), most characterizations of political consumers are based on research that combines boycotters and buycotters under a single construct of political consumers, and yet these consumers are driven by different motivations - while boycotts aim to punish the organization, buycotts aim to reward the targeted organization. These factors highlight the importance of researching separately each nature of political consumption manifestation. This study addresses this research gap, by researching the characteristics of European consumers that engage in boycotting behaviour. To attain this objective, the study recurred to data provided by the European Social Survey (ESS ERIC, 2022a; ESS ERIC, 2022b) covering twenty-five European countries countries.

The article is organized as follows: the next section contextualizes boycotts within the anti-consumption and political consumerism literature. The following section outlines the methodological procedures. The main body of the article presents and discusses the study´s results. The final section offers conclusions, points the limitations of the study and identifies some avenues for future research.

2. Background

Contrary to the tendency verified in traditional political activities such as voting or participating in a political party, this century is characterized by alternative forms of political activity (Baptista and Rodrigues, 2018). This development has been related with globalization and the widespread use of information and communication technologies, which have triggered lifestyle politics and a sense of moral obligation (Acik, 2013). Political consumerism is generally understood as a form of political activity beyond the traditional manifestations, in which consumers use their purchasing power to attain political-related objectives (Koos, 2012). The concept of political consumerism is traditionally employed in reference to the boycott or buycott of products or services undertaken by consumers (Ferrer-Fons and Fraile, 2014).

Previous research indicates that political consumers tend to be prevalently female, young, well-educated and intensive users of digital media technologies (Kelm & Dohle, 2018; Grasso & Smith, 2022; Schwalb et al., 2022). However, most characterizations of political consumers are based on research that combines boycotters and buycotters under a single group of political consumers (Schwalb et al., 2022). The motivations of boycotters and buycotters are significantly different, while buycotting aims to reward the targeted organization, boycotting, which is the focus of this research, refers to actions intended to punish the organization. As such, it is important to characterize separately each group of political consumers. Furthermore, a dualistic approach to study anti-consumption, in which dominance/resistance models oppose consumption to anti-consumption is not suitable to understand the complex nature of the phenomenon in stake. As stressed by (Chatzidakis and Lee, 2012) the assumption that the “reasons against” are always the logical opposite of the “reasons for” is conceptually erroneous.

3. Materials and Methods

The data used in this study was collected between the 25th of May, 2022 and the18th of September, 2022, and was retrieved from the European Social Survey (ESS ERIC, 2022a) [dataset]. The European Social Survey (ESS) is a cross-national survey, that in its 10th edition (2022) covered several European countries. Data was collected through face-to-face interviews, however due to the COVID-19 pandemic some interviews were done via web or videoconference. The survey covers several aspects of the Europeans life, including social conditions and indicators, social behaviour and attitudes, general health and well-being, political behaviour and attitudes, political ideology, minorities, cultural and national identity, media, equality, inequality and social exclusion, language and linguistics, religion and values, family life and marriage (ESS ERIC, 2022b). The represented universe in the sample includes persons aged 15 and over resident within private households, regardless of their nationality, citizenship, language or legal status, in the following countries: Austria, Bulgaria, Switzerland, Czechia, Germany, Estonia, Spain, Finland, France, Greece, Croatia, Hungary, Iceland, Italy, Lithuania, Montenegro, North Macedonia, Netherlands, Norway, Poland, Portugal, Serbia, Sweden, Slovenia, and Slovakia. The survey contains a total of 18.060 entries.

With the aim of studying consumerism in the Europe, we have selected specific variables from the ESS. The surveyed individuals were asked several questions including a particular question of interest for this study and

herein used as independent variable: "Have you boycotted certain products in the last 12 months?". As independent variables we have selected questions related with demography, individual perception of the society and its policies, and exposure to internet and/or mobile communication systems. These variables were selected based on extant literature that profiles political consumers (Kelm & Dohle, 2018; Grasso & Smith, 2022; Schwalb et al., 2022). The following were used as independent variables:

- Demographic: age, gender, marital status, years in education, and household size;
- Individual perception of the society and its policies: trust in others, trust in the legal system, trust in scientists, satisfaction with the state of the economy, satisfaction with the government, satisfaction with the democratic system, satisfaction with the state of the education system, satisfaction with the state of the health services;
- Wellbeing: happiness, subjective general health;
- Online behaviour and individual perception of information and communication technology: time spent on the internet and individual perception about personal privacy and misinformation in online/mobile communications.

Due to the dichotomic nature of the dependent variable (Yes, No) we have used logistic models to explain it. The statistical package use was the IBM Corp.® SPSS® Statistics, Armonk, NY, USA. Version: 28.0.1.1 (15). The analysis was performed via the general linear model routine, using the binomial option and selecting the logit link.

4. Results and Discussion

Extant research indicates that political consumers are mostly female, young, well-educated and affluent and are intensive users of digital media technologies (Kelm & Dohle, 2018; Grasso & Smith, 2022; Schwalb et al., 2022). To confirm the validity of such general characterization we tested demographic variables and variables that reflect boycotters' trust in public institutions as well as the level of satisfaction with the government and perceptions of online and mobile communications. The model obtained is summarised in Table 1.

The parameters of the model indicate that the probability of boycotting is lower in males than females. The gender gap is theoretically supported by previous literature indicating that in general females tend to engage more frequently in political consumption due to traditional woman roles in provisioning (Yates, 2011; Koos, 2012). Results also indicate that the probability of boycotting decreases as age increases. The reduced prevalence of boycotting in older publics has been attributed to life-cycle and generational effects (Acik, 2013). Life-cycle effects are reconfirmed by this study´s results indicating that the probability of boycotting decreases as the household member numbers increases. It was found that the probability of consumers engaging in boycotting activities is lower in widows or if the civil partner has died, followed by legally separated, none of the stated or single, legally divorced or civil union dissolved, legally married, and legally registered civil union. The influence of digital communication on younger generations also seems to play a key role in explaining the prevalence of boycotting in younger publics. The internet provides improved access to information allowing political consumers to quickly disseminate information about boycotts and persuade peers to participate (Seyfi et al., 2021).

Table 1: Adjustment of the Independent Variables to the Dependent Variable "Have you Boycotted Certain Products in the Last 12 Months?" The Logistic Models Fit Use "Yes" As Response and "No" As Reference. The Akaike's Information Criterion for the Degree of Adjustment of the Models Is Given, Together with the Intercept and the Parameter. The model confirms that the probability of boycotting increases as the years of full-time education increase. This finding is consistent with the literature of critical consumption. Yates (2011) found that individuals with higher levels of education are more likely to critically consume. Verba and Nie's (1972) socio-economic status model offers a possible theoretical explanation for this result by suggesting that high levels of scholar education provide political consumers with the information, knowledge, and the capacities to interpret complex social issues, thus enabling them to be involved in politics. Individuals from higher socio-economic status are equally more likely to have the resources and interest to be involved (Acik, 2013). However, our study indicates that the probability of European consumers engage in boycotting decreases with the time spent paying attention to politics and current affairs. This result suggests that people may engage in extreme forms of political consumerism, such as boycotting, without proper information about the issues in stake. because of peer and group pressures.

The link between institutional trust and political consumerism is not clear: some research indicates that political consumption is positively associated with institutional trust (Stolle and Hooghe, 2004) and other studies conclude the inverse, that institutional distrust motivates political consumers (Aish et al., 2013). Our findings suggest that the probability of boycotting increases with the level of institutional trust, since it was found a positive relationship between past boycotting behaviour and consumers’ trust in the legal system as well as trust in science. This result was further explored by testing the satisfaction of boycotters with the

government. Results confirm that the probability of boycotting increases with consumers' satisfaction towards the government, the state of the democracy, the state of the health system and the state of the economy.

The data indicates that the probability of boycotting increases with the time spent on the internet and that is also positively affected by adverse perceptions about information and communication technology, including the notions that mobile communications and internet makes work and personal life interrupt each other, expose people to misinformation and undermine personal privacy. Mobile communications and the internet have increased consumers' awareness about boycott initiatives by allowing consumers to interact with like–minded individuals, consequently affecting the size of boycott initiatives and their effectiveness (Tuominen et al., 2022). Online social networks like Facebook, Twitter, Instagram, LinkedIn, online communities in Reddit, WhatsApp and other digital platforms, are making consumers more aware of their agency and active role as political consumers and constitute sources of information for consumers to learn about the boycott plans (Seyfi et al., 2021). On the other side, some of these digital platforms are also becoming the target of boycott actions. In recent years some big-tech companies have been accused of misuse of users' personal data, cancellation of services with minimal justification, interference in political life, programmed obsolescence of products, and the use of legal (although morally questionable) mechanisms to pay reduced taxes outside the countries of origin. For example, Facebook has repeatedly came under consumers' boycott due to misinformation on its platform as well as the way it handles information related to political issues (He et al., 2021; Bright et al., 2022).

The study´s results indicate that the probability of boycotting decreases with increased self-general health perception. Anti-consumption, at the individual level, is not necessarily the result of purposeful acts of altruism, ideological protest or the outward expression of countercultural sentiments (Nixon and Gabriel, 2016). Some consumers may oppose consumption of certain products for their personal well-being (e.g. unhealthy food). In addition, results also indicate that the probability of boycotting increases with declared self-happiness. The actual motives of boycotting are unlikely to divide themselves very precisely between a continuum of altruistic and egoistic motives. Previous research indicates that some practices of anti-consumption are motivated by individuals prioritizing their self-interests (Black and Cherrier, 2010). For example, voluntary simplifiers tend to adopt anti-consumption driven primarily by objectives of happiness and living the "good-life", and reject consumption of products or services that do not correspond to their projected lifestyle and self-concept (Craig-Lees, 2006). Consumers that reveal a concern for societal goods, such as sustainability, may also be motivated by self-interests. Studying anti-consumption practices, motivations and values within attempts to live a more sustainable lifestyle, Black & Cherrier (2010) empirically found that anti-consumption for sustainability is affected by the subjectivity of the consumer, due to consumers' multiple identities and conflicting values, and a focus on personal needs, including the need to secure a better world for their descendants, to save money and improve health conditions. Hence, these authors concluded that, contrary to the general notion that sustainability will be associated to socially-aware consumers, that are prepared to sacrifice personal pleasure for communal well-being, sustainability does not require sacrificing personal pleasure. In addition, and as highlighted by Soper (2007) we should not overlook the extent to which anti-consumption behaviour is also motivated by an interest in acquiring status and distinction rather than altruistic concerns for collective well-being.

By what was presented so far it can be tempting to dismiss all boycott manifestations as ultimately individualistic and egocentric. However, for some consumers, boycott decisions may indeed be an expression of altruistic principles. Soper (2007) alerts to the fact that in some genuinely altruistic motives underlying anti-consumption, the elements of self-pleasuring and self-happiness often extends to, and include, as a condition, an interest in the pleasures and well-being of others. For example, Iyer and Muncy's (2009) characterization of global impact consumers and market activists consists in individuals to whom their boycott decision is mostly motivated by societal concerns.

It is also possible to question the extent to which boycott, in the current post-modern, fragmented and globalized society, really reflects a disposition towards social ethos. Consumers' contact point with society has shifted from its once solid-modern and genuine community footings, based on shared identities expressed through consumption, to its present "liquid" and unstable simulacra of community (Colling et al., 2017). Drawing on Bauman's (2001) thesis on liquid modernity, Binkley (2008) proposed a theory of liquid consumption in which anti-consumption practices shape personal identities by mediating the conflicted demands for individual autonomy and collective belonging, and by highlighting consumer freedom from the structures imposed by social bonds, without completely abandoning the consumer to the risks and anxieties of solitary ventures. In the context of liquid modernity boycotting becomes a practice of "liquid consumption", in

which the tensions between freedom and security, or individual autonomy and group solidarity are increasingly disembodied from any binding social context. As expressed by Binkley (2008, p. 611) " for the liquid consumer, the elimination, or liquification of goods (in contrast to their solidifying accumulation), provides a much needed sense of personal mobility, changeability and fluidity".

According to Zukin et al. (2006) people engaged in consumer activism such as boycotting overwhelmingly understand it as an individual activity rather than as part of an organized effort. Earl and Copeland (2016) studied the distinction between self-directed and organizationally-directed finding that three distinct macro-social changes explain current preferences for self-directed political consumption: i) shifts toward movement societies, meaning that social movements became so embedded in contemporary society that these movements, and the tactics they use, are now commonplace and institutionalized; ii) lifestyle politics, meaning increasing levels of self-directed political activity as citizens embed politics in their daily life and do not require organizational cues or recruitment in order to take politics into their everyday lives and iii) changing citizen norms, specifically the rising of entrepreneurial values, that imply a decline in associational life and a move away from traditional models of citizenship and political engagement towards self-organization. These changes are facilitated by the development of digital media, allowing individuals to access countless opportunities to act entrepreneurially, unbinding the accessible supply of opportunities from organizations and traditional providers.

5. Conclusions

This research set out to characterize the profile of European political consumers that engage in boycotting actions. The parameters of the models suggest that European political consumers tend to be female, young and well-educated. European boycotters also tend to trust on national political institutions and make intensive use of digital media. However, and despite European boycotters' consumption of digital media technologies, it was found that these consumers have negative perceptions about digital media. The study also revealed that boycotting may be affected by self-centred reasons and not societal concerns, including subjective perceptions of health and happiness. The results of this exploratory study enrich the literature on consumer boycotts and confirm the predicting power of various socio-demographic, psychological and attitudinal variables. The present research is not without some theoretical and methodological limitations, which suggest the need for future research. First, we tested the general sample of boycotters without taking in consideration the specific characteristics of these consumers in each country. This limitation should be overcome by future cross-sectional studies, comparing the profile of boycotters in different countries. Second, the definition of the independent variables was supported on the literature, however, it is possible that some relevant explanatory variables are missing from the model. Third, given the nature of this study, causality relationships cannot be proven, although extant literature has hinted the explanatory power of the selected variables.

Acknowledgments

The authors would like to express their gratitude to the Instituto Politécnico de Lisboa (IPL) for the approval of the research project *BIGTECHCon* (IPL/2022/BIGTECHCon_ESCS) and for providing this publication opportunity by granting financial assistance.

Managing Human Capital With Employee Clustering through the Interplay of the Persona Concept

Anastasia Mikhlina and Juha Saukkonen
Jamk University of Applied Sciences, Jyväskylä, Finland

anastasiia.mikhlina@jamk.fi
juha.saukkonen@jamk.fi

Abstract: Nowadays, employees are seen as active Human Capital Management (HCM) consumers. Megatrends such as individualization and flexible work impact the workforce, especially generations Y and Z. Finding and retaining talent is a challenge that companies try to address, from employer branding to covering the whole lifespan of the company-employee relationship. Management is likely to know every employee in small and medium-sized enterprises (SMEs); however, larger companies need to categorize their human capital into certain entities. This paper explores the usability of the Persona concept for HCM. Persona is a service design approach widely applied in marketing, and a few research papers have argued that personas may have a role in improved people-oriented HCM. In short, personas aim to create a limited set of archetypes that differ from each other regarding demo- and psychographics. Generally, they are a mix of real-life people and some imaginary attributes. Different personas will likely request different services to feel fully motivated and supported. The core target of this article was to identify the common awareness of personas among HCM experts across industries and countries. Also, the ideation of future use of Personas was studied with marketing experts actively using personas in their professions. The qualitative study based on twelve semi-structured individual interviews was conducted in November-December 2022. The results indicate that the HCM community is well aware of the persona concept, which is widely used. However, the current usage of personas is mainly focused on employer branding and recruitment, and only in a few cases the usage covered the design of internal HCM processes. The study also revealed some limitations for HCM that are not present in the marketing field. Demands for transparency, equality, data privacy, and personal integrity set challenges in clustering the workforce. The results indicate the further need for research on best practices of creating and using Personas in a way that ethically serves the interests of both the company and the employee.

Keywords: Human capital, Persona, People clustering, Employer branding, HRM/HCM services

1. Introduction

While human resource management (HRM) covers employees' core needs and an administrative agenda, human capital management (HCM) represents the organization's overall human side of the organization, like skills, intelligence, and expertise (Hossain, Roy, 2016). HCM is of utmost importance in any organization, and its management requires constant optimization and development. The efficiency of HCM processes determines how well an organization can improve its results, extend goals, and increase competitiveness (Karahoca, 2008). The work environment has been changing rapidly in recent years due to factors such as globalization, an increased need for flexibility, a shift towards online environments, and a new generation entering the workforce. These factors contribute to the need to re-examine and re-evaluate traditional practices and approaches in HRM and HCM (Rodriguez - Fernandez, 2017). Also, a new generation entering the workforce brings change and challenges that organizations must adapt to attract new employees (D'Incerti, 2022). However, organizations still need help developing and improving their HCM services to respond and adapt to the abovementioned transformations. There has been a clear need for a more individual and personalized approach to employees in organizations and new solutions (Averbook, 2022). Organizations can individualize their policies and services through employee clustering to serve employees better (Sitaram, 2021). There are several employee clustering methods, but this research focuses on the method called the employee persona concept. The persona concept represents one of the clustering methods for user-centered design. Alan Cooper created the persona concept in the 1990s as a goal-directed design tool. According to Blomkvist (2002), the persona is a model initially used in product design. This tool is used to represent archetypical users instead of average users. The persona captures users' features such as behaviors, needs, and motives and combines them into a single individual representative.

The research questions of this study are 1) to identify the awareness of the persona concept among HRM/HCM professionals and 2) in what HRM/HCM processes personas can be used. This research paper is structured as follows. First, the authors overview and examine the existing research on the key concepts in the literature review. The authors explore employee clustering, its rationale, and the persona concept. The authors explain the research methodology in section three and the empirical findings in section four. The fifth section highlights the main conclusions and discussion.

2. Literature Review

The literature review represents a comprehensive review of existing literature about the topic in question and is used to strengthen the knowledge base (Paul, Criado, 2020). The subchapters below investigate the principal concepts of this research paper, such as employee clustering, the persona concept, and the rationale behind it.

2.1 Employee Clustering

Several global HCM trends, such as changing demographics, digitalization, flexibility, individualism, and skills shortage, urge organizations to adapt to changes and rethink their HCM processes (Farndale et al, 2022). This research concentrates on some significant trends that can be seen as the rationale behind employee clustering, which can be done using the persona concept.

The concept of flexible work has existed in professional and academic HCM discussions for most of the 2000s. Flexible work arrangements (FWA) have been seen as practices that help employees manage work and non-work responsibilities (Allen et al, 2013). FWA can be defined as work options that permit flexibility regarding where and when the work is done. (Rau & Hyland, 2002). Before Generation Z's entrance and the pandemic-driven shift to remote working, FWA practices were considered critical parts of the strategy to attract, motivate, and retain key talent (Hill et al, 2008).

A simultaneous trend to added HCM flexibility has been the rise of individualism as a larger societal current and as a trend directly impacting how HCM will be conducted. Linthorst and DeWaal (2020) note that "organizations need to address this increasing demand for individual attention. Client experience and employee experience have become key performance indicators that need close monitoring". As a result, corporate training and mentoring approaches are becoming more tailor-made to fit the employees' career ambitions better (Linthorst & DeWaal, 2020). According to Dundon and Rafferty (2018), this individualistic view has impacted organizations' reward systems, performance evaluation, and talent management practices. Mass tailoring companies aim to offer each customer a unique and individually considerate product/service. However, companies build these offerings by modularizing and standardizing some components to gain efficiency in their processes (Skjevdal & Idsoe, 2005).

The generational difference between Generation Z and Y has been actively researched in recent years as Gen Z enters the workforce, bringing change and challenges into the labor market. Although different sources define generation timeframes differently, it is often considered that people born in 1980–1994 belong to Generation Y and people born after 1995 belong to Generation Z. Pinto et al (2015) argue that the ageing population and new generation entering the workforce have a significant impact on human resource and human capital management processes. Each generation requires a different approach based on needs, characteristics, motivation, and expectations. The study by Urick, Hollensbe & Fairhurst (2017) argues that Gen Z is more prone to technology use, which can lead to challenges within the multigenerational team. According to Novotna (2019), Gen Z is the first interconnected generation, as its representatives have used the internet and digital tools throughout their lives. Gen Z shows a clear motivation for life-long learning, on-site training, location-independent work, flexibility, and focused work-life balance. Instead, they are looking toward changes in their roles, tasks, and education. Unlike Generation Y, Gen Z's career path is not linear as they will be changing employers frequently, and many will change their careers entirely. (Klein, 2020). For employers, it means that they have to adapt to the needs of a new generation and simultaneously develop processes to fit both Gen Z and Gen Y. All these factors call for more individual arrangements. Research by Sitaram (2021) argues that clustering techniques can help organizations develop personalized approaches.

Clustering is a statistical method that groups similar objects (or people) into categories based on set shared variables (Cornish,2007). This method can be used in many industries. For example, customer segmentation/ clustering has been used for many years in the marketing field to improve customer experiences, customer satisfaction, and increase customer quality. Similarly, this approach can be applied in HRM analytics since employees are increasingly seen as active customers of HCM (Sitaram, 2021). By clustering employees based on shared characteristics, organizations can make informed decisions to improve recruitment and retention, training, employee engagement, workforce diversity, and performance management. Several clustering algorithms have been used, for example, k-means or Fuzzy c-means. Such clustering algorithms divide massive chunks of data into smaller clusters based on shared similarities. Fan (2021) argues that the K-means clustering algorithm can be used to improve the employee performance evaluation process. A recent case study by Fernandes et al (2017) showed that it is possible to cluster employees into groups using multivariate clustering analysis using both algorithms.

Despite the societal trends and employee expectations, some forces are counteractive to the clustering of the human capital, i.e., the people that the organization employs and, as a result, offer these people differing levels and types of HCM services. These forces can be divided into ethical, (data) privacy, and legal matters. Generally, the concept of ethics can be understood by, e.g., how Cornock and Johns (1995) define its contents: acting with fairness, decisions on what is right and wrong, practices, and rules that stress responsible conduct between individuals and stakeholder groups. Ekuma and Akobo (2015) claim that "the ethics of HRM, while sharing many features with general organizational ethics, must at least be relatively unique in several respects". In HCM, ethical dilemmas have been described to cover the subcategories of misrepresentation and collusion, data misuse, manipulation and coercion, value and goal conflict, and technical ineptness. (Ekuma and Smith, 2012; Wooten, 2001). On the legal front, the frameworks and risks that set limits to the usability of some principles and techniques of modern employee clustering approaches, such as employee personas, are an inadvertent violation of Title VII of the U.S. Civil Rights Act, the Equal Employment Opportunities Act, the Americans for Disabilities Act (ADA), equivalent European Union regulations such as the Employment Equality Framework Directive (Hamilton and Sodeman. 2020). The European Union-wide General Data Protection Rights -directive (GPDR) and other job discrimination laws and regulations nationally and globally also impact how and how far organizations can use novel approaches and techniques. The non-legal guidelines and standards of sound and fair HCM operations, such as ISO Standard 30408:2016 on Human Governance (International Standardization Organization, 2016), as well as the more commercial approaches of Investors in People-analysis and Great Place to Work At-framework, stress the engagement of all members of the working community, fairness, and trust that the novel approaches may hurt, especially in case if not managed and communicated correctly.

To summarize, in HCM practice, the ethics, privacy, and law concerns oblige the companies to act based on equal treatment for all working community members. In the same vein, the objects of the HCM action, employees have a right to know what data is collected of their behavior and performance, how that data is used and by whom, what is the purpose of that data collection and analysis, and even up to the right to ask the personal data not necessary to the employer to be destroyed. All this is in the spirit of transparency. However, equity and equality are not the same things. According to Rodriguez & Morrison (2019), equity refers to implementing policies and practices that enable opportunities for success for everyone. For equality, treating every individual the same way would suffice. To be equitable, the organization needs to treat individuals according to their needs, and multiple opportunities for success must be created (Rodriguez & Morrison, 2019).

2.2 The Persona Concept

Personas are by origin a concept deriving from marketing discipline but have been increasingly used in generic design thinking processes with practical approaches of the method ranging from educational systems (Siricharoen, 2021) to cybersecurity systems (Almahri, Bell and Arzoky, 2019) and sustainable development (Carey et al., 2019).

According to Haak (2017), the concept of a user persona, traditionally used in marketing, has also been actively spreading to human capital management. Employee persona represents groups of employees with common characteristics in a fictional figure, which can vary from demographics to skills and competencies. When applying the persona concept, it is crucial to establish desired goals and objectives. For some companies, the goal may be developing a new talent acquisition initiative and, for some – strengthening the employer brand (McLeod, 2022).

Employee personas can be created using different methods depending on the end goal and available resources. It can be created by conducting surveys, interviews, or holding focus groups. Combining data collection methods, e.g., holding focus groups/interviews supplemented by a survey, is shown to improve the application of the employee personas (Brennan, 2017). Based on the research by Ditton, Swinbourne & Myers (2022), there is a tendency towards automated persona development since manual persona development can be both time and resource-demanding. That is especially relevant to larger companies. Currently, a semi-automated persona approach is based on manual guidance and data filters entered by a human. With increased data analytics in HCM, the persona concept can be fully automated using algorithms and big data analytics. A study by Jansen, Jung & Salminen (2021) shows that automated persona generation (APG) allows combining big data and persona concepts, creating a multi-layered cast of personas that can enrich the result in comparison to traditional data collection such as surveys or interviews. APG can identify unique behavioral patterns and associate them with demographic groups. Such solutions open new opportunities for decision-makers.

McLeod (2022) argues that the persona method can be used in talent acquisition and employer branding as it can help attract suitable candidates. Using personas in employer branding allows HR to identify key employee drivers, motivations, needs, and expectations of the workplace. A study by Zhao et al (2018) shows that

employee personas can be used in recruitment, training, performance appraisal, and employee engagement. According to Brennan (2017), there are several benefits that organizations can get from adopting a persona approach, such as a better and deeper understanding of the current human resource capital, its experiences from various processes like onboarding, performance reviews, and company policies; keeping the focus on what matters for HCM; more effective employee management; improved communication with stakeholders; mapping out existing and potential challenges; more appealing image for potential candidates; building a stronger employer brand to reduce bias in recruitment.

3. Methodology

This research is exploratory, indicating that its primary purpose is to explore the research questions and identify the current situation of the topic. Exploratory research does not imply any final solutions to the problem (Saunders et al, 2012). Chosen research approach enabled authors to change the direction based on the acquired data. The primary data was collected in the form of twelve semi-structured individual interviews. Semi-structured interviews are often used in qualitative research and allow discussion to evolve during the interview while following the structure (Magaldi & Berler, 2020).

Candidates for interviews were chosen from the authors' professional network. In order to increase validity, the authors selected candidates from different fields and in different positions. In addition, the work experience and the age of candidates varied a lot. Table 1 below provides an overview of the informants based on their field of expertise, the size of their company in terms of personnel number, and their current country of residence. The interview outline was designed and sent to all interviewees in advance. The interviews were conducted as face-to-face or online interviews lasting from 25 to 45 minutes. The authors recorded interviews with the interviewees' consent and transcribed them verbatim. The data was then analyzed, and the main findings were presented in the following chapter.

Table 1: Background of Informants

Field of expertise	The size of the company in terms of the personnel number	Country
HRM	500+	Canada
HRM	500+	Finland
HRM	20-49	Finland
Marketing	100-250	Netherlands
Marketing	11-50	Finland
HRM	500+	Finland
HRM	251-500	Germany
Marketing	500+	Finland
HRM	500+	Finland
Marketing	500+	Finland
HRM	500+	Finland
HRM	500+	Finland

4. Results

Results highlight the increasing need for a more individualized approach in organizations. More flexibility is expected from employers as the workforce is looking for more personalized solutions that would fit them precisely. Many informants outlined cultural differences occurring even within one country that requires certain employee clustering/ segmentation to accommodate their needs better. Results indicate a need for a mindful understanding of retainment, organizational culture development, and flexible work arrangements. Most informants from HR field confirmed that flexibility and individual arrangements are what matter for their employees. More and more employees take job positions that can offer flexibility, possibility for remote work, work-life balance, and other benefits. Employees more often appreciate the culture of individual arrangements and expect to be given the freedom of choosing own schedule.

