One of the first writers in Sweden to acknowledge the need to measure intangible assets was Karl-Erik Sveiby, who is credited with founding the knowledge management and intellectual capital movements.

In June 1991, Stewart published an article titled "Brain Power - How Intellectual Capital Is Becoming America's Most Valuable Asset," which effectively introduced "intellectual capital" into the management lexicon despite Sveiby's assertiveness. In this essay, Stewart argues that various forms of knowledge, such as patents, procedures, management talents, technology, data on suppliers and consumers, and prior experience, are growing in significance for the entire firm. The collection of knowledge and expertise is referred to as intellectual capital. In other words, the company's competitive advantage arises from the combined expertise of its

whole workforce. He contributed to the rise in the significance of intellectual capital by penning the cover story "Your Company's Most Valuable Asset: Intellectual Capital" for Fortune magazine in 1994 and later publishing the book "Intellectual Capital: The New Wealth of the Organization" (Stewart, 1997).

Nonetheless, Sveiby's (1997) work inspired Leif Edvinsson, the corporate director of Skandia AFS, who was among the first to refer to intangible assets as intellectual capital. He created the idea and defined intellectual capital as the body of information, practical experience, organizational technology, professional skills, and client relationships that provide a business with a competitive edge.

Edvinsson (1997) explains intellectual capital using a metaphor. The author likens a business to a fruit tree, with financial outcomes as the fruits and intellectual capital as the roots that ensure long-term sustainability.

Edvinsson and Malone (1997) divide intellectual capital into two categories: human capital and structural capital.

These writers define human capital as the capital of the organization's human resources: talents, creativity, relationship-building ability, cumulative value of practices, and values. This capital also includes the organizational principles and culture of the business. These writers contend that this capital is the fundamental wellspring of creativity and rebirth.

The worth of databases, software, manuals, pamphlets, client lists, and other items still in the company after employees "go home" is known as structural capital. Customer and organizational capital are two categories into which this capital can be separated. Organizational capital is subdivided into innovation capital (the company's capability for innovation) and process capital (the company's value creation and non-value creation processes). Customer capital, sometimes called relational capital, is the worth of a business's connections with its clients. This perspective holds that intellectual capital, the foundation of the capacity to produce value of the highest caliber, is the total of structural and human capital.

Since Edvinsson is considered the intellectual capital theorist who contributed most to developing the notion, this study concentrates on his definition.

To enhance intellectual capital management, it was necessary to develop a variety of models so that it would be possible to determine which is the most effective and how it should be managed (Matos, 2011; Matos, 2013). Despite the emergence of various frameworks (see Edvinsson and Malone (1997); Stewart, 1997; Sveiby (1997); Kaplan and Norton, (1992, 1996) Mouritsen et al.,(2001); Andriessen & Tissen, (2000); Viedma, (2001); and Andriessen, (2004) there is currently no consensus regarding the optimal model for intellectual capital management.

This study opted to utilize the Intellectual Capital Management model (ICM), as suggested by Matos and Lopes (2009). This model is widely used in the business sector and offers a more robust capability than alternative models to address the complexity associated with the elements comprising intellectual capital and organizational knowledge (Matos, 2011).

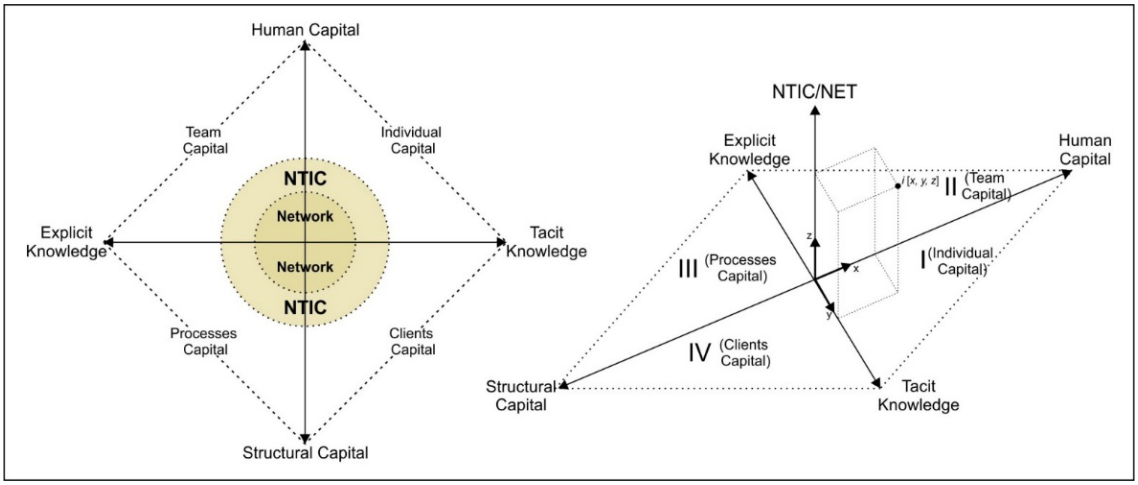

Figure 1: ICM - Intellectual Capital Model (Matos and Lopes, 2009)

According to this model, the intellectual capital assets is organized by two axes that reflect Knowledge (with Tacit Knowledge and Explicit Knowledge as opposed factors) and Organization (with Human Capital and Structural Capital as opposing factors). The four quadrants are categorized as follows: Quadrant I represents Individual Capital, Quadrant II represents Team Capital, Quadrant III represents Processes Capital, and Quadrant IV represents Clients Capital. The core component of the model illustrates the impact of New Technologies of Information and Communication (NTIC) in conjunction with Networks (NET) on all functions and tasks related to intellectual capital management (Matos et al., 2020).

3. Methodology and Data Sources

This study's target population corresponds to the workers of OPART and, more specifically, the collaborators of SCNT and VCS, a total of 262 collaborators. A convenience sample was extracted, taking into account the risk of respondents refusing to participate in the investigation or bureaucratic limitations.

As it was impossible to obtain authorization to administer a questionnaire to NCB workers, the decision was made to administer questionnaires to all workers at TNSC and VCS, regardless of their professional category, to obtain a representative sample of this universe. Responses were obtained from 39 individuals, approximately 15% of the population.

A questionnaire aimed at verifying workers' perceptions of Intellectual capital management was developed based on the questionnaire that supports the model proposed by Matos (2013).

Due to the constraints of the data frame, sample size, and response rate, the findings cannot be extrapolated to the Target Population. The current work is regarded as a preliminary study to support future research endeavors.

Following the ICM model proposed by Matos and Lopes (2009), the survey was divided into six parts: a set of questions that focus on respondents' social characterization and five sets of questions corresponding to the five dimensions of intellectual capital proposed by Matos and Lopes (2009): individual capital, team capital, processes capital, customer capital, networks, and new communication technologies.

The questionnaire has a total of 73 questions.

The same 5-point Likert scale tested by Matos (2013) was used.

4. Data Analysis

The Cronbach's Alpha Coefficient and the Pearson Correlation Coefficient were used to verify the internal consistency of the variables and the reliability of the questionnaire survey.

Given that the ICM is based on a theoretical structure, it was considered appropriate to carry out principal components analysis for exploratory analysis of adjusting data to a low-dimensional factorial structure.

This research was carried out using IBM SPSS Statistics 25 software.

4.1 Sample Characterization

The data that seems most relevant to the social characterization of the sample are presented below.

Approximately 54% are female, with the remaining 46% being male.

Regarding the level of education, it appears that most participants obtained a bachelor's degree (33.3%), and 15.4% of participants obtained a master's degree.

It can be observed that the majority of participants who were given the questionnaire indicated the NTSC as their place of work, with approximately 90% of responses, and the remaining 10% as the minority who responded that they were working at the VCS. Regarding the years of work at OPART, it was possible to verify that most participants have worked for more than ten years in the company (65.8%), and only 15.8% of participants say they have worked for OPART for between five and ten years. Only 2.6% say they have worked at OPART for less than one year.

4.2 Analysis of the Average Responses to the Quadrants of the ICM Model

To better understand how participants' opinions in this study are formed, an analysis was carried out on the response averages per Quadrant, among the four quadrants and NTIC and NET that make up the ICM model used in this investigation.

Table 1: Average responses from participants, according to ICM Quadrants.

	N	Average	Minimum	Maximum	Standard Deviation
Individual Capital Quadrant	39	2,47	1,00	5,62	,91
Team Capital Quadrant	39	3,22	1,21	5,71	1,05
Processes Capital Quadrant	39	4,10	1,31	5,69	1,28
Clients Capital Quadrant	39	3,99	1,00	5,80	1,38
NTIC + Network	39	2,52	1,29	3,57	,71

4.2.1 Individual Capital Quadrant

The proposed model analyzes a quadrant focusing on human capital with an average response level of two. It indicates that most respondents believe the situation presented is minimally relevant to their real context (M=2.47).

4.2.2 Team Capital Quadrant

The second quadrant of the team capital quadrant focuses on the collective aspect of a company's work, with a level 3 average response indicating a higher representation of the collective element. Given that the average response is at level 3 of the measurement scale (M=3.22), the collective element of the company ends up having more representation than the individual element.

4.2.3 Processes Capital Quadrant

The third quadrant of the model is associated with the formalization and development of the team's organizational memory, that is, processes that allow this formalization of a company's knowledge. Considering the average responses, most of the respondents agree that this applies very much to their professional context: the average response was centered on level 4 of the scale (M=4.10).

4.2.4 Clients Capital Quadrant

This quadrant is closely linked to the relationship that workers and the company establish with their customers and also to the way they develop services and products, taking into account their target and the concern about how they can increase the satisfaction of its customers. It can be observed, through the answers, that the respondents believe that it applies moderately to the professional reality they experience, considering that the average answer is at level three of the scale (M=3.99).

4.2.5 New Technologies and Networks

This last dimension is shared between the four main quadrants of the model, establishing a relationship between them. It is the company's added value in that it facilitates certain types of functions, such as administrative functions, so that certain functions are not time-consuming, thus enabling increased labor productivity. It can be seen that the average of this quadrant is centered on level 3 of the scale, meaning, therefore, that the working reality of the respondents differs, as the set of situations included in this last quadrant, on average, apply little to the professional context of each respondent (M=2.52).

4.3 Analysis of Correlations between Quadrants of the ICM Model

Knowing that the Pearson correlation is measured using a scale from <0.19 (very weak) to 1 (very strong), it was considered appropriate to apply this measure of association to the quadrants that form the ICM model simultaneously (see Table 2).

It is possible to observe that, in all cases, a positive correlation was identified as the following:

1) correlations were observed between the individual capital quadrant with the team capital quadrant (rs=0.587, p<0.001), the processes capital quadrant (rs=0.516, p<0.01) and the customer capital quadrant (rs=0.543, p<0.01) in which the correlations are positive and moderate, and with the new technologies and networks capital quadrant (rs=0.718, p<0.01) where the correlation is positive and strong;

2) correlations were observed between the team capital quadrant with the process capital quadrant (rs=0.539, p<0.01), the customer capital quadrant (rs=0.474, p<0.01), and the new quadrant technologies and networks (rs=0.546, p<0.05) in which, in all three cases, the correlations are positive and moderate;

3) correlations were observed between the processes capital quadrant and the customer capital quadrants (rs=0.736, p<0.001) and new technologies and networks (rs=0.516, p<0.05);

4) the last correlation to observe is between the customer capital quadrant and the new technologies and networks quadrant, and we found a positive and moderate correlation (rs=0.536, p<0.05).

Table 2: Correlations between the quadrants of ICM Model

	Quadrant TC	Quadrant PC	Quadrant CC	NTIC/NET
Quadrant IC	,587***	,516**	,543**	,718**
	(N = 37)	(N = 34)	(N = 33)	(N = 14)
Quadrant TC		,539**	,474**	,546*
		(N = 34)	(N = 33)	(N = 14)
Quadrant PC			,736***	,516*
			(N = 31)	(N = 12)
Quadrant CC				,536*
				(N = 13)
* p < 0,05 ** p < 0,01 *** p < 0,001				

4.4 Questionnaire Reliability and Validity

The purpose of carrying out Cronbach's Alpha for this part of the study was to verify the credibility of the questionnaire survey applied to the sample based on the values obtained.

Two of the questions that made up the ICM model had to be excluded after applying Cronbach's Alpha, as they contributed to reducing the reliability of the same questionnaire.

Table 3 presents the estimated value of Cronbach's Alpha (0.940), concluding that we have excellent internal consistency.

Table 3: Alfa de Cronbach

Reliability		
Cronbach Alpha	**Cronbach Alpha based on Standardized Items**	**N Items**
0,940	0,963	66

By carrying out an analysis of the Pearson Coefficient, it was possible to verify that there are correlations among the variables that make up the ICM model, which in some cases are considered significant because they are very close to (1).