Some informants noted that younger employees (Gen Z) have different career and work expectations than their older colleagues. While the research did not explore the generational differences in expectations, numerous informants touched upon this topic pointing out that Gen Z's way of work and work expectations differ drastically. For example, Gen Z expect more work-life balance, flexibility, and on-site learning, while being online 24/7. Informants highlight that when creating personas in multigenerational company, it is important to account for Gen Z differences and expectations.

As described in the literature review, the user persona concept can be perceived as a marketing tool. Based on the data collected from professionals from the marketing field, they have been actively using the user persona method to segment and identify their potential customers and their needs when designing new products. One informant noted that the user persona concept allows them to customize the approach and expand the customer base. Some experts have been using personas according to different markets, while others based on experience. Results indicate that before informants decide whether to use the user personas, it is necessary to understand the goal and objectives. Some HR experts pointed out that their current roles are interconnected with marketing, for example, when recruiting talent. One informant expressed a strong opinion that although not very popular yet, employee personas are coming to the HR field, and their use in HR and HCM will increase in the coming years. Below are some of the quotes from informants.

> *"Even before personas, we categorized our teams to get a better understanding. We used mapping and used categories."*
>
> *"We did think that in this case technology is better at making personas than a person because we are all biased."*
>
> *"When making personas, it's important to understand generational differences. With the new generation, we need to understand how they want to be led or hired."*
>
> *"Generation Z is completely different from others, so the persona thinking can be beneficial."*
>
> *"There's a big employee power now, and they need more autonomy, they want more flexibility, but at the same time, we see the rising need for support, for counseling, and we want to do things in equal and ethical way."*

Regarding HR, talent acquisition can be partly perceived as a marketing process since getting the best talents to the company requires effective and suitable marketing when advertising the position. Results highlight that some methods of employee segmentation are actively used according to several categories, such as employee types, roles, needs, skills, etc. Informants pointed out that employee personas allow the company to identify what matters to their employees. They discussed that for personas to work and add value to the business, they must be concrete and simple enough to be understood by employees and management and, simultaneously, not oversimplified or too generic. Table 2 below is based on the results and summarises the application of the persona concept across different HRM/HCM functions.

Table 2: Where and why to use Personas

Where to use personas	Why to use personas
Employer branding	For employer branding to strengthen the employer image and increase competitiveness, to modify the audience to target the suitable candidates
Recruitment	To tailor job descriptions/ advertisements to appeal to eligible candidates. Later, it can be used to tailor recruitment efforts
HR initiatives	To develop targeted initiatives and/or programs that respond to the unique needs/ expectations of different employee clusters
Training & career development	To gain a deeper understanding of the competencies and experiences employees have and would like to have
Diversity and inclusion	To better understand Gen Z, their expectations, motivations, and need for leadership to manage a heterogeneous workforce. To better respond to the needs of a diverse workforce

Results indicate that the persona concept has multiple advantages when used in HCM. It allows HR professionals to relate to groups of employees more personally and emotionally, creating personalized approaches and supporting individual career paths. The concept is visually simple, easy to use, scalable, and transparent and

allows employees to choose where they belong. Also, it improves the analysis of potential recruits and assists in decision-making. However, the results also underline several disadvantages of the concept. The concept might be misleading if oversimplified or too generic. It can lead to a more homogenous and one-minded workforce if recruiting processes rely only on this concept. It may require data analytics and AI skills, as well as it can be expensive and time-consuming. Another disadvantage is that it creates an unwanted possibility of comparing employees with each other, which can lead to missing out on their unique strengths and abilities. Also, it might be too restrictive and limited due to GDPR. If and when Personas are created systematically especially in a large organization, it should be rule-based/algorithm-based and working based on data of e.g. existing successful employees (in order to train others to reach the same potential or to recruit new ones who would be likely to succeed). Howewer, based on EU-wide General Data Protection Regulation (GDPR) the organizations have limitations on how to store and use such information about their employees. According to the regulation, sensitive data is a set of special categories that should be handled with extra security. These special categories are: 1) Ethnic or racial origin. 2)Political opinions. 3) Cultural or social identity 4) philosophical or religious beliefs. (GDPR, 2023). On the other hand, leaving out these debatable "soft issues" out of the personas would reduce the personas back to skill/competence listings, and thus offer no added value to earlier HCM practices.

To sum up, employee personas can be used as a supportive tool in decision-making but cannot be the only source of information.

5. Conclusions and Discussion

This study served as an introduction to the persona concept. It aimed at exploring the awareness of the personas among HRM/HCM experts and in what HRM/HCM processes personas can be used. In order to reach research objectives, a knowledge database was created based on the existing research. Previous research has identified the need for a more personalized approach and recognized the use of the persona concept for employee clustering.

Based on the results, the persona concept is well-known among HRM/ HCM professionals. It is used in the following processes: employer branding, recruitment, HR initiatives, and training. While the use of personas is mainly perceived as human-driven, the actual clustering cannot be done without the help of technology, including artificial intelligence. Some organizations use software to cluster the data. Based on the results, the following can be confirmed: the persona concept has been used for a while in marketing, and now HR is catching up with the concept. Also, results demonstrate a need for a more individualized approach and flexibility.

The research has certain limitations. Most interviews were conducted among companies with more than five hundred employees. The validity of the results is affected by a small number of interviews. Despite the limitations, the study provides the foundation for further research on this particular topic. Further research is needed to understand the real implications of the concept and how it can be applied efficiently in organizations. A larger data sample can increase the validity of the results and allow authors to explore the practical side of the persona concept more in-depth and to identify the process of persona development in HCM functions.

Supporting Knowledge Communities: Examples From Organisations With Innovative Management Models

Ludmila Mládková
Prague University of Economics and Business, Czech Republic

mladkova@vse.cz

Abstract: The paper discusses how three organisations with innovative management models support the creation and work of knowledge communities. In the current unstable environment, knowledge, the ability to acquire it, create it and share it becomes one of the most critical aspects of the success of any organisation. Even though organisations may not be consciously aware of this, some adopt specific innovative management models that support their work with knowledge. The management model is how an organisation is managed, e.g. how managerial activities are executed, interlinked and organised into the systemic approach. Traditionally, management models were based on hierarchies and clear rules concerning managerial functions (planning, deciding, organising, leadership and controlling). Innovative management models are flatter; employees are empowered to decide and set objectives; control is decentralised. Some innovative management models are self-managing and look unusual, even crazy, as they deny our expectations about how organisations should be managed. Innovative management models help improve knowledge flow and sharing in an organisation. The paper provides examples of organisations whose unusual management models go even further and support or are intended to support the creation and work of knowledge communities. Knowledge communities usually benefit organisations by providing an environment where employees extensively interact, share and create knowledge. They are the silos of new knowledge, inventions and innovations. Organisations with unusual management models use different managerial tools and methods to support knowledge communities. Some organisations are successful, and some fail. In the paper, we show examples of both groups of organisations and explain why some management models work and support knowledge communities, and others do not. The paper uses secondary data about organisations available in the theoretical and managerial literature on these organisations and information from their web pages.

Keywords: Knowledge community, Knowledge, Management model

1. Introduction

The paper discusses how organisations with innovative management models support the creation and work of knowledge communities. In the current unstable environment, knowledge, the ability to acquire it, create it and share it becomes one of the most critical aspects of the success of any organisation. Even though organisations may not be consciously aware of this, some adopt specific innovative management models that support their work with knowledge. The management model is the way how an organisation is managed, e.g. how managerial activities are executed, interlinked and organised into the systemic approach. Traditionally, management models were based on hierarchies and clear rules concerning managerial functions (planning, deciding, organising, leadership and controlling). Innovative management models are flatter; employees are empowered to decide and set objectives; control is decentralised. Some innovative management models are self-managing and look unusual, even crazy, as they deny our expectations about how organisations should be managed.

Innovative management models usually help improve knowledge flow and sharing in an organisation. The paper provides examples of organisations whose unusual management models go even further and support or are intended to support the creation and work of knowledge communities. Organisations usually benefit from knowledge communities as they provide an environment where employees extensively interact, share and create knowledge. They are the silos of new knowledge, inventions and innovations. Organisations with unusual management models use different managerial tools and methods to support knowledge communities. Many organisations are successful, but many fail. In the paper, we show examples of both groups of organisations and explain why some management models work and support knowledge communities while others do not.

The paper uses secondary data about organisations available in the theoretical and managerial literature on these organisations and information from their web pages.

2. Background

2.1 Knowledge Communities

The term knowledge community is a covering term for different types of knowledge work supporting groups, from knowing communities, cooperative communities, occupational communities, learning communities,

innovative communities, and internal knowledge networks to communities of practice or question and answers communities, discussion boards and online forums or user innovation communities. Even though these communities were founded on different principles and for different concrete objectives, the primary reason for their existence is knowledge sharing and creation (Boland and Tenkasi, 1995).

In this paper, we understand knowledge communities as communities whose members interact and, via this interaction, share and create knowledge (Amin and Roberts, 2008; Boland and Tenkasi, 1995). Or as Harvey et al. (2015, p. 47) specify, "entities that rely on repeated and continuous interactions between individuals sharing a common interest or objective. Knowledge is at the core of both the activities and the outcomes of these communities, whose members actively exchange and accumulate knowledge. Through this regular exchange, group members come to share common mental schemas, social norms, and even a language, all of which can help to guide creative activities and accelerate innovation". Compared to traditional communities, knowledge communities are more professional, and users can exchange knowledge related to specialised topics such as health, academics and software development (Zhou, 2018). "Everyone can bring in the community her own view or perspective, as well as interpretations and values" (Cabitza et al., 2014, p.391), which influences the knowledge a community possess and works with. Knowledge communities are important, especially in a volatile environment where they serve as silos of knowledge creation, innovativeness and collective intelligence on one side and the other as places of stability and friendly environment.

As Harvey et al. (2015) mention, knowledge communities in organisations may be formal and informal. Formal knowledge communities are intentionally developed and managed by an organisation and may be part of its organisational structure. Informal knowledge communities emerge naturally from human interaction and communication.

Knowledge communities develop based on two mechanisms, common identity or common bonds. Some knowledge communities, for example, communities of practice, are based on both.

In common identity-based knowledge communities, "the attachment to the group is dependent foremost on the identification with the group as a whole, its goal, and its purpose" (Sassenberg, 2002, p. 28). Sassenberg (2002, p. 28) goes on: "An example of this type of group is a sports team: The common goal of the group members and the purpose of the group is much more important than the perceived interpersonal attraction between the single players." Alternatively, differently, "In these groups, the strength of group attachment depends first and foremost on one's commitment to the identity of the group" (Prentice et al., 1994, p. 85).

Common identity develops via social categorisation, interdependence, and intergroup comparisons (Ren et al., 2007; Turner, 1985; Turner et al., 1987). Social categorisation is based on the group's shared identity. Interdependence is supported via common tasks, common purposes or fate. Intergroup comparisons, e.g. community members comparing themselves to other groups and communities, increase people's commitment to their group (Ren et al., 2007).

In common bonds-based knowledge communities, "the bonds between group members primarily make up the attachment to the group. These groups can be characterised by the interpersonal conception of group cohesion, where the attraction of the group for the individuals does not play a role; rather, what is important is the attraction of the individuals to one another (personal attraction). An example is a group of friends" (Sassenberg, 2002, p. 28).

"Researchers have identified three main causes of bond-based attachment to a group: social interaction with others, personal knowledge of them, and interpersonal attraction toward them often through similarity." (Ren et al., 2007, p. 387). Social interaction helps people to learn about each other and to develop trust. Frequency is one of the factors that increase relationship development. Personal information builds understanding and interpersonal bonds. People like interacting with people with similar ideas, values, hobbies, ages, etc. (Ren et al., 2007).

Both common identity and common bonds support trust and openness toward others. They may cooperate in knowledge communities. "Further, despite their conceptual distinction, an identity-based attachment may evolve into bond-based attachment and vice versa" (Ren et al., 2007, p. 401).

In a volatile environment, the importance of knowledge is growing. Knowledge is not, and cannot, be concentrated in a single mind, and no single mind can specify in advance what kind of practical knowledge will be relevant, when and where (von Hayek, 1945). Therefore "firms would do well to understand the knowing

(knowledge) communities with which they are linked, the activities in which those communities engage, and the avenues through which they may be nurtured" (Harvey et al., 2015, p. 446).

2.2 Innovative Management Models

Management models can be defined as paradigms (Guillén, 1994), models of control (Ouchi, 1980), "the choices made by a company's top executives regarding how they define objectives, motivate effort, coordinate activities, and allocate resources; in other words, how they define the work of management" (Birkinshaw and Goddard, 2009, p. 82) or "distinct bodies of ideas that offer organisational managers precepts for how best fulfil their technical and social tasks." (Bodrožić and Adler, 2018, p. 86). Differently, a business model is what the organisation does; a management model is how they do it (Birkinshaw and Goddard, 2009).

Traditional management models used and recommended since the beginning of the 20th century (for example, by H. Fayol or M. Weber) were based on strict deciding hierarchies, bureaucracy, top-down planning, extrinsic motivation and centralised control (Birkinshaw, 2012). Traditional models fit well into a relatively stable economic environment. However, they turned out to be one of the limits in a volatile knowledge-focused environment.

Innovative management models, an alternative to the traditional ones, started to develop approximately from the 50thof the 20th century, some of them (for example, Semco and Gore models) inspired by the book of Douglas McGregor, The human side of enterprise (McGregor, 1960). Innovative management models changed hierarchies to empowerment in the field of deciding. Top-down planning was replaced by bottom-up planning that enables employees to express their ideas and comments on and participate in creating objectives and plans. Organisations discovered the importance of intrinsic motivation. Empowerment in decisions resulted in control decentralisation.

These days, organisations know the importance of knowledge and knowledge sharing for their businesses and try to support it with a knowledge-friendly environment. Many organisations (intentionally or intuitively) create new innovative management models that, as Alder (2015, p.446) notes, "support community work within and beyond firm". In this paper, we provide examples of companies with alternative management models and discuss how they support the work of knowledge communities in these organisations.

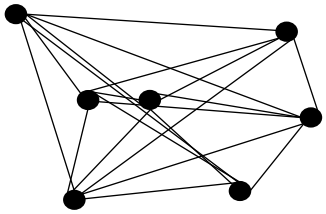
3. Objective and Methodology

This paper discusses how three organisations with innovative management models support the creation and work of knowledge communities.

The data used in this paper are secondary data from the literature. The literature on knowledge communities and innovative management models was collected by WOS search. We searched the following keywords: "knowledge community", "knowing community", and "management model". The additional literature was collected based on relevant citations found in these journals and further keyword searches in other types of academic and practice-oriented resources. Our previous research on these topics collected literature on common identity and common bond theories.

Companies discussed in this paper were chosen from the pool of companies already known and discussed in the literature on different types of management models. The collection of data about the company started with corporate web pages and materials. This search provided us with basic data about companies and their management. The next step was the key-world search in the EBSCO database. We searched for three fundamental keywords – the company's name, the company's name with the word management model and the company's name with the word case. This search provided us with research papers on companies. The third step was the Google search which allowed us to collect data from professional journals and blogs.

4. Findings



In this part of the paper, we would like to provide examples of how organisations with innovative management models support the creation and work of knowledge communities. We introduce three management models; up till now, a fully functional model of W. L. Gore & Associates, the Semco model that worked under the company owner R. Semler (he sold the company, and there is no information about the management model now) and the Spotify model that, even though well prepared, failed to work.

4.1 W. L. Gore & Associates

W. L. Gore & Associates (Gore) was founded in 1958. The founders, Bill and Vieve Gore, influenced by D. McGregor's theory Y, created the company with a fundamental belief in the individual, the collaboration of small teams, a long-term view and guiding principles of freedom, fairness, commitment, and so call waterline (rule to discuss with colleagues whatever may be dangerous for the company) (Gore, 2023).

Knowledge communities are supported by organisational structure, a limited number of teams and employees in plants, teams built from different professions, cooperation of people from different teams, and the hiring system.

Gore's "lattice" organisational structure builds on the principle of an informal network of relationships and connects every individual to every other. Therefore, as Hamel (2010, A lattice, with self-managed teams) writes: "At Gore, there would be no layers of management, information would flow freely in all directions, and personal communications would be the norm. And individuals and self-managed teams would go directly to anyone in the organization to get what they needed to be successful".

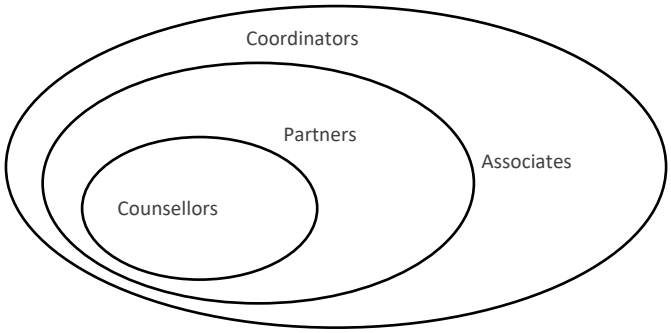
(Source: Author)

Figure 1: Lattice Organisational Structure

"The Gore Company limits the size of teams to facilitate direct communication. In addition, each Gore Company site contains only a small number of teams to promote interaction between associates and the pursuit of common goals. Also, in some locations, production occurs in multiple small plants clustered together rather than in one large factory. The teams may, in those cases, pursue their day-to-day work within their mini-plant but may also collaborate occasionally with associates or the teams in another nearby mini-plant if this makes sense in connection with, for example, a development project. Such clustering thus encourages interaction among unrelated teams" (Grønning, 2016, Challenges That the Gore Company has Experienced). Each plant has different professions (engineers, chemists, salespeople, etc.) to support cross-functional knowledge sharing and cooperation. Plants are not allowed to grow over 200 people so that people could know each other and decide together. Teams from different plants meet regularly to ensure employees know each other and cooperate.

Job descriptions are general, and employees negotiate their roles and responsibilities with their teams. Once negotiations are finished, the result becomes an unbreakable commitment, and the individual is accountable to his team. The negotiation process can be time-consuming, but it helps to bring together different talents, perspectives, and knowledge. People work in different teams, and teams also always cooperate, which may look chaotic from the outside. Employees get mentoring and support; new employees get a sponsor who helps them to understand the Gore management model, its rules and how it works.

Compensation is based on the evaluation of co-workers. Employees can use 10% of their working hours for their personal projects. They are encouraged to implement the idea if they persuade their colleagues to join them and create a team for implementation. This rule supports knowledge sharing and creativity.



Gore is cautious about new employees. The hiring process is very long and challenging to ensure that only people who match and can sustain the specific Gore management model are hired. Applicants are interviewed and observed by members of involved teams who decide whether to employ the person.

4.2 Semco

Semco, a Brazilian industrial equipment manufacturer, was founded in 1953 as a traditional company. Since 1980 its management model was transformed by Richard Semler, the son of the founder, to a self-managed model based on employee participation in planning, decision-making and implementation. Semco adopted the management model first used by groups responsible for technical innovations, which turned out to be knowledge-work supportive (Semler, 1998).

The organisational structure, the limited size of units, open meetings, open communication and the hiring process, supported knowledge communities.

Three circles created the structure of the company; a circle of counsellors and partners, coordinators and associates. "Counsellors are like vice presidents and co-ordinate the general policies and strategies; partners run the business units; coordinators comprise the first level of management, such as marketing, sales, and production supervisors or engineering and assembly-area foremen; associates are the workers" (Petersson and Spängs, 2006, p. 34).

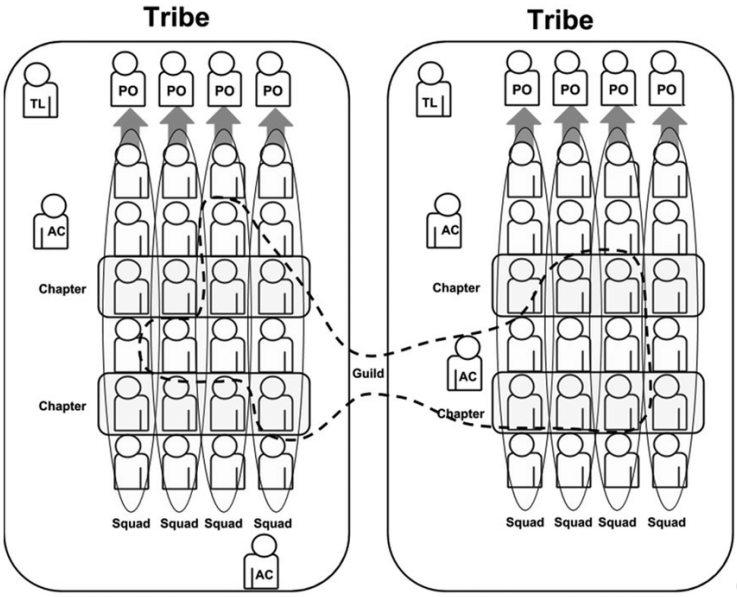
(Petersson and Spängs, 2006, p. 58)

Figure 2: Semco Circles

The company structure was replicated to individual business units organised in fully autonomous small units (max 150 so they could know each other). Units developed on different criteria (product, market, etc.), but each unit had full accountability for their business, including finances and communication with suppliers and customers. Each unit had a committee (5-10 workers, engineers, executives, and support clerks) that discussed its production issues. About two-thirds of employees worked in such units. (Semler, 1998). There was voting in case of important decisions, and all employees were empowered to vote. Once a month, there was a meeting focused on new ideas.

Managers became facilitators whose role was to support employees. All meetings in Semco were open to all employees, and whoever was present could vote. The management model was endorsed by the hiring process. Employees decided about new hires and could bid for new positions every half a year. Applications were evaluated by managers and the company as a whole (Semler, 1998).

4.3 Spotify



Spotify developed and tried implementing a sophisticated matrix-type management model to support knowledge communities in horizontal and vertical dimensions. Even though the model never worked in the company (Michou, 2020), it was an interesting attempt.

The Spotify management model comprises squads, tribes, chapters, guilds, and trios. The vertical level is built of stable teams of squads and trios where people with different skills collaborate. Due to extensive collaboration and stress on face-to-face communication, the team have the potential to transform into a knowledge community. Horizontal level, chapters and guilds were intended to become and work as knowledge communities.

Squads are cross-functional, autonomous, self-managing teams of experts (typically 6-12 individuals) focusing on one feature area. They are the primary value creators understood and treated as mini-startups (Knitberg and Ivarsson, 2012). "Each squad has a unique mission that guides the work they do, an agile coach for support, and a product owner for guidance" (Cruth, n.d., Squad). Product owners prioritise the work in the squad and collaborate with other product owners on coordination among their squads. They are not responsible for how the work is done. Agile coaches help to improve how squads work. Squads are encouraged to spend about 10% of their work time on their ideas and knowledge sharing. Squads are supposed to cooperate with squads in their tribe but not with squads from a different tribes.

Tribes are groups of squads that work in a similar area. Tribes consist of 40-100 people. They are located in one place and have a tribe leader. Squads and tribes meet regularly and informally when they need to. Chapters are groups of experts in specific areas and help to keep engineering standards in place across a discipline. Chapters are led by a senior technology leader, who may also be the manager for the team

members in that chapter. Guilds are communities of interest. Members are from different squads but meet to share knowledge, tools, and practices. They have a guild coordinator (Knitberg and Ivarsson, 2012; Cruth, n.d.). The trio combines a tribe lead, a product lead, and a design lead. Each tribe has a trio to ensure continuous alignment between these three perspectives when working on feature areas. Alliances are a combination of tribe trios (typically three or more) that work together to help their tribes collaborate on a bigger goal than anyone's tribe (Cruth, n.d.).

(Bäcklander, 2019, p. 45)

Figure 3: Spotify Structure

The model is supported by stress on face-to-face communication and a long and careful hiring process.

The Spotify knowledge work supporting model was never fully implemented in the company. It turned out to be very complicated, and required extensive communication among employees, shared responsibilities and cross-team collaboration (Michou, 2020). It was implemented quickly in the period of extensive company growth, which probably caused problems with implementation.

4.4 Developing Knowledge Communities via Common Bonds and Common Identity

This chapter summarises how innovative management models of three organisations discussed in this paper support creation and work of knowledge communities via common bonds and common identity.

Table 1: Developing Knowledge Communities via Common Bonds and Common Identity

Company	Gore	Semco	Spotify
Common identity			
Social categorisation (group shared identity).	Employees are called associates and are company owners through the associate stock plan.	Vote of all employees on important decisions.	Based on squads perceived as startups. Squad mission.
Interdependence (joined tasks).	Associates are encouraged to cooperate with other associates on different projects and ask for help.	Possible to participate and decide in any meeting.	In tribes. Chapters. Guilds.
Intergroup comparisons.	Comparison to other companies – a feeling of exclusivity.	Comparison to other companies – a sense of exclusivity.	Comparison to other squads/tribes. A feeling of exclusivity.
Common bonds			

Company	Gore	Semco	Spotify
Common identity			
Social interaction with others.	Supports frequent interactions.	Supports frequent interactions.	Supports frequent interactions.
Personal knowledge of them.	Factories max 200 people.	Units max to 150 people.	Tribes max 100 people.
Interpersonal attraction toward them, often through similarity.	The careful and demanding hiring system.	Careful and challenging hiring system (including reallocation to different work).	The careful and challenging hiring system.

5. Discussion

"If we can agree that the economic problem of society is mainly one of rapid adaptation to changes in the particular circumstances of time and place, it would seem to follow that the ultimate decisions must be left to the people who are familiar with these circumstances, who know directly of the relevant changes and of the resources immediately available to meet them. We cannot expect that this problem will be solved by first communicating all this knowledge to a central board which after integrating all knowledge, issues its orders. We must solve it by some form of decentralisation. But this answers only part of our problem. We need decentralisation because only thus can we ensure that the knowledge or the particular circumstances of time and place will be promptly used" (von Hayek, 1945, p. 524). This over seventy years old quote supports the fact that organisations are searching for ways how to intensify their knowledge, its utilisation, creation and sharing because "knowledge is not the inalienable product of each individual's own reasoning. It is essentially transmissible, capable of being made a common possession" (Welbourne, 1981, p. 305). "Research has shown that a firm's creativity and innovation depend heavily on its knowing communities, which reach beyond formal RandD activities or individual employees' initiatives" (Harvey et al., 2015, p. 46).

Organisations discussed in this paper understand that "A firm is seen as the repository of knowledge and the physical locus of its creation and deployment because it provides the social, political, and economic context under which knowledge is constructed" space (Lee and Cole, 2003, p. 634). Therefore they introduced innovative management models where "the lateral-flexible organizational form relies on peer-to-peer collaboration (as opposed to a vertical hierarchy) in achieving organizational objectives" (Boland and Tenkasi, 1995, p. 350). Their management models support "face-to-face interactions among knowledge developers to facilitate trust building over a long period of association and through sharing a common space" (Lee and Cole, 2003, p. 634).

Management models of organisations presented in this paper prove the statement that "Many of new management models support community work within and beyond firm" (Adler, 2015, p. 446) and that "knowledge-intensive firms are composed of multiple communities with specialized expertise, and are often characterized by lateral rather than hierarchical organizational forms" (Boland and Tenkasi, 1995, p. 350).

6. In Conclusion

The objective of this paper was to show the example of three companies and how they adapted their management models to support the development and work of knowledge communities. W. L. Gore & Associates created the management model that proved its viability through decades. The Semco model successfully helped the company in years when R. Semler owned it. Spotify model, though only partially implemented in Spotify, offers an interesting option for developing knowledge communities in organisation and supporting their interaction.

Companies discussed in this paper are not the only companies that adopted specific management models to support knowledge communities; we can name Google, Facebook, Morning Star, Buurtzorg, and Favi, among many others. The number of such companies will be growing because of the pressure of the economic environment on knowledge sharing. Therefore it will be necessary to research these organisations, their management models and how they support knowledge communities.