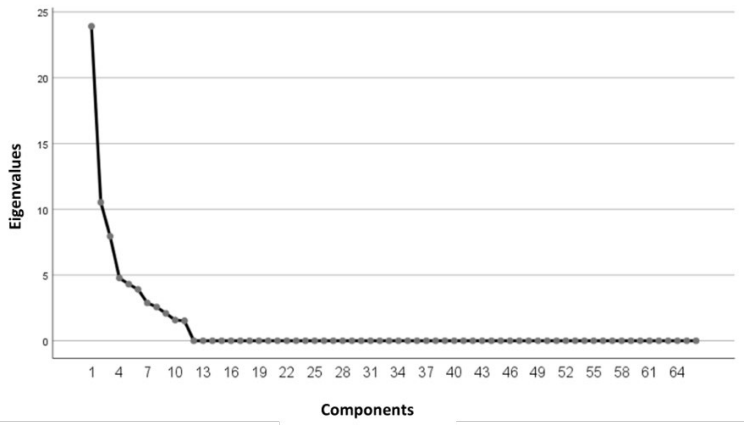
These correlations between different ICM variables allow us to conclude that the greater the concern for the satisfaction of its audiences, the better the business entity-public relationship is established, and the more easily the quality of the service is guaranteed. It can also be concluded that the new technologies depend on improving the quality of internal organization processes, and their greater use will be in recording and systematizing internal organization processes. It is also possible to understand that the greater the investment in internationalization through networks with international companies, the greater the motivation to create new internationalization strategies.

The greater the investment in innovation at the market level, the greater the investment in new services/products. It is observed that the greater the investment in the innovation of new internal organization processes, the greater the response to resolving external complaints. When new technologies are used to encourage a culture of teamwork, they are used more to record important knowledge.

It is verified that by developing partnerships to help create value and improve the company's internal functioning, greater recognition is also being given to professional training as a tool for acquiring new skills. It is also concluded that the more investment in creating events within Portugal, the greater the need to include internationalization in the business entity's ongoing strategies. Finally, by promoting new technologies to record essential knowledge, their use will be greater in recording and systematizing all internal organization processes.

In the final analysis, a principal component analysis was carried out to confirm the validity of the questionnaire. The aim is to understand whether reducing most variables that make up the ICM model of intellectual capital management to fewer factors is possible.

Following the criterion of the proportion of total variance explained, it is possible to observe the extraction of 11 possible components. If only the first three components were extracted, we would reach the desired percentage, with 64% of the variance explained by the five IC components (see Graph 1).



Graph 1: Principal Component: *Screen Plot*

5. Conclusions and Limitations

Following the objectives defined for the research, it was possible to verify that the research support model (ICM), with the necessary adaptations, allows auditing the management of intellectual capital in Performing Arts organizations. Some quadrants are more critical at OPART, such as the quadrant of team capital, client capital, and processes capital, but this does not imply that the other quadrants are not equally important. Given OPART's area of activity, it is natural that there is greater involvement in teamwork, as is the great concern for the satisfaction and pleasure of its audiences. However, it is also necessary not to forget that individual capital tends

to override team capital, requiring permanent intellectual capital management in areas where each employee can be an artist unique.

Processes capital quadrant proved to be the most relevant. Through this quadrant, it is understood that there is a promotion of the development of teamwork and, with it, the sharing of ideas and knowledge through its collaborators, which allows not only a closer relationship between people through their professional experiences but also the creating value through the sharing of different working methods, whether they are old values passed down within the company, or new ones, integrated into the company by new employees. This knowledge-sharing leads to the need to retain and systematize the same knowledge. The importance of professional training as a tool for acquiring new skills was also recognized.

Although it is not possible to prove the second objective - verifying whether it is possible to evaluate the performance of organizations in the Performing Arts sector through the management of their intellectual capital - the results indicate the existence of a relationship between the management of intellectual capital and the performance of the same organizations.

It is important to highlight some of the main limitations in the context of the research carried out. Therefore, although the results are pretty interesting and raise clues about the importance of managing intellectual capital in the performing arts, we can only analyze this case study from an exploratory perspective, and the results cannot be extrapolated to other organizations.

Another limitation resulting from OPART employees' poor adherence to this research is that it is impossible to obtain a homogeneous sample of all the entities that make up OPART since more responses were obtained from the SCNT.

Greening the Innovation Landscape: Leveraging Open Innovation Channels for Sustainable Technology Adoption

Marita McPhillips
Faculty of Management and Economics, Gdansk University of Technology, Gdansk, Poland

marita.mcphillips@pg.edu.pl

Abstract: Open innovation offers a great potential for accelerating sustainable technology adoption. This study presents the diverse interaction channels of open innovation and their role in facilitating the development and integration of sustainable solutions. Through an analysis of collaboration mechanisms associated with various open innovation channels in sustainable technology adoption projects, this paper offers a comprehensive framework for partnerships to strategically execute innovation strategies geared towards furthering sustainability objectives. The findings highlight the transformative potential of different open innovation interaction channels in advancing sustainability agendas. Several collaboration mechanisms support the benefits of employing the open innovation interaction channels. By categorizing and evaluating different interaction channels conducive for sustainable solutions this study explores the interplay between open innovation processes and sustainable innovation, assesses the role of different collaboration mechanisms in driving sustainable open innovation, discusses metrics to measure the effectiveness of open innovation interactions in sustainable initiatives and provides new ideas for managers to improve sustainable innovation performance.

Keywords: Open Innovation; Sustainable Open Innovation; Sustainability; Open Innovation Partnerships; Interaction Channels; Collaboration Mechanisms

1. Introduction

Open innovation (OI) and sustainability represent interconnected themes that have gained recognition within the field of innovation management. The concept of OI, characterized by engaging with external actors, is being recognized for its role in advancing sustainability-oriented innovations through the facilitation of knowledge exchange, the enhancement of creativity, and the adoption of a more inclusive stakeholder approach (Kimpimäki et al., 2022; Rauter, 2019). Empirical studies have demonstrated that the application of OI strategies can foster the development of more sustainable business models and innovation practices (Cappa et al., 2019; Franco et al., 2021). This, in turn, contributes to the enhanced performance and growth of organizations, underlining the synergistic potential between OI and sustainability efforts.

While the significance of OI and sustainability is widely acknowledged, there has been limited research on their interplay and joint impact (Cillo et al. 2019). Most studies have traditionally examined these phenomena in isolation, with only a few delving into their interconnectedness (Beck et al., 2022; Rangus et al., 2016; Slavec et al., 2019). This paper aims to bridge this gap by integrating insights from both fields to shed light on how various OI interaction channels can facilitate the achievement of sustainability objectives. There's an increasing awareness of OI's potential in tackling major societal and environmental challenges, positioning it as a catalyst for sustainable development. However, there's a need for a deeper understanding of how OI practices themselves can be rendered sustainable (Kimpimäki et al., 2022). The recent efforts to merge the concepts of openness and sustainability, such as the notion of 'sustainable open innovation' proposed by Bogers et al. (2020), remain the specific role and implications of OI interaction channels in this context underexplored. This paper seeks to shed light on the ways in which OI channels can contribute to sustainable goals within R&D oriented OI partnerships, the collaborative mechanisms that enhance the effectiveness of these channels, and the possible limitations associated with various approaches.

Considering the complex nature of our study, we employed a qualitative approach to research, as outlined by Yin (2009). Given the exploratory character of our study, our goal was to deepen the understanding of complex OI processes and their role in achieving sustainability objectives, from the viewpoint of OI partnership coordinators. Our research seeks to uncover recurring patterns and key elements, exploring the interplay between different dimensions of OI and sustainability, particularly through various forms of interaction channels. The findings of this investigation indicate that several factors facilitate OI for sustainability, such as cross-sector collaborations, knowledge sharing mechanisms and active engagement with stakeholders.

2. Open Innovation Interaction Channels Driving Sustainability

OI can be characterized as a decentralized innovation approach that involves the governance of knowledge flows across organizational lines, both inbound and outbound, for financial and non-financial gains, conforming to the

organization's commercial approach (Chesbrough et al., 2014). Comprehensive studies on OI has confirmed its significant benefits across various types of innovation (Bogers et al., 2018). However, the existing body of literature also acknowledges the presence of costs and downsides associated with OI (Dahlander et al., 2021; Stefan et al., 2022).

Within an OI ecosystem, individual actors do not operate in isolation; instead, they engage in collaborative efforts, co-creating knowledge, and continuously adapting their range of interaction channels to generate new value (Ogink et al., 2023). The growing complexity of knowledge necessitates multiple innovation partnerships and diverse interaction channels to increase the potential of addressing appropriate innovation demands (Bogers et al., 2017). Open innovation interactions encompass different inbound, outbound, and coupled processes encompass representing the diversity of functions, relations, and organizational setups (Bogers et al., 2017; Audretsch & Belitski, 2023). These interactions can take many forms, including co-creation of innovation in science-industry partnerships and user innovation, crowdsourcing, patenting and licensing, utilizing open data, among others (Beck et al., 2022) Each of interaction channels has a core purpose to establish an environment that fosters innovation success. Bogers et al. (2017) emphasize the significance of OI channels, such as platform-based systems, crowdsourcing communities, and open data, as important contexts for future research on the network level. The requirement for a specific OI interaction type depends on the industry and commercial approach (Chesbrough and Bogers, 2014). The choice of interaction channels depends on various elements, such as the nature of the partnership, and the preferences of the partners involved.

There are several types of OI interaction channels that can be used for sustainable goals (Mcphillips et al., 2024; Kimpimäki, 2022; Urbinati et al., 2022). External knowledge sourcing involves harnesses knowledge from science and non-science partners, through various means such as university-industry collaborations and inter-organizational partnerships, facilitating both knowledge sharing and acquisition (Radziwon & Bogers, 2019). These interaction type can extend beyond formal projects to include commission projects and staff exchanges, significantly impacting knowledge flow through both formal and informal channels (Hossain & Kauranen, 2016). According to Hendricks & Matthyssens, (2022), in an institutionalized business market, strategic collaborations among key market players are crucial. This study highlights the significance of intensified interactions and carefully chosen partnerships in driving sustainable innovation initiatives within such markets.

OI platforms facilitate open and distributed innovation, characterized by modularity and interoperability, but face governance issues such as intellectual property control and technology access (Gawer & Cusumano, 2014). According to (Čolić et al., 2023), collaborative platforms have the potential to enhance transformative learning beyond academia, showcasing the outcomes of transformative experiences for sustainable development. Technology transfer in OI involves mechanisms like patents and licensing, aiming to enhance innovation performance by capitalizing on knowledge assets, yet is challenged by knowledge leakages and the need for novelty in patent applications (Bogers et al., 2017). Many scholars have emphasized the importance of technology transfer in driving sustainable innovation (e.g. Fernandes et al., 2021)

User innovation, where individuals modify or create products, contributes significantly to OI by meeting unmet needs and fostering user loyalty, though organizations often underestimate its potential (Piller & West, 2014). Arancio et al. (2022) discusses the utilization of open innovation through user challenge competitions to promote sustainable development goals. Crowdsourcing, another OI interaction channel, leverages the crowd's wisdom to enhance innovation performance, requiring careful task design and participant management (Brabham, 2013). Testa et al. (2023) highlights the importance of environmentally sustainable projects in attracting funds and engaging crowd investors, emphasizing the significance of framing messages on environmental protection for crowdfunding success. Public sector partnerships in OI, involving open data from public organizations, offer new innovation opportunities but necessitate robust management and transparency (Sadiq & Indulska, 2017; Urbinati et al., 2023). Bertello et al. (2023) points out the need for exploring sustainable innovation within the realm of open data. According to Hrustek et al., (2022), the integration of open governmental and public data, along with contractual sharing, is crucial for creating sustainable value in agricultural systems.

OI interaction channels have the capacity to shape more sustainable business models and innovation practices, empowering organizations to remain competitive and aligned with the latest advancements in technology (Obradović et al., 2021). The relationship between OI and sustainability is complex and multifaceted, with implications for various industries and research areas. While the interaction channels through which open innovation promotes sustainability may vary, the evidence suggests that embracing OI practices can be instrumental in driving sustainable innovation and addressing environmental challenges (Milana & Ulrich, 2022)

As OI interaction channels serve as the infrastructure facilitating the absorption and dissemination of heterogeneous knowledge assets, the collaboration mechanisms are the orchestrated processes that govern the dynamics of interaction within these channels, ensuring the alignment of objectives, the mitigation of intellectual property risks, and the optimization of synergistic potential (Miranda et al., 2023). They refer to the processes, structures, and strategies used to coordinate and align the activities in an OI partnership. Collaboration mechanisms can include joint planning and decision-making processes, shared goals and performance metrics, division of labor and responsibilities, intellectual property agreements, and governance structures. Effective collaboration mechanisms can help to overcome challenges prevailing in some of the OI interaction channels such as misaligned incentives, conflicting priorities, and differing levels of commitment among partners.

Moreover, they can help partnerships to access new knowledge resources leading to more innovative and sustainable solutions. Reficco et al., (2018) suggest that several collaboration mechanisms positively influence innovation targeted at sustainablility, but the effectiveness of these mechanisms largely depends on the kind of partners involved. OI projects for sustainability purposes lead to increased creativity and reduced project duration. However, the potential benefits of OI projects are obstructed by the high degree of complexity that they entail. Collaboration mechanisms are mitigating those obstructions. Lappalainen et al. (2023) suggests that managing governance, control, and social relations are critical to the success of OI projects. Effective communication and knowledge flows among partners are also essential to ensure successful collaboration. Furthermore, a study by Rauter et al. (2019) uncovers the influence of diverse OI partners, including customers, universities, and broader ecosystem stakeholders like intermediaries or NGOs, on the economic and sustainability innovation performance. External actors' involvement in OI seems to be a key factor for performance. By engaging a diverse array of stakeholders, partnerships can gain access to a wealth of ideas, expertise, and resources. This multi-stakeholder engagement thus significantly contributes to overcoming the barriers associated with OI, driving forward the agenda of sustainable innovation. Kimpimäki et al., (2022) also highlight the importance of a broader stakeholder approach to sustainable innovation and emphasizes the need for a mindset shift from "inside-out" to "outside-in" to become truly sustainable. Overall, the studies suggest that effective collaboration mechanisms are essential to the success of OI projects geared towards furthering sustainability objectives.

Challenges faced in utilizing OI interactions include innovation capability, partnership expectations, and risks (Howells et al., 2012; Steinmo & Rasmussen, 2018; Radziwon & Bogers, 2019). Implementing OI for sustainable innovation presents similar challenges (Rauter et al., 2019). OI may lead to a loss of control (or perceived loss) over the innovation process, as partnerships involve collaboration with external partners and share intellectual property. Coordinating and managing a varied group of stakeholders in the sustainable context can be complex, requiring additional resources and expertise. Partnerships must carefully select partners that align with their sustainability goals and have the necessary expertise to contribute. The solutions not always can be scaled up and implemented across different operations. Measurement and assessment of the impact is also complex and multifaced. Many researchers struggle with evaluating how opening up internal innovation processes impacts innovation results and economic performance. Studies like Kratzer et al. (2017) suggest this impact might be limited, potentially leading to smaller gains in innovation over time or even negative effects, as pointed out by Greco et al. (2017). This inconsistency in findings could be because we don't yet fully understand how OI contributes to a organization's competitive edge or under what specific conditions it is most effective (Zhang et al., 2023).

3. Methods

This research focused on examining the adoption of OI interaction channels to explore their role in advancing sustainable objectives within OI partnerships. We began by identifying key attributes and roles of these channels in fostering sustainable innovation, drawing on a review of existing literature on the subject (Bogers et al., 2020). This review informed the creation of deductive codes that guided the analysis of our data. Because of the innovative and complex nature of our study, we grounded our investigation in a qualitative research methodology (Yin 2009), which allowed for a comprehensive exploration. Employing a qualitative framework was particularly pertinent for delving into the relatively underexplored domains of OI and sustainability processes (Kimpimäki et al., 2022). The exploratory angle of this study was defined by its aim and research queries, which were to enhance the comprehension of OI interaction channels and processes, along with their influence on sustainability objectives, from the individual perspectives of OI partnership managers. Theoretical

frameworks were employed not only to craft the research questions and objectives but also to outline the initial coding schema. The study was characterized by open-ended, process-focused questions.

The respondents were managers coordinating European OI partnerships, that had 7 to 11 years of experience in various OI projects and possessed significant expertise in sustainability, classifying them as elite informants. The focus was on OI partnerships engaged in R&D and technology adoption. The study involved eleven in-depth, semi-structured interviews conducted in three different countries, each lasting about 60 minutes on average. The OI partnerships were chosen using the maximum variation criterion to ensure a wide representation of the diverse OI interaction channels and the range of perceptions among respondents in varied contexts. Due to the adoption of purposive sampling, strict participation criteria were enforced (Patton 2002). Respondents were required to possess a minimum of three years' experience in managing an OI partnership. Additionally, they had been in contact with sustainability processes and presented familiarity with essential concepts and definitions pertinent to the field. These prerequisites were verified at the beginning of each interview. For the analysis of the data, MaxQDA, a software tool designed for qualitative data analysis, was used to facilitate the process.

4. Results

The most common OI interaction channels reported by respondents were sourcing of external knowledge, technology transfer, platforms and complex systems and engaging users. Utilizing open data or crowdsourcing were much less common. The effect of utilizing those channels on sustainability goals was prevalent. Despite initial hesitance among participants about how to assess the direct connection and the impact of interaction channels on sustainability, all respondents reported a beneficial influence on achieving sustainability goals.

OI interactions were perceived as a set of beneficial practices that drive the innovation processes in all areas, including sustainability. The OI partnership managers emphasized three key factors influencing sustainable outcomes in OI partnerships regardless the interaction channel in terms of collaboration mechanisms: (1) cross-sector collaborations, (2) knowledge sharing mechanisms (3) active engagement with stakeholders.

Cross-sector collaborations emerged in the study as a vital catalyst for fostering innovation and driving widespread adoption of sustainable technologies. Respondents underlined importance of combining varied expertise, which they saw as key to solving complex problems. This blending of skills not only filled technological gaps but also encouraged a culture of creative thinking. Knowledge sharing mechanisms were pointed to as playing role in leveraging collective expertise and accelerating the pace of sustainable innovation. Open communication and fair distribution of both risks and benefits, trust and clear governance were highlighted as crucial for the success of these collaborations. The use of digital tools for collaboration was another important theme. These tools were found to significantly improve the efficiency and effectiveness of projects. The results highlighted the importance of actively involving stakeholders throughout the project lifecycle. Participants from various sectors stressed the value of engaging a broad spectrum of stakeholders, including customers, suppliers, and ecosystem members, right from the early stages. This approach brought diverse perspectives into the project, making the innovations more relevant and widely accepted. Feedback loops with stakeholders were particularly noted for their role in addressing sustainability challenges effectively, allowing projects to adapt based on ongoing input.

Our study identified several metrics, used to measure the effectiveness of OI interactions in sustainable initiatives. Some implemented metrics includes: input metrics, when the resources and activities invested in OI were measured, such as the number of partners, projects, or platforms used; output metrics, connected to the results and outcomes generated from OI, such as the number of ideas, prototypes, or patents produced; as well as process metrics, measuring the efficiency and effectiveness of OI processes, such as the time and cost of innovation activities. Even though the most popular metrics for projects outside of sustainability scope is return on investment (ROI) it was not commonly used for sustainability efforts. Environmental impact metrics, including carbon footprint reduction were also rarely used, aligning the assessment with the sustainability goals of the projects.

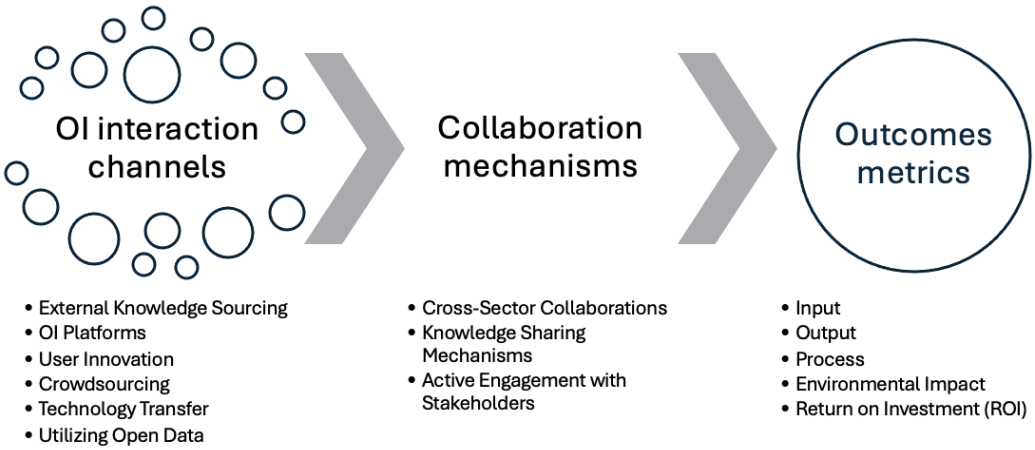

Figure 1: OI interaction channels, knowledge mechanisms and outcome metrics in OI partnerships towards sustainable objectives

Respondents pointed to several barriers that hinder the effectiveness of sustainable OI. A predominant challenge identified by participants was the misalignment of organizational goals and governance models, which often led to conflicting priorities and approaches to sustainability. Intellectual property concerns were also frequently cited, with the protection and sharing of proprietary knowledge creating tensions within collaborative frameworks. Furthermore, the complexity of coordinating across diverse stakeholder groups, each with their unique expectations and communication styles, was highlighted as a significant obstacle. These barriers, compounded by the inherent challenges of integrating sustainability into OI processes, underscore the need for indicating best practices in utilizing collaboration mechanisms targeted at OI partnerships driving sustainability projects.

5. Discussion

The research question of the role of OI interaction channels in driving the sustainability goals proved to be complex. First, the research highlighted the absence of a universally accepted framework defining sustainability within the context of OI processes. Second, the fields of OI and sustainability are characterized by a dense overlap of concepts, themes, and terminologies, leading to diverse interpretations among respondents who might use disparate terms for similar concepts. Third, different OI interactions and levels of engagement in sustainable processes produced a broad spectrum of perspectives among scholars and industry professionals (Hassan, 2022).

The respondents in this study were unable to agree on a definite description of the sustainable OI phenomenon. Nonetheless, echoing the existing literature, the results of the study indicate that sustainable OI is regarded as a process of distributed innovation that is aimed at fostering development in a manner that satisfies current requirements without hindering future generations' capacity to fulfill their own needs, aligning with the definition presented by Bogers et al. (2020). The majority of participants in this research did not mention sustainability as a priority in OI partnerships. This observation comes from the fact that OI partnerships typically do not place sustainability at the forefront of their agendas, but rather adopt sustainable practices when they coincide with, or emerge as a byproduct of, their business objectives. Even though, OI partnerships are known for having relatively modern cultures, embracing experimentation, they tend to be very cautious when it comes to financial expenditures and investments.

The existing OI literature provides frameworks of OI interaction channels (McPhillips et al.,2024). Not all of them were utilized in all of the OI partnerships. These OI channels are not easy to adopt, and sectoral preference might play a role in adoption. The extant literature frequently highlights the benefits of OI (e.g. Bogers et al., 2018). From the many advantages described in the literature, responding OI partnership managers were mostly focused on the improved process efficiency aspect, which directly contributes to reduced costs and shorter project durations. These operational improvements were mostly quantified through input and output metrics, focusing on the resources utilized and the tangible outcomes achieved.

All of the respondents declared that OI practices positively affected drive towards sustainability goals, and the unique combination of the OI interaction channels was perceived as instrumental in leveraging the effectiveness of OI, thereby facilitating significant sustainability improvement. OI managers monitor progress towards sustainability mostly by noting reductions in time and cost, which are indicative of enhanced efficiency in OI processes. Environmental impact metrics, including carbon footprint, were not used mainly due to complexity of innovation focusing of sustainability, diverse stakeholder involvement, long term impact and data availability and quality (Kemp and Pearson, 2007; Milana and Ulrich, 2022).

However, many OI partnerships do not inherently prioritize sustainability within their projects, often integrating sustainable practices only when they align with business objectives. This lack of strategic emphasis on sustainability can significantly impede progress in this area. The cautious, risk-averse culture still prevalent among many partnership members further compounds the challenge of investing in sustainable solutions. According to the data, sustainability is frequently regarded by OI managers as a context rather than a core objective, leading to a hesitancy to overhaul business models for the sake of sustainability.

6. Conclusions

Open innovation and sustainability have gained significant attention from researchers and industry professionals alike. The pressing need for collective measures to address the climate crisis underscores the growing relevance of these themes. Organizations that adopt OI are often at a competitive advantage compared to those that maintain closed innovation systems. Research and practical evidence suggest that OI contributes positively to sustainability outcomes, although with the challenge of establishing and leveraging a variety of OI interaction channels. The sustainability context imposes additional considerations on OI processes, making the adoption of OI a complex challenge with each partnership navigating its path towards sustainability in different ways (Bogers et al., 2020).

This study highlights the importance of collaboration mechanisms such as cross-sector collaborations, knowledge sharing mechanisms, and stakeholder engagement in streamlining OI processes towards sustainability. These "innovation-producing" mechanisms, as termed by Majchrzak et al. (2023), encourage the sharing of not only solutions but also essential insights into underlying problems, fostering the emergence of optimal solutions through diverse knowledge contributions within each of the OI interaction channels. Certain factors, like intellectual property issues and the complexity of governance structures, can hinder the development of sustainable OI. However, the research results suggest that successful sustainable OI emerges from the interplay of various elements (Milana & Ulrich, 2022).

The results of this paper offer valuable insights for managers in OI partnerships. A critical takeaway is the awareness of importance of different OI interaction channels. Our research demonstrates that a diverse range of OI interaction channels can markedly enhance the drive towards sustainability objectives within OI partnerships. Enhanced efficiency in OI partnerships can refine the innovation process, bringing not only financial gains but also advancing sustainability efforts. Consequently, OI partnerships that strategically embrace a variety of OI interaction channels stand a better chance of securing a competitive edge in the field of sustainability.