Abstract: In the contemporary need for continuous upskilling and reskilling, higher education has an important role to play. While the traditional university programmes are designed for students in their early twenties our knowledge society has a demand for lifelong learning in a wider age span. This paper is a part of a Delphi study on the ongoing transformation of higher education for lifelong learning. A qualitative Delphi study has been carried out in the four steps of 1) A literature study to explore the chosen topic, with the selected publications sent out to an expert panel, 2) A survey with questions to the experts based on the findings in the literature study, 3) Email interviews to dig deeper into the answers from the survey, and finally 4) Focus group interviews. The aim of the paper is to analyse, present and discuss the international expert panels' views on the infrastructural needs in the transformation of higher education. Data gathered from the three first steps, with a focus on the email interviews, have been analysed according to the Grounded Theory concepts of open, axial coding and confirmatory coding. The categories from the Open coding analysis were later, in the axial coding, grouped around the central axis of 'Higher education transformation for lifelong learning'. The confirmatory coding found the common denominator of 'Infrastructure', and its interrelationships with the attributes of 'Multimodal delivery', 'Pedagogical change', 'Quality and organisation', 'Equity, diversity and inclusion', 'Digital literacy', 'Accessibility', and 'Financial aspects'. Findings align to the Anna Karenina principle in the sense that a happy and healthy infrastructure for continuous lifelong learning in higher education, depends on all the attributes listed above. This leads to the Tolstoyan conclusion that every variation of failing attributes would result in its own state of unhappiness.

Keywords: Higher education reform, Lifelong learning, Technology enhanced learning, Inclusive education, Delphi study

1. Introduction

Lifelong learning and its place in higher education has been frequently debated in the 21st century. In the new knowledge society today, most countries face a high demand for retraining and reskilling. This requires a continuous professional development where the traditional university programmes are redesigned to support a continuous lifelong learning. This is a transition that higher education has to address (Lang, 2023), a reform that also must ensure inclusion and support equitable quality education (Atchoarena, 2021). The study presented in this paper is part of a larger Delphi study on the ongoing transformation of higher education for continuous lifelong learning. The aim of the study is to analyse, present and discuss the views on the infrastructural needs in the transformation of higher education, based on structured interviews with the Delphi expert panel.

The complete Delphi study was carried out with the four steps of 1) A literature study to explore the chosen topic, with the selected publications sent out to an expert panel, 2) A survey with questions to the experts based on the findings in the literature study, 3) Email interviews to dig deeper into the answers from the survey, and finally 4) Focus group interviews, extended with a pre- and a post step. Data from the three first steps of this Delphi study, and with a strong focus on the email interviews in Step 3, have been analysed according to the Grounded Theory concepts of Open, Axial coding and Confirmatory coding. The results from the Open coding were used as an input to the Axial coding and the results from the Axial coding have been refined in the Confirmatory coding phase.

2. The Transition of Higher Education for Continuous Lifelong Learning

The transition of higher education for lifelong learning has been in focus during several decades. This research field was initiated long before the Covid-19 pandemic outbreak (Schuetze & Slowey, 2013). However, the pandemic has acted as a catalyst for the transformation of lifelong learning and higher education, and highlighted the need for technology-enhanced lifelong learning (Davidović, 2020; Ivenicki, 2021; Mozelius, 2021). A development that involves the adjustment of lifelong learning structures within higher education in

regard to educational design and the model of content distribution. Reflected and well-designed changes in the structure of lifelong learning could provide beneficial outcomes. At the same time, there are critical aspects of the higher education transformation that are crucial to address for a successful lifelong learning in a digital era.

As the contemporary societies become increasingly dynamic, socio-economically complex, and globally connected, the need for technology-enhanced lifelong learning in virtual environments grows stronger (Nygren et al., 2019; Hansen et al., 2020). This is one of many challenges that higher education institutions must address. Jarvis (2014) defines lifelong learning as a process in which humans of any age, and with a broad range of needs and interests, together should acquire new knowledge and skills. To establish well-designed teaching institutions such as universities might be seen as one source of delivery, but are not the only one (Jarvis, 2014). In the growing field of lifelong learning, higher education institutions could take on two different roles. One role would be to ensure that graduates of formal, credit, and accredited programs are empowered with the skills required for a lifelong learner. At the same time higher education institutions can also offer continuous and adapted courses and programs designed for meeting the specific needs of prospective and lifelong learners. In both scenarios, higher education will play a main role, but together with other important actors.

3. Method and Materials

The Delphi method is a structured communication strategy to capture an expert panel's view of complex phenomena (Okoli & Pawlowski, 2004). This study was based on the adapted four-step Delphi method described in (Mozelius et al., 2023), as ' The Alberta approach'. A four-step approach that also involved a pre- and a post-step as listed in Table 1 below.

Table 1: The Steps in the Adapted Delphi Approach

Pre-step	**2020-2021**	**Literature review** **Invitation to experts**
Step 1	Dec, 2021	Online survey
Step 2	Jan, 2022	Reading assignment
Step 3	May, 2022	Structured email interviews
Step 4	June/July, 2022	Focus group interviews
Post-step	September, 2022	Validation of focus group summary Preliminary conceptual framework

4. Data Collection

This study was based upon the data from the answers to the email interviews in Step 3, in which eight selected experts on lifelong learning answered a questionnaire with open ended questions. Experts have been selected with the idea of a purposive expert sampling (Rai & Thapa, 2015), involving informants that all have a long experience of teaching in higher education. All experts have several research publications in the field of lifelong learning and lifelong education. Moreover, these experts have a wide geographical spread, and are representing five countries and three continents. A geographical spread that resulted in a variation of socio-cultural contexts. Before the email interviews the experts in the Delphi panel were given a reading assignment with the five texts in Table 2. The texts have been analysed in detail in an earlier literature study on lifelong learning and higher education (Håkansson Lindqvist et al., 2020).

Thriving for knowledge, industry and humanity in a dynamic higher education ecosystem?. *Journal of Applied Research in Higher Education*.	Presents challenges that have been identified in higher education and the need for a new dynamic higher education ecosystem. The concept of Education 4.0.

5. Data Analysis

Interview answers have been analysed according to the Grounded theory method of data being 1) fractured and labelled, 2) conceptualised around a central category, and 3) integrated with a description of their interrelationship for further theory building (Moghaddam, 2006). In the first analysis phase, referred to as Open coding, data were broken down into units of meaning to label and conceptualise data as outlined by Khandkar (2009). The open coding was conducted with an investigator triangulation approach where three of the authors collaborated in a 'triangulating analysis' to find preliminary categories based on codes and subcodes that were identified in the interview answers. The next phase of Axial coding was guided by the idea of *"coding that treats a category as an axis around which the analyst delineates relationships and specifies the dimensions of the category"* (Bryant & Charmaz, 2007, p. 603). The first version of preliminary categories were built around the most frequent codes, but later some categories were merged and renamed.

In the Axial coding the preliminary categories from the Open coding were reassembled into more abstract conceptual categories around the central axis of 'Higher education transformation for lifelong learning'. Finally, the third phase that sometimes is referred to as Confirmatory coding (Cleveland-Innes and Campbell, 2012), and sometimes as the phase of Selective coding (Walker and Myrick, 2006). In this study the choice was to use the term Confirmatory coding, but with the same fundamental approach as when Vollstedt and Rezat (2019, p. 89), described Selective coding as "the process of choosing the core category and relating it with the other categories from axial coding". This third analysis phase should also involve a strive to answer the important questions "What seems to be going on here?" and "What is the research all about?" (Corbin and Strauss, 2008; Teppo, 2015; Vollstedt & Rezat, 2019).

6. Findings and Discussions

With the Grounder theory idea of an iteratively refined analysis data, have been reread and discussed among the authors in the phases of Open coding, Axial coding and Confirmatory coding. The overall aim was according to the main idea in the Gioia method to begin the development of "a theory that explains, at a broad conceptual level, a process, an action, or interaction about a substantive topic" (Magnani & Gioia, 2023).

6.1 Results from the Open Coding

In the Open coding data were broken down units of meaning or subcodes. Out from the subcodes or data extract, codes and preliminary categories were created in three different analyses conducted separately by three of the Delphi study researchers. Later, the results from the different analyses were discussed in research team meetings where the preliminary categories were split, merged and renamed. An example of how subcodes and codes aggregated the category of 'Pedagogical change' is illustrated in Figure 1 here below.

Pedagogical change Codes: ***Pedagogy - Instructional design – Interaction - Social presence – Learner centred design***
Subcodes / Data extracts: Improved learning design based on affordances of digital technology/ digital interaction instead of converting f2f modes into digital pedagogy. have transformed their pedagogy to make it more focused on students' learning, by using in their course synchronous and asynchronous activities. They also were able to provide their students with the advantages described in the literature on blended and online courses: flexibility, accessibility, complementarity between synchronous and asynchronous activities using pedagogical approaches such as problem-based or project-based learning by integrating technologies and in particular Internet research. However, in some developing countries, these resources are weaker or even non-existent problem-based or project-based learning, emphasize the acquisition of skills and

Figure 1: A Preliminary Category Aggregated by Codes with Some Examples of Subcodes/Data Extracts

The final categories in the Open coding phase were aggregated into 1*) ' Digital literacy'* with the subcategories (or codes) of 'Rich media tools', 'Learner digital literacy ' and ' Teacher digital literacy¸ 2) *'Multi-modal learning delivery'* with the subcategories of 'Content development', 'Instructional design', and 'Rich media tools, 3) *'Infrastructure'* with the subcategories 'Blended learning', 'Policies', 'MOOCs', 'Instructional design', 'Open Source', 'Open learning' and 'Internationalisation', 4) *'Quality considerations'* with the subcategories 'Aim', 'Outcomes', 'Credits', 'Certificates', and 'Quality assessment', 5) *'Pedagogical change'* with the subcategories 'Pedagogy - Instructional design – Interaction - Social presence – Learner centred design as in Figure 1 above, 6) *'Continuous lifelong learning'* with the subcategories 'Lifelong learning', 'Work-integrated learning', 'Lifelong learning' 'Collaboration with society', 'Social aspects', and 'Employability', 7) *'Accessibility'* with the subcategories 'Anytime-Anywhere', 'Older adults', 'Inclusion policies', 'Open Educational Resources', 8) *'Equity, diversity, inclusion (EDI)'* with the subcategories 'Inclusion', 'Open Education', 'The Mathew Effect', 'Older adults', 'Women', 'Disaffected youth' and 'Diversity', and finally 9) Miscellaneous.

All categories and subcategories had a relation to the central theme for the Delphi study, 'The Transition of Higher Education for Continuous Lifelong Learning'. However, their focus and their interrelationship needed to be further analysed in the Axial coding phase.

6.2 Results from the Axial Coding

In the Axial coding the Open coding category 'Continuous lifelong learning' was merged with parts of the category 'Miscellaneous', and extended to the new axial category. This new central category for the analysis was 'Higher education transformation for lifelong learning'. A central axis connecting the categories of, 'Multimodal delivery', 'Pedagogical change', 'Financial aspects', and 'Quality and organisation', 'Infrastructure', 'Digital literacy', 'Accessibility', and 'Equity, diversity and inclusion (EDI)' as depicted in Figure 2.

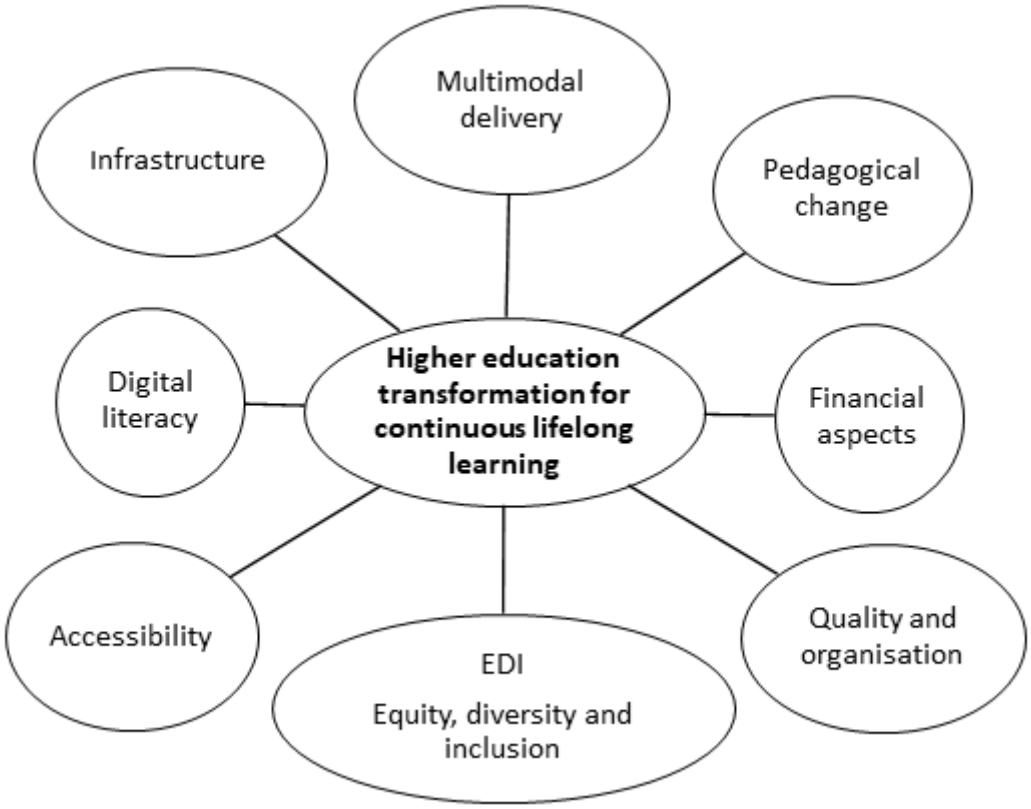

Figure 2: Critical Aspects of 'Higher Education Transformation for Lifelong Learning' and its Dependencies

6.3 Higher Education Transformation for Lifelong Learning

The found central category, that the axial coding focused on was Higher education transformation for lifelong learning. A new category that is a merge of the earlier category of 'Continuous lifelong learning' and its subcategory of 'Transformation of higher education'. Several experts brought up the pandemic as a catalyst for this transition, and as expressed in an interview answer *"I think we have learned a number of important lessons during the pandemic, some of which provide insights about future drivers for change in HE"*. Another transition driver mentioned by some experts were the new demands in the contemporary knowledge society and the labour market. There were comments on the currently huge needs for reskilling and upskilling. One of the experts highlighted the importance of a more demand driven lifelong learning, and to *"increase research-led education to focus on innovation, increase engagement, and focus on capability"*. Furthermore, one expert brought up the ongoing climate change as a driver *that "will continue to be a backdrop for many initiatives, policy shifts, etc"*. An essential part of the transition is that lifelong learning in higher education has to use more of technology and online learning in the future. However, as pointed out by an expert:

> *"I don't think it's wise to say that technology is itself a driver. Better to say that improvements in the capabilities of affordable digital devices + enhancements to networking infrastructures are entangled with changing habits and expectations"*

The implementation of educational technology is an ongoing process, but what might be more important, and mentioned by the experts is the effort to enrich the traditional higher education with other experiences such as work-based experiences, and work integrated education. Another trend that was brought up was the request for shorter courses, smaller modules or so-called micro credentials. There were also comments on MOOCs and non-credit offerings, and that these already are pushing the boundaries between academy and industry, with

the aim of employability and 'job readiness'. An advice from an expert was to "*Be clear about the added value of education in the context and meaning of lifelong learning. Re-define what educational institutions are in the context of emerging corporate training and industry academies"*. Another given advice was *about "favoring the integration of practice into training, such as, internships in companies or in the industry, projects carried out in partnership with industry and joint supervision between university faculties and professionals"*, with the idea of a *"focus on both the development of the canonical knowledge required, for instance a set of occupational capacities, but also some variations of how that knowledge will be applied, for instance in a particular workplace setting."*

Moreover, there was several remarks on the importance of opening up the university to a hybridity where the professional development and lifelong learning are built around the evolving needs in companies and societal organisations. A constantly evolving field mentioned in the interview answers is healthcare, with a need for continuous lifelong learning, involving the fact that *"healthcare workers must keep up to date with this new knowledge, and must quickly integrate it into their practices''*. The expert panel recommendation was to build courses around *"These kinds of activities that individuals face every day in their working life, and having the capacities to respond to them both those that are routine and those that are none routine"*. Panel experts point out many challenges in the transition of lifelong learning, but there is also answers with positive expectations and of hope that *"the deeper structures and values of lifelong learning as well as the long history of how to do technology-enhanced learning in ways that foster human flourishing, learning fulfilment and worth-while fusions of academic and professional development*".

To foster this human flourishing the expert recommendation was to involve both the aspect of lifelong education for improved employability, and lifelong learning for personal development. This should be "thought about in ways that encompass the whole life course", comprising the idea of enriching participants daily life and to empower participants. These two aspects should be combined, and as expressed by one of the experts: *"on the one hand, functional lifelong learning in the form of upskilling with a focus on socio-economic value, and, on the other hand, personal lifelong learning in the form of 'life-world becoming'"*. Finally, experts raised the idea of a human centred lifelong learning, and: *"putting human flourishing before efficient or smart tech set-ups, worth-while learning before technological upskilling of the workforce the deeper purpose of lifelong learning before the construction of massive technology-enhanced lifelong learning courses*".

To outline a continuous lifelong learning that is not only about professional development and employability is also the recommendation by Boyadjieva. and Ilieva-Trichkova (2018), a publication that was part of the earlier mentioned reading assignment.

6.4 Results from the Confirmatory Coding

In the beginning of this phase the aspects in Figure 2 were discussed among the authors in online meetings. An emerging idea was that all the categories around 'Higher education transformation for lifelong learning' could be classified as 'Infrastructure'. This idea was later confirmed in the coding, and that 'Infrastructure' was one of the largest and dominating categories early in the Open coding. In the Axial coding 'Infrastructure' was aggregated and presented as below.

6.5 Infrastructure

The transformation of higher education for lifelong learning seems to be clearly dependent on the transformation of the overall infrastructure. According to one of the panel experts this should be developed as an "open learning environment where new formats, forms and formations emerge". Another expert's opinion was to *"Hybridizing learning experiences and interactions through opening up learning environments for the public"*, with the lifelong learners *"participating in courses with people in different roles, contexts and localities or having institutions that are open to all and offer valuable knowledge or products for the public"*. An ongoing transition at several universities in many regions of the world. However, as one of the experts pointed out, this could be met with *"the idiotic but often repeated claims that university education hasn't changed since the middle-ages"*. Attitudes are different in different parts of the world, and many politicians and policy makers in other continents could have the diametral opinion to *"In Australia, we had a prime minister asserting that only face-to-face classes really 'count' as education; 'screen time' is wasted time"*. There are certainly some identified advantages with technology enhanced learning, and an expert highlighted the global aspect of *"Educational provision for international students interacts in an interesting way with use of online/blended learning"*.

Other possibilities with a user-friendly technology enhanced redesign of the infrastructure could be what one of the experts expressed as the "*development of a computed curriculum and further automation of the delivery of*

education", and that this could *"likely further increase in the area of educational consumption and supply driven individualised learning pathways"*. In all transition, the aim must be to combine de desired individualisation and accessibility with new forms of collaborative learning based on, what was brought up in an answer as *"technological systems and tools to technology-enhanced learning communities"*. The main objective ought to be what an expert expressed as to *"foster technology-enhanced places for lifelong learning that 'vibrates' and make learners flourish"*. Several experts mention that ongoing technology enhancement, and the general digitalisation of society definitely will change the way higher education is outlined and practised. One of the interview answers brings up the OECD vision from 2020 for education systems in the future. An expert vision involves four alternative scenarios: schooling extended, education outsourced, schools as learning hubs, and learn-as-you-go. Each of these sketched scenarios would require infrastructural changes, where the expert sees that:

> *"The first two scenarios would require less transformation of the school system, while the latter two would require greater change in how we design and deliver education — and unless institutions are able to adapt agilely to this change, other providers will step in to fill the gap"*

'Infrastructure' is depending on 'Quality and organisation' with the two subclasses of 'Pedagogical change' and 'Multimodal delivery'. A hasty and careless transition could result in lower quality and an organisation that would not benefit either learners or teachers. Furthermore, there is a dependency on 'EDI – equity, diversity, and inclusion' and its two subclasses 'Accessibility' and 'Digital literacy'. Finally, as depicted in Figure 3, all infrastructural categories are depending on 'Financial aspects'.

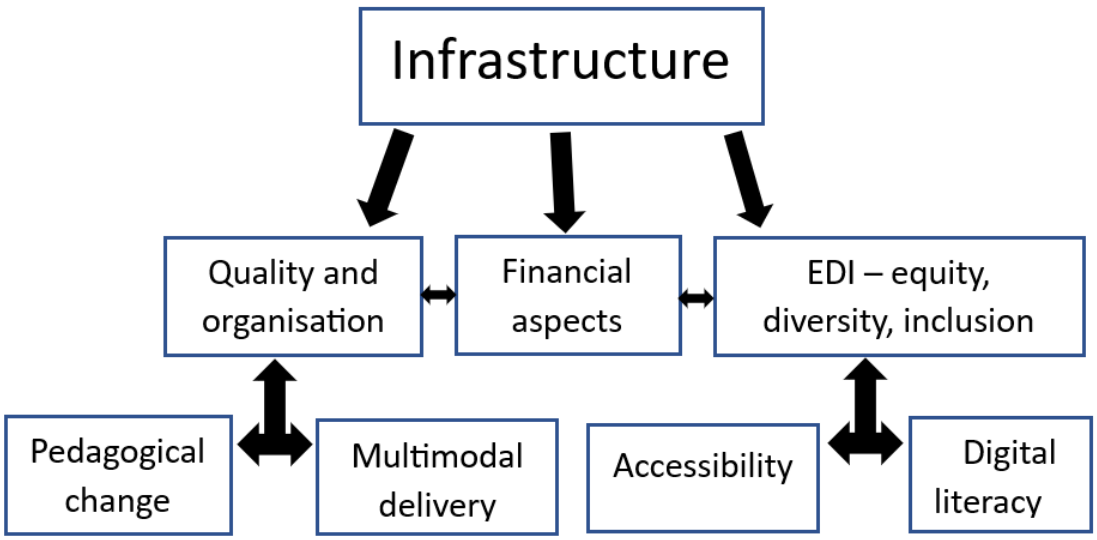

Figure 3: Important Aspects of a New Infrastructure for Continuous Lifelong Learning

7. Conclusion

To answer the questions posed in the end of the method chapter "What seems to be going on here?" and "What is the research all about?". The transition of higher education for continuous lifelong learning has started and is an ongoing process, and the umbrella phenomenon that needs attention is a transformed infrastructure adapted to the need for a continuous lifelong learning for all. A quality transformation will not be for free, but probably with a decent return on investment in the longer perspective. The categories and their interdependencies in the presented conceptual model align to the Anna Karenina principle: "success in complex undertakings does not depend on a single factor but requires avoiding many separate causes of failure" (McClay and Balciunas, 2005, p. 197). A happy and healthy continuous lifelong learning in higher education, depends on a successful transformation of all the involved aspects. All in all, this leads to the Tolstoyan conclusion that every variation of failing attributes in this relationship would result in its own state of unhappiness, and in this case dysfunctional lifelong learning.

8. Future work

With the Grounded theory idea of developing hypotheses and theory, the results from this study should be further elaborated in Step 4 and the Post-step of this Delphi study (see Table 1).

Abstract: Despite the significant role of family firms in economies throughout the world, their academic research is relatively young. Furthermore, previous empirical studies in the field have focused on general topics, rather than examining how family firms are similar or different from other types of organisations in the decision-making process. Little is known about what drives family firms to implement environmental concerns in their strategies. Based on the above-mentioned findings, the research aims to analyse what the main drivers of environmental responsibility are in family firms in Central and Eastern Europe (CEE) countries. The empirical study uses logistic regression that examines how selected important factors influence the adoption of strategic objectives that mention environmental or climate change issues. The study uses a data set from the World Bank Enterprise Survey 2019 and examines the attitudes of family businesses in four CEE countries (Czech Republic, Slovak Republic, Poland, and Estonia). The findings revealed a significant influence of the environmental manager, the customer's environmental requirements, and the energy performance standards on adopting strategic environmental objectives in family companies. We also consider the environmental manager as a key factor in terms of knowledge transfer and management of environmental responsibility in the firm. The results of this research provide a new perspective on the environmental responsibility of family businesses and explain which drivers should be considered when deciding to establish strategic objectives related to environmental issues. Managers should take these findings into account when deciding which tools to use to increase pro-environmental behaviour and implement environmental strategies.

Keywords: Environmental strategy, Family firms, Knowledge management, Drivers, Environmental manager

1. Introduction

The concept of sustainable development has been at the forefront of global discourse since 1987, when the World Commission on Environment and Development published its report "Our Common Future" (Brundtland, 1987). In recent years, this push for sustainability has put pressure on businesses to behave in a responsible and sustainable manner, which is often at odds with shareholder objectives (Barnea and Rubin, 2010).

Previous studies have found that family businesses with diverse values are more likely to innovate and adopt sustainable practices than businesses with homogeneous values (Giachetti and Marchi, 2015). Additionally, research has shown that family businesses are more concerned with environmental responsibility issues than other types of firms (Ludeke-Freund and Dembek, 2017). Ultimately, family firms have the potential to contribute to the Sustainable Development Goals (SDGs) given their commitment to long-term sustainability and their focus on stakeholder relations (Cheng and Krumwiede, 2012). Although research in this area is still lacking, evidence suggests that family firms can be at the forefront of sustainable development efforts.

The existing literature on the factors that lead family businesses to introduce environmental aspects into their strategies has been significantly influenced by developments in Western countries (USA, Canada, Western European countries). A gap in existing research can be seen in the lack of published studies on family businesses in the transition economies of Central and Eastern Europe (CEE) countries (Duh, Tominc and Rebernik, 2009).

The contribution of this paper is the identification of factors that influence environmental responsibility and can serve for the successful implementation of environmental strategies in family firms in CEE countries. The empirical study is framed under the umbrella of knowledge management, since knowledge management has a long-term orientation, it fits well with sustainability and sustainable management (Chow and Chen, 2012).

This paper has been divided into the following parts: the second chapter provides theoretical background, chapter 3 presents the data and methodology, and chapter 4 shows the empirical results and describes the discussion of results. The last chapter considers conclusions and limitations.

2. Theoretical Background

2.1 Environmental Responsibility of Family Firms

Family businesses are an increasingly common form of entrepreneurship around the world. According to a survey conducted by PricewaterhouseCoopers (PwC), family businesses account for 85% of all businesses

worldwide and generate more than 70% of gross domestic product (GDP) (PwC, 2018). With the growing number of family businesses, it is important to research and address these issues so that family businesses can maintain their competitive advantages and survive in the marketplace.

One of the key advantages of family businesses is strong family ties and loyalty, which translates into long-term strategy and greater stability of the business (Hussain et al., 2017). Another advantage can be seen in flexibility and quick adaptation to market changes (Jaskiewicz et al., 2017). On the other hand, these family ties can lead to conflicts and unprofessional behaviour, especially when a new generation joins the leadership of the firm (Dawson et al., 2017; Berrone et al., 2012). It is important to ensure adequate preparation and training of potential successors so that they are able to take over the leadership of the firm without major problems (Miller and Le Breton-Miller, 2017).

Brundtland (1987) emphasizes the principles of sustainability and environmental protection in economic development. Shareholders prioritize profit maximization and increasing shareholder value, while corporations face pressure to be responsible and sustainable (Barnea and Rubin, 2010). Family firms may have higher levels of environmental responsibility than non-family businesses due to their long-term focus and nurturing of customer and community relationships (Cheng and Krumwiede, 2012). Many authors agree that family firms are more concerned with environmental responsibility issues than other types of firms (Ludeke-Freund and Dembek, 2017; Giachetti and Marchi, 2015). Craig and Dibrell (2015) observed that environmental sustainability and a positive attitude towards innovation positively affect firm performance.