OI managers take on a strategic challenge to navigate the OI interaction channels within the context of sustainability dynamics. It is crucial for them to cultivate a strategic perspective of the sustainable OI process that will be deeply integrated into the fabric of the OI partnership. Such a holistic approach can facilitate the development of sustainable OI strategies that are conducive to sustainable outcomes. An essential recommendation for OI managers is to prioritize sustainability measures within the innovation process. Also, even in the face of time limitations and resource constraints, it's vital to establish sustainability objectives that also contribute to achieving financial targets, ensuring that sustainable innovation remains aligned with the overarching business strategy.

Finally, our study has uncovered that sustainable OI presents a considerable challenge for many OI managers, largely due to its complexity and unpredictability. Although OI managers are typically well-versed in OI processes, their expertise in sustainability may be lacking. It's crucial to recognize the dynamics at play, where financial gains often overshadow sustainability efforts. Consequently, sustainable OI practices may be underutilized or entirely overlooked, hindering the realization of sustainable goals. Tackling the uncertainties surrounding sustainability could empower OI managers to shift towards more structured investment risk assessments, moving away from decisions solely based on previous experiences or conventional wisdom.

While this study has provided valuable insights into the interplay between sustainability and OI interaction channels from the perspective of OI partnership managers, it's important to acknowledge its limitations, that can also pave the way for future research opportunities. The qualitative, exploratory nature of the research was designed to paint a broad picture of sustainability within the OI context as perceived by these managers. Consequently, the findings are specific to these perceptions and are not intended for broad generalizations, but rather to invite deeper examination. The study's scope did not extend to a detailed investigation of individual characteristics or the subtleties of personal experiences. Nor did it delve into the micro-level analysis concerning specific sustainability-related decisions. Essentially, while the research was centered on a meso-level analysis, it has also laid the groundwork for future studies to explore sustainability in OI at various analytical levels, thereby contributing to a more nuanced, multi-dimensional understanding of the subject.

Funding This research was supported by the Gdansk University of Technology under Grant DEC-4/2021/IDUB/II.2/Sc in the Scandium Programme within Excellence Initiative—Research University Programme.

Data availability statement Our manuscript has no associated data. The interview transcripts are available upon request.

Abstract: Family businesses represent the most widespread entrepreneurial form. Within knowledge management studies, a large amount of research has focused on family businesses, highlighting the particular needs they require. At the same time, several studies have highlighted the existence of barriers and enabling factors in the adoption of new technologies within family businesses. Currently, we are seeing the spread of artificial intelligence (AI) within business organizations. On these premises, this study has a dual objective. The first objective, from a theoretical point of view, wants to trace the link between AI and knowledge management. The second objective of this study aims to identify the main barriers to the application of AI in family businesses. This study is based on a systematic literature review using the phases of data collection, bibliometric analysis and content analysis. Two international scientific databases were used: Scopus and Web of Science (Clarivate). A search string was created by identifying keywords. Subsequently, only scientific documents published in double blind review journals, in English, were selected. The sample used in this study contained about 40 scientific documents. The results of this study offer initial reflections on the adoption of artificial intelligence in family businesses. Artificial intelligence represents a new way of managing knowledge within organizations. The peculiar characteristics of family businesses impose reflections on the methods of adoption and barriers that may emerge. This study contributes to the understanding of family businesses, under the theoretical perspective of knowledge management. Family businesses represent complex but widespread organizations. For this reason, academics, entrepreneurs and practitioners must understand the obstacles that could make the adoption of AI difficult.

Keywords: Family Firm, Barriers, Knowledge Management, AI, Absorptive Capacity.

1. Introduction

Family businesses represents the most common element in the entrepreneurial system. For this reason, family business assumes a relevant role in economic and social system. This relevance has attracted the attention of management and organization theory scholars. Consequently, an intensive and active academic debate has developed around family businesses. In recent decades, scholars have focused attention on the peculiar characteristics of family businesses (Salganicoff, 1990; Sharma, et al., 1997; Ventura, et al., 2020; Daspit, et al., 2021), often, through a comparison with non-family businesses (Conz and Magnani, 2020; Rovelli, et al., 2022; Baltazar, et al., 2023). Above all, a growing research area on knowledge management studies in family business has developed. This line of studies aimed to understand the dynamics and practices of knowledge management in family businesses (Chaudhary and Batra, 2018; Pütz and Werner, 2023).

The family business, under the theoretical lens of knowledge management theories, emerges the paradox of family businesses. In fact, family businesses are organizations recognized as slow to introduce innovation and new knowledge (Nieto, et al., 2015; Soluk and Kammerlander, 2021). Innovation and technological progress represent levers for maintaining or increasing competitive advantage. For this reason, family businesses must increase their capacity to absorb new technology and knowledge. Artificial Intelligence (AI)-based systems represent the latest and greatest challenge for family businesses. Artificial intelligence (AI) is a relatively recent phenomenon, which is spreading rapidly and across various sectors.

Although the first attempts to define artificial intelligence date back to the 1950s, even today, it appears difficult to offer a complete and exhaustive definition of artificial intelligence. AI represents a complex and multidimensional phenomenon. With the aim of analyzing AI, under a theoretical perspective typical of knowledge management studies, we can preliminarily define artificial intelligence (AI). AI, and the systems connected to it, can be defined as systems capable of absorbing, creating, managing and transferring the knowledge of an organization, within it, through different combination techniques. Knowledge management (KM), therefore, is supported through AI systems.

AI systems rely on external and internal knowledge sources. External sources are represented by the ability to store, collect and use quantities of data (big data); instead, internal sources are the absorption of professional knowledge to carry out a certain task and knowledge of the organization.

With these premises, the main objective of this study is to identify the Factors and barriers for AI Adoption that can influence the adoption of AI systems in family businesses.

2. Theoretical Framework

2.1 Family Firms in Knowledge Management Studies

In recent decades, knowledge has assumed the role of a strategic resource and source of competitive advantage (Mårtensson, 2000). For knowledge to become a strategic resource, the organization's processes must be based on the creation, storage, sharing and enhancement of knowledge. Knowledge Management (KM) becomes a crucial and transversal element in all organizational processes (Martinez-Conesa et al., 2017). KM can be traced back to all activities oriented towards the acquisition, storage, sharing and application of knowledge (Alavi and Leidner, 2001; Lee, 2012). Organizations, therefore, find themselves having to develop the ability to organize their internal processes by enhancing knowledge (Durst and Edvardsson, 2012; Del Giudice and Maggioni, 2014).

In the modern debate within knowledge management studies, a growing and solid line of studies has focused on family businesses (Ventura, et al., 2020; Arzubiaga, et al., 2022; Vesperi, et al., 2023).

Despite this, knowledge management appears particularly complex. First of all, knowledge is an intangible and complex element with results that cannot be measured in the short term and, above all, cannot be defined a priori. On the other hand, family businesses are particularly complex organizations with intrinsic characteristics, equipped with a system of values dominated by opposing strategic orientations (Reid, et al., 1999; Hernández-Linares, 2020). Different analytical perspectives and facets emerge in KM studies on family businesses (Letonja and Duh, 2016; Ge and Campopiano, 2022; Ratten, 2023). More specifically, previous research on KM has mainly focused on the difference between family and non-family businesses.

Studies analyzing the multiple facets of KM have mainly focused on non-family businesses (Obeso et al., 2020), while KM research on family businesses is still at an early stage. although it is broad and offers insights for both research and management practice, there is a lack of coherent and adequate conceptualizations of KM for the development of theoretical models and the design of empirical work in the always complex area of the family. businesses. The objective of this study is to offer the theoretical basis for understanding the adoption of artificial intelligence, identifying the main barriers and enabling factors, in family businesses, under the theoretical perspective of KM.

3. Methodology

The main purpose of this study is to offer a theoretical framework on the adoption of artificial intelligence in family businesses, under the theoretical perspective of knowledge management. The academic contributions on family businesses, also from the perspective of knowledge management studies, appear substantial and in a mature phase. On the contrary, the impact of artificial intelligence on the dynamics of family businesses appears poorly studied and fragmented.

With these premises and with the aim of offering a broad picture of existing scientific contributions, a qualitative methodology was adopted (Bell, et al., 2004), of an exploratory nature (Alcácer, et al., 2016), based on the literature review. The systematic literature review also allows future research to be linked to studies conducted in the past (Vesperi and Coppolino, 2023).

The collection and analysis of scientific documents followed the following steps:

I. Source of the data. The scientific documents analyzed in this study are all the scientific documents on family firms contained in the databases (a) SCOPUS and (b) Web of Knowledge (WoS). Scientific documents were extracted and retrieved in April 2024. Only peer-reviewed journals articles published in English were considered (not considered: books, chapters/book reviews, professional articles, conference proceedings, working papers, reports, unpublished works; see on this point Tranfield et al., 2003). We selected only scientific papers with the following keywords in article titles, abstracts and keywords: “knowledge”, “family firm*” OR “family business*”, “Artificial Intelligence*” OR “AI”, “barrier*”, “enabl*”.

Only scientific documents were considered in the areas "*Business, Management and Accounting*" and "*Social Science*". No time limitation criteria has been inserted.

Finally, 178 records were produced from the sources.

II. File format and database preparation. All bibliographic data have been saved in CSV (Comma Separated Values) format, sorted in alphabetical order by title. In addition, other entries not considered useful or duplicate entries have been removed from the file. (Karamali, et al., 2020).

III. Visualization of keywords. The database was exported and analyzed using the VOSviewer software (see van Eck and Waltman, 2007; 2010; 2014) with the aim of identifying the link between the keywords used by the authors of the scientific documents identified.

IV. Selection of scientific documents. The implementation of qualitative methodological processes could generate "non-transparent areas". According to Yin (2012), to solve this limit the authors must analytically describe all the steps taken for the selection of scientific documents. To overcome this limit, the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyzes) guidelines have been adopted. The selected scientific papers will be analyzed to define the theoretical framework on the topics under study.

The PRISMA guidelines guarantee transparency in the systemic literature review process (Liberati, et al., 2009).

In the study, attention had to be paid to duplicates that were removed from the databases. The final database is made up of n. 41 relevant documents of which 10 open access. The remaining papers were read to ensure their alignment with the research objective according to the theoretical quality and methodology/robustness of the data.

4. Main Results and Discussion

From the analysis of the scientific documents identified, numerous contributions emerge which deal with understanding the enabling factors and barriers to the adoption of new technologies and knowledge. The literature on the topic, therefore, is rich in theoretical and empirical analysis perspectives. With the aim of offering the most complete academic debate, the graphic representation of the scientific panorama was created. The scientific panorama was created by highlighting the relationships between the keywords that scholars have used to analyze the phenomenon of enabling factors and barriers.

Figure 1 shows the representation of the scientific panorama based on the intensity of use of keywords.

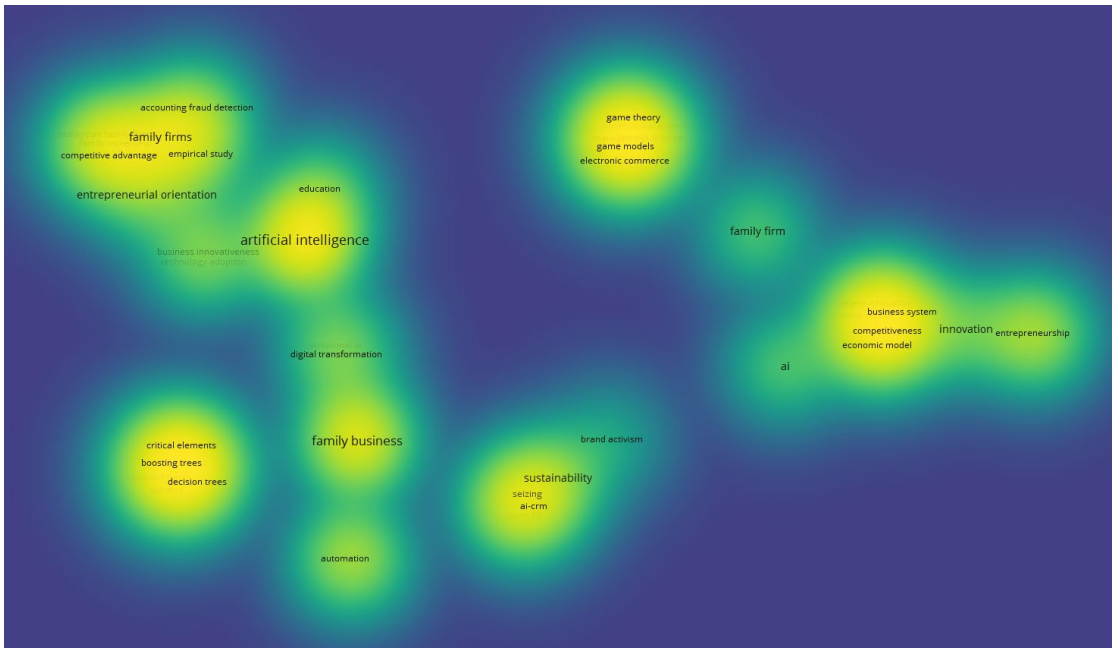

Figure 1: Scientific landscape

Source: Vosviewer software

Figure 1 shows the scientific landscape, highlighting the density (i.e. numerousness) of the words. The keywords that are at the center of larger circles define a greater number of uses than that keyword. The scientific landscape is characterized by the presence of various centers that focus the attention of scholars. In fact, we can identify the main centers around the keywords "family firms", "family business", "competitiveness", "sustainability" and "critical elements". Although the first two centers are representations of the same phenomenon but with different terminology, the other centers of the scientific landscape determine different analysis perspectives of the scholars.

First of all, it is possible to identify the historical evolution of the number of manuscripts published over time. The first paper published on the topic dates back to 2010. Since 2019, there has been an increase in published articles. In fact, over 50% of the selected papers were published from 2019 to 2023.

This allows us to draw the conclusion that the topic of the adoption of AI systems represents an emerging topic in the field of knowledge management studies, linked to family businesses.

A further consideration, under the temporal perspective, that emerges is linked to the focus on AI systems. In fact, the less recent selected articles adopt an analysis perspective focused mainly on the theoretical definition of artificial intelligence and the impacts of new technologies.

The most recent articles, on the other hand, focus on a hybrid perspective, that is, the selected papers begin to offer some empirical reflections.

A further element of preliminary analysis is linked to the countries from which the greatest number of contributions come.

The country from which the greatest number of contributions come is the United States with 13 contributions. Subsequently, the major countries that have contributed are Australia (with 10 contributions) and Germany (with 7 contributions). Finally, there are Italy and the United Kingdom (with the same number of contributions, that is 5) and Spain (with 1 contribution).

Finally, the last data is the number of papers published in open access. Of the 41 selected articles, 10 articles were published in open access. Open access articles represent easily consultable articles that can influence the scientific community and practitioners more quickly.

From reading the abstracts and selected articles, it emerges that introducing an AI system within a complex organization such as a family has a profound impact on internal processes.

Several authors have highlighted that the introduction of new technologies.

By focusing attention on enabling factors and barriers, numerous contributions emerge. Although it is possible to identify different taxonomies of enabling factors and barriers, the most recent and modern literature focuses on the presence or absence of some factors that could Favor or hinder the adoption of new technology, particularly in family businesses.

By analyzing the selected scientific documents, 9 factors capable of influencing (positively or negatively) the adoption of artificial intelligence (AI) in family businesses were identified.

Subsequently the factors were divided based on a micro or macro dimension. Table 1 reports the factors identified.

Table 1: Dimension Factors

Micro Dimension Factors	Macro dimension Factors
Know-how or new knowledge needed	Compagny Dimension
Perceived ease of AI System	IT system diffusion
Human Capital	HRM and Organizational Culture
Use of team work	Organizational Structure
	External economic and fiscal incentives

Source: our elaboration

Table 1 breaks down the factors based on their direct impact. Two dimensions have been identified: micro and macro dimensions. All the factors that are directly influenced by individuals have been grouped in the micro

dimension. Micro factors are internal factors and are unique to each organization. For this reason, it is included i) Know-how or new knowledge needed; ii) Perceived ease of AI System; iii) Human Capital and iv) diffusion of teamwork.

The first micro dimension is know-how or new knowledge needed. In fact, the selected papers highlight that it is necessary to understand the organizational needs that AI systems must respond to. In fact, it is necessary to create a map of the knowledge present within the organization and understand which knowledge needs the AI system must respond to. The second element is the way in which the AI system is perceived. Some articles have highlighted that there is often a wrong perception of the AI system and its functioning. Human capital is a further micro dimension factor. Finally, the diffusion of culture and the diffusion of teamwork becomes a crucial element.

Instead, all factors connected to a dimension of organizational structure or external to the organization have been identified as macro dimension factors. They are micro dimension factors: i) Company Dimension; ii) IT system diffusion; iii) HRM and Organizational Culture; iv) Organizational Structure and v) Economic and fiscal incentives.

5. Limits and Future Research Directions

This study can represent a first element of reflection in the debate on the adoption of artificial intelligence in family businesses. Understanding the enabling factors or barriers that can favor or hinder the introduction of AI systems in family businesses takes on an important economic and social value, especially considering the role that family businesses play in economic and social systems. Helping entrepreneurs and professionals of family businesses can promote the value of a local socioeconomic system. Family businesses are very complex socio-economic systems. In fact, the presence of two systems (family and business) often determines tensions in the adoption of new innovations. In fact, from the selected articles a consolidated line of studies emerged focused on the causes that determine the failure of the adoption of new technologies by companies. This line, which also characterizes the studies on the adoption of AI systems in family businesses. In fact, several studies have used this theoretical framework. This aspect therefore determines a starting point for scholars of family businesses and AI systems who want to understand the barriers and enabling factors of AI systems.

In assumption, this study, although analyzing a recent topic such as the adoption of AI systems in family businesses, benefits from a consolidated reference literature. In fact, to understand this very specific phenomenon, it is necessary to resort to the consolidated literature on the socio-economic characteristics of family businesses, with reference to internal innovation processes and the enabling factors and obstacles to the adoption of new technologies. At the same time, AI systems have been considered in this study as a tool for knowledge transfer within the family business. For this reason, it is also necessary to resort to the theoretical framework on knowledge transfer and KT tools. These considerations therefore determine a very high complexity for scholars who approach this study.

The study is not without limitations. The first is related to the methodology used. The analysis was based on a limited number of scientific papers, selected through a keyword search string. Further future studies should expand the number of keywords and scientific papers analyzed. Another limitation of this study is related to this aspect. Changing the keywords could reveal additional barriers and enablers that have not yet emerged.

Further research steps could highlight other factors that are not yet present. In fact, the study analyzed a limited number of scientific papers. In fact, the results of this study could be integrated, identifying a larger number of scientific papers. Finally, the study analyzed the relationship between family business and AI, with the sole purpose of identifying barriers and enablers. Many aspects require further investigation.

Future studies should focus on the empirical investigation of AI barriers and enablers in family businesses. Future studies could investigate barriers and enablers in a variety of contexts in terms of geographical location, sector, size, level of family involvement. A further step could be represented by using a methodology based on empirical observation. Future studies in this sense could validate the factors identified through interviews or case study analysis.

This study contributes to the academic debate on knowledge management studies, offering a first element of reflection on artificial intelligence and family businesses. In particular, the results of this study can help to understand how to promote the introduction of artificial intelligence systems in knowledge management in family businesses.

Adopting a Learning Organization Philosophy to Promote Knowledge Sharing in the University

Patrick Mbongwa Mhlongo
Durban University of Technology, Durban, South Africa

patrickm@dut.ac.za

Abstract: Higher education institutions, as with organizations in other sectors, are operating in an environment characterized by rapid change, complexity, competition and stakeholder demands. Therefore, these institutions are continuously exploring and adopting effective strategic approaches to survive and remaining competitive. The Learning Organization philosophy is one of the concepts that has been predominantly adopted by organizations in the private sector in order to remain competitive. The aim of this study was to investigate the applicability of a Learning Organization philosophy as a strategy to promote knowledge-sharing across functional boundaries in a university. The study adopted a survey design underpinned by a post-positivism philosophical worldview. Hence, a cross-sectional design was adopted. Stratified simple random sampling was used to select participants from a population of employees at a University of Technology. The data collection instrument used in the study was a self-administered questionnaire. The Statistical Package for the Social Sciences (SPSS) was used to analyze the data. Overall, the findings of the study revealed that the adoption of a Learning Organization philosophy would promote knowledge-sharing beyond functional boundaries in Universities of Technology. Knowledge in an organizational context is regarded as a strategic asset and the Learning Organization is regarded as a philosophy that fosters knowledge creation and sharing. It is through learning that knowledge is created, and knowledge becomes useful when it is shared. Therefore, this study provides organizations, especially Universities of Technology, with necessary insights into the adoption of a Learning Organization philosophy as a strategy to promote knowledge-sharing beyond functional boundaries.

Keywords: Learning Organization, Knowledge-Sharing, Knowledge Management, Continuous Improvement, Higher Education. University of Technology

1. Introduction

To compete and remain relevant in today's turbulent and competitive environment, higher education institutions need to explore effective strategic approaches (Wang and Rashid 2022). Given this context, the aim of this study was to investigate the applicability of a Learning Organization philosophy as a strategy to promote knowledge-sharing across functional boundaries in the University of Technology. Previous researchers have investigated the knowledge-sharing concept from different perspectives (Santhose and Lawrence 2023). This study focuses on knowledge-sharing from a Learning Organization perspective in a university context. In addition, Yoon and Park (2022) argue that few studies have empirically examined individual and organizational factors together in relation to knowledge-sharing. Knowledge -sharing is the fundamental activity that facilitates learning through sharing knowledge to improve organizational processes and products (Chua, Thinakaran and Vasudevan 2023). Furthermore, Igbal and Ahmad (2020) eloquently stated that a Learning Organization has the ability to learn, adapt and outperform competitors. It is therefore critical to have a conducive environment that fosters knowledge-sharing in an organization, hence exploring effective knowledge-sharing strategies becomes critical. Consequently, the focus of the study was to explore the applicability of a Learning Organization philosophy to foster a knowledge-sharing culture in the University of Technology because institutions of higher learning are under pressure to continuously improve their offerings in line with the needs of relevant stakeholders (Jhaj 2019).

1.1 Problem Statement

The lack of an overarching philosophy that is internalized and institutionalized to foster knowledge-sharing within and beyond functional boundaries in a university encumbers knowledge -sharing. Moreover, the prevalence of silo practices in the university is also a challenge, where the focus is more on departmental or faculty goals than broader institutional goals. This is posited by Annansingh et al. (2017), who refer to this problem as knowledge silos in higher education institutions. Proponents of a Learning Organization philosophy, Robbins and Judge (2013) identify the Learning Organization philosophy as a remedy for fragmentation, competition and reactiveness in an organization. Bento, Taliabue and Lorenzo (2020) alluded to the fact that a silo mentality creates a problem, with a reluctance to share knowledge across university departments. Furthermore, Yoon and Park (2022) state that there are many barriers to knowledge-sharing in an organizational context.

2. Literature Review

The environment in which universities operate is characterized by globalization, the new economy and a number of other factors (Austin and Jones 2016). Hence, Elenezi (2021) describes the higher education environment as becoming increasingly more competitive. Universities have a role to play, not only in teaching and learning, but also in generating new knowledge to benefit society (Rossouw and Goldman 2023). Therefore, remaining relevant and to survive in such an environment requires adaptive capabilities. This highlights the importance of an overarching philosophy that will encourage the learning and sharing of knowledge in the university. Learning at an individual and collective level has been identified as key to gaining competitiveness (Sarder 2016). In addition, knowledge must be shared within and beyond functional boundaries for universities to respond to the needs of their stakeholders. Rossouw and Goldman (2023) alluded to a need for higher education institutions to continuously review their operations as they advance society in general.

Kinicki and Fugate (2018) describe a Learning Organization as an organization that has the ability to create, acquire and transfer knowledge, and as a result its behavior changes on the bases of new knowledge and insights. Learning in an organization is critical for continuous improvement purposes (Kinicki and Fugate 2016). Moreover, learning in an organization is associated with competitive advantage and innovation. Marquis and Huston (2021) succinctly state that the concept of a Learning Organization was introduced and popularized by Peter Senge. This is also espoused by Ortenblad (2018), who explains that the term 'Learning Organization' was coined by Peter Senge. A Learning Organization has the ability to operate effectively by responding to a rapidly changing business environment (Sarder 2016). Central to the Learning Organization philosophy is the understanding that business models and strategies that were previously effective, have become obsolete and no longer effective to respond to the global economy, as well as changing customer preferences. Watkins and Marsick's (1993) theory underpins this study from a Learning Organization perspective. This theory emphasizes promotion of learning and the effective management of knowledge at all levels of the organization (Nakaziba and Ngulube 2023).

2.1 Continuous Improvement of University Operations

Continuous improvement is generally viewed as a learnt and interiorized capacity that is demonstrated through a set of organizational daily routines (Jurburg et al., 2018). In other words, continuous improvement is an internalized and institutionalized philosophy to inspire a continuous improvement culture across the organization which is necessary to achieve excellence and competitiveness in an environment that is continuously changing (Juburg et al., 2018). Given the importance of continuous improvement, Singh and Singh 2015) have described it as a world-class approach to improving organizational effectiveness. Organizational members at different levels of the organization are encouraged to play their part to improve organizational processes and practices. Therefore, it becomes necessary that a conducive environment is created in an organization to encourage employees to embrace continuous improvement through learning and knowledge-sharing. According to Gasper and Mwenda (2023), the Continuous Improvement concept is receiving attention from all sectors of the economy due to increasing global competition and stakeholder demands. Hence knowledge -sharing plays a central role in continuously improving university operations to meet stakeholder needs.