However, the impact of family involvement on environmental responsibility can vary depending on cultural and institutional factors (De Massis et al., 2018). Bianchi et al. (2018) noted that family involvement in the role of CEO or chairman is significantly related to environmental responsibility. Family businesses can play a significant role in addressing environmental issues and promoting sustainable development, but research in this area is still lacking (Rondi and Tognoni, 2018). Díaz-Garcia and González-Márquez (2019) found that family influence, organisational culture, stakeholder pressure, and resource availability can affect innovation in sustainability of family firms. Patuelli et al. (2022) suggest that family companies have the potential to contribute to achieving SDGs, considering their commitment to long-term sustainability and their focus on stakeholder relationships.

2.2 Role of Different Stakeholders in the Implementation of Knowledge Management in Environmental Responsibility

It is known that strategic commitment and integration of sustainable aspects into the existing business system and corporate strategy is necessary to enhance the environmental benefits of a company's operations (Evangelista and Durst, 2015). Sandberg and Aman (2010) also argue that organisational learning is a key element for achieving competitive advantage based on environmental responsibility. Knowledge management can be seen as crucial to achieving sustainability goals (Gloet, 2006; Robinson et al., 2006) and to developing environmentally sustainable strategies (Evangelista and Durst, 2015).

The issue of environmental responsibility cannot be dealt with by just one body. This means that companies must seek to involve other stakeholders to increase the success of any environmental activities. As knowledge management should not only have an internal focus, companies should also consider how best to involve different stakeholders in the knowledge management approach to improve the effective use of existing and future knowledge (Evangelista and Durst, 2015). Given the interconnectivity of the economic, environmental, and social issues that form the pillars of sustainability, organisations must adapt to even greater involvement of different stakeholders (Van Kleef and Roome, 2007). Stakeholders can be viewed not only as internal or external, but also as primary and secondary (Sarkis et al., 2010). Primary stakeholders (shareholders and investors, employees, customers) are essential to the survival of the business (Helmig et al., 2016); secondary stakeholders (central government, local government, and pressure groups) have influence on the implementation of environmental responsibility through regulation and other sanctions to create and maintain a safe environment (D'Souza et al., 2022). Implementing environmentally sustainable practises can help organisations improve stakeholder relations (Singh and Mittal, 2019). Korsakienė and Raišienė (2022) state that the influence of stakeholder groups differs between firms, sectors, and countries, and future research could focus on understanding different stakeholders and their impact on environmental responsibility.

On the basis of the above-mentioned, a research question was determined: What are the main determinants of environmental responsibility in family businesses in CEE countries?

3. Data and Methodology

This study uses data from the World Bank Enterprise Survey (WBES) 2019, which provides firm-level cross-sectional data from a representative sample of companies in the private manufacturing and service sector. The survey covers a wide range of topics related to the business environment, including access to finance, environmental issues, corruption, infrastructure, competition, research and development, knowledge, performance measures, and others.

The research is based on a multi-industry sample of 1,176 family firms in the transforming economies of CEE, Czech Republic, Slovakia, Poland, and Estonia. These countries have gone through similar developments since the 1990s, and some studies suggest that family businesses are becoming the main driving force behind economies in former socialist, or transition, countries (Dana and Ramadani, 2015; Duh et al., 2009; Duh and Tominc 2005; Galetic 2002).

The family business field has traditionally employed several definitions of family firms (Miroshnychenko et al., 2022; Duh et al., 2009; Chua et al., 1999; De Massis et al., 2012), and there is no generally accepted definition of a family business in either developed economies or transition countries. For the purpose of our research, we rely on definitions (European Commission, 2009) that simultaneously capture family ownership and the presence of family members in firm management positions. Thus, we consider a family-owned firm to be one where more than 50% of the firm is owned by a single family, and at the same time more than 10% of key managerial positions are occupied by family members.

As the explained variables are dichotomous (binary; 1: yes, 0: no) for the estimated model, we used a binary logistic regression, that examines how selected important factors influence the adoption of strategic objectives that mention environmental or climate change issues.

For the dependent variable, a question was chosen from the Green Economy Module of the WBES, which determines whether the company had strategic objectives that mention environmental or climate change issues. Successful integration of environmental concerns into corporate strategy cannot be achieved without clear leadership, resource allocation and active support from top management (Fugate et al., 2012). The absence of strategic objectives for environmental and climate change issues and related strategies is likely to have a dual impact on the enterprise, i.e. externally and internally. It may lead to difficulties in terms of informing employees about the environmental stance of the business, as well as managing and structuring environmental work within and across the business (Evangelista and Durst, 2015).

The independent variables are divided into two groups, primary and secondary stakeholder pressure. Primary stakeholders include employees, customers, suppliers, and shareholders in the research, and secondary stakeholders mainly include government, local government, and pressure groups (D'Souza et al., 2022; Hillman and Keim, 2001; Maon et al., 2009).

Table 1: Description of Variables

Variable name	Notation	Variable Definition
Dependent variable	DV	
Strategic objectives for environmental and climate change issues.	Strat_obj	
Independent variable	IV	
Primary stakeholder pressure		
Environmental Manager	Env_manager	Existence of a manager responsible for environmental and climate change issues.
Meetings with the top manager	Engag	How often does the top manager meet with employees involved in production activities in a typical working week?
Female owner	Fem_own	There is a woman among the owners of the firm.
Female top manager	Fem_manager	There is a female top manager in the firm.
Market pressure	Mark_pres	A request from any of the customers for environmental certification or compliance with

Variable name	Notation	Variable Definition
		certain environmental standards as a condition for doing business with this business.
Secondary stakeholder pressure		
Energy standard	Ener_stand	The establishment was subject to an energy performance standard in its operations.
Energy tax	Ener_tax	This establishment was subject to an energy tax or levy.
Control variable	CV	
Country	Country	CZE – Czech Republic EST – Estonia POL – Poland SVK - Slovakia

4. Results and Discussion

The results in Table 2 show that it is possible to identify drivers that impact environmental responsibility in family businesses. The greatest influence is the existence of a manager responsible for environmental and climate change issues. His presence increases the chance of environmental responsibility 15 times. This corresponds to Greenwood et al., 2012 who says that environmental managers play an important role in an organisation's pursuit of environmental sustainability. Similarly, Daily and Huang (2001) state that environmental managers must provide adequate training to all employees in terms of reducing negative environmental impacts, since this requires active and knowledgeable participation from all employees at an organisation. In connection with this, Šperková and Skýpalová (2020) state that employees, especially the Y generation (born in the 1980-90s), have begun to require more employer activity in the field of corporate social responsibility. This result is also consistent with the findings of Jang et al. (2017) who report that environmental managers prioritise environmental issues when developing strategies and operational procedures and incorporate environmental stakeholder demands into corporate strategies.

Table 2: Results

Then, a request from any of the customers for environmental certification or compliance with certain environmental standards as a condition for doing business with this business increases the probability by about 2.27 times. This is confirmed by Johnstone and Labonne (2009), who state that customers, if they do not have enough information about suppliers, may choose to purchase goods from firms that have Environmental Management System certification. In the area of customer satisfaction measurement, companies do not focus only on past performance, but seek a comprehensive understanding of their customers' needs and attitudes (Striteska and Jelinkova, 2015). In the context of growing concerns about the quality of the environment, customers have started to put pressure on companies to address the environmental impact of their activities (e.g. Henriques and Sadorsky, 1996; Buysse and Verbeke, 2003; Horbach, 2008; Delmas and Montiel, 2009; Guoyou et al., 2013). As part of their research by Canadian companies, Henriques and Sadorsky (1996) confirmed

that the adoption of an environmental plan is positively influenced by customer pressure. Buysse and Verbeke (2003) and Guoyou et al. (2013) observed that pressures from customers motivate environmental proactivity. Khanna and Anton (2002) found that firms that are more exposed to consumer pressures to their environmental performance are more likely to adopt a comprehensive environmental management system. Researchers (Rueda-Manzanares et al., 2008; Carballo Penela and Castromán-Diz, 2015; del Mar Miras-Rodriguez, 2018) point out that general awareness and interest in the environment are growing among customers, who are increasingly taking environmental factors into account in their purchasing decisions. Although the authors of empirical studies do not always show identical results, most of them have agreed on the importance of customer pressure on environmental responsibility (Carballo-Penela and Castromán-Diz, 2015), which is in line with our results.

Similar results to the influence of customers are achieved by the influence of the energy performance standard, which increases the chance of environmental responsibility in family firms by 2.2 times. This result agrees with D'Souza et al. (2022), who report that governments are influential in implementing environmental responsibility using energy performance standards and other regulations to create and preserve a safe environment.

Similarly, the variable of the female owner also appeared to be significant, increasing the probability by more than 1.5 times. Similar results were obtained in empirical evidence that suggests (Nadeem et al., 2020) that women on boards are associated with better corporate social responsibility ratings (Bear et al., 2010; Nadeem et al., 2017; Post et al., 2011) and that female representation on corporate boards is considered a significant determinant of corporate policymaking (Levi et al., 2014; Mohan, 2014). Nadeem et al. (2020) also found that female representation on boards is positively associated with the creation of environmental values in family firms, but it has no impact on the creation of economic and social values.

Regarding our control variables, we show that the differences between the examined CEE countries are also significant. Our model shows that the countries that are the least likely to adopt strategic environmental and climate change goals are Estonia and Poland, which are basically the same. This is followed by the Czech Republic, where there is about 1.5 times more chance than Estonia (and Poland), which is not significant. In Slovakia, there is almost 3.5 times greater chance than Estonia (and Poland). In Slovakia, there is a significantly higher chance than in the Czech Republic, about 2.3 times.

Other variables (Female top manager, Meetings with the top manager, Energy tax) are no longer significant (at level α=0.05) in this model.

5. Conclusion

This paper reveals the relationships between the variables examined that may serve to successfully implement environmental strategies through knowledge transfer and provides new insights into environmental behaviour through the lens of family business. Using the logistic regression method, we identified the determinants that influence environmental responsibility in family firms in selected CEE countries. We found that the presence of a manager responsible for environmental issues increases the chance of environmental responsibility 15 times. We also found that customer demands for environmental compliance increase the likelihood by 2.27 times, and the influence of energy performance standards increases the chance of environmental responsibility in family firms by 2.2 times. The presence of a female owner still emerged as a statistically significant variable, increasing the odds by more than 1.5 times. The other variables examined do not have a statistically significant effect on the dependent variable.

The benefits of this research are that the results provide a new perspective on the environmental responsibility of family businesses and explain which factors should be considered when deciding to set strategic goals related to environmental issues. The findings of this study have several applications for family business owners, managers, and policy makers in other transition countries. Managers should take these findings into account when deciding what tools to use to increase pro-environmental behaviour and implement environmental strategies. The presence of an environmental manager has been found to increase the likelihood of adoption of environmental sustainability programmes. From this perspective, employee education and training plays a vital role in the creation and development of environmental knowledge both inside and outside of the company. Therefore, it is important for managers to focus on training and education programmes that anchor environmental sustainability thinking in the minds of employees. The expected benefits that knowledge management can bring to the field of environmental responsibility open up the potential for researchers from different disciplines.

This study has its own limitations as well, which in turn provide an opportunity for future research. First, our study is based on a sample of firms from selected CEE countries, whose historical development after 1990 is similar. A further study could be extended to other post-communist countries. Second, the study does not consider the effect of company size. Further research could focus on the determinants of environmental responsibility in small and medium-sized enterprises and large enterprises. Third, it would be interesting to carry out research to compare the behaviour of family and non-family firms in terms of environmental responsibility issues. To conclude, more input variables can be added, and a different analysis method can be used in the future.

Knowledge Sharing and Lean Manufacturing in Companies: An Empirical Investigation

Justyna Maria Myszak
Department of Logistics, Institute of Management, University of Szczecin, Poland

justyna.myszak@usz.edu.pl

Abstract: Manufacturing companies seeking to be competitive in the market must, in particular, accomplish time saving through precisely planned production processes. One of the main routes to reaching higher production efficiency is Lean Manufacturing (LM) by way of the methods and tools that it brings. However, the key to successful implementation of LM is the employees' approach to knowledge sharing, an essential component for continuous improvement. This paper is an empirical study whose purpose is to answer the following question: Is knowledge sharing more widely adopted (and if so, how exactly) by companies who have implemented Lean Manufacturing, compared to those who have not? As a result of literature studies, six types of knowledge sharing were identified, related to the way knowledge is shared (formal and informal knowledge sharing), knowledge sharing strategies (codification and personalization strategies) and the scope of knowledge that the company focuses on in its core business (broad and deep knowledge). The relation between the use of LM and knowledge sharing types was examined based on a questionnaire survey conducted among 219 small, medium and large manufacturing enterprises operating in North-West Poland. The data analysis was performed using the ANOVA and post hoc tests. The results demonstrated a significant correlation between the companies' use of the Lean Manufacturing concept and certain types of knowledge sharing. In particular, it was observed that, compared to the other companies, the companies showing wider use of LM practiced formal ways of knowledge sharing, used the knowledge codification strategy, and were more focused on development and dissemination of broad rather than specialized knowledge. The results also demonstrated that the knowledge sharing approach adopted by the companies was largely determined by other approaches and management methods. It also means that the processes related to knowledge sharing are components of Lean Manufacturing solutions applied in practice.

Keywords: Knowledge sharing, Lean manufacturing, Production companies, Formal and informal knowledge sharing, Codification and personalization strategies, Broad and deep knowledge

1. Introduction to Lean Manufacturing (LM)

Manufacturing enterprises operating in a highly competitive market have noticed that offering high-quality products with higher performance and shorter delivery lead times than competitors while reducing operation costs may become a key to their success. However, such measures have forced companies to seek far more flexible processes and a larger variety of products, which in turn has generated various wastes in the manufacturing processes (Cortez et al, 2020). An effective solution to these problems seems to be the Lean Manufacturing concept (Nallusamy, 2021).

Lean Manufacturing is a methodology of production management, which consists in proving value that is expected by the customer. From the customer perspective, value (in LM) is understood as everything for which a customer is willing to pay (Rodríguez et al, 2012). This refers for example to a physical process which actually transforms a product or service (e.g. welding, assembly) or to an activity done according to the "first time right" concept (i.e. flawlessly). However, any other activities which directly do not add value to the offered product or service are considered by the customer to be wasteful. Therefore, to meet the customer's demanding expectations, manufacturing companies seek the highest possible production efficiency which is obtained via continuous optimization of the manufacturing process by reducing redundant activities. Hence, Lean Manufacturing focuses primarily on reducing 7 wastes (*muda* in Japanese) from all company processes, such as: overproduction, inventory, defects, waiting time, transportation, motion and excess processing (Ohno, 2008).

What is interesting, since only recently the literature on the subject has been enumerating one more waste: non-utilized human talent or potential. The reason for earlier disregard of this waste among the 7 cardinal *muda* can probably be attributed to the Japanese culture. As suggested by Nicholas, for the Japanese, or more precisely the Toyota Motor Company, for a long time, recognizing employees as its most valuable assets and encouraging them to learn, develop their skills, and to engage in process-improvement activities (Nicholas, 2018) is something natural.

It is therefore worthwhile to view Lean Manufacturing from a wider perspective. On the one hand, LM is a concept of an approach to business operations management focused on improving the processes and taking measures aimed at elimination of redundant activities. On the other hand, LM emphasizes the importance of knowledge and skills of the people employed in the organization. Hence, it may be concluded that LM shows a

somewhat more extensive approach to business management, which contains elements of other concepts, e.g. knowledge management. An ability to gather and apply appropriate resources of knowledge and information plays an invaluable role in manufacturing companies (Berawi, Woodhead 2005; Cortez et al, 2020), hence this issue is an important focus of this study.

2. Knowledge Sharing (KS) in Lean Manufacturing Contexts

Although there have been many independent studies on Lean Manufacturing and knowledge sharing in organizations, "studies that integrate lean thinking in dynamic knowledge research are still absent in the literature" (Tyagi et al, 2015). When analyzing the existing body of research related to knowledge management in Lean Manufacturing implementation, Zhang, Niu and Liu (2020) noticed that among 341 full-text academic articles from Science Citation Index Expanded, only 65 were empirical. Moreover, amongst them only nine articles were related to Knowledge Management. Furthermore, it is worth noting that the issue of knowledge in the Lean Manufacturing context was usually addressed in relation to the overall concept of Knowledge Management, and only in few cases in relation to the SECI model (e.g. Nordin et al, 2020, Tyagi et al, 2015, Lindlöf, Söderberg, Persson, 2013) authored by Nonaka and Takeuchi, which focuses on conversion of explicit knowledge into tacit knowledge (Nonaka, Takeuchi, 1995). Hence, a research gap was identified in the literature, as there are no research studies focused on selected processes of the knowledge management concept (i.e. the process approach) in the lean context, including i.a. the knowledge sharing process. Consequently, this paper is an attempt to bridge this gap.

Dombrowski et al (2012) claimed that "the development of a detailed reference model of knowledge flows is not possible so far, because Lean Production Systems implementation offers too many possible knowledge flows". Moreover, they added that in such a case it might be worthwhile just to identify adequate methods for single knowledge flows. Also Babaei Meybodi et al (2018) drew attention to the fact that "the majority of the lean production execution processes explain sequences of required works, but they fall short of taking knowledge blending into consideration". In view of the above, an interesting proposal of such a solution was presented in the study completed by Tyagi et al (2015) who indicate a specific list of lean tools/methods supporting the knowledge generated in SECI models. One of the findings of their analysis was that Scrum, PDCA, and the 5 Whys can fit and support knowledge creation and sharing mechanisms in every SECI model.

Vlachos et al (2019), in turn, found out in a single-case study analysis that knowledge sharing plays a key role when an organization wants to transform from the traditional to Lean Management. However, the authors stressed the need to depart from the more operational view of lean to a "softer" paradigm.

Also Zhang et al (2020) noticed that adoption of lean tools had a positive impact on knowledge acquisition, knowledge integration and knowledge application. The authors also noticed that knowledge is an indispensable factor in the application of lean tools. Due to the special importance of knowledge in Lean Manufacturing implementation, the following section deals with the definition of knowledge sharing and different approaches to it.

3. Knowledge Sharing in an Organization

In the literature on management, the term "knowledge sharing" is very often used interchangeably with "knowledge transfer". However, it should be noted that many researchers increasingly oppose to taking this approach and propose that these terms be distinguished from one another. For example, Cavaliere and Lombardi (2015) pointed out that "while knowledge transfer describes the identical or partial replication of knowledge from one place to another, knowledge sharing is more than transferring knowledge: it is about creating it through social interaction". Moreover, King (2006) underlined that knowledge may be shared in unintended ways (around a specific issue or otherwise), and, as knowledge sharing is a multi-directional process, usually there is no clear, a priori goal. A knowledge transfer, in turn, implies focus, a clear objective, and unidirectional communication of knowledge between individuals, groups, or organizations such that the recipient of knowledge has a cognitive understanding, has the ability to apply the knowledge, or applies the knowledge (King, 2006). Summing up: as opposed to a knowledge transfer, knowledge sharing focuses strictly on individuals (in particular on the knowledge sharer) and social interactions, and it concentrates on the mechanisms and practices of knowledge communication. It therefore entails the need to create appropriate conditions to entice employees to make decisions on communicating their personal knowledge, whereas in the case of a knowledge transfer more focus is laid on the knowledge recipient, i.e. whether the transferred knowledge has been effectively received. Therefore, in research on knowledge transfers it is important to pay attention to absorption capabilities and specificity of the recipient (Rudawska 2013).

4. Approaches to Knowledge Sharing

The literature on knowledge management comprises many research studies on various approaches to knowledge sharing in an organization. The studies most often show the approach using two independent, opposite types of knowledge sharing (Figure 1), characterized by specific features. Moreover, even though the scope is increasingly explored, it still has not been systematized.

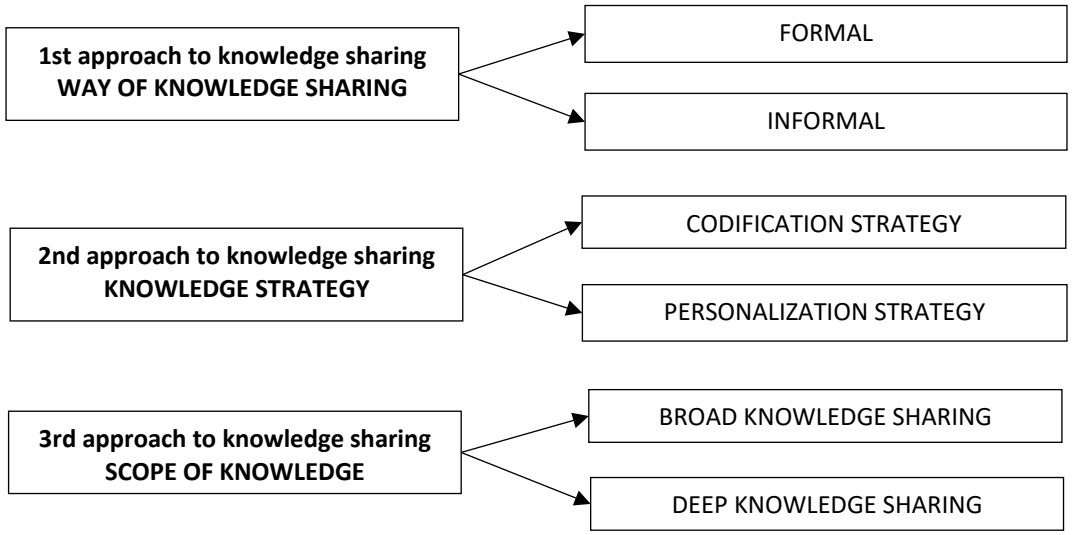

Figure 1: Approaches to Knowledge Sharing in Organizations

Each approach, including each type of knowledge sharing, has a different impact on employee behavior in the organization. In view of the above, the next section outlines various types of knowledge sharing.

4.1 Formal and Informal Approach to Knowledge Sharing

Formal and informal knowledge sharing refers to the situation and circumstances in which employees exchange knowledge among each other. A formal approach to knowledge sharing encompasses behaviors that are institutionalized by management by creating specific opportunities that enhance and enable knowledge exchange. These are practices (e.g. procedures, instructions, regular meetings, brainstorm sessions) and services (e.g. communication and resource sharing platforms), that have been designed and organized by the company in such a way that knowledge sharing or organizational learning occurs in a systematized way (Taminiau et al, 2009). Thus, these take the form of certain practices developed by the organization, which designate areas and channels of interaction as well as its frequency.

In turn, informal knowledge sharing encompasses all forms of knowledge sharing "by which individuals communicate on issues that are not directly laid down and governed by management" (Schwaer et al., 2012). These are resources (e.g. meeting room), services (e.g. chats, telephones), and activities (e.g. casual face-to-face conversations) (Taminiau et al, 2009). Employees voluntarily engage in these types of actions for the purpose of knowledge exchange, at the time and in the form that are the most suitable for them. It is a knowledge sharing system that often emerges ad hoc within an organization.

Rudawska (2019) noted that informal and formal mechanisms of knowledge sharing compete with each other, as according to her "while the informal mechanisms are used in current problem solving, the formal ones help create shared knowledge, develop a common language and the *who knows who* knowledge map". It is also worth noting that the formal and informal types of knowledge sharing should blend with the adopted knowledge management strategy, for that reason the second approach was identified.

4.2 The Strategy for Knowledge Codification and Personalization

Hansen et al (1999) distinguished two knowledge strategies, namely codification and personalization. The knowledge codification strategy refers to the development of the electronic system that enables knowledge codification, storage, dissemination, and reuse (the "people-to-document" approach). In this strategy, the knowledge of how to work or how to behave in a specific situation is well-defined and it is shared in the formal way. In view of the above, employees know which documents they should use, where they can find them quickly

(easy access) and they remember to regularly document their work progress (storage). The codification strategy will therefore be applied in organizations that offer standard products and/or services, i.a. mass production, but also products that in fact are based on standardized components, e.g. Dell (Hansen et al, 1999).

The personalization strategy "seeks to capture and share tacit knowledge that resides in human minds, behavior, and perception" (the "person-to-person" approach) (Chang, Yen, 2019). In this strategy, knowledge is mainly obtained from experienced and qualified co-workers, and also via face-to-face help provided by experts (Choi, Lee, 2003). The strategy consists in obtaining and sharing tacit knowledge first and foremost via informal social interactions (Choi, Lee, 2002). The personalization strategy works perfectly in organizations that offer personalized and innovative products and/or services. In this kind of organization, people in search of innovation must share their knowledge that would otherwise "get lost" in the documented form (Hansen et al, 1999).

4.3 Broad and Deep Knowledge

The third approach draws attention to the knowledge scope on which the organization focuses in its core business operations, therefore a distinction was made between broad knowledge and deep knowledge. Broad knowledge "refers to the extent to which the firm's knowledge repository contains distinct and multiple domains" (Zhou, Li, 2012). This means that the enterprise taps into heterogeneous knowledge, which in turn translates into creating more diversified products (Asoh, 2004). Also Yang et al (2016), when analyzing the impact of the knowledge scope on the product efficiency, noticed that due to "broad knowledge covering various areas, a firm can gain new ideas, insights and expertise from multiple disciplines".

The idea of deep knowledge sharing "refers to the level of sophistication and complexity of knowledge in key fields" (Zhou, Li, 2012). Deep knowledge should be understood as homogeneous, complex and unique knowledge in a given area. De Luca and Atuahene-Gima (2007) stated that technical knowledge depth is the amount of within-field knowledge the firm possesses. Hence, as Asoh (2004) pointed out, this type of knowledge sharing applies to more specialized products.

5. Research Methods and Data Collection

In order to collect the research data, a structured and standardized questionnaire was applied. The survey encompassed two interviewing techniques: CAWI (*Computer Assisted Web Interview*) and PAPI (*Paper&Pen Personal Interview*). The survey involved small, medium and large production companies operating in North-West Poland. The reliance of the research on industrial enterprises was due to the fact that this sector employs the highest number of people (both on the national and regional scale). Moreover, the selected kind of business operations is also connected with the complexity of their technological processes that require specific standards of conduct and continuous improvements. Hence, an issue of key importance for them should be developing appropriate attitudes so that employees readily share their knowledge. The survey questionnaire was addressed to persons who manage and/or co-manage the industrial enterprises (i.e. the ones that coordinate other people's work, e.g. production managers). A total of 643 survey questionnaires were distributed and 254 were returned. Finally, 219 correctly completed questionnaires were used for the purposes of the research study (the total response rate amounted to 34%).

To examine the six types of knowledge sharing, 27 measurement items were adapted from the existing scales found in the literature. The tool for measuring the formal way of knowledge sharing contained four statements, based on Willem and Buelens (2007), Wei and Li (2014), and Schwaer et al (2012). A sample item was: "I usually share my experience in a meeting or through other official channels" (Cronbach's α=0.714). The variable regarding the informal way of knowledge sharing was also measured using four statements based on Yi (2009) and Schwaer et al (2012). These included e.g. "I usually spend time in personal conversation (e.g., discussion in hallway, over lunch, on the telephone) with others to help them with their work-related problems" (Cronbach's α=0.741). The tool for measuring the codification and personalization strategies encompassed the total of ten statements, five for each of the knowledge sharing type, based on Choi and Lee (2002), Azyabi et al (2012) and López-Nicolás and Meroño-Cerdán (2011). For the codification strategy, (Cronbach's α=0.884) the statements included e.g. "Results of projects and meetings are regularly documented in my company", whereas in the case of the personalization strategy (Cronbach's α=0.745) e.g. "It is easy to get face-to-face advise from experts in my company". Broad knowledge sharing was measured with five items (Cronbach's α = 0.728) and deep knowledge sharing was measured with four items (Cronbach's α=0.447). In both cases, the statements were taken from the studies by Zhou and Li (2012), Asoh (2004) and Azyabi et al (2012). With regard to broad knowledge, there were statements such as "The company focuses on organizing trainings to support employees in performing multiple tasks", and in the case of deep knowledge - e.g. "The company invests in developing specialized professional

skills". The five-point Likert-type scales were used in the questionnaire, ranging from ''1'' (totally disagree) to ''5'' (totally agree). As for measures in the area of Lean Manufacturing, they were examined in the context of the degree of LM implementation in the given enterprise, therefore the surveyees were asked to select one out of five statements as follows: "I don't know what LM is", "no interest in LM", "preparing for implementation of selected LM tools and methods", "yes, we're applying selected LM tools and methods" and "yes, we fully implemented LM".

The statistical analysis started with examining the validity of the survey questionnaire by means of the Exploratory Factor Analysis (EFA) and Confirmatory Factor Analysis (CFA). The completed analysis at the level of the measurement model verification rejected only one type of knowledge sharing, i.e. deep knowledge (which did not meet the criteria of convergent and discriminant validity). Next, for all the statements which were not rejected as a result of CFA, an analysis of measurement reliability was conducted applying Cronbach's α, standardized α, and Composite Reliability (CR).

Table 1: Reliability Measures for the Measurement Model

Types of knowledge sharing	Cronbach's α	standardized α	CR
Formal approach to knowledge sharing	0.714	0.718	0.728
Informal approach to knowledge sharing	0.741	0.744	0.744
Codification strategy	0.884	0.886	0.786
Personalization strategy	0.745	0.763	0.877
Broad knowledge	0.728	0.731	0.747

As for the five types of knowledge sharing shown in Table 1, all of them met the reliability criteria, i.e. exceeded the assumed threshold value of 0.7 for both Cronbach's α and standardized α (Taber, 2018) as well as for CR >0.6 (Lombardia et al, 2019).

6. Results

In order to show correlations between various types of knowledge sharing and the Lean Manufacturing concept, all the analyses were done with the use of the ANOVA test and the post hoc Scheffe test. The ANOVA (Analysis of Variance) test showed significant relationships between various degrees of engagement in Lean Manufacturing in five types of knowledge sharing, i.e. excluding the informal knowledge sharing. Next, in order to examine the detailed relationships, the multiple comparison test (i.e. post hoc Scheffe test) was performed. The obtained results are presented in Table 2.

Table 2: Types of knowledge Sharing in Relation to Degrees of Engagement in Lean Manufacturing – Results of the Post Hoc Scheffe Test Analysis

	Types of knowledge sharing				
	Formal KS	Informal KS	Codification strategy	Personalization strategy	Broad KS
Engagement in Lean Manufacturing	F=5.910; p=0.000	F=1.871; p=0.117	F=4.413; p=0.002	F=3.517; p=0.008	F=3.746; p=0.006
I don't know what LM is {1}	$\overline{Y}$=2.686{5}	$\overline{Y}$=3.765	$\overline{Y}$=3.219	$\overline{Y}$=3.990{3}	$\overline{Y}$=3.295{5}
no interest in LM {2}	$\overline{Y}$=2.780{5}	$\overline{Y}$=3.760	$\overline{Y}$=3.520	$\overline{Y}$=4.073{3}	$\overline{Y}$=3.250{5}
preparing for LM implementation {3}	$\overline{Y}$=2.542{5}	$\overline{Y}$=3.740	$\overline{Y}$=3.117{5}	$\overline{Y}$=3.458{2; 4}	$\overline{Y}$=3.417
yes, selected LM tools {4}	$\overline{Y}$=3.146	$\overline{Y}$=3.776	$\overline{Y}$=3.676	$\overline{Y}$=3.985 {3}	$\overline{Y}$=3.561
yes, fully implemented LM {5}	$\overline{Y}$=3.733{1; 2;3}	$\overline{Y}$=3.250	$\overline{Y}$=4.040{1; 3}	$\overline{Y}$=4.000	$\overline{Y}$=4.067{1; 2}

Note: {1,2,3,4,5} – significant difference between groups based on post hoc test p<0.05

It was found that the enterprises which had fully implemented LM tools and methods were characterized by a far more formalized approach to knowledge sharing ($\overline{Y}$=3.733) compared to the companies that were still preparing for LM implementation ($\overline{Y}$=2.542), were not interested in the concept ($\overline{Y}$=2.780) or did not know about LM ($\overline{Y}$=2.686).

Moreover, the companies that had fully implemented Lean Manufacturing used the codification strategy to a greater extent ($\overline{Y}$=4.040) than the enterprises still preparing for LM implementation ($\overline{Y}$=3.117) or those not knowing what Lean Manufacturing means ($\overline{Y}$=3.219).

In turn, among the enterprises which were not interested in LM, the knowledge personalization strategy was applied to a greater extent ($\overline{Y}$=4.073) in comparison with the companies that were still preparing for LM implementation ($\overline{Y}$=3.458). The enterprises that had already implemented selected LM tools ($\overline{Y}$=3.985) also used the personalization strategy to a greater extent than the companies that were still preparing for LM implementation.

The data analysis has also shown statistically significant differences in the extent of knowledge used. The enterprises that had fully implemented Lean Manufacturing used broad knowledge more often ($\overline{Y}$=4.067) than the companies that showed no interest in the LM concept ($\overline{Y}$=3.250) or did not know about LM ($\overline{Y}$=3.295).

7. Conclusions

The specificity of industrial enterprises, production processes complexity, and also the ageing society contribute to the fact that nowadays organizations increasingly often take more and more interest in knowledge sharing, and first and foremost in the ability to identify the process within the organization. Each organization has its own, learned and practiced, individual way of knowledge sharing. Nevertheless, the results of this study have shown that companies that had implemented the Lean Manufacturing concept were characterized by a far more formalized approach to knowledge sharing, application of a knowledge codification strategy and use of broad knowledge, compared to the enterprises that were still preparing for LM implementation, did not show interest in LM or did not know the LM concept.

It is worth noting that Lean Manufacturing is a concept connected with measurement, control and continuous implementation of improvements in production processes. In view of the above, companies that have implemented the LM concept will keep striving for unification and replication of the hitherto developed organizational solutions in a formal manner, i.a. communicating the knowledge via reports or exchanging information and best practices within the framework of IT systems adapted specifically for this purpose. Moreover, in addition to providing space for formal knowledge sharing among the employees, organization of regular meetings or teleconferences ensures a specific rhythm of work.

An important role in Lean Manufacturing is played by the knowledge codification strategy which makes it possible to write down the obtained results of meetings, studies, projects, experiences or insights of employees, so that it is feasible to quickly retrieve and standardize them. In production enterprises, collection of data regarding the production process, the process analysis and the ensuing documentation are aimed at “structuring the knowledge and (…) presenting it in an accessible form so that it is comprehensible for all the employees” (Kąkol, 2010). Thus, the strategy of codification of various LM tools prevents the knowledge dispersion e.g. in case an employee suddenly quits the company. What is more, the strategy helps retain the process repeatability, as it makes it possible to write down the detailed knowledge regarding performance of individual operations by employees directly involved in production (e.g. development of standard operating procedures).

It has been further found that broad knowledge is used more than deep knowledge in production companies which implemented Lean Manufacturing. This means, among other things, that enterprises with the implemented LM concept encourage their employees to obtain universal competences and skills so that they are able to work in various positions. Thus, any unplanned absence will not disturb the rhythm of work.

This research study provides information on various approaches to knowledge sharing emphasized by enterprises that have implemented the LM concept. Moreover, the presented data analysis is appropriate and consistent with the idea of Lean Manufacturing. Therefore, from a practical viewpoint, enterprises planning to switch to Lean Manufacturing should pay attention to various possibilities of knowledge sharing and focus in particular on those that are strongly connected with LM, whereas the companies that are already operating in accordance with the LM concept should make sure the said types of knowledge sharing are continuously improved and enhanced, e.g. via creating appropriate corporate policies.

This study has several limitations that also suggest directions for future research. Firstly, the research sample is limited only to companies operating in North-West Poland. In addition to that, the sample firms operate only in the production sector. For this reason, it would be advisable to conduct future research with a research sample based on various sectors from various countries, which would make it possible to carry out comparative analyses and provide a more international perspective to the subject. Secondly, this study was performed only at the organization level and was based on information obtained from key persons in the entities, predominantly the owners and line managers. Future research studies should also be multi-level, which would make it possible to unearth any differences in the types of knowledge sharing at various positions within the organizations. Thirdly, the analyses described herein constituted a part of a larger research project where the Lean Manufacturing concept was not examined in detail. However, the obtained findings have shown there is a research gap in this area.

Viwem@gautrain.co.za

Abstract: The success of Sub-Saharan South Africa's public sector could be deemed dependent on context-relevant knowledge sharing and transfer (KST) frameworks to facilitate knowledge exchange. Knowledge sharing and transfer frameworks which facilitate knowledge management (KM) are still largely influenced by Western research studies, these contributions dominate the field. The extant knowledge sharing and transfer public management frameworks increasingly reflect a predominantly western oriented bias towards objectivist perspectives on knowledge, the alternate practice-based knowledge sharing and transfer frameworks, considered responsive to Sub-Saharan African knowledge exchange problems are under-investigated. This paper thus aims to understand 'what KST framework factors enhance public management in Sub-Saharan South Africa'. The research was designed as a qualitative study underpinned by interpretivist philosophy. Qualitative data were collected from 15 public sector practitioners, using the semi-structured interview technique. Thematic Analysis and Trans Positional Cognition Approach was used to analyse the data collected. The findings from this study yielded four themes namely, Unique antecedent performance factors; Human performance factors; Organisational performance factors and Continuous learning performance strategies. Rahman's knowledge sharing and transfer conceptual model was adopted as a theoretical framework and used to better understand the findings of this work. Applying the theoretical framework, we note elements within Rahman's model could be deemed more applicable in a Western context as it only confirmed two of the study's four findings. We therefore propose the output of this study as new knowledge within the Knowledge sharing and transfer frameworks' domain. Our contribution is compatible with the Sub-Saharan South African organisational context. The implication of this within context is that KST implementation in sub-Saharan South Africa could deemed bottom up oriented as against the western approach which is top-down. This study thus contributes to a better understanding of KST Framework implementation in Sub Saharan South Africa and provides opportunity for future research work in this field.

Keywords: Knowledge; Knowledge sharing and transfer, South Africa, Qualitative research, Performance management, Performance innovation, Innovation nablers

1. Introduction

Public sector administrators in Sub-Saharan South Africa in recent times have given priority to knowledge transfer partnerships (KTPs), some, in the form of private-public partnerships (PPP) to achieve their knowledge sharing and transfer priorities in public management with their internal research and development units and employees playing leading roles to innovate performance (Fan et al., 2010). Osborn et al (2013) supported this idea, noting that effective public administration of sub-Saharan South Africa, should be underpinned by a well-managed state-based public sector organisation. Agreeing Levinthal & March (1993), postulated that for effective management to happen, there should be contextual congruence between knowledge flow and innovation performance sought devoid of myopia output if the goal of institutional knowledge sharing and transfer is to be met. Therefore, it is inconceivable within context to postulate about effective public management without understanding the factors which facilitate effective knowledge management in the public sector. Massaro et al. (2015) point out that factors which facilitate effective knowledge sharing and transfer in the public sector service, have not been systematically investigated in Sub-Saharan Africa. Glaser et al (2019) further postulated that existing knowledge management practice studies in the public sub-sector like the transport sector is characterised by traditional engineering, and objectivist management approaches. These authors argue this area is over-analysed while practice-based knowledge sharing, and transfer management needs to be studied more deeply, particularly within sub-Saharan African countries context where it is under-researched. It is hoped that findings from this study could provide new understandings of how to better facilitate knowledge sharing and transfer in the public sector through public management practice. Werr (2013) observed that applying knowledge sharing and transfer in its local context would hold the potential of developing interesting insight when it comes to knowledge management more generally.

Using public sector operators in South Africa as a study lens, this work seeks to answer the question; 'what knowledge sharing, and transfer framework factors enhance public management in Sub-Saharan South Africa'. It is hoped that this study contributes new knowledge that will provide opportunity for future research

direction for academician and practitioners. This paper started with an introduction, while the remaining sections include literature review, followed by research methods, presenting the findings, discussion and conclusion.

2. Literature Review

2.1 Effective Public Management in Sub-Saharan Africa

Effective public management is dependent on knowledge as a critical resource, both private and non-profit sectors, including the government, to capitalise on this knowledge, must understand how knowledge like performance innovation is created and shared to be effective (Nonaka and Takeuchi, 1995). A large body of literature produced extensive research on KM frameworks and explanations of knowledge-sharing factors which facilitates knowledge transmission to understand public management practices (Heisig, 2019). These frameworks and factors paid much attention to developed country frameworks, they are over-investigated while Sub-Saharan Africa KM frameworks and their categories of influential success factors is under-investigated. In addition, public administration scholars have not provided clarity on what the term public management and the related concept of New Public Management (NPM) precisely mean. Scholars suggest the concepts deserve closer scrutiny to understand them (Mirit and Vigoda-Goda, 2017). Scholars, Christensen and Laegreid (2011a; 2011b) confirm that the public management literature and public sector organizations understand it to be about the role of political actors with dynamic internal and external relations operating in society (Christensen, Fimreite, and Lægreid 2007). Public sector organizations, Rainy (1990;2009) posits, have specific decision-making capacity because of factors such as political interventions, political constraints, and their diffuse objectives. This traditional definition emphasizes a rational approach to decision-making which is mostly applicable to stable public sector organisations. Though this earlier NPM definition, emphasized inter-organisational management, it did not capture the Sub-Saharan African intra-organisational dimensions, its diversity, institutional instability, and fragmented nature of its public sub-sector. Hood's (1991, 1995) concept of New Public Governance (NPG) has now been incorporated into NPM. According to Osborne (2011), it is less fragmented, the new definition incorporates governance such as knowledge strategy which integrates intra-organisational management processes of public management. The combination of terms is more appropriate to capture the South African diverse nature of public management and its multiple state actors, it offers a lens to understand knowledge management factors which facilitate effective knowledge sharing and transfer in Sub-Saharan South Africa.

According to Nooshinfard and Nemati-Anaraki (2012), the literature has not developed a KM framework to understand the diverse factors which influence knowledge sharing and transfer. This gap is more pronounced in Sub-Saharan Africa, this paper intends to address this gap by exploring the knowledge sharing and transfer factors that enhance public management in Sub-Saharan South Africa, which may result in developing a knowledge management framework for organisations in South Africa which can serve as a roadmap of significant factors for African researchers and managers considering options to foster KM within the context of New Public Governance. In this study, the New Public Management (NPM) approach has been adopted for the GMA investigation, because the dynamism of the new economy of Sub-Saharan South Africa requires an integrated concept of public management so KM professionals should not only create knowledge but must transfer it quickly through knowledge sharing and transfer, to not lag their European counterparts. In addition, the NPM does not treat KM and its enabling factors as technocratic, it is about engaging employees in innovative ways, it's a practice-based approach because it combines both tacit and explicit factors in contrast to technocratic objectivist knowledge practices that suggest knowledge sharing and transfer strategies (tactic and explicit) are binary.

NPM through the application of the practice-based approach is relevant to this study because it could offer this study a further lens to explore and potentially develop a KM framework based on performance innovation enablers to enhance the following public management Sub-Saharan Africa principles: Managerialism: the reduced size government; Decentralization: devolving government functions like the rail to the provincial state level; Efficiency: flexible structures to improve decision-making to benefit service recipients ; Modernised state: restructuring government delivery through a partnership with business.

These principles provide context so knowledge sharing and transfer framework for sub-Saharan South Africa, is derived from African public sector knowledge sharing and transfer practices which continue to modernize the public sector. Given the priority to implement knowledge transfer partnerships (KTPs) in South Africa, a requirement of the new economy, to direct services to outside firms (Weikart, 2001), the framework of

performance innovative factors, must capture soft internal and hard competitive factors which facilitate effective knowledge sharing and transfer.

2.2 KST in Public Sector Management

Scholars Leisink and Knies (2018), suggest definitions vary and there is no clarity on what the term public sector and its domain entail, pointing out that the term public sector does not exist. Bozeman (1988: 2004) supports this view, however, also posits common criteria that can be used to bring clarity to the concept, such as government ownership, sources of funding, and degrees of political control, used to distinguish public and private sector organizations. Scholars have argued public sub-sectors exist, and include sectors such as the transport sector, etc., which are regulated by legislation (Rainey, 2009). The focus of this study sheds light on this under-investigated area of the existing public sector literature on knowledge management, it will examine the antecedent and enabling framework factors which facilitate effective knowledge sharing and transfer in the public sector, in a transport management research setting. While contributions of scholars on public sector studies and its public sector transport management context are extensive in developed markets (Vigar, 2017; Glaser et al., 2019), Bharba (1994) the post-colonial theorist confirms the public sector and its various context setting are under-investigated in Africa, as models from developed countries are often mimicked in emerging markets. The field is preoccupied and focused on more technocratic Western objectivist engineering, centred on the means-end rationality approach to transport management (Vigar, 2017; Glaser et al., 2019). Practice-based approaches to public sector KST transport management is a knowledge gap, worth exploring. Moreover, Glaser et al., (2019) suggest that a shift from Western conventional objectivist transport management to a less technical and more subjective interactive approach is needed.

2.3 KM Theoretical Frameworks Brief Overview

Literature review show various frameworks that exist which explains and provides context for implementing knowledge sharing, and knowledge transfer (Nonaka and Takeuchi 1991; Heisig, 2009; Wang and Noe 2010; Rahman et al.,2018), and many others. These frameworks comprise elements that explains what knowledge sharing and knowledge transfer are. They also enable understanding how these concepts are implemented albeit from a western lens perspective. Of particularly interest is the Rahman postulations about Knowledge sharing presented in their model (see model in figure 1) which highlighted factors such as organisational culture, organisational leadership, organisational structure and organisational commitment with top management support and ICT support as a moderating and mediating factor if knowledge sharing in organisation is to be achieved.

Thus, this study seeks to employ this model as a lens to answer the question, ‘what knowledge sharing, and transfer framework factors enhance public management in Sub-Saharan South Africa’. As this study involve collection of subjective views from public sectors practitioners a qualitative study was used to enable answering the research question.

3. Research Methodology: Data Collection and Analysis

This study designed as qualitative research adopts an interpretivist philosophical approach, it supports subjective views and inductive approach (Saunders et al., 2016; Olekanma and Soomro, 2020; Olekanma, et al., 2022). The study adopted a single case study approach as focus was on South Africa public sector only. Single case study is relevant because it explored the phenomenon in depth in its natural context (Yin, 1984). The study seeks to understand ‘what KST framework factors enhance public management in Sub-Saharan South Africa’. Purposeful sampling was used to interview fifteen public sector practitioners, to answer the research question ‘what knowledge sharing, and transfer framework factors enhance public management in Sub-Saharan South Africa’. Participants were drawn from a single public sector organisation, consent was obtained from participants, before the commencement of this work.

Data Collection

Semi-structured interviews questions were used to collect data from the 15 participants, each interview lasting 45-90 minutes (Creswell, 2013). The questions were open ended to allow the participants to describe their experiences participating in a knowledge sharing and transfer project. Where it is believed that questions were not fully answered prompts were used to elicit further information. Interviews for data collection for this study were stopped when saturation point were reached. The key inclusion criteria were that participants would have participated in successful and failed knowledge exchange projects. They would also have had a minimum of five years of working experience in the KT/KS public sector environment. Analysis of the demographics of

the participants show of the 15 people interviewed, 53% were male while 46% were female, however, analysis of qualifications revealed that 100% held graduate degrees. The reliability and validity of the data was enhanced because of the perspectives from multiple well-informed participants. All interviews were recorded and transcribed verbatim; all ethical considerations were duly observed (Saunders, 2019; Olekanma et al, 2022; Olekanma, 2023).

Data Analysis Tools

The study data collected through semi-structured in-depth interviews were initially analysed using Braun and Clarke's (2006) thematic analysis method (TA) to obtain study participants themes. After initial text analysis, using Braun and Clarke's (2006) thematic analysis method, this study diverged and adopted Trans Positional Cognition Approach (TPCA) stepwise analytical method (Olekanma, et al., 2022). The rationale for this diversion, was based on Braun and Clarke's (2006) method which is considered too complex, with no clear guidelines on how to go about the researcher's interpretation of the study participants' themes (Todres and Holloway, 2010). Thus, TPCA analytical Stage 3, steps 11 and 12 (Olekanma, et al., 2022) were adopted and used to analyse study participants themes. The outcome of this divergence led to the emergence of 4 researchers' themes namely Unique antecedent performance indicators, Human performance factors, Organisational performance factors, Continuous learning performance factors as key drivers of knowledge sharing and transfer in Sub Saharan South Africa public sector Step 13 were adopted and used to enable emergence of the essence of the study (Table 1 – Data display structure). The next section presents the study findings.

4. Findings

The four key findings shown under researchers' interpretation column in Table 1 to be presented in this section that include Unique antecedent performance indicators, Human resources performance factors, Organisational performance factors, and Continuous learning performance factors were sent to 10 out of the 15 purposively selected participants for validation. All the 10 participants confirmed that the outcome of the analysis as showing in Table 1, represented their descriptions and experience delivering KST related projects in Sub Saharan South Africa public sector.

Table 1: Study Findings

Study Participant themes	Researchers Interpretations	Essence of study
Knowledge Strategy (hard antecedent factor)	**Unique antecedent performance factors**	**Enabling Factors of Knowledge Sharing and Transfer in Sub Saharan South African Public Sector for effective service delivery**
Change Management (soft antecedent factor)		
Coupling Knowledge strategy and change management		
Trust	**Human resources performance factors**	
Individual intrinsic motivation		
Individual extrinsic motivation		
Culture	**Organisational performance factors**	
Rewards and Incentives Systems		
Partnerships and networks		
Adult learning practices		
Knowledge integration		
Continuous learning requires an open KST climate, performance measures and incentives	**Continuous learning performance factors**	
Continuous learning requires a Knowledge Management unit with a new mandate and budget; integrated technology; interaction with industry		

Source: Adaption from TPCA stage 4 data display structure (Olekanma et al., 2022)

4.1 Theme 1: Unique Antecedent Performance Indicators

There was overwhelming agreement about unique performance antecedent indicators. The responses to interview questions highlighted the three unique factors, knowledge strategy, change management and coupling knowledge strategy and change management. The participants expressed the view that they were originating factors for effective KST implementation and performance management. All the participants

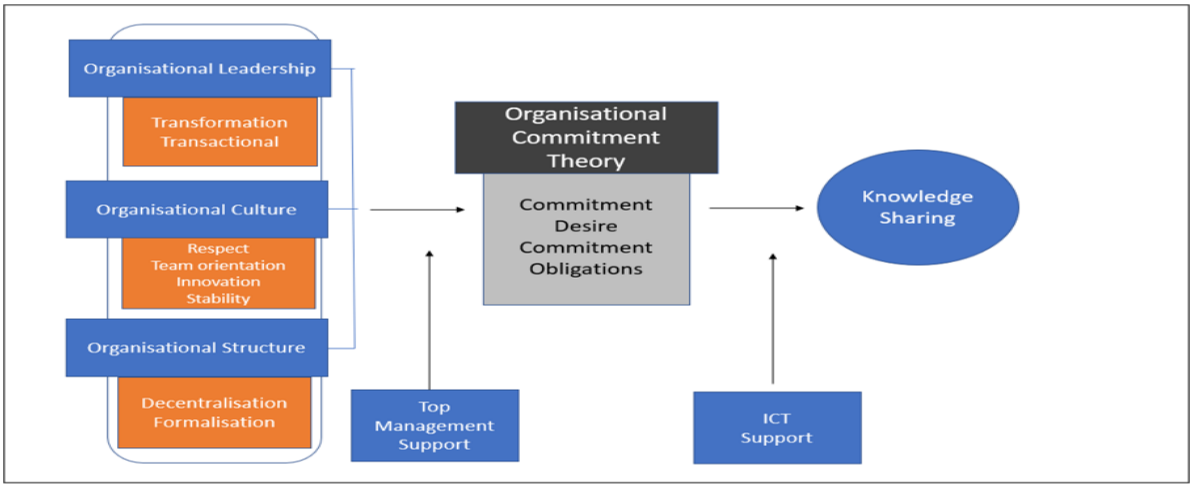
emphasized coupling of antecedent factors, that a new knowledge strategy happens when knowledge strategy and change management converge. Respondent 1 summed it up, "the knowledge strategy initiatives led to reducing distrust and helped all understand how the strategy as the first step for knowledge sharing and inter organisational transfer supports the organisation's goals' (M1). Participants 8, 11 and 1 explained the coupling of factors thus, 'You need to bring the Knowledge strategy with change management for people to buy into it (M8). "We need to link knowledge strategy and change management because historically it showed one without the other do not facilitate knowledge sharing and transfer" (M11). "When organisation puts knowledge strategy and changes management together it allays fears" (M1)

4.2 Theme 2: Human Resources Performance Factors

While all participants expressed support for trust, views on motivation varied, the majority accepted extrinsic motivation as positive for knowledge exchange while a few resisted, suggesting intrinsic motivation was more desired. The people performance factor, accounted for the importance of all three human-related factors, namely trust, individual motivation, and organisational motivation. These people enablers were reported to be critical, after the antecedent factors. Respondent 13 explained why their trust was a people enabler. 'Trust is a very effective enabler that encourage knowledge exchange, I think its primary because for any person to share knowledge it is a moment of great vulnerability, the environment must be one of trust (M13). Participants summed up intrinsic and extrinsic motivation; thus, participants 1 and 2 said, 'Motivation is a personal factor for me, I am moved by the organisations goals to do it'(M1); 'In project knowledge sharing there is a need to be motivated through rewards and incentives, categories for rewards must be created to acknowledge those who knowledge share and transfer' (M2).

4.3 Theme 3: Organisational Performance Factors

The process organisational enabling factors were aggregated by four issues culture; rewards and incentives; partnerships and networks; adult learning. Some of the participants did see rewards and incentives as negative drivers for knowledge transmission, however the majority considered it as positive for KST implementation and performance improvement. While participants placed the onus of successful organisational enablers on leadership, they all expressed the desire as a recurring theme for the adult education principles, not identified in the public sector KM literature reviewed. Culture was described as contingent and linked to trust. M12 said, 'Culture is influenced by how people behave, it must be nurtured, it is related to trust. One of the participants summed up the importance of rewards and incentives and said, 'Incentivising people through a rewards policy to knowledge sharing is important, it is the big question that comes up, not only in the studied organisation but in many organisations, we should consider it' (M1). All the participants also referred to the growing list and varying types of networks and partnership. Participant M12 said, 'Both social networks and partnerships are important, no one is more important than the other. Participants repeatedly indicated the importance of adult learning principles, participants M11 said 'adult learning methods are positive as it improves the content shared and delivery method used, that works for us as adults.' (M11).



4.4 Theme 4: Continuous Learning Performance Factors

This fourth theme, continuous learning was seen as the quintessential knowledge strategy and was a recurring theme raised by all participants. It was aggregated by (1) lessons learnt from knowledge exchange successes and (2) lessons learnt from knowledge exchange failures and difficulties. Participants M5 said, 'We should continue linking people through MOUs or SLA's, these agreements are important success factors (M5)'. A unique industry related knowledge transfer obstacle was linked to learnings from error, described by M7, "There appear a mismatch between what organisations want and what industry needs, experience reveal this mistake. Our organisation needs an industry repository of knowledge, the sector repository is not good enough.

5. Discussion

Results from the current empirical work identified as performance innovation enablers; Unique antecedent performance indicators, Human resources performance factors, Organisational performance factors, and Continuous learning performance factors as elements underpinning knowledge sharing and transfer for effective public management and performance innovation in the studied South African public sector organisation. Wang and Noe (2010), Knowledge sharing framework study also found that people and organisational factors, including motivation and culture, are interrelated factors which facilitate knowledge sharing and transfer albeit globally. The result of the current study confirms two out of the four enablers put forward by Wang and Noe (2010) study. To better explain the study findings, Rahman, et al., (2017, p.280), a

framework of knowledge sharing, adopted as theoretical study framework was employed. The theoretical framework, presented in Figure 1 below provides a western perspective lens with which to compare the current sub-Saharan South Africa work setting findings. Rahman et al (2017) framework identified organisational leadership, culture, structure; and organisational commitment factors as key enablers of knowledge sharing and transfer. It also shows the relationship between top management and organisational commitment as moderators and mediating factors during knowledge sharing and transfer activities in organisation.