2.2 Knowledge-Sharing in the University

The knowledge-sharing concept is a knowledge management technique, and it is viewed as the key to gaining competitiveness in an organizational context (Santhose and Lawrence 2023). From a theoretical perspective, the Social Exchange Theory underpins knowledge sharing. According to Tsai and Cheng (2012), the Social Exchange Theory covers knowledge-sharing robustly and it is widely used to study knowledge sharing behavior. Yoon and Park (2022) emphasize the importance of having effective systems and a culture that will promote knowledge creation and dissemination in an organization. Universities are competing in a global environment and are thus under constant pressure to continuously improve their services to respond to the needs of their stakeholders (Garcia-Sanchez 2019). The Learning Organization philosophy promotes a strong learning culture across the organization, which fosters the sharing of knowledge. As a result, productivity improves. Chua, Thinakaran and Vasudevan (2023) emphasize that in an organization where knowledge is effectively shared, such a practice leads to organizational effectiveness. Santhose and Lawrence (2023) state that in a conducive environment where there is trust and a sense of shared values, it becomes possible for members of the organization to share their knowledge.

2.3 The Learning Organization as a Strategic Choice to Achieve Organizational Effectiveness

Organizational effectiveness is the organization's ability to operate effectively, to remain competitive and to respond to the needs of its stakeholders (Ofor-Douglas 2022). Learning therefore becomes key in this context. Through learning, the organization develops its capacity to adapt in a rapidly changing environment. Ofor-Douglas (2022) further opines that organizational effectiveness is about the effective use and management of the organization's resources to achieve its strategic goals. Defined in simple terms by Ofor-Douglas (2021), organizational effectiveness refers to an organization's ability to achieve its strategic goals. In essence, organizational effectiveness is about the ability to adapt and the continuous improvement of the organization's process and practices. According to Ahmad et al. (2020), organizational effectiveness is key to responding effectively to the needs of the stakeholders. The Learning Organization philosophy creates a conducive environment for knowledge -sharing, which leads to organizational effectiveness. Yoon and Park (2022) concur that organizations need relevant competencies to adapt to a rapidly changing environment.

3. Research Methodology

The study adopted a survey design, underpinned by a post-positivism philosophical worldview. Hence, a cross-sectional design was used. The study was quantitative in nature as quantitative data was collected to achieve the objectives of the research. Leavy (2017) describes quantitative research as research characterized by measuring and testing relationships between variables to identify patterns and correlations. This point is posited by Leedy and Ormrod (2019) as well, that quantitative researchers focus on identifying relationships between variables. A sample of 291 participants was selected from a population of 1213 employees of a selected University of Technology. Staff from both the academic and academic support sectors of the university participated in the study. A response rate of 70% was achieved. Cronbach's Alpha was used to determine the reliability of the measuring instrument with an overall reliability score of 0.912.

3.1 Sampling

A stratified simple random sampling technique was used to select the sample from the population. This sampling technique has the advantage of guaranteeing the equal representation of each strata (Leedy and Ormrod 2019). Stratified random sampling is further defined by Trochim, Donnelly and Arora (2016) as a sampling method whereby the population is divided into homogenous sub-groups, then using a simple random sampling in each group to select participants.

3.2 Data Collection Method

Data collection in a research project relates to the technique used to gather a specific type of data (Spickard 2017). A self-administered questionnaire was used as the data collection instrument for this study. The questionnaire contained Likert scale statements. Leedy and Ormrod (2019) mention that questionnaires are popular for quantitative researchers because they can be distributed to a large number of participants.

3.3 Data Analysis

The Statistical Package for the Social Sciences (SPSS) version 20.0 was used to analyze data. This computer software is regarded as a user-friendly and effective statistical computer program for quantitative data analysis (Gaur and Gaur 2009).

3.4 Profile of Participants

This section presents descriptive statistics based on the biographical information of the participants of the study. Information solicited was in relation to whether participants were part of the academic or administration sector in the university.

3.5 Sector in the University of Technology

The sample constituted participants from two different sectors (academic and administration), as presented in Figure 1 below.

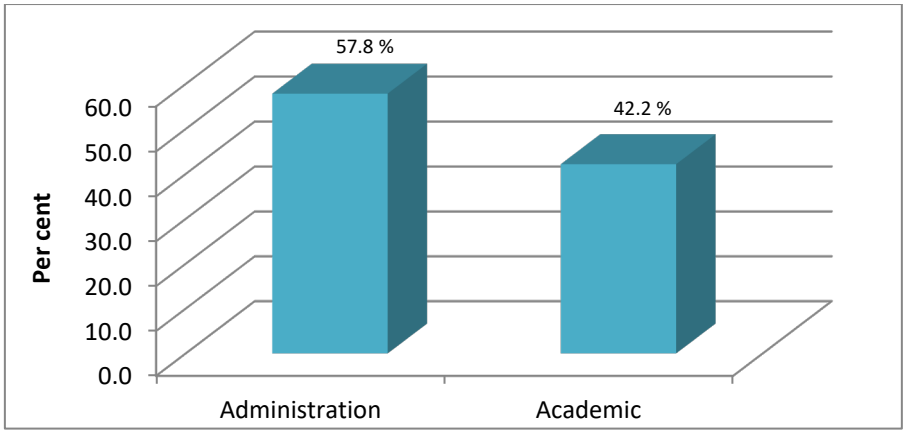

Figure 1: Sector in the University of Technology

The results show that 57.8% of the participants were from the administration sector, and 42.2% from the academic sector. It was found that the number of respondents was almost in the ratio of 6:4 for the administrative and academic sectors. This revealed that the university had more employees in administration than in the academic sector.

3.6 Opportunities for the application of a Learning Organisation philosophy in the University of Technology

This section examined opportunities for the application of a Learning Organisation philosophy at the University of Technology. Figure 2 below presents participants' responses on opportunities for the application of a Learning Organisation philosophy at the university.

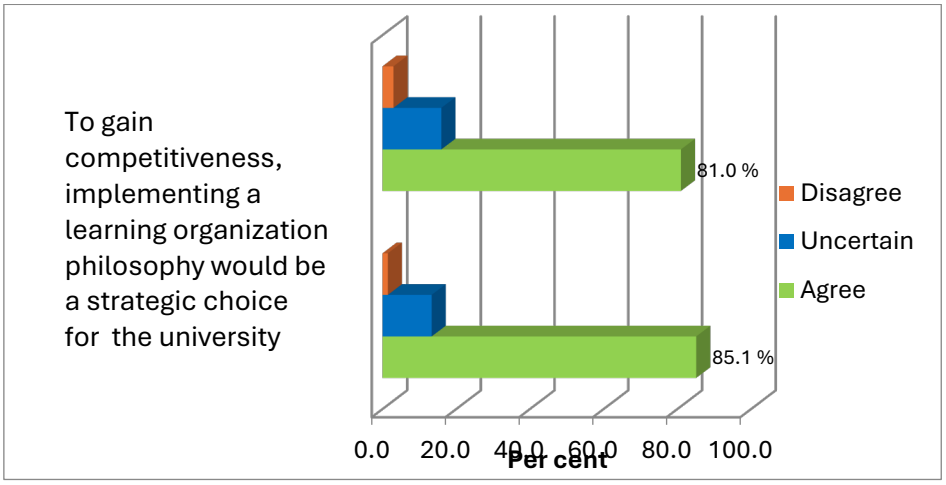

Figure 2: Opportunities for the implementation of a Learning Organisation philosophy

The majority of participants were optimistic that the application of a Learning Organisation philosophy would improve processes and practices in the university. Approximately 85% were of the view that the university would be able to respond effectively to the needs of its stakeholders through the implementation a Learning Organisation philosophy. The results further revealed that 81% of the participants felt that the adoption of a Learning Organization philosophy would be a strategic choice for the university. Lin, Eichelberger and Leong (2020) state that the rapidly changing environment in which universities operate requires new approaches with new perspectives.

3.7 Challenges with the Application of a Learning Organisation Philosophy in the University

Information is presented in Table 1 below on the possible challenges with the application of a Learning Organisation philosophy in the university.

Table 1: Challenges with the application of a learning organisation philosophy

		Frequency	Per cent	Valid Per cent	Cumulative Per cent
Valid	Lack of staff motivation	72	35.3	39.1	39.1
	Lack of support systems	66	32.4	35.9	75.0
	Lack of a shared vision	40	19.6	21.7	96.7
	Other	6	2.9	3.3	100.0
	Total	184	90.2	100.0	
Missing	System	20	9.8		
Total		204	100.0		

Almost 39.1% of the participants highlighted the lack of staff motivation and 36% identified the lack of support systems. In addition, 22% of the participants felt that the lack of a shared vision might also be a problem for the implementation of a Learning Organization philosophy in the University of Technology. Overall, these are the key challenges identified by participants. Besides these challenges, Wang and Rashid (2022) argue that transforming an organization into a Learning Organization has a number of benefits, mainly the ability to compete.

3.8 University Governance and Institutional Culture From Employees' Perspective

Figure 3 below provides a summary of the responses illustrating the views of participants on university governance and institutional culture.

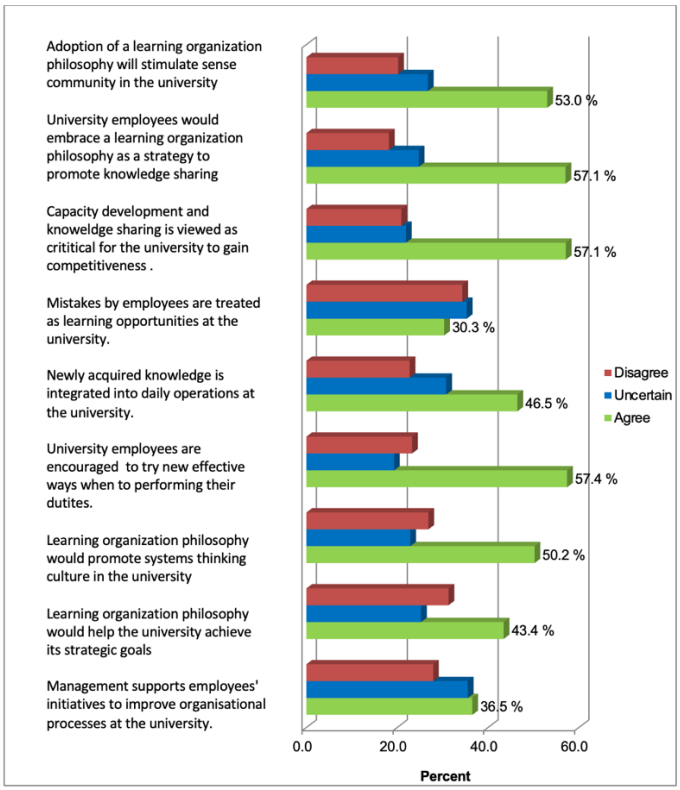

Figure 3: University governance and institutional culture

Overall, the responses show higher levels of agreement for most statements. Comparatively, the findings indicated low levels of agreement on just two statements, namely mistakes by employees are treated as learning opportunities and management supports employees' initiatives to improve organisational processes in the university. Agreement levels on both variables were at 30.3% and 36.5% respectively. The majority of participants indicated that the university is an organisation where employees strive for excellence, at 57.1%; they are encouraged to be innovative, at 57.4%; and capacity development and knowledge sharing is viewed as a priority, at 57.1%. Furthermore, there was a high level of agreement that adopting a Learning Organization

philosophy would stimulate a sense of community, and employees are willing continuously to improve on what they do, at 53.0%. The Learning Organisation philosophy places strong emphasis on the importance of a sense of community within an organisation. Matic (2022) posits that a Learning Organization philosophy has been identified as a strategic option for competing in a highly demanding and rapidly changing environment.

3.9 ANOVA Test Results on University Governance and Institutional Culture

Table 2 below presents ANOVA test output in relation to university governance and institutional culture.

Table 2: ANOVA : Test results on University governance and institutional culture

ANOVA : Employee Perceptions						
	ANOVA	**Sum of Squares**	**df**	**Mean Square**	**F**	**Sig.**
Adoption of a Learning Organization philosophy will stimulate sense of community in the university.	Between Groups	.739	1	.739	.606	.437
	Within Groups	239.301	196	1.221		
	Total	**240.040**	**197**			
University employees would embrace a Learning Organization philosophy as a strategy to promote knowledge sharing.	Between Groups	1.805	1	1.805	1.599	.208 .
	Within Groups	221.371	196	1.129		
	Total	**223.177**	**197**			
Capacity development and knowledge sharing is viewed as critical for the university to gain competitiveness.	Between Groups	.209	1	.209	.171	.679
	Within Groups	236.709	194	1.220		
	Total	**236.918**	**195**			
Mistakes by employees are treated as learning opportunities at the university.	Between Groups	.792	1	.792	.723	.396
	Within Groups	217.934	199	1.095		
	Total	**218.726**	**200**			
Newly acquired knowledge is integrated into daily operations at the university.	Between Groups	1.244	1	1.244	1.214	.272
	Within Groups	200.917	196	1.025		
	Total	**202.162**	**197**			
University employees are encouraged to try new, effective ways when performing their duties.	Between Groups	1.224	1	1.224	.982	.323
	Within Groups	249.232	200	1.246		

ANOVA : Employee Perceptions						
	Total	**250.455**	**201**			
Adopting a Learning Organization philosophy would promote systems thinking culture in the university.	Between Groups	14.177	1	14.177	10.407	.001
	Within Groups	271.077	199	1.362		
	Total	**285.254**	**200**			
Learning Organization philosophy would help the university to achieve its strategic goals.	Between Groups	.269	1	.269	.220	.640
	Within Groups	239.771	196	1.223		
	Total	**240.040**	**197**			
Management supports employees' initiatives in improving organisational processes at the university.	Between Groups	6.092	1	6.092	6.016	.015
	Within Groups	197.441	195	1.013		
	Total	**203.533**	**196**			

The ANOVA test results in Table 2 reveal variables with statistically significant differences, as well as variables with no statistical significance. These variables relate to perceptions of both academic and administration sectors on university governance. Study variables with a significance difference include: Adopting a Learning Organization philosophy would promote a systems thinking culture in the university, with a p-value of **0.001;** and that university management supports employees' initiatives in improving organisational processes, with a p-value of **0.015**. However, all other variables have no statistical significance.