Source: Rahman et al. (2018, p.280)

Figure 1: Conceptual Framework of Knowledge Sharing for Business Organisation

The implication is that the organisational commitment theory which mediates the knowledge sharing and transfer enablers suggests the willingness of social actors to participate in knowledge sharing and transfer is dependent on the Top management and ICT support, commitment factors. The current study findings identified factors not considered enablers of knowledge sharing and transfer by the Rahman et al., (2018) study framework. First, context, and purpose factors which are preconditions for knowledge sharing and transfer to happen identified in the current study are not included in the theoretical framework. These are the antecedent factors, (knowledge strategy, change management, and coupling knowledge strategy and change management) factors. Secondly, the theoretical framework elements lack reference and inclusion of human - related factors, which engenders trust and motivation, essential commitment factors to facilitate knowledge sharing and transfer between knowledge actors. It also does not include the implementation factor – continuous learning culture from success and failure. Despite several antecedent and enabling factors which facilitate knowledge sharing and transfer in the literature (Ipe, 2003; Wang and Noe, 2010) most studies such as Rahman et al. (2018, p.280) framework separated the leadership antecedent factor from organisational enablers in knowledge sharing and transfer models in the literature. Rahman et al., (2018) framework did not include change management as a bottom up antecedent, ignored the influence of people factors (trust and motivation) and implementation strategies (continuous learning) to boost antecedents and enablers. Rahman et al., (2018) framework considered the business sector, Bangladesh and its eastern zone factors. The Sub-Saharan region was not its focus. While the work is a contribution to the field, it creates a gap in knowledge, particularly for the sub-Saharan African practitioner still dependent on the Western models for guidance. The South African framework identified bottom antecedents, people and continuous learning factors, not identified in previous studies. To bridge this gap, this work proposes Sub-Saharan South African Public Sector Practitioners' Knowledge Sharing and Transfer Model presented in Figure 2 below.

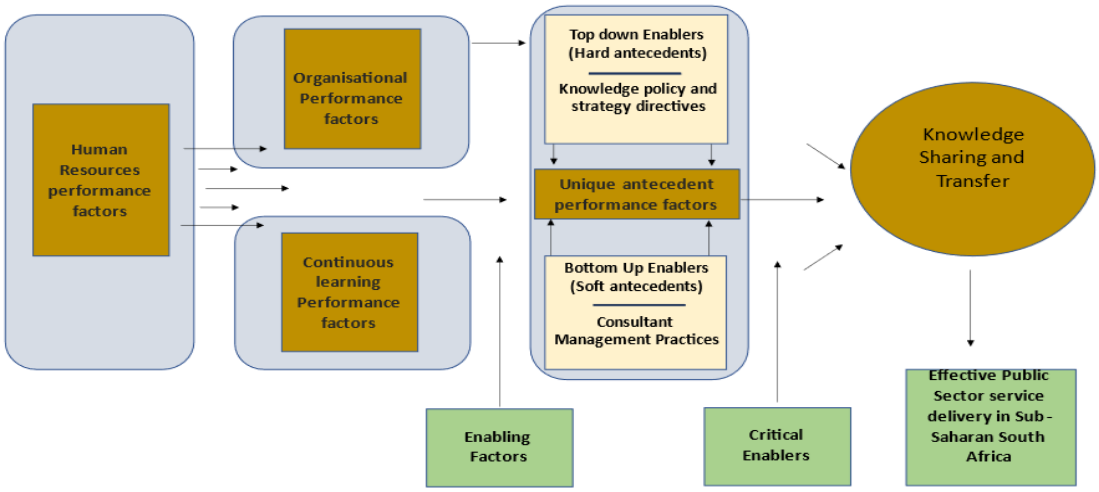


Figure 2: Sub Saharan South African Public Sector Knowledge Sharing and Transfer Conceptual Model

6. Conclusion

The research sought to answer the question; what knowledge sharing, and transfer framework factors enhance public management in Sub-Saharan South Africa? The study fully achieved its set aim and answered the research question, through exploring lived experiences of 15 public sector practitioner managers working in Sub Saharan South African public sector. Data collected yielded four key themes namely, Unique antecedent performance indicators, Human resources performance factors, Organisational performance factors, and Continuous learning performance factors. These findings represented factors that enhance public management in Sub-Saharan South Africa, it does point to further study in this area. The study results extended the extant Rahman conceptual theoretical framework, which is a contribution to knowledge. The novel model also potentially contributes to practice as it will help practicing public sector managers understand the enabling factors which facilitate effective knowledge sharing and transfer, particularly in South Africa, which is a major economic powerhouse in Africa, only second to Nigeria. The limitation of this work is its sample size (15 participants) used in the study the findings may not be generalisable. While it makes a valid contribution to the field, it is also not a representative study across Sub-Saharan Africa. The study provides future studies opportunities for knowledge share and knowledge transfer academics, practitioners and researchers that include considering the studied organisation as a unit of analysis to compare the novel KST model within a different organisation in any South Africa public sector research setting.

Abstract: This paper aims for verify the role of knowledge management as a mediator in the relationship between organizational memory building and human resource management to develop high education institutions into human resource management organizations. In this study, the researchers relied on empirical study to test the relationship between the variables. Therefore, a survey questionnaire was conducted. The study population consisted of faculty members in Palestinian universities, whose number is (7,367) members. The study sample consisted of (360) professors from Palestinian universities. The results show that the mediating variable (KM) affects the dependent variable (HRM) by (0.675); and it is statistically significant at a significance level less than (0.001). Including the independent variable (OM) in the same model, its effect on the dependent variable (HRM) vanished, and the value of the statistical significance became (0.051).

Keywords: Mediating role, Knowledge Management (KM), Organizational Memory Building (OM), Human Resource Management (HRM)

1. Introduction

To ensure the organizational strength of higher education institutions, it is necessary to increase the strength of their organizational immunity, which requires three processes (organizational learning, organizational memory, and organizational genes). Hence, the importance of (OM) is significant to the strength of the organization's immunity (the body of the institution). There must be a strong human resource to ensure the effectiveness of organizational immunity; and knowledge management facilitates this human resource. Thus, this research paper consists of three variables: Knowledge Management (KM), Organizational Memory (OM), and Human Resource Management (HRM).

Organizational immunity is a virtual concept that shows the organization's ability to cope with crises through the framework of an action plan consisting of a set of processes that include (organizational learning, organizational memory, and organizational genes) in order to determine appropriate strategies for crisis management. (Aladdin, 2021: 9)

Organizational memory is defined as frameworks of common meaning among members of the organization. This definition represents the focus of the organizational learning process model in order for individuals within the organization to learn how to think and act like other members. (Al-Faroukh, 2010:28)

As for knowledge management, Antunes and Pinheiro view it as managing the processes of creating, storing, accessing, and disseminating the intellectual resources of an organization (Antunes and Pinheiro, 2020: 141). (Saha et al.) define human resource management as a distinct personnel management that seeks to achieve a competitive advantage through the strategic development of a highly capable and committed workforce, through the application of a combination of cultural, structural, and personnel techniques.

Organizational memory is an important concept in the study of organizational behavior and performance. It refers to the ability to store and retrieve information, experiences, and knowledge obtained in the past; and to use it in the future. Organizational memory is formed through organizational processes that identify, store, aggregate, and distribute important information in the organization. It is used to support decision-making processes, improve institutional performance, and promote innovation and development.

Many studies indicate that organizational memory is an important element in achieving organizational success. Organizations that invest in forming a strong organizational memory have a greater ability to adapt to institutional transformations and the challenges they face. Therefore, understanding the concept of organizational memory and its importance can help improve Institutional performance and promotion of innovation and development in organizations.

Organizational memory constitutes a broad cognitive process that takes place within a general framework interacting among its parts, consisting of a mixture of tangible and intangible assets, working to extract new knowledge from its sources in order to store and retrieve it when needed (Al-Baghdadi, 2007). Also, organizational memory is the creation of organizational learning that takes place within the organization. What this learning leads to can only be tangible after it is embodied in the organization's outputs. For their work, they are poured into molds referred to as organizational memory receptacles or stores (Jawadi, 2020, p. 28). Organizational memory contributes significantly to the creation of value for the organization. It enhances the routine operations of the organization by reducing the transaction costs associated with the repeated selection of alternatives that have been proven effective in the past. It is the basis for recycling organizational knowledge and a source of competitive advantage. It is a strategic resource that cannot be replaced due to its implicit and abstract nature (Dahinen and Ibn Sahel, 2022).

Characteristics of organizational memory: It enables the use of information based on the organizational context; and represent it in the cognitive context, especially with regard to solving problems, processes, and decision-making. It increases the automating ability to assist the user in decision support, by providing access to the accumulated cognitive stock. It stores diffused, unstructured, and documented knowledge, and expresses processes that include maintenance, research, and access, which indicate the importance of organizational memory for the organization. It enables the retrieval of knowledge, which aims to locate important knowledge in the organization, and use it to support decision-making processes and solve various organizational problems through communication and interaction (Qawsi and Anan, 2021, page 196).

Dimensions of organizational memory: It is based on professional knowledge, including technology, and related experiences that support and strengthen the regular operations of the organization. It includes variables and systems for product development, production control methods, information technology, the Internet, equipment, and technical method used. The organization should innovate and be interested in the technologies that occur in the environment, and learn from them (Dashash and Zaydi, 2022, pg. 30). It also includes frameworks, policies, rules, programs, and strategies tending to the knowledge that controls the operations within the organization, which refers to the organization's structure, management, human resources training, documentation management, and knowledge management.

Human resource management must enjoy flexibility and respond to new variables in light of developments within the internal and external environment of the organization; and thus develop policies and systems, and design programs and rules of its own in several areas, such as selection and employment, empowerment, training and development, compensation, and Performance evaluation (Abu Anza, 2021, p. 27).

Dessler dealt with the most important dimensions of human resource management, namely recruitment, selection and appointment, training, employee performance evaluation, compensation and benefits for human resources (Dessler, 2015, p. 70).

Al-Salami believes that the most important dimensions of human resource management are human resource planning, organizing human resource affairs, directing human resource affairs and work, procuring the necessary resources to handle human resources, monitoring and following up of human resource affairs, and evaluating performance in the field of human resource affairs (Salmi, 1997, p.134).

The contemporary world is witnessing a great development in the field of knowledge, which contributed to the development of various institutions and the change of their administrative methods. In addition, the discovery of new methods brought about a quantum leap in the field of work and production. Universities were not far from this transformation. Rather, the knowledge revolution affected them, and contributed to their development; and to dissemination of their three functions: education, scientific research, and community service.

The university and knowledge are inseparable. The concept of the university has been linked through its long history to the concept of knowledge. On this basis, it is seen as representing the knowledge resources of society. As much as society needs natural resources to build its economic entity, it also needs resources to build its cognitive and intellectual entity. This is the function of the university. It is a source of knowledge. It derives its identity and the legitimacy of its existence from this important role. Therefore, it is the responsibility of universities to enrich and develop the knowledge structure of society (Al-Aidarous, 2012 AD, p. 16). Knowledge management as a new concept for higher education institutions is considered one of the available administrative solutions that give them the opportunity to keep pace with the accelerating changes. The effective application of knowledge management strategies and techniques inevitably leads to improving the

ability of these institutions in decision-making, encouraging creativity, increasing competitiveness, and achieving goals. In addition, it improves their strategy, value, and performance (Sabrina, Hada, 2018 AD, p. 250).

Knowledge management may gain its importance through the goals it seeks to achieve. It provides knowledge to the organization permanently. It translates knowledge into practical behavior that serves the goals of the organization. Thus, it helps organizations achieve efficiency and effectiveness through planning and organizing knowledge efforts, in a way that leads to achieving its strategic goals. In addition, it works to provide distinctive competitive capabilities to reflect on the behavior of individuals in the organization. It affects work methods and adopted technology, which works in harmony with current and future practices and directions. (Al-Malkawi, 2007).

2. Study Problem

The researchers formulated the study problem with the following main question:

- What is the role of knowledge management as a mediating variable between organizational memory building and human resource management?

2.1 Study questions:

In light of the main study question, the sub-questions were:

- What is the level of organizational memory building in higher education institutions in the governorates of Gaza?
- What is the level of human resource management in higher education institutions in the governorates of Gaza?
- What is the level of knowledge management in higher education institutions in the governorates of Gaza?
- Does knowledge management as a mediating variable affect organizational memory building and human resource management in higher education institutions in the governorates of Gaza?

2.2 Objectives

- Clarifying the role of (KM) as a mediating variable between (OM) and human resource management.
- Determine the level of (OM) in higher education institutions in the governorates of Gaza.
- Determine the level of (HRM) in higher education institutions in the governorates of Gaza
- Determine the level of (KM) in higher education institutions in the governorates of Gaza
- Exploring the impact of (KM) as a mediating variable on (OM) and (HRM) in higher education institutions in the governorates of Gaza.

3. Literature Review

- *Kordab et al. (2020) study entitled* "Mediating Role of Knowledge Management in the Relationship between Organizational Learning and Sustainable Organizational Performance." This study aimed to examine the impact of the whole knowledge management cycle on the relationship between organizational learning and sustainable organizational performance in intensive knowledge-based sectors, specifically the audit and consulting companies in the Middle East region. Systematic scientific literature analysis, expert evaluation (structured questionnaire), and structural equation modeling (SEM) technique were used to develop and verify the research model.
- *Antunes and Pinheiro (2020) study entitled* "Linking Knowledge Management, Organizational Learning and Memory." It aimed to understand the link and evolution between the concepts of knowledge management, organizational learning, and memory. Seeking a better clarification of concepts; discussing them in the theoretical field; and understanding their evolution in the last decades. A systematic literature review was developed by synthesizing concepts. From two databases, a total of 2511 scientific articles between 1960 and 2017 were analyzed and divided into two studies.
- *Almomani et al. (2019) study entitled* "Organizational Memory, Knowledge Management, Marketing Innovation and Cost of Quality: Empirical Effects from Construction Industry in Jordan." It aimed to achieve fourfold objectives. First, to explore the effect of organizational memory (OM) on marketing

innovation (MI). Second, to recognize the effect of OM on cost of quality (COQ). Third, to verify the effect of knowledge management (KM) on MI. Finally, to find out the effect of KM on COQ.

- *Dahinen (2017) study entitled* "The Contribution of Knowledge Management to the Development of Organizational Memory: An Applied Study on a Group of Institutions." It aimed to discover how knowledge management can build and develop organizational memory. The case study was a group of Algerian companies (Sonatrach, Saidal, Condor). The study highlights the most important criteria that can be used as a tool to assess and compare best practices in knowledge management.
- *Sudharatna (2015) study entitled* "Organizational Memory System as a Foundation of Knowledge Management." This study aimed to certify the organizational memory system as an essential part of Knowledge management in the Thai Bank Industry. It focused simply on methods of memory system being applied in the sample bank. Aiming to develop an organization towards a Learning Organization, 'managing knowledge' is compulsory.

4. Methodology

The researchers in this study will adopt the empirical study to test the relationship between the variables. A questionnaire survey will be conducted for this study. The research is divided into three parts. In the first part, the independent variable is characterized by the organizational memory building, and the dependent variables are characterized by the (KM) processes (knowledge acquisition, creation, storage, sharing, and application). In the second part the five (KM) processes represent the independent variables, and the (HRM) represents the dependent variable. In the third part, the effect of (OM) on (HRM) is addressed, where (OM) represents the independent variable, and (HRM) represents the dependent variable.

Study population: The study population consisted of faculty members in Palestinian universities, whose number is (7,367) members.

Figure (1) shows the distribution of educational academics by type of institution.

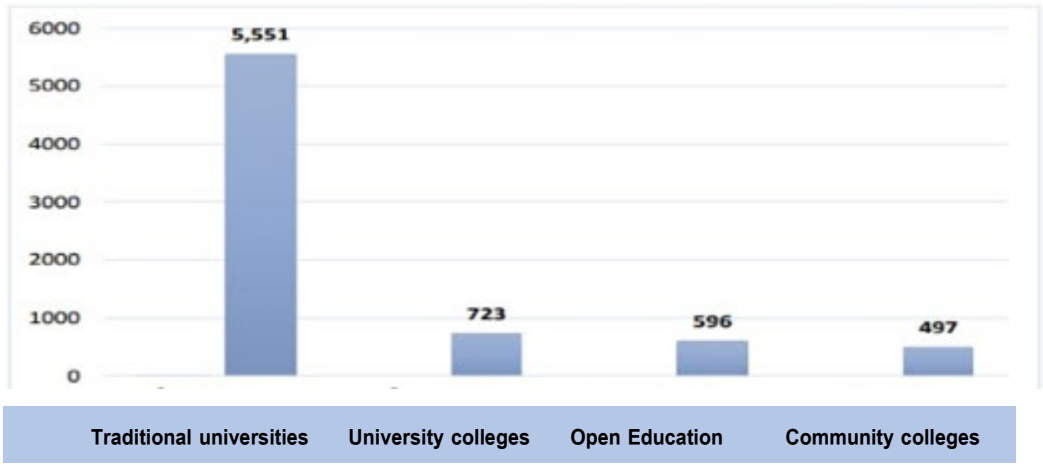

Figure 1: Number of Educational Academics by Type of Institution 2021- (Statistical Book, 2022)

4.1 Study Sample

The exploratory sample: The exploratory sample consisted of (40) members of the teaching staff in Palestinian universities from the targeted study population, and from outside the study sample, in order to verify the validity and reliability of the study tool.

Actual sample: The study sample consisted of (360) professors from Palestinian universities. The sample was selected in a simple random way, where the researchers presented the study tool through Google Forms to all members of the study population, and the number of respondents reached (360) individuals. Table (1) shows a description of the study sample:

Table 1: Description of the Study Sample

Variable		Frequency	Percent
Region	Gaza strip	249	69.2

Variable		Frequency	Percent
	West Bank	111	30.8
Gender	Male	288	80.0
	Female	72	20.0
Years of Experience	Less than 5 years	12	3.3
	From 5 to ten 10	45	12.5
	More than 10 years	303	84.2
Specialization	Human sciences	255	70.8
	Applied Sciences	105	29.2
Academic degree	Assistant professor or less	246	68.3
	Associate Professor or more	114	31.7
Position	Yes	192	53.3
	No	168	46.7
University type	Government	105	29.2
	Eligibility	162	45.0
	Specialized	93	25.8

Study tool: For research purposes, a questionnaire was prepared according to the following steps:

Defining the purpose of the questionnaire: The questionnaire aimed to identify the mediating role of knowledge management between organizational memory and human resource management in Palestinian universities.

*Sections of the questionnaire***:** After reviewing the previous studies that dealt with the variables of the study: knowledge management (KM), organizational memory (OM), human resources management (HRM), the areas of the questionnaire were identified. The questionnaire included two sections as follows:

The first section: includes the basic data of the respondents, which are (university location, gender, years of service, specialization, academic degree, administrative position, and type of university).

The second section: contains (57) items distributed over (11) areas as follows:

Table 2: The Distribution of the Questionnaire Items

Variable	Dimensions	Number
Independent variable (organizational memory)	The first domain: technical organizational memory	4
	The second domain: administrative organizational memory	4
	The third domain: cultural organizational memory	4
Dependent variable (human resource management)	The first domain: selection and employment	4
	The second domain: empowerment	4
	The third domain: training and development	4
	The fourth domain: compensation	4
	The fifth domain: performance evaluation	4
Mediating variable (knowledge management)	The first domain: knowledge organization and management	8
	The second domain: knowledge generation and storage	9

Variable	Dimensions	Number
(knowledge acquisition, creation, storage, sharing, and application)	The third domain: sharing and applying knowledge	8
Total		**57**

Formulation of the questionnaire items: The questionnaire items were formulated in the light of the researchers' review of the studies and research that dealt with the three variables of the study (organizational memory, human resource management, and knowledge management., The researchers considered that items were formulated in a clear and specific manner, and measure what was set to be measured. The initial form of the questionnaire consisted of (57) items.

*Determining the method of estimating the questionnaire***:** a five-point Likert scale was used to estimate the respondents' answers to the questionnaire items. The answer is graded in five levels (very high, high, medium, low, very low). And it corresponds quantitatively (1,2,3,4,5) respectively. Three levels (high, medium, low) were adopted for the mean for each domain of the questionnaire. and Table (3) shows the levels of the approved criterion:

Table 3: Levels of Approved Criterion

High	Medium	Low
5 - 3.67	3.66 – 2.34	2.33 – 1

*The validity of the questionnaire***:** The validity of the questionnaire means that it measures what it was set to measure. The validity was measured in the following ways:

- *The veracity of the arbitrators***:** The initial draft of the questionnaire was shown to a group of (5) professors with specialization in educational administration. The required modifications were made. Thus the questionnaire consisted of (57) items distributed over (11) domains in three variables.
- *Structural validity***:** It means that there is a statistically significant positive correlation between each domain with the total score of the variable. The results showed that the correlation coefficients are all statistically significant at the level of significance (0.01), which indicates that the questionnaire has acceptable internal validity.
- *Stability of the questionnaire scores:* The stability of the questionnaire scores was confirmed using Cronbach's alpha coefficient for the resolution items. Table (4) shows the correlation coefficients and stability coefficients for the questionnaire domains:

Table 4: Stability Coefficients of the Questionnaire using Cronbach Alpha

Variable	Dimensions	Number	Correlation coefficient	Cronbach's alpha
Independent variable (organizational memory)	The first domain: technical organizational memory	4	0.904**	0.889
	The second domain: administrative organizational memory	4	0.956**	0.939
	The third domain: cultural organizational memory	4	0.928**	0.941
	total	12	--	0.962
Dependent variable (human resource management)	The first domain: selection and employment	4	0.928**	0.890
	The second domain: empowerment	4	0.950**	0.966
	The third domain: training and development	4	0.946**	0.950

Variable	Dimensions	Number	Correlation coefficient	Cronbach's alpha
	The fourth domain: compensation	4	0.934**	0.970
	The fifth domain: performance evaluation	4	0.933**	0.966
	total	20	--	0.984
Mediating variable (knowledge management)	The first domain: knowledge organization and management	8	0.953**	0.965
	The second domain: knowledge generation and storage	9	0.948**	0.963
	The third domain: sharing and applying knowledge	8	0.992**	0.968
	total	25	--	0.985

The stability coefficients for the domains ranged between (0.889 - 0.971), all of which are high values indicating that the questionnaire has high stability. The correlation coefficients between the domains of the questionnaire with the total degree of its variable ranged between (0.928 - 0.992), all of which are statistically significant at the level of significance (0.01).

*The final version of the questionnaire***:** After confirming the validity and reliability of the questionnaire, the final version consisted of (57) items, distributed over (11) main areas in three variables: organizational memory (the independent variable), human resource management (the dependent variable), and knowledge management (the mediating variable).

*Statistical methods***:** The researcher used the statistical package for social sciences (SPSS) and the (AMOS) program to process the data. Descriptive statistical methods and simple linear regression were used to test the hypotheses of the study.

Answering the research questions:

The first question: What is the level of (OM) in higher education institutions in the governorates of Gaza?

To answer this question, the mean averages and standard deviations of the organizational memory domains were extracted, as shown in table (5)

Table 5: The Means and Standard Deviations for the Level of Building Organizational Memory in Palestinian Universities

Domain	Mean	SD	Weight	Rank	Level
Technical organizational memory	4.223	0.669	84.46 %	1	Large
Administrative organizational memory	3.996	0.755	79.92 %	3	Large
cultural organizational memory	4.100	0.749	82.00 %	2	Large
OM	4.106	0.662	82.13 %	--	Large

It is clear from table (5) that the mean for the organizational memory variable was (4.106), with a standard deviation of (0.662), and a relative weight of (82.13%), with a high degree of agreement. This indicates that the level of building organizational memory in Palestinian higher education institutions is high from the point of view of faculty members in higher education institutions. The domain of technical organizational memory ranked first with a mean of (4.223), while the domain of cultural organizational memory ranked second with a mean of (4.100), and in the third and last rank came the field of organizational-administrative memory with a mean of (3.996).

The fact that the domain of technical organizational memory ranked first indicates that universities have an integrated technical infrastructure to achieve their requirements and goals. Furthermore, it shows that they are constantly updating the content of their website; have a database for all their information; and their workers have access to stored data and information.

The domain of administrative organizational memory in the third (last) rank indicates that institutions need to store ideas and knowledge in developed methods, to document the experiences and expertise of the institution, and transform tacit knowledge into explicit and structural one. They also need to employ information in planning and setting priorities.

The second question: What is the level of human resource management in higher education institutions in the governorates of Gaza? To answer this question, the means and standard deviations of the human resource management domains were extracted, as shown in table (6).

Table 6: Means and Standard Deviations for the Level of Human Resource Management in Palestinian Universities

Domain	Mean	SD	Weight	Rank	Level
Selection and employment	3.879	0.815	77.58 %	1	Large
Empowerment	3.748	0.929	74.96 %	3	Large
Training and development	3.717	0.916	74.33 %	4	Large
Compensation	3.454	1.018	69.08 %	5	Large
Performance evaluation	3.792	0.918	75.83 %	2	Large
HRM	3.718	0.839	74.36 %	--	**Large**

It is clear from the table (6) that the mean for the (HRM) variable was (3.718), with a standard deviation of (0.839), and a relative weight of (74.36%), with a high degree of agreement. This shows that the level of (HRM) in Palestinian higher education institutions is high from the point of view of faculty members in higher education institutions. The domain of selection and employment ranked first with a mean of (3.879). While the domain of performance appraisal ranked second with a mean of (3.792). Third came the domain of empowerment with a mean of (3.748). Fourth came the domain of training and development with a mean of (3.717). Finally in the fifth rank was the domain of compensation with a mean of (3.454).

In the light of these results, it is clear that there is satisfaction among faculty members in higher education institutions about the policy of selecting and employing of faculty members. This indicates that these institutions seek to obtain highly qualified individuals through advertisements and interviews that are transparent and objective.

The third question: What is the level of knowledge management in higher education institutions in the governorates of Gaza? To answer this question, the mean averages and standard deviations of knowledge management domains were extracted, as shown in table (7).

Table 7: Means and Standard Deviations for the Level of Knowledge Management in Palestinian Universities

Domain	Mean	SD	Weight	Rank	Level
knowledge organization and management	3.818	0.123	76.37 %	3	Large
knowledge generation and storage	3.939	0.825	78.78 %	2	Large
sharing and applying knowledge	4.017	0.817	80.33 %	1	Large
KM	3.919	0.782	78.39 %	--	**Large**

It is clear from the table (7) that the mean for the knowledge management variable was (3.919), with a standard deviation of (0.782), and a relative weight of (78.39%), with a high degree of agreement. This indicates that the level of knowledge management in Palestinian higher education institutions is high from the point of view of faculty members in higher education institutions. The domain of knowledge sharing and its application ranked

first with a mean of (4.107). The domain of knowledge generation and storage ranked second with a mean of (3.939). Third and final rank was the domain of knowledge organization and management with a mean of (3.818).

The domain of sharing knowledge and its application ranked first indicates that the universities administrations encourage faculty members to participate in scientific meetings and conferences to enhance the process of sharing knowledge and encourage the provision of an appropriate environment for the exchange and sharing of knowledge among faculty members.

that the third and last rank of the domain of knowledge organization and management indicates the need to define performance levels for faculty members based on the integration of knowledge, and work to provide a high-quality system in information technology, that institutions need to enhance the capabilities of faculty members to be able to obtain knowledge and manage it.

The fourth question: Does knowledge management as a mediating variable affect organizational memory building and human resource management in higher education institutions in the governorates of Gaza?

To answer this question, the (AMOS) program was used to explore the effect of knowledge management as a mediating variable between building organizational memory and managing human resources in Palestinian higher education institutions. The validity of the formulation of the hypothesis was tested, which states: Knowledge management does not play an intermediate role between building organizational memory and managing human resources in Palestinian higher education institutions.

To test this hypothesis, a causal model was built on a theoretical basis by extrapolating previous studies and related models. The causal model was relied upon for its suitability to the subject of the study, as building organizational memory is related to human resource management in Palestinian higher education institutions. If knowledge management was introduced as an intermediate variable between them, it might affect the nature of the relationship between building organizational memory and human resource management.

In order to verify that knowledge management is a mediating variable between building organizational memory and managing human resources, the researchers relied on the Baron & Kenny (1986) model, which indicated that in order to consider a variable as a mediating variable, three conditions must be met:

1. The independent variable (building organizational memory) should affect the dependent variable (human resource management); and this represents the regression equation of the dependent variable on the independent variable.
2. The independent variable (building organizational memory) must affect the mediating variable (knowledge management); and this represents the regression equation of the mediating variable on the independent variable.
3. The mediating variable (knowledge management) have to affect the dependent variable (human resource management); and this represents the equation of regression of the dependent variable on both the independent variable and the mediating variable together, i.e. the influence of the two independent and mediator variables together on the dependent variable.

If the three conditions are met, the direct effect of the independent variable on the dependent variable must be less in the third equation than it was in the first equation.

The test of these three conditions is illustrated in the tables below:

1. The effect of the independent variable (OM) on the dependent variable (HRM):

Table 8: The Path of Direct Influence between (OM) and (HRM)

			Estimate	S.E.	C.R.	P
HRM	<---	OM	1.606	0.072	22.213	0.001

It is clear from table (8) that the independent variable (OM) affects the dependent variable (HRM) by (1.606), which is statistically significant at a significance level less than (0.001), meaning that (OM) affects (HRM), and thus the first condition is fulfilled.

2. The effect of the independent variable (OM) on the mediating variable (KM):

Table 9: The Path of Direct Influence between (OM) and (KM)

			Estimate	S.E.	C.R.	P
KM	<---	OM	2.081	0.069	30	0.001

It is clear from table (9) that the independent variable (OM) affects the mediating variable (KM) by (2.081), which is statistically significant at a significance level less than (0.001), meaning that (OM) affects (HRM), and thus the second condition is fulfilled.

3. The effect of the mediating variable (KM) on the dependent variable (HRM) in the presence of thendependent variable (OM):

Table 10: The Path of Indirect Influence between (OM) and (HRM)

			Estimate	S.E.	C.R.	P
KM	<---	OM	2.081	0.069	30	0.001
HRM	<---	KM	0.675	0.042	16.101	0.001
HRM	<---	OM	0.202	0.103	1.953	0.051

It is clear from Table (10) that the intermediate variable (KM) affects the dependent variable (HRM) by (0.675), with a significance level (0.001), and it is statistically significant at (0.01), meaning that the effect of (KM) on (HRM) statistically significant. Thus, the third condition is fulfilled.

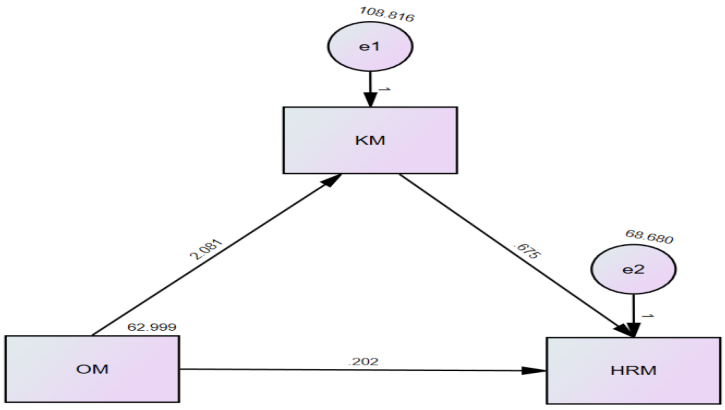

Figure 2: The Mediation Model of the Intermediate Variable (KM) between the Independent Variable (OM) and the Dependent Variable (HRM). In Order to Determine the Type Of Mediation (total or partial)

Many studies like: Aladdin, Y. (2021), Antunes and Pinheiro (2020), Kordab et al. (2020), Al-Saidi, (2020), Almomani et al. (2019), Shabat, j. A., & Al-Masry, N. H. (2020), Dahinen (2017), Saha et al. (2016), Amer, B., & Dahinen (2016), Sudharatna (2015), Vrîncianu et al. (2009), and Karreman (2002) dealt with the subject of knowledge management. However, this study alone linked the knowledge management variable (KM) as an intermediate variable with the independent variable (OM) and the dependent variable (HRM).

It is noted from the results in Table (10) and Figure (2) that the mediating variable (KM) affects the dependent variable (HRM) by (0.675), and it is statistically significant at a significance level less than (0.001). Including the independent variable (OM) in the same model, its effect on the dependent variable (HRM) vanished, and the value of the statistical significance became (0.051), meaning that a statistically significant effect was found at the level of significance (0.001) for the intermediate variable (KM) on the dependent variable (HRM). There is no statistically significant effect at the level (0.05) of the independent variable (OM) on the dependent variable (HRM). Thus, the third condition of the test conditions for the mediation of the mediating variable (building organizational memory) is achieved. The mediation of the intermediate variable (KM) is entirely between the independent (OM) and dependent (HRM) variables.

This means that the direct effect of the independent variable (OM) on the dependent variable (HRM) in the third equation has become less and is not statistically significant than it was in the first equation. Therefore knowledge management is a mediator in the relationship between (OM) and (HRM) in Palestinian higher education institutions. Thus, it is confirmed that knowledge management plays a mediating role between (OM) and (HRM) in Palestinian higher education institutions.

Vulnerabilities and Knowledge Risks in Knowledge Processes

Andrei Ștefan Neștian and Alexandra Luciana Guță
Department of Management, Marketing and Business Administration, Faculty of Economics and Business Administration, Alexandru Ioan Cuza University of Iași, Romania

nestian@uaic.ro
luciana_guta@yahoo.com

Abstract: This study aims to put forward measuring scales for two central concepts – vulnerabilities and knowledge risks – and identify the factors composing the two constructs. The research presented in this paper is part of a larger project investigating knowledge vulnerabilities and risks appearing in knowledge processes of organizations. In this sense, a new ontology developed by Brătianu et al. (2022) was used to design an instrument for measuring risks and vulnerabilities related to knowledge processes in organizations. Organizational knowledge dynamics perspective (Brătianu et al., 2022) was used to group knowledge risks typologies into the following clusters: knowledge creation, knowledge acquisition, knowledge loss, knowledge sharing, knowledge use, emotional knowledge dynamics, spiritual knowledge dynamics. Examples of knowledge risks belonging to such clusters may include a knowledge risk of non-creation and a knowledge risk of bad timing (for knowledge creation cluster), knowledge spillover or knowledge forgetting (for knowledge loss), as well as knowledge hiding and knowledge hoarding (for knowledge use). Our study fills a gap in the literature by suggesting a scale for measuring knowledge risks and grouping them by factor, and also a scale for measuring vulnerabilities and grouping them by type of vulnerabilty by means of principal components analysis. Current state of knowledge on vulnerabilities and knowledge risks comprises mainly theoretical approaches. Also, most studies do not discuss the concepts of knowledge risks and vulnerabilities together. The main novelty of our study lies in its quantitative approach to analysing knowledge-related vulnerabilities and risks. For this purpose, a questionnaire was applied to a sample of employees comprising both managers and non-managers from Romanian organizations. The factors resulted after having applied the principal components analysis have provided a clearer picture of the constructs of vulnerabilities and knowledge risks, leading to a deeper understanding of knowledge processes and their risks.

Keywords: Knowledge risks, Vulnerabilities, Knowledge processes, Knowledge dynamics

1. Introduction

The concept of knowledge risk has been the topic of several studies over the last three decades (Becerra, Lunnan and Huemer, 2008; Cooper, 2003; Massingham, 2010; Niwa,1989; Scott and Walsham, 2005; Zieba, Durst and Hinteregger, 2022). Its importance is given by the dificulties of pinpointing the invisible mecanisms determining the manifestation of such risks and the practical conditions favouring their occurrence. As knowledge risks are abstract concepts, several taxonomies have been coined over the years. This research is based on the study of Bratianu, Neștian and Guță (2022) that developed a taxonomy of knowledge risks based on the correspondence of knowledge risks with the knowledge processes in which they occur.

2. Literature Review

The theoretical approach is based on the assumption which has been derived from the general theory of risk, stating that each knowledge process containts actions, where knowledge represents the objects of specific processings, such actions taking place in contexts or modes favouring the apperance of knowledge risks that generate specific vulnerabilities in each knowledge process. The study sees knowledge vulnerabilities as the states of organisational knowledge systems that are perceived as triggering or facilitating the appearance of negative consequences in the organization's activity.

This study aims to suggest measuring scales for the concepts of vulnerabilities and knowledge risks and identify the factors of these two constructs. We present an instrument for measuring knowledge risks and vulnerabilities related to knowledge processes using a new ontology of Bratianu, Neștian and Guță (2022) towards knowledge risks based on organizational knowledge dynamics.

This new classification takes into account the dynamics of knowledge value for the firm, namely, how the value of an organization's knowledge may be affected by the presence of knowledge risks grouped by nature of knowledge processes. There is an implicit relation between knowledge processes and knowledge risks, while the nature of processes determines the nature of knowledge risk (Bratianu, Neștian and Guță, 2022).

In this study, the concept of knowledge risk is seen as a particular use of a generic concept of risk in knowledge processes, reflecting situations of negative consequences occurring due to decisions made regarding

knowledge processes under the influence of internal and external factors (Cameron and Raman, 2005; Massingham, 2010; Massingham, 2020; Society for Risk Analysis, 2018).

These concepts were used to develop seven clusters of knowledge risks grouped using a criterion of a relation between knowledge risk and knowledge process: (KC) – knowledge creation risks, (KA) – knowledge acquisition risks, (KL) – knowledge loss risks, (KS) – knowledge sharing risks, (KU) – knowledge use risks, (EKD) – emotional knowledge dynamics risks, and (SKD) – spiritual knowledge dynamics risks (Bratianu, Neștian and Guță, 2022). Several prominent papers in the field of knowledge risks were used to extract the risk typology, each presenting a slightly different knowledge risk typology (Bratianu et al, 2020; Durst and Henschel, 2020; Durst and Wilhelm, 2013; Durst and Zieba, 2017; Durst and Zieba, 2019; Durst and Zieba, 2020; Durst, 2019; Durst, Hintereger and Zieba, 2019; Zieba and Durst, 2018; Zieba, 2017). Also, we have analysed an array of perspectives to knowledge processes (Andreeva and Kianto, 2011; Andrews and Delahaye, 2000; Kraaijenbrink, 2012; Staab et al, 2001) as to suggest a list of knowledge processes to be used in the taxonomy.

The study questionnaire was constructed by utilising the above-mentioned taxonomy, alongside with scale development for knowledge risks and knowledge vulnerabilities.

As for the second concept of knowledge vulnerabilities, we reviewed the literature in the field on risk management. An accepted perspective is that vulnerability is a measure of likelihood for an asset to be attacked successfully by a given threat (Avci and Ozbulut, 2018) that may cause losses or damages. In case of knowledge vulnerabilities, the idea of an attack is not the most suitable perspective. Instead, we may see a threat as an event or context causing loss of knowledge to an organisation.

Vulnerabilities differ from risks as they possess three specific underliyng caracteristics related to the manifestation of knowledge risks. The first characteristic is the *deterministic capacity*, being the root of likelihood of knowledge risks manifestation (Bratianu, Neștian and Guță, 2022). A risk is a potential for loss and damage when a threat occurs. Knowledge vulnerabilities are the weak points of the knowledge system and the knowledge management routines that trigger or facilitate the apperarance of risks, exposing the organisation to threats. These weak points are the determinants of knowledge risks as they initiate the knowledge risks under the pressure of external forces (Bratianu and Bejinaru, 2022; Fuchs, Birkmann and Glade, 2012; Sarawitz, Pielke and Keyhah, 2003). The second caracteristic of vulnerabilities is the *capacity to respond* with a countering action (Marandola and Hogan, 2006). If the system has a vulnerability, the system's capacity to respond, when a risk is manifested, may be hindered. Third, vulnerabilities reduce system's *absorptive capacity*. When a risk is manifested, the presence of a vulnerability is related to a lower capacity of loss prevention or decrease, or recover to a normal state (Marandola and Hogan, 2006).

Starting from the conceptual framework and theoretical meaning of the concept of vulnerabilities, we developed a list of vulnerabilities related to each of the knowledge risks in the taxonomy put forward by Bratianu, Neștian and Guță (2022).

3. Methodology

3.1 Nature of the Study

The nature of our study is exploratory. Current state of knowledge on the concepts of knowledge vulnerabilities and knowledge risks is theoretical, comprising mostly taxonomies of knowledge risks, the literature on this topic being scarce. Our approach is deductive and our research strategy is survey-based, with the use of quantitative methods of analysis (Saunders, Lewis and Thornhill, 2007). The novelty of the study lies in a quantitative approach to the analysis of knowledge-related vulnerabilities and risks.

3.2 The Research Instrument

The instrument is a questionnaire comprising a filter question, a scale for measuring the types of knowledge risks, a scale for measuring the types of knowledge vulnerabilities, three questions at the end of the questionnaire regarding the following: position within the organization (management or execution), length of service within the organization (under one year, between one and five years, over 5 years), the organization's field of activity (open question).

Both scales for the latent variable "type of knowledge risk" and "type of knowledge vulnerability" range from one to five, 1 – total disagreement (the situation is not found in the organization); 2 – disagreement (rarely found in the organization); 3 – neither disagreement, nor agreement (found sometimes); 4 – agreement (frequently found); 5 – total agreement (the situation is curently found in the organization).

The scale for types of knowledge vulnerabilities and knowledge risks contains 21 and 19 items, respectively. Both scales were developed based on vulnerabilities and risks that may be associated with the following seven clusters of knowledge processes: knowledge creation, knowledge acquisition, knowledge loss, knowledge sharing, knowledge use, emotional knowledge dynamics and spiritual knowledge dynamics.

The cluster „knowledge creation" contains the following risk typologies: knowledge risk of non-creation and knowledge risk of bad timing. The cluster „knowledge acquisition" comprises the knowledge risk of not acquiring the necessary knowledge at the required time and knowledge risk of wrong acquisition. „Knowledge loss" contains risks of knowledge loss with the retirement of people, risk of knowledge spillover and risk of knowledge forgetting. „Knowledge sharing" contains the risk of knowledge hiding and knowledge hoarding. The „knowledge use" cluster includes the risk of knowledge attrition when embedding it into products and services; the risk of knowledge waste. „Emotional knowledge dynamics" contains the emotional risk of organizational change and that of changing the managers. „Spiritual knowledge dynamics" comprises spiritual knowledge risk of changing the organzational values system and spiritual knowledge risks, when people work in different cultures in multinational companies (Bratianu, Neștian and Guță, 2022).

The filter question was applied as we were interested in analysing only private companies, and not public institutions or not-for-profit organizations. The survery was conducted online (between 20th and 26th of March 2023) using Google Forms. It helped us eliminate 13 out of 130 answers, which lead to a total of 117 valid questionnaires. To provide answers to all questions and items was mandatory for a questionnaire to be considered complete and then accepted to be sent.

3.3 The Sample

A link to the questionnaire was sent via different online channels (social media, software used in our teaching and research activities, etc.).

Out of a total of 420 people who received the questionnare, 130 respondents completed the questionnaire, 13 not working in private companies. There were 117 valid questionnaires and a valid rate of response of 27.8%.

We were interested in the perspectives of both managers and non-managers: 46.15% and 53.85% of the respondents, managers and non-managers, respectively.

Regarding the length of service in organisations (seniority), 35.04% of the respondents worked for over five years in the organization, 47.01% between one and five years, and only 17.95% under a year. Sample distribution by seniority of 117 respondents in companies strengthens the level of trust in the relevance of respondents' answers, considering that an employee with a longer length of service could know the company better.

As for organizations' field of activity, the sample comprising 117 respondents mentioned such areas as transportation, construction, retail, consultancy, online commerce, outsourcing, construction materials production, banking, drug promotion, automotive sector, real estate, metallurgy, legal sector, information technology, agriculture, medical equipment, marketing and services, finance consultancy, management consultancy, pharmaceutical industry, accounting, evaluation of movable and immovable properties, clinical research, commerce, audit and consultancy, hospitality industry, non-banking financial services – currency exchange, real estate and facilities, human resources, health, consultancy and training, public power supply and energy from renewable sources, sales and education.

3.4 Methods and Techniques Used for Data Analysis

For data processing and analysis, we used Microsoft Excel and Statistical Package for the Social Science (SPSS, version 20). Consistency (reliability) and factor analyses (principal components analysis - PCA) were conducted in SPSS. We have used reliability analysis for determining the internal consistency of the entire instrument (without the nominal scales), the scale for types of knowledge risks and knowledge vulnerabilities, respectively, the results obtained for the constructs' components "type of knowledge risks" and "type of knowledge vulnerability", respectively. PCA was used for extracting the components, also called factors, for each of the two latent variables: knowledge vulnerabilities and knowledge risks. The study also suggests the scales for both latent variables. Since similar quantitative studies have not been found in the literature on the topic, we applied exploratory factor analysis. There were no missing values as all items were mandatory for questionnaire completion and sending. Some items had to be reversed as they were positively or negatively formulated. Since we were measuring the vulnerabilities and risks, we chose to reverse the positively formulated items.

4. Results

4.1 Consistency Analysis

We tested the reliability of the entire questionnaire (only the ordinal scales, withouth nominal variables and open questions) and the reliability of the latent variables "type of knowledge vulnerability" and "type of knowledge risk".

The reliability analysis shows that the instrument and the scales for both latent variables have internal consistency, and therefore are reliable, since all Cronbach Alpha coefficients exceed the value of 0.7 (Hair et al, 2006). The values are shown in Table 1.

Table 1: Consistency Analysis of the Instrument and the Scales

Scale	Cronbach alpha coefficient
Entire instrument (both scaled: 40 items)	0.923
Scale for type of knowledge vulnerabilities (21 items)	0.883
Scale for type of knowledge risks (19 items)	0.856

4.2 Components Resulted for Knowledge Vulnerabilities and Knowledge Risks

The components resulted from principal component analysis for the latent variable "Types of knowledge vulnerabilities" are shown in Table 2 below. In the following table, K means "knowledge", C – "creation", A – "acquisition", L – "loss", S – "sharing" and U – "use". Also, EKD means "emotional knowledge dynamics" and SKD stands for "spiritual knowledge dynamics". The abbreviation "V" stands for the word "vulnerability". The number of each item (for example 2, from KA2_V) is its number in the cluster, as it was included into the theoretical cluster (knowledge acquisition, knowledge creation, etc.). For example, KA2_V is the second item included in the cluster of vulnerabilities related to knowledge acquisition.

Varimax rotation with Kaiser normalization was used. In Table 2, the items are displayed in descending order of their loadings, and only loadings higher than 0.5 are shown. According to Hair et al (2006), only loadings higher than 0.5 have practical relevance.

The solution contains 15 out of 21 items in the scale for knowledge vulnerabilities. Six items were eliminated due to such problems as individual measure of sample adequacy (MSA) lower than 0.5; very few significant correlations with other items; low communalities; loadings on two components (we guided after Hair et al, 2006). The total variance explained by four extracted components is 67.14%.

Table 2: Results for "Types of knowledge Vulnerabilities"

Rotated Component Matrix				
	Component			
	1	**2**	**3**	**4**
KA2_V: To obtain the necessary knowledge, we have ways that are aligned with organizational strategies.	0.818			
KA1_V: We have solutions through which, when necessary, we obtain the knowledge we need in time.	0.812			
KC2_V: We are connected in real time to the challenges / issues in the business environment.	0.658			
KC1_V: We have the capability to create new knowledge when it is needed.	0.649			
KU1_V: The organization has mechanisms through which it pursues access to new knowledge in the field.	0.619			
EKD2_V: Changing managers causes emotional problems for employees, affecting their performance.		0.876		
EKD1_V: Employees are put in situations where they feel strong negative emotions at work, affecting their performance.		0.822		
SKD1_V: The values shared by employees in the organization form a rigid system,		0.762		

Rotated Component Matrix				
	Component			
	1	2	3	4
which can be affected by the change of some of the managers or of the preferred ways of working.				
KL3_V: Sporadic use of some ways of working makes it difficult to remember the details that lead to the most efficient way of accomplishing tasks.			0.738	
SKD2_V: In the organization, there is a chance of occurrence of problems related to a different interpretation of some of the communicated information due to different cultural origin of those involved.			0.684	
KA4_V: Decision-makers are not prepared for some situations that require decision-making.			0.620	
KU3_V: Some employees have skills useful to the organization, which are being neglected.			0.609	
KA3_V: Decision-makers are ignorant of the new knowledge that we need.			0.579	
KS1_V: The organization requires employees to share with colleagues the knowledge they use in their work.				0.856
KS2_V: Employees' current work includes activities that involve sharing knowledge with each other.				0.776
Extraction Method: Principal Component Analysis. Rotation Method: Varimax with Kaiser Normalization.				

The value of Kaiser-Meyer-Ohlin (KMO) test is 0.835, which indicates that the solution obtained by applying principal components analysis is very good; Sig value of Chi-square (Bartlett's Test of Sphericity) is 0.00, which guarantees us a likelihood of 95% that there are statistically significant correlations between the variables (Pintilescu, 2007).

According to the items loaded on each component and taking into consideration the majority of the items included in each component (Hair et al, 2006), we suggest the following names for the four knowledge vulnerabilities components: component 1 – *vulnerabilities related to knowledge creation and knowledge acquisition* (Cronbach alpha 0.822), component 2 – *vulnerabilities related to emotional and spiritual knowledge dynamics* (0.845), component 3 – *vulnerabilities related to knowledge loss and knowledge use* (0.770) and component 4 – *vulnerabilities related to knowledge sharing* (0.759).

Table 3 includes the results obtained by applying PCA, with Varimax rotation with Kaiser normalization for types of knowledge risks. "R" stands for "risk". Items are displayed in descending order of their loadings; only loadings higher than 0.5 are shown. The solution contains nine out of 19 items in the scale for knowledge risks. We have eliminated 10 items due to such problems as very few significant correlations with other items and / or individual measures of sample adequacy (MSA) lower than 0.5; low communalities. Total variance explained by the three extracted components is 70.95%.

Regarding some problems with corellations and with MSA values, we looked for explanations in the literature. According to Lorenzo-Seva and Ferrando (2021), MSA can highlight two types of problematic items: *noisy* items – items that behave almost randomly, and *redundant* items – the items sharing specific content with the other ones. Based on the exploratory factor analysis, we consider risks related to knowledge sharing to be related to other items in the scale for knowledge risks, and therefore reflecting other types of risks.

Table 3: Results for "Types of Knowledge Risks"

Rotated Component Matrix			
	Component		
	1	2	3
KU1_R: Some knowledge used in my organization is outdated / obsolete as new inventions have appeared.	0.842		
KU2_R: Some knowledge used in my organization is corrupt as we had waited too long	0.839		

Rotated Component Matrix			
	Component		
	1	2	3
before it was used.			
KC2_R: Employees' ideas are sometimes expressed too late compared to the time when they could have been used.	0.636		
KA1_R: We do not sometimes obtain new knowledge in the needed time-frame.	0.615		
EKD2_R: Changing managers led to negative employee emotions, causing further deterioration of the way employees use or make their knowledge available to the organization.		0.863	
EKD1_R: When employees experience strong negative emotions at work, it causes further deterioration of the way they use or make their knowledge available to the organization.		0.827	
SKD1_R: Making changes in the organization's system of values had negative consequences on the way employees used or made their knowledge available to the organization.		0.797	
KA3_R: We sometimes acquire knowledge that is not useful for the needs of our organization.			0.893
KA2_R: We sometimes acquire knowledge „unsuitable" to the needs of our organization.			0.878
Extraction Method: Principal Component Analysis. Rotation Method: Varimax with Kaiser Normalization.			

The value of KMO test is 0.728, which indicates that the solution obtained by applying principal components analysis is good. Sig value of Chi-square (Bartlett's Test of Sphericity) is 0.00, which guarantees with a likelihood of 95% that there are statistically significant correlations between the variables (Pintilescu, 2007).

We propose the following names for the three components obtained for knowledge risks, in line with the items loaded on each component and taking into consideration the majority of the items included in each component (Hair et al, 2006): component 1 – *risks related to knowledge creation and knowledge use* (Cronbach alpha 0.775), component 2 – *risks related to emotional and spiritual knowledge dynamics* (0.809) and component 3 – *risks related to knowledge acquisition* (0.846).

Figures 1 and 2 below present the components obtained for knowledge vulnerabilities and knowledge risks.

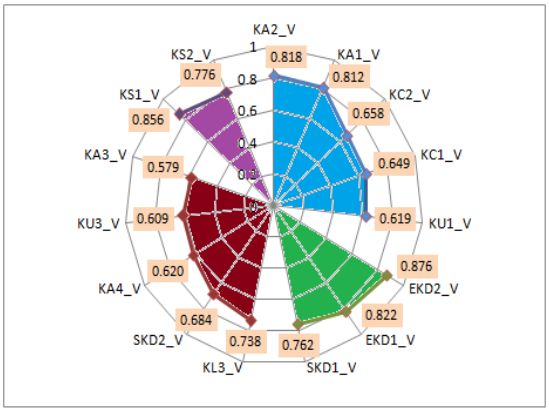

Figure 1: Components for Knowledge Vulnerabilities

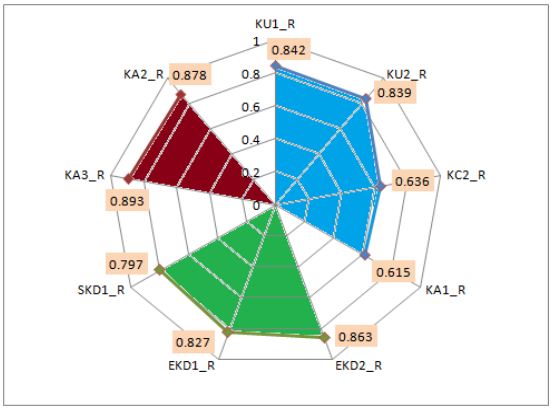

Figure 2: Components for Knowledge Risk

5. Conclusion

This study aimed to suggest measuring scales for knowledge vulnerabilities and knowledge risks and identify the factors composing the two constructs. Thus, a first conclusion is that we can see different associations, both for vulnerabilities and risks, in the grouping of different knowledge processes. For the vulnerabilities scale, knowledge creation grouped together with knowledge acquisition, knowledge loss with knowledge use, emotional and spiritual knowledge dynamics, knowledge sharing resulted by itself in a component. For risks, knowledge creation grouped with knowledge use, emotional and spiritual knowledge dynamics also grouped

together, knowledge acquisition resulted by itself in a component. There are some major differences between the components for each of the two constructs. These differences concerning knowledge-related processes comprise knowledge creation vulnerabilities combining in a single factor with knowledge acquisition vulnerabilities, and knowledge creation risks combining in a single factor with knowledge use risks; knowledge use vulnerabilities combining in a single factor with knowledge loss vulnerabilities, while knowledge use risks combining in the same factor with knowledge creation risks. Knowledge sharing as a knowledge process appears only in the factorial solution for vulnerabilities, being though eliminated from the solution for knowledge risks. Table 4 is a visual representation that compares the results by types of knowledge vulnerabilities and knowledge risks.

Note: We used different shades of gray to mark different knowledge processes

A potential explanation for the combining of knowledge *loss* and knowledge *use vulnerabilities* in the same factor, and knowledge *creation* with knowledge *use risks*, lies in the fact that when companies have vulnerabilities leading to loss of knowledge, it could also involve vulnerabilities related to knowledge use. Further, this complex vulnerability may correlate with risks related to knowledge use, which may also lead to knowledge creation risks, since it is harder to create new knowledge when organizations have problems related to knowledge use.

Another interesting result is related to the process of knowledge sharing. Regarding vulnerabilities, PCA led us to a factor referred to as vulnerabilities related to knowledge sharing. However, for the factorial solution for risks related to knowledge processes, we decided that it was correct to eliminate the items measuring knowledge sharing, thus the solution for this type of risks does not contain a factor for knowledge sharing. A possible explanation may be the fact that vulnerabilities related to knowledge sharing do not transpose in risks related to the process of knowledge sharing but in risks related to other knowledge processes. However, an alternative explanation may be related to the small size of the sample, which is a limitation of the present study.