3.10 Chi-Square Tests Output on University Governance and Institutional Culture

Table 3 below presents Chi-square test results relating to university governance and institutional culture.

Table 3: Chi-square results on university governance and institutional culture

Pearson Chi-Square Tests			
	Sector	**Department**	
Adoption of a Learning Organization philosophy will stimulate sense community in the university.	0.515	0.134	
University employees would embrace a Learning Organization philosophy as a strategy to promote knowledge sharing.	0.486	0.022*	
Capacity development and knowledge-sharing is viewed as critical for the university to gain competitiveness.	0.287	0.189	
Mistakes by employees are treated as learning opportunities at the university.	0.082	0.006*	
Newly acquired knowledge is integrated into daily operations at the university.	0.263	0.015*	
University employees are encouraged to try new effective ways when performing their duties.	0.641	0.267	
Adopting a Learning Organization philosophy would promote systems thinking culture in the university.	0.009*	0.137	
Learning Organization philosophy would help the university to achieve its strategic goals.	0.498	0.144	
Management support employees' initiatives to improve organisational processes at the university.	0.182	0.158	

The chi-square results in Table 3 indicate a statistically significant relationship between the academic and administration sectors on the following variables:

University employees would embrace a Learning Organization philosophy as a strategy to promote knowledge-sharing,

Mistakes by employees are treated as learning opportunities at the university,

Newly acquired knowledge is integrated into daily operations at the university.

The results further indicate that with the rest of the study variables, there is no statistically significant relationship between the academic and administration sectors. Study variables with no statistically significant relationship have a **p-value** greater than **0.05**.

3.11 Adaptability and Continuous Learning in the University

This section deals with the continuous learning culture and adaptability in the university.

Figure 4 below presents a summary of the responses.

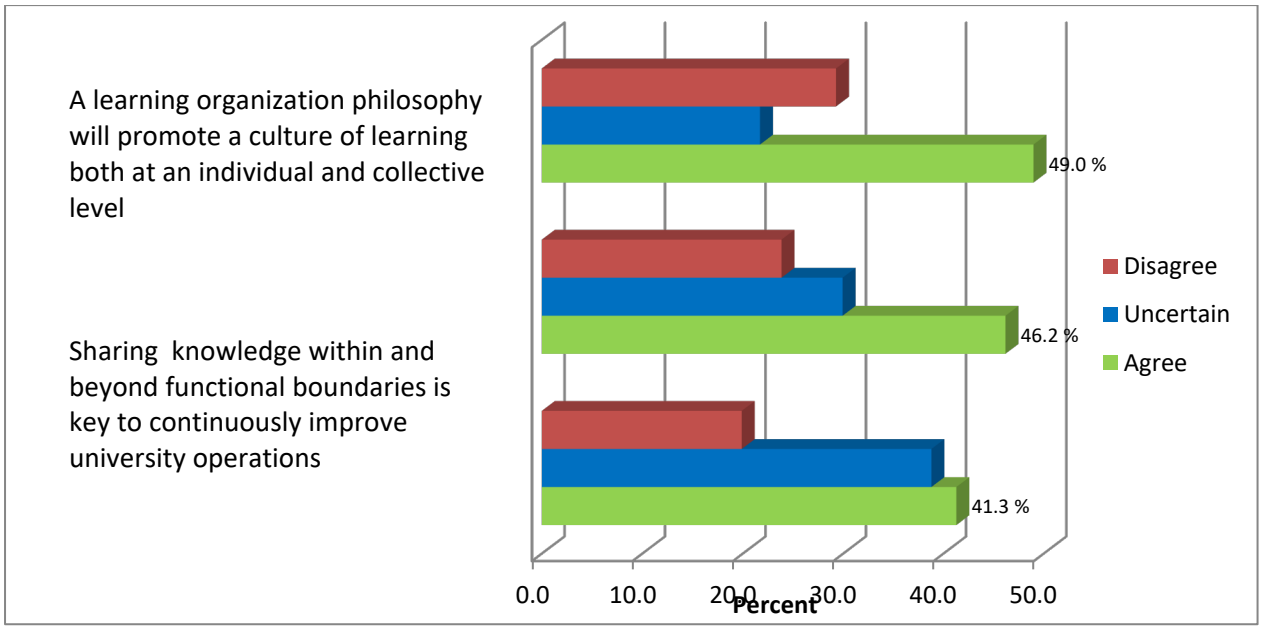

Figure 4: Adaptability and continuous learning in the university

The levels of agreement on all variables are less than 50% in this section. The findings revealed that participants at 49.0% were of the view that the implementation of a Learning Organization philosophy would promote learning at both the individual and collective levels. The results indicate that learning and sharing of knowledge was critical to responding effectively to the needs of the university's stakeholders. Although levels of agreement with statements in this section were less than 50%, the information helps to provide the perspective of participants on statements raised in this section.

4. Results and Discussions

The questionnaires were self-administered to employees of a selected University of Technology and a 70% response rate was achieved from 291 questionnaires.

Based on the findings, participants were optimistic about the implementation of a Learning Organisation philosophy in the university. The results indicate that employees at all levels would embrace the implementation of a Learning Organization philosophy in the university. Importantly, participants were of the view that the implementation of a Learning Organization philosophy would be a strategic decision to promote knowledge sharing in the university. Wang and Rashid (2022), who are proponents of a Learning Organization philosophy, accentuate that becoming a learning organization is critical in a rapidly changing environment. According to Chua, Thinakaran and Vasudevan (2023), knowledge is a key resource for solving problems, making informed

decisions, as well as improving processes and practices in an organization. The results revealed that the university environment was conducive to the implementation of a Learning Organization as a strategy to promote knowledge -sharing in the university. Overall, participants were also optimistic that adopting a Learning Organization philosophy would help the university to achieve its strategic goals, and as a result be able to respond to the needs of relevant stakeholders. Malik and Garg (2020) emphasise that continuous learning and adaptability are key characteristics of a Learning Organization. Participants raised some concerns regarding the application of a Learning Organisation philosophy at the university. However, overall, positive sentiments in the study outweigh the negative sentiments on the application of a Learning Organisation philosophy in the organisation. Hence, knowledge has been identified as a key resource for organizational success. Therefore, it is necessary to adopt, internalise and institutionalize the Learning Organization philosophy as an overarching philosophy to promote knowledge -sharing in Universities of Technology. Based on the findings, it could be concluded that a conducive environment is important to successfully implement a Learning Organisation as a strategy to promote knowledge-sharing in the university.

4.1 Research Contribution

This study has demonstrated that a Learning Organization philosophy is paramount in both creating a conducive environment and fostering a knowledge-sharing culture within and beyond functional boundaries in a university. Practically, this study provides necessary and actionable ideas on the adoption of a Learning Organization philosophy, amongst other things, to promote knowledge-sharing. This study highlights the connection between learning and knowledge. Yoon and Park (2022) argue that knowledge-sharing facilitates new ideas for innovation. Literature on the Learning Organization is copious. However, the Learning Organization has not been researched from a knowledge -sharing perspective in the context of the UoTs. The findings of the study provide necessary insights for UoTs to gain competitiveness. Furthermore, the adoption of a Learning Organization as an overarching philosophy is necessary considering the constant pressure under which UoTs operate to respond to the needs of their stakeholders. As highlighted, learning and knowledge serve as a cornerstone for organizations to compete and remaining relevant in a highly demanding global environment (Matic 2022). This study contributes to the literature by capturing knowledge-sharing from a Learning Organization perspective, in a university context.

4.2 Ethical Requirements

This research project was conducted in accordance with the ethical guidelines of the institution. The researcher obtained ethical clearance from the Research Committee at the institution. Participation in the study was on a voluntary basis and participants had to sign a consent form.

4.3 Study Limitations

One of the limitations of this study was that it focused on only one University of Technology, which was one of the two Universities of Technology in the province of KwaZulu- Natal, South Africa. This university was selected based on its historical background as it was formed after a merger of two Technikons in 2002.

5. Conclusion

The Learning Organization philosophy serves as an overarching philosophy in an organization where continuous learning and the sharing of knowledge happens beyond functional boundaries. Marquis and Huston (2021) state that knowledge developed through various initiatives in an organization should go beyond the boundaries of individual learning. In other words, acquired knowledge both at an individual or collective level should be shared within and beyond functional boundaries in an organization. It is also further emphasized by Matic (2022) that the ability to learn and effectively manage acquired knowledge is necessary to achieve organizational effectiveness and remain competitive. This study has demonstrated that a Learning Organization philosophy could be used to foster knowledge-sharing in a university.

5.1 Future Research

It is recommended that future research should be extended to include more Universities of Technology. Furthermore, future researchers should investigate or evaluate the impact of a Learning Organization philosophy in relation to the promotion of knowledge-sharing beyond functional boundaries in a university.

Abstract: Knowledge is a fundamental element to enable organizations in anticipating and responding to Operational Safety Events (OSE). The identification and analysis of knowledge flows emerge as strategies to strengthen the potential for organizational resilience, as they qualify the knowäedge necessary for risk mitigation and the strengthening of operational safety. This article presents the results of an empirical research conducted in a sanitation company, aiming to investigate critical knowledge and its flows in complex sociotechnical systems. The research involved interviews with professionals who faced OSEs in their daily activities. OSEs were defined as situations where professionals were able to prevent accidents and/or incidents, successfully dealing with potential threats. To achieve the research objectives, two sequential instruments were used. The first instrument was employed to identify critical knowledge related to OSEs, exploring those mainly related to situational awareness and the repertoire for implementing responses to an OSE. This process revealed a diversity of knowledge, much of which was tacitly present in the minds of professionals and was not formally documented in the company's standard operating procedures. The second instrument was developed to map knowledge flows associated with the identified OSEs. This mapping provided a deeper understanding of how these critical knowledge were shared and used within the organization. The research results evidenced various critical knowledge in the analyzed OSEs, going beyond the information available in tutorials, work plans, or organizations' standard operating procedures. Both instruments used in the interviews were validated and yielded positive results. As a result of this empirical research, the organization now has a valuable understanding of the critical knowledge evidenced, which has the potential to drive organizational learning and strengthen the resilient capabilities of the organization, considering that knowledge resources are a fundamental element for resilience. As a next step, it is aimed to investigate the visual representation of knowledge flows, assess their effectiveness, and provide specific guidelines to enhance knowledge management processes in organizations.

Keywords: Knowledge Flow, Resilient Capabilities, Complex Sociotechnical Systems, Knowledge Management, Resilience.

1. Introduction

In recent years, the work environment has faced a significant increase in complexity, driven by technological advancements, market digitization, and the data revolution. This increase in complexity is particularly notable in high-reliability organizations, where risks and uncertainties are paramount. To understand this evolution, the theory of complex systems has been increasingly utilized to attempt to explain why activities evolve with a high degree of uncertainty and unpredictability, as the combination of activity variability generates complex scenarios whose outcomes become difficult to predict (Oedewald & Gotcheva, 2015; Hirose & Sawaragi, 2020; Reiman et al., 2021).

The Cynefin framework, developed by Snowden and Boone (2007), offers an approach to understanding and making decisions in different operational contexts. Comprising four distinct domains - simple, complicated, complex, and chaotic - Cynefin helps categorize organizational environments and adjust strategies according to each context. Figure 1 presents the framework.

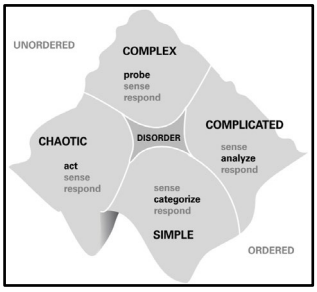

Figure 1: Framework Cynefin. Source: Snowden e Boone (2007).

Specifically in the complex quadrant of the Cynefin framework, situations and activities are characterized by high uncertainty and unpredictability. In this context, interactions between system elements are nonlinear and emergent, meaning that outcomes cannot be easily predicted based on simple cause-and-effect relationships. Instead, relationships are dynamic and may evolve in unexpected ways. As characteristics of this complex quadrant, Saurin and Sosa (2013) defined four main attributes: (i) a large number of elements that interact dynamically; (ii) a wide diversity of elements; (iii) anticipated variability; and (iv) resilience, with resilience being the primary attribute of these systems.