Another potential explanation that needs to be cautiously treated (due to sample size and the exploratory nature of the study) is the fact that we may need to rethink some of the items, and reformulate or conceptually reframe them into other clusters than the initial ones (considering the current empirical results).

Althouth it needs further improvement and testing, the proposed scale is a first step in performing a quantitative assessment of risks and vulnerabilities related to knowledge processes in organizations. We believe that the components resulted by applying principal components analysis offer a clearer picture on the constructs of vulnerabilities and knowledge risks, leading to a deeper understanding of knowledge processes and their associated risks.

The results of this study need to be cautiously treated due to the small size of the sample (117 valid responses) and the applied convenience sampling technique. Therefore, future research can include sample extension and a systematic sampling; scale refinement and further testing – exploratory and confirmatory; longitudinal studies for companies interested in knowledge risks and vulnerabilities.

After refinement, the scale will be useful for organizations intending to assess their knowledge vulnerabilities and risks. Correlations between the components of knowledge risks and knowledge vulnerabilities, as well as the calculation of means for each component could offer valuable information for taking managerial decisions.

Abstract: Higher Education Institutions (HEIs) have the fundamental role of teaching, research, and interaction with society, which are the three main vertices in the creation and dissemination of knowledge. HEIs can enhance their sustainability and competitiveness by effectively managing the knowledge of each collaborator and creating more value. In this way, HEIs lay the foundation for sustainable growth and extend their competitive advantages. However, it requires motivated and committed collaborators aligned with the mission, values, and objectives of the organization. Therefore, we suggest that the incorporation of spirituality can promote innovation, organizational sustainability, and increase knowledge management practices. To address the research gap on the integration of KM and spirituality in HEIs, we conducted a literature review using three databases, Web of Science, Scopus, and EBSCO. The review revealed that the integration of KM and organizational spirituality has not been studied in an integrated way. As such, we present suggestions for future research and practice, emphasizing the need for HEIs to focus on managing knowledge and incorporating spirituality into their practices to enhance their competitiveness and sustainability. Accordingly, this study contributes to the literature by awarding and discussing KM and spirituality as two key components of HEIs. Once, incorporating spirituality can promote innovation, organizational sustainability, and increase knowledge management practices. Moreover, this study provides valuable insights for HEIs to improve their management practices, promote sustainability, and enhance their competitive advantages.

Keywords: Knowledge management; Knowledge management practices, Spirituality, Organizational spirituality, Education, Higher education institutions

1. Introduction

Knowledge is seen as a key source of competitive advantage within an organization (Feiz et al., 2019; Dei and Van Der Walt, 2020) , as it provides new opportunities and enables problem solving (Feiz et al., 2019). In this way, and in this knowledge society all organizations operate in a global economy that is characterized by intense competition, economic interdependence and collaboration (Van Laar et al, 2017). Thus, organizations are increasingly humanized and dedicated to determining values at the individual and organizational levels. In this sense, Knowledge Management (KM) is an important topic for organizations and specifically for Higher Education Institutions (HEIs), whose continuous improvement strategy involves achieving international standards of quality and excellence, which is only achieved if they practice an effective KM (Moscoso-Zea and Lujan-Mora, 2017).

However, rational knowledge is not enough to ensure that appropriate decisions and actions are taken for organizations to achieve the competitiveness they desire (Rocha and Pinheiro, 2021). In this way, and so that HEIs fulfill their function of contributing to the economic and sustainable development of any country (Madboulya et al., 2021; Roopaa and Gopinath, 2021) it is important to integrate spirituality, since it inspires innovation, enhances productive work, emotional intelligence, employee involvement and loyalty (Alomar et al., 2022). That is, in HEIs, an environment marked by spirituality is favorable to the creation of knowledge, which on the one hand promotes efficient knowledge management and on the other hand enhances trust and promotes sharing (Shahzadi, 2017).

This paper aims to analyze the state of the art of research on KM and spirituality in HEIs. The objectives are to identify existing literature that addresses KM and spirituality in HEIs and to analyze the practices of KM and spirituality in HEIs present in the literature. By achieving these objectives, this work aims to contribute to the understanding of how HEIs can effectively manage knowledge and enhance their competitiveness by integrating spirituality.

2. Insights on Knowledge Management and Spirituality in HEIs

As IHEs represent the highest level of learning and education, as education has as its main focus the student as a whole, with all their facets and dimensions, from intellectual to professional, psychological, moral, and spiritual dimensions (Kassaye, 2018). They are the places where students develop in various areas and where research is

promoted. In other words, they are a community of people committed to studying, to research, in a place that is a universal source of knowledge (Kassaye, 2018). Similarly, they also seek to instill confidence in individuals, in order to increase their motivation, and thereby improve organizational capacity, opportunities to learn and acquire knowledge to obtain positive results (Dei and Van der Walt, 2020).

Moreover, IHEs are one of the few places where knowledge is used by all employees. They are responsible for the production and transfer of knowledge, so they must have a greater concern for knowledge management (Asiedui et al, 2022; Saleh et al, 2018). Rowley (2000) points out that the norms, values, and practices associated with the creation, sharing, and dissemination of knowledge in IHEs are complex, so in line with knowledge management, organizational spirituality also has strategic importance. These should encourage the spirituality of their employees, motivating them to deal with their own knowledge (Lakshmi and Das, 2021). Although IHEs have not yet explored these themes in depth, as other organizations have done (Ramachandran et al, 2009; Ojo, 2016; Marouf and Argarwal, 2016; Lakshmi and Das, 2021; Asiedui et al, 2022), we see from the analysis carried out that there is already a concern with knowledge sharing and with existing knowledge management practices in IHEs. However, with regard to spirituality, this is not so evident.

Organizational spirituality is often considered when discussing the organizational culture of IES. Also, spiritual intellectual capital is interpreted as encompassing the spiritual values of the organization, including adaptability, commitment, motivation, trust, responsibility, respect, justice, receptivity, integrity, mutualism, benevolence, humanism, and generativity (Jurkiewicz and Giacolone, 2004). These values, in order to be efficiently practiced, must be present in the organizational culture and serve as drivers of proactive, entrepreneurial, and creative behavior capable of leading to innovation and sustainability. Furthermore, IHEs with a more dynamic organizational culture advocate an atmosphere where all employees feel truly integrated, where everyone identifies with their fellow collaborators. If different employees have the capacity for acceptance, a spirit of collaboration, and a sense of responsibility, then we are faced with a voluntary environment for sharing knowledge.

Nevertheless, little attention has been given to the connection between organizational spirituality, that is, an organizational culture marked by higher order values focused on individual well-being, the well-being of others, and knowledge management (Khari and Sinha, 2018). To be effective, spirituality needs to be integrated into the organizational culture and reflected in everyday organizational practices. And this is only possible if the administration and the administrative council adopt it as part of their vision, so that its benefits grow for employees and the organization (Dandona, 2013). That is, organizational spirituality is influenced by the environment, organizational culture, mission, vision, and organizational values (Rocha and Pinheiro, 2020). Likewise, Shahzadi (2017) points out that IHEs that possess an environment marked by spirituality are conducive to the creation of knowledge, promote trust among team members, which increases knowledge sharing.

3. Research Design

We conducted a systematic literature review to address our research goals. A literature review article provides a comprehensive view of the literature related to a topic, identifies current knowledge as well as existing gaps at the research level (Paul and Criado, 2020). The procedure is shown in Figure 1.

4. Analysis of the Results

In this section, we report an in-depth analysis of the systematic review outcomes to provide a comprehensive view of the latest findings and insights regarding KM and spirituality in IES. Through our analysis, we identify the most valuable findings and trends in the literature and offer critical insights that can inform future research and practice. Overall, the research includes themes as spiritual knowledge and intellectual capital in HEIs. A compilation of the research, considering spirituality and KM in HEIs in provided below in Table 1.

Saad and Haron (2013) conducted a qualitative study with a sample of 15 academics to explore and describe the types of knowledge shared among academics in a public university in Malaysia. The authors adopted Van den Hooff and De Ridder's (2004) definition of knowledge sharing as "a process where individuals mutually exchange their knowledge and together create new knowledge" (p. 118). They concluded that categorizing/classifying knowledge is extremely important for Higher Education Institutions (HEIs), particularly as academic knowledge producers, as it facilitates the process of capturing, using, sharing, and retrieving the knowledge necessary for faculty.

They found that academics share three types of knowledge: corporate knowledge, social knowledge, and codified knowledge. (i) Corporate knowledge pertains to the organization's core activities and management

procedures, including disciplinary knowledge (knowledge of the discipline and research) and operational knowledge (knowledge of the institution's policies and practices). Social knowledge refers to knowledge related to shared beliefs, ethics, norms, culture, values, entertainment, national political affairs, and common interests, with prevailing knowledge of culture, spiritual knowledge, hobby knowledge, and common interest knowledge. Finally, (iii)codified knowledge is shared electronically (photos, videos, conference slides) and/or in writing (research articles, lecture notes, tutorials, books, among others) (Saad and Haron, 2013).

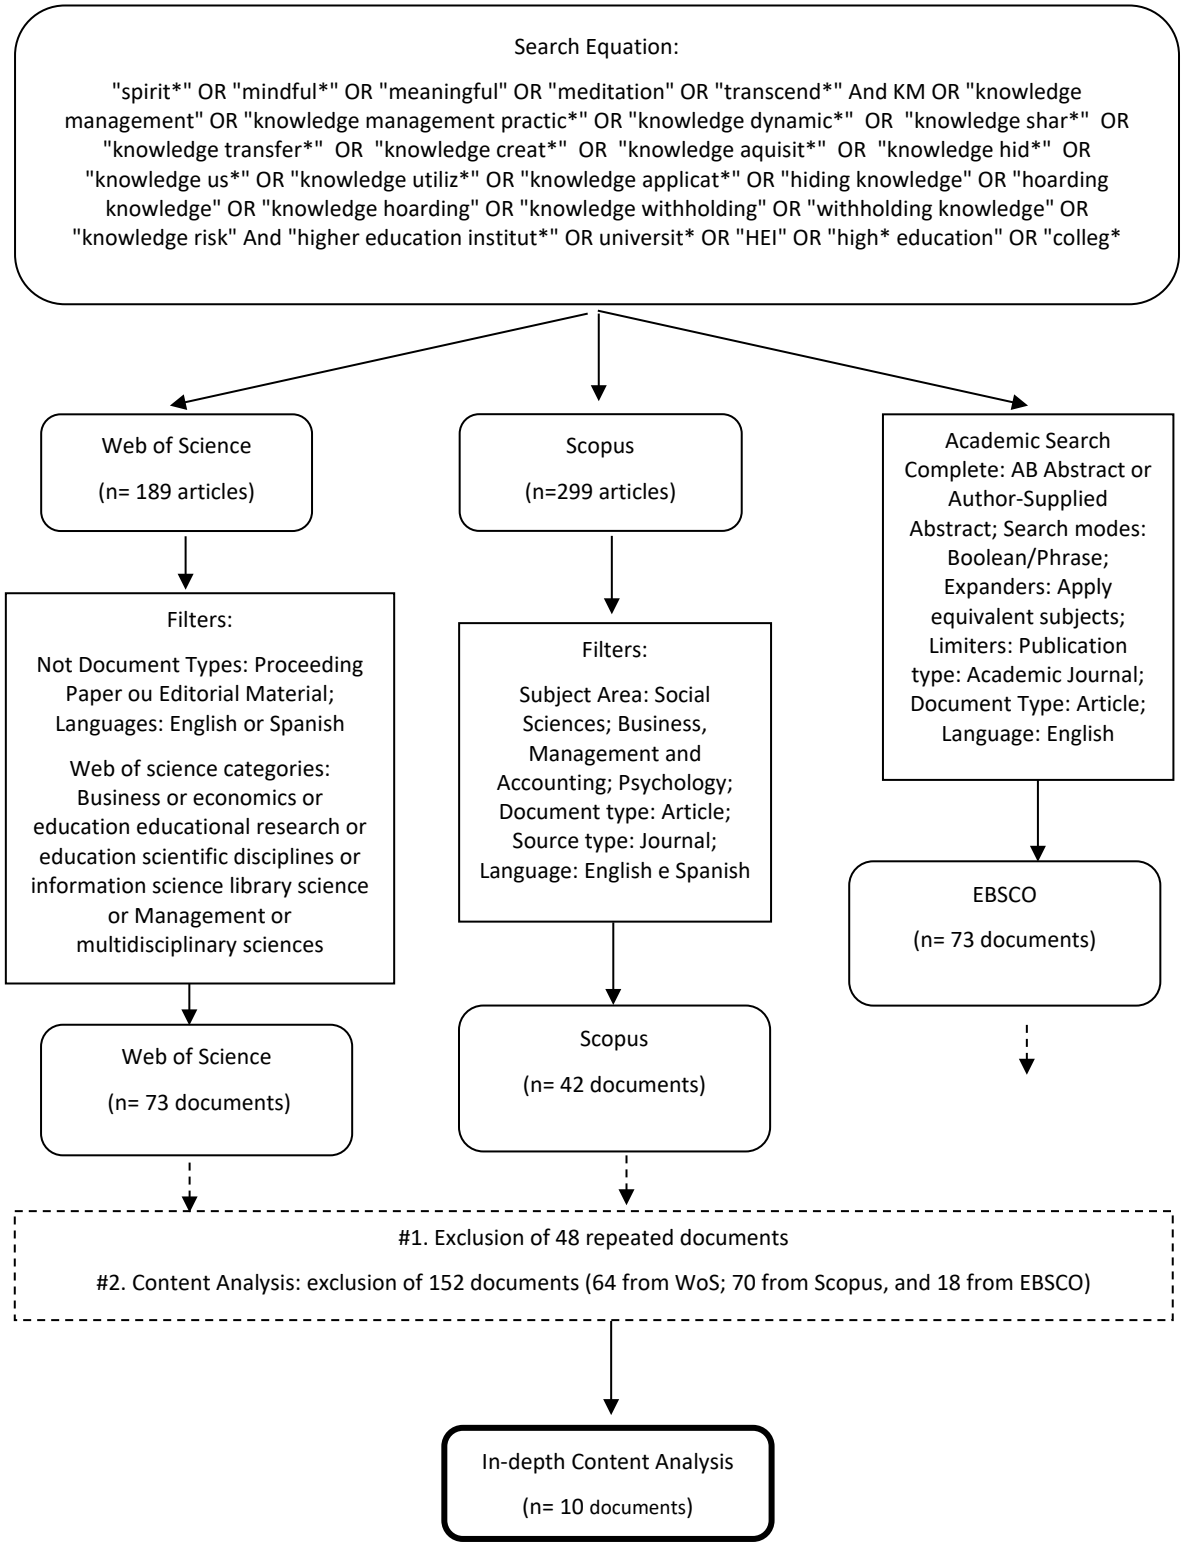

Figure 1: Structure of the Systematic Literature Review

Feiz et al. (2019) conducted a study on the effect of knowledge sharing on the psychological empowerment of faculty members at an Iranian university. They distributed three questionnaires to 350 faculty members and found that knowledge sharing positively affects psychological empowerment and organizational memory. The authors suggest that planning for knowledge sharing among faculty members can improve resource management and develop knowledge-based skills. They also encourage universities to incentivize knowledge sharing to increase confidence, effectiveness, and productivity among faculty members.

Nawaz et al. (2020) emphasize the importance of a systematic knowledge management approach in universities due to their role in creating and transferring knowledge and dependence on and vulnerability to knowledge erosion. Their study focuses on knowledge management practices in Europe, Asia, and the Gulf Cooperation Council countries, analyzing perception, gathering, creation, sharing, dissemination, and retention of knowledge. Using a quantitative methodology and a sample of professors, the authors conclude that there are similarities between most of the practices analyzed, except for knowledge gathering and retention, where considerable differences exist. Furthermore, the authors suggest the need for integrated knowledge management systems in universities.

Leon and Vătămănescu (2015) explores how storytelling is used as a knowledge strategy among faculty members in Romanian HEI. The qualitative study involved 29 professors who were selected through snowball sampling, based on their two-year professorship and professional experience in the private sector. They highlight the critical role of human and structural capital in knowledge creation, acquisition, and sharing, and recommend storytelling as an easy-to-implement and cost-effective knowledge strategy.

The authors propose storytelling as a knowledge strategy that is easy to implement and has lower costs compared to other strategies. Storytelling involves the sharing of various types of knowledge, such as cognitive, emotional, and spiritual. Cognitive knowledge encompasses an understanding of the work environment by transmitting tacit and explicit knowledge based on shared mental models. Emotional knowledge enables employees to know what others expect of them, promoting cultural adaptation, while spiritual knowledge transmits norms and values from generation to generation, allowing employees to internalize organizational culture and stimulate its adaptation. Storytelling allows faculty members to share their experiences inside and outside the classroom, demonstrating availability and openness to hearing their colleagues' experiences.

In sum, the study by Leon and Vătămănescu (2015) highlights the importance of leveraging storytelling as a knowledge strategy in HEIs. This strategy has the potential to bridge the gap between explicit and tacit knowledge by creating a platform for knowledge sharing, thus promoting innovation and strategic renewal. It is crucial for HEIs to recognize and prioritize storytelling as an effective knowledge strategy to unlock the full potential of their intellectual capital. By doing so, they can cultivate a culture of collaboration and learning that fosters the development of a knowledge-based society.

Bejinaru (2017) and Bratianu and Bejinaru (2017) propose a new construct of intellectual capital structure using the multi-field theory of knowledge and the concept of non-linear integrators. They identify knowledge strategies that can increase intellectual capital in HEIs. The authors introduce three new categories of intellectual capital: rational, emotional, and spiritual. They suggest that HEIs should focus on analyzing emotional and spiritual intellectual capital.

The authors propose four knowledge strategies that can increase intellectual capital. These strategies include creating knowledge through a rewards system to encourage research, sharing knowledge to increase operational intellectual capital, acquiring new knowledge from external sources, and exchanging knowledge within a university network through the exchange of students and faculty. The goal is to identify and overcome barriers to knowledge sharing in order to improve university strategies and increase intellectual capital. However, they also suggest that further research is needed to understand the impact of these strategies on intellectual capital and to develop ways to implement them in HEIs according to their mission and vision (Bejinaru, 2017; Bratianu and Bejinaru, 2017).

Bratianu and Vătămănescu (2018) provided a new approach of the entropic knowledge dynamics and investigate the impact of the decision-making process. Through a quantitative methodology using a survey of 700 management and business administration students, they present the multifield theory of the knowledge based on the energy metaphor of knowledge. They attribute to the three forms of energy: mechanical, thermal, and electric, the three forms of knowledge: rational, emotional, and spiritual. The entropic dynamics of knowledge assumes that these three forms of knowledge are in continuous interaction, and any one of them can transform into any form of knowledge. In this context, for Bratianu and Vătămănescu (2018), the decision-making process

is not purely rational but results from the contributions of rational, emotional, and spiritual knowledge, as well as the entropic dynamics of each of these. The authors' findings suggest that the decision-making process should consider the entropic nature of knowledge, as it could lead to more effective decisions.

Pavlidou et al. (2021) address concerns about business education, which often focuses on instructional design and individual disciplines rather than developing students' holistic knowledge and long-term employability skills. The authors draw on the domain of knowledge management and dynamic knowledge theory to approach business education as a dynamic field of knowledge composed of three forms of interaction: rational, emotional, and spiritual knowledge, following the work of Bratianu and Bejinaru (2019a) and Bratianu and Bejinaru (2019b). Moreover, Pavlidou et al. (2021) emphasize that hybrid learning environments stimulate different aspects of rational, emotional, and spiritual knowledge due to the diversity of learning modes and sources, which guides teachers to use knowledge structure as a guide to assess student experiences. Therefore, it is crucial to understand the dynamics of knowledge and to consider its role as an essential force in business education, which challenges traditional teaching methodologies.

Power and Handley (2019) developed an interdisciplinary model of best practices in UK HEIs with a focus on teaching, learning, and the student experience. This model brings together six enablers that promote interdisciplinarity: (i) Positioning: Interdisciplinarity should be positioned outside the curriculum, which allows for the reduction of disciplinary barriers and removes some knowledge niches; (ii) People: Authentic leadership and selection of support group members; (iii) Environment: Spaces, resources, and infrastructures; (iv) Rewards: Target measures, talent management, incentives, and clarity of impact; (v) Conduct factors: Mutual respect, intellectual fusion; and (vi) Communication: Articulation in terms of benefits, values, impact, challenges, barriers, and facilitators of interdisciplinarity. However, the authors consider that more research is needed to validate this model, including integrated research that allows for an understanding of the implications of this model within British HEIs involving all stakeholders and also the commercial sector so that interdisciplinarity progresses.

Alwaheeb et al. (2020) provide a comprehensive review of studies that explore the relationship between organizational commitment and knowledge sharing in order to develop a conceptual framework that links these two concepts in HEIs. The analyzed literature reveals a lack of evidence on how organizational commitment influences knowledge sharing in the context of HEIs in Malaysia. In other words, there is still a gap in knowledge sharing in HEIs that could be filled if institutions motivate knowledge-sharing behavior and promote it (Alwaheeb et al., 2020). Likewise, the authors suggest that academics need to focus on increasing the level of organizational commitment to improve knowledge-sharing behavior, as well as workplace spirituality, which will ultimately enhance the effectiveness and performance of HEIs. However, according to the authors, there may be other organizational factors that can influence knowledge sharing, and these should be examined in future studies (Alwaheeb et al., 2020).

Table 1: Knowledge Management Practices and Spirituality Dimensions.

Studies	Knowledge Management	Spirituality
Alwaheeb et al. (2020)	Knowledge Sharing	Workplace
Bejinaru (2017)	Knowledge Creation, Sharing, Acquisition	Individual and Workplace

Feiz et al. (2019)	Knowledge Sharing	Individual
Leon and Vătămănescu (2015)	Knowledge Creation, Sharing, Acquisition	Individual and Workplace
Nawaz et al. (2020)	Knowledge Creation, Sharing, Perception, Collection; Dissemination, Gathering	Workplace
Pavlidou et al. (2021)	Knowledge Creation, Sharing	Individual and Workplace
Power and Handley (2019)	Knowledge Sharing	Individual
Saad and Haron (2013)	Knowledge Sharing	Individual and Workplace

5. Discussion

The presented analysis of the results explored the relationship between KM and spirituality in HEIs providing valuable insights. It highlights the need for systematic knowledge management approaches to manage and transfer knowledge effectively, thereby improving resource management and developing knowledge-based skills. The study also emphasizes the critical role of human and structural capital in knowledge creation, acquisition, and sharing, and recommends storytelling as an easy-to-implement and cost-effective knowledge strategy that promotes innovation and strategic renewal. The proposed knowledge strategies, including creating knowledge through a rewards system, sharing knowledge to increase operational intellectual capital, acquiring new knowledge from external sources, and exchanging knowledge within a university network, can increase intellectual capital in HEIs, but further research is needed to understand their impact and to develop ways to implement them according to mission and vision.

The outcomes indicate that most authors do not examine organizational spirituality and KM together in HEIs. However, Leon and Vătămănescu (2015) present storytelling as a knowledge-sharing strategy, indicating that through it, educators share rational, emotional, and spiritual knowledge. In contrast, Bejinaru (2017), Bratianu and Bejinaru (2017), and Bratianu and Vătămănescu (2018) integrate these two constructs into their work. When presenting the main knowledge strategies to increase the potential of HEIs and operational intellectual capital, they refer to KM practices that interconnect with spiritual intellectual capital.

Furthermore, it is observed that Bejinaru (2017) and Bratianu and Bejinaru (2017) address the main knowledge strategies for increasing the potential of IES and operational intellectual capital, which are related to knowledge management practices. Therefore, it can be inferred that they are among the few authors who, in the same work, articulate the two constructs: knowledge management and organizational spirituality. Bejinaru (2017) and Bratianu and Bejinaru (2017) emphasize the importance of emotional and spiritual knowledge in knowledge creation, as they contribute to a culture that encourages research efforts and stimulates new ideas in science, technology, and business. This perspective aligns with the idea that knowledge management and organizational spirituality should be viewed in an integrated manner. Organizational spirituality may serve as the primary motivator for employees to act on their individual capacity to increase organizational effectiveness and reinforce knowledge management tools and techniques (Lakshmi and Das, 2021). Thus, spirituality serves as the foundation for ethical and committed behavior within and outside of HEIs.

The theoretical and practical contributions of this literature review are significant. The review highlights the importance of knowledge management and spirituality in HEIs and provides evidence that HEIs must adopt a culture that supports knowledge dynamics. The findings of this review have important implications for policymakers, educators, and researchers who are interested in the effective functioning of HEIs. Policymakers should pay more attention to the organizational culture and leadership style in HEIs to ensure that these institutions can promote knowledge dynamics effectively. Additionally, educators should be encouraged to share their knowledge and experiences, and researchers should be supported in their efforts to explore the complexities of knowledge management and spirituality in HEIs. Furthermore, the results of this analysis have significant implications for the effective functioning of HEIs and can be used to inform future research in this area.

6. Conclusions

HEIs face intense competition and rapidly changing behaviors. To thrive, HEIs must decide between a more creative, dynamic, and collaborative approach that enhances their longevity and competitiveness or a more passive and stagnant one. Implementing coherent and interconnected knowledge management and spirituality practices is a path they must undertake to choose the former option. Thus, to assess the state of research on KM and spirituality in HEIs, we conducted a study using three databases. We aimed to determine whether the literature integrates these two themes and to identify the most focused KM and spirituality practices in the literature.

Effective KM in HEIs is crucial, as it allows us to gauge how knowledge can be created, shared, transferred, stored, and reused to achieve organizational goals. Thus, it is essential to analyze the KM practices used in HEIs. However, research on such practices in isolation are insufficient. Thus, it is important to incorporate the concept of organizational spirituality, which can lead to a better organizational climate and greater sustainability. Both constructs should work together rather than in separation. Unfortunately, most authors do not integrate these concepts in their analysis. Therefore, KM and organizational spirituality should be studied together, as they feed into each other, resulting in a more beneficial outcome for HEIs. Leaders should promote effective KM and

develop practices that contribute to a work environment guided by spiritual values. Our analysis also revealed that this area remains relatively unexplored, despite its potential importance in the future of HEIs.

Notwithstanding of the research contribution, it has limitations, namely, the small number of documents analyzed. Thus, it is necessary for example, to search in other databases and try other search terms.

In conclusion, our study emphasizes the importance of integrating KM and organizational spirituality in HEIs. Doing so can lead to a more competitive and sustainable institution. However, further research is necessary to better understand how to effectively integrate these concepts into HEIs.

7. Future Research Avenues

The current literature on the integration of KM and spirituality in HEIs has several research gaps. Future research suggestions can enhance understanding of the integration of KM and spirituality in HEIs and its influences. Hence, this research offers valuable contributions to the literature, and offering below insights and recommendations for future research and practice.

Firstly, future studies should focus on the identification and analysis of the relationship between spiritual knowledge and intellectual capital in HEIs. For example, to provide a deeper understanding of the relationship between spiritual knowledge and intellectual capital would be beneficial in facilitating the creation, utilization, sharing, and transfer of knowledge in HEIs.

Secondly, future studies should examine the role of leadership in promoting the integration of KM and spirituality in HEIs. Leaders can play a crucial role in fostering a culture of spirituality and knowledge sharing in organizations. Therefore, research should investigate the characteristics of effective leaders in HEIs who facilitate the integration of KM and spirituality, as well as the potential barriers to this integration.

Thirdly, future research could explore the impact of cultural differences on the integration of KM and spirituality in HEIs. HEIs operate in a globalized world, and each country has its cultural and social specificities, which may impact the integration of spirituality and KM. Hence, comparative studies between different countries could provide insights into the cultural and institutional factors that affect the integration of KM and spirituality in HEIs.

Finally, future studies should investigate the impact of KM and spirituality on the well-being and job satisfaction of employees in HEIs. Given the importance of well-being and job satisfaction in organizational performance, it would be valuable to explore how the integration of KM and spirituality could contribute to these outcomes.