Given that resilience is the primary attribute of these systems, it becomes imperative for organizations to seek ways to enhance their capabilities for monitoring, anticipation, response, and learning in the face of unexpected events (Hollnagel, 2011). This article proposes the use of two guiding instruments - scripts for identifying applied knowledge in the face of OSEs, with questions - applied to professionals within an organization in the context of SSTC. The objective is to identify critical knowledge and knowledge flow in OSEs, seeking to qualify this knowledge in a way that makes it accessible and applicable within the organization. Additionally, the article also aims to verify and validate these instruments as part of its contribution to understanding and effectively managing organizational resilience in the face of the complexity of the current work environment.

The article is structured as follows: The first section contextualizes the problem in the introduction, establishing the foundation for the subsequent discussion. In the second section, theoretical foundations are provided, exploring the two main themes: knowledge flow and complex sociotechnical systems. Next, details of the knowledge flow identification process are presented, including the scenario, interview conduct, and results achieved. In the final section, concluding remarks are made, providing a conclusion on the study conducted.

2. Concepts

2.1 Knowledge Flow

The pioneering study on the construct of knowledge flow dates back to 1953, with the article titled "Planning Concepts and Regional Research," written by the American author Harvey S. Perloff. In this seminal work, Perloff investigated knowledge flow in the context of regional planning. However, until the late 1990s, publications on the topic were relatively scarce, and in several years, no publications related to knowledge flow were recorded. From 1991 onwards, a significant growth in works addressing the topic was observed, with the year 2020 standing out as the period with the highest number of publications (Miranda Junior et al., 2022b).

Despite the growing interest, there is still no consensus in the literature on a definitive definition for the concept of knowledge flow. However, the fundamental essence remains consistent, centered on the exchange, diffusion, or movement of ideas, knowledge, and concepts (An, Han & Park, 2017). In a comprehensive literature review, Bittarello (2014) identified several definitions for the term "knowledge flow," highlighting three levels of analysis: (i) team level, (ii) inter-team, and (iii) within the organization. Table 1 presents the definitions evidenced by the author, as well as others found throughout the research.

Table 1: Definition of knowledge flow

Authors	Definition
Wu, David C. Yen (2012)	The process of knowledge transfer between individuals or knowledge processing mechanisms.
Rodríguez-Elias (2008)	Transfer of knowledge from where it is created or stored to where it needs to be applied.
Nissen (2002)	It considers the flow of knowledge in terms of dynamic knowledge, where the flow engages in activities such as knowledge conversion, transfer, sharing, integration, reuse, movement, and application of that knowledge over a period of time.
Zhuge (2002)	It is a process of passing knowledge between individuals or knowledge processing mechanisms. It possesses three crucial attributes: direction, content, and carrier, which respectively determine the sender and receiver, the content of shareable knowledge, and the medium that can transmit the content.

Source: adapted of Bittarello (2014).

The definition of knowledge flow adopted in this work will be the one proposed by Zhuge (2002).

In studies on the topic of knowledge flow, three essential characteristics emerge to qualify this flow: (i) the study objective on knowledge flow; (ii) the representation of knowledge flow; and (iii) the level of analysis of knowledge flow. According to Miranda Junior, Potrich, and Todesco (2021), most research on knowledge flow is focused on three main objectives: (i) improving organizational processes, (ii) supporting senior organizational management, and (iii) stimulating organizational innovation. These objectives have been identified in various organizational contexts, from public and private organizations to research institutes, where the topic of innovation is particularly relevant.

The use of knowledge flow as a tool in knowledge engineering allows for its identification and qualification, aiming at the application of this knowledge in other related constructs, such as organizational learning and knowledge management.

In the next chapter, the second construct of this research will be presented, namely, complex sociotechnical systems.

2.2 Complex Sociotechnical Systems

Characterizing a complex sociotechnical system involves interrelations among diverse elements, including people, technology, physical environment, procedures, and regulations. In this context, activities performed are knowledge-intensive, with a strong technological presence and subject to residual risks and uncertainties. Moreover, such systems are constantly exposed to influences from the external environment (Saurin & Sosa, 2013; Schneider, 2019).

According to Saurin and Sosa (2013), four categories of characteristics define complex sociotechnical systems: a large number of elements interacting dynamically, a wide diversity of these elements, anticipated variability, and resilience.

Resilience, in particular, is a crucial attribute of these systems, denoting their ability to adjust their functioning before, during, or after changes to sustain unexpected conditions (Hollnagel, 2011; Saurin & Sosa, 2013). Woods (2015) emphasizes that resilience became a popular concept in the early 2000s due to pressure for more efficient and economical systems.

However, the popularization of resilience has also generated confusion, as the term is employed in various ways. Woods (2015) identifies four distinct approaches: resilience as recovery and return to equilibrium, as synonymous with robustness, as the opposite of fragility, and as network architectures capable of adapting to future surprises.

It is crucial to situate resilience within a specific research context. In this article, we adopt the perspective of recovery and adaptation, emphasizing the importance of a complex sociotechnical system's ability to overcome adversities and adjust to future changes, following the guidelines of Hollnagel (2011) as a central reference. Hollnagel highlights knowledge as an essential element for a system's resilience, being a fundamental component of resilient capabilities, as resilience only manifests in practice. Figure 2 presents the four capabilities described by the author.

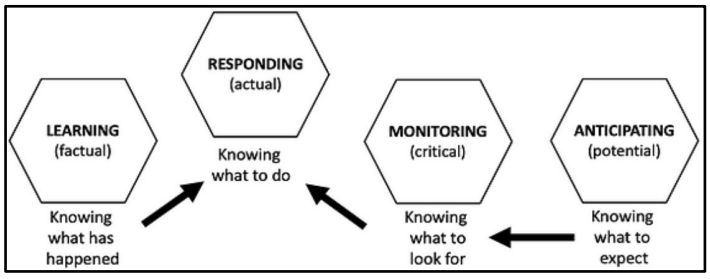

Figure 2: The capabilities of a resilient system. Source: Hollnagel, 2011.

As illustrated in Figure 2, knowledge plays a direct role in strengthening anticipation and monitoring capabilities, as well as significantly contributing to responsiveness. In this sense, knowledge is essential as a resource to guide effective action.

3. Knowledge Flow Identification Process

In this section, the process of identifying knowledge flow in a sanitation company in Brazil will be detailed. A description of the company where the research was conducted will be provided, along with details about the operational safety events that were addressed during the interviews.

3.1 Methods

The research was conducted in a public sanitation company. This organization is part of complex sociotechnical systems, characterized by dynamic interrelations among people, technology, physical environment, procedures, and regulations. In addition to its fundamental operations, the company also performs a series of other complex activities, such as water quality control and waste management. Its relevance in the context of basic sanitation and its representation as a large-scale organization make it a conducive setting for investigations into knowledge flow and resilient capabilities. The company has approximately 2.000 employees, serving around 2.7 million people across 195 municipalities within the Santa Catarina state in Brazil. For the research, two professionals from the technical department of the company were selected, who held different hierarchical levels and also had a minimum of 10 years of experience in the company. These professionals were intentionally selected due to their extensive knowledge about the operations that are the focus of this study.

Thus, the semi-structured interviews were encouraged to recall operational safety events (OSE) they witnessed during their experience in the company, events that, in some way, managed to prevent accidents and/or incidents based on their expertise. The two operational safety events (OSE) identified by the interviewees for the interviews were: (1) water reservoir rupture; (2) maintenance of pumped sewage network. To achieve the proposed objective and conduct the interviews effectively, two instruments were used. The first instrument was employed to identify the operational safety event and to highlight critical knowledge, as proposed by Miranda Junior et al. (2022a). The second instrument was sequentially used to identify the knowledge flow in the operational safety event in question, also proposed by Miranda Junior et al. (2023). Table 2 presents a synthesis of the field of study.

Table 2: Summary of aspects of the field work carried out.

Item	Description
Population	Approximately 2.000 employees, serving approximately 2.7 million people in 195 municipalities in a state in Brazil
Method used to select interviewees	Should possess varying hierarchical levels within the organization, a minimum of 10 years of experience, and extensive knowledge about the company's operations.
Type of interviews carried out	Two semi-structured interviews were conducted using instruments developed by Miranda Junior et al. (2022a) and (2023).
Analysis method used	Conducted content analysis on the responses provided by the interviewees.

Source: Authors (2024).

Tables 3 and 4 present a portion of the two instruments used to elucidate the interviews.

Table 3: Critical knowledge identification instrument.

Activity	Description
Interviewee identification	What is your name, job title, and/or role? How many years of experience do you have in this field, both at your current organization and at other companies? Could you provide a brief overview of your daily activities?
OSE identification	Could you tell me an episode where your experience helped in solving a problem?
Diagnosis	How did you realize that the event would be unusual/difficult? What were the primary pieces of information or clues available when you first realized an accident was imminent? What knowledge did you employ to interpret this information?

Activity	Description
Intervention	Considering the perception of the event, what action plan was established? What information and critical knowledge were used to develop this plan? How were the necessary skills mobilized for the implementation of the action plan?
Difficult or facilitating factors	Were there any factors that impeded the design or implementation of the action plan?

Source: Miranda Junior et. al. (2022a).

Table 4: knowledge flow identification instrument.

Activity	Description
Reaffirm the critical knowledge identified	In the previous script, critical knowledge was highlighted, enabling the detection of clues and the conception of the action plan. Would it be possible to reaffirm this knowledge? Among those related, which are the two most relevant?
Origin of the knowledge	Would it be possible to share details about the source (origin) of the knowledge in question and provide additional insights about where this knowledge emerged? Could you provide a more detailed explanation of the process of obtaining this knowledge?
Destination of the knowledge	With regard to the recipient's receptiveness to this knowledge, was it easily assimilated? Was the content presented easily understood and absorbed by the recipient, without significant difficulties or barriers to understanding?
Channel of knowledge dissemination	In what specific way was this knowledge transmitted? Which medium, media, or channel was used to convey this knowledge to the recipients, allowing them access to it?
Context of the knowledge	Can you envision that this knowledge can be applied in other contexts (ESO) beyond the current one, or is it more specific and applicable only in this particular context?
Barriers and/or facilitators for the knowledge	During the dissemination of this knowledge, was it possible to identify any barriers or facilitating elements that may influence the movement of this knowledge?

Source: Miranda Junior et. al. (2023).

Each interview was conducted with the consent of the interviewee and carried out online via the Zoom platform, with an average duration of one hour each. The interviews took place in early 2024. A summary of the research implementation is presented in Table 5.

Table 5: CDM Roadmap application scenario

Activity	Description
Complex sociotechnical system	Water supply, collection and sewage treatment company
OSE within the operation performed	Maintenance of pumped sewage network Bursting of water reservoir

Source: authors, 2024.

In the next section, the research results will be presented.

3.2 Results and Discussions

The interviews were conducted using two instruments, as previously mentioned in Tables 3 and 4. The first instrument aimed to define the operational safety event and identify the critical knowledge involved in the event. Subsequently, using the second instrument, the qualification of this knowledge was further explored through the identification of information flow. The first interview addressed the Operational Safety Event (OSE) related to Pumped Sewage Network Maintenance, while the second discussed the water reservoir rupture. Tables 6 and 7 highlight the main evidence resulting from the analysis of the first OSE.

Table 6: Main evidence of application of the critical knowledge identification instrument.

Block	Description
Interviewee identification	*The professional, referred to as interviewee 01, has thirteen years of experience in the organization, always working in the sewage operational system. He began working in a specific sewage system of a certain area, and soon after was invited to work at the central, where he oversees the sewage for the entire city.* *"On a particular day, the team had scheduled and was executing maintenance on a pumped sewage network. When I arrived at the site to oversee the operation, I immediately noticed some signs that something could go wrong. This operation posed risks of both death and environmental hazards because there was a lift station shut down, which could cause overflows."*
ESO identification	*"Maintenance of pumped sewage network"*
Diagnosis	*"The sewage network operates by gravity, meaning it has sewage pipes 4 meters, 6 meters deep. So, when excavating for sewage maintenance, one must be careful with the soil because here, the soil is very sandy and has a high water table. During excavation, if precautions are not taken, it can collapse, burying anyone present."* *"The team was conducting maintenance on a certain sewage network, and when I arrived at the site, I immediately noticed cracks in the asphalt, noticed sand around, and realized that everything was about to collapse. I halted the entire operation, asked everyone to come out of the trench, and within a minute, everything collapsed. It even caught the foot of an engineer, but thankfully it wasn't anything serious."* *"We were supposed to shore up with iron plates and lower the water table around. To avoid influencing the soil. Because here, each region has a different type of soil. When I arrived and saw that none of this was done, I immediately realized that there could be an accident."*
Intervention	*"Knowledge of technical standards and regulations."* *"Knowledge of the company's work plan and procedures."* *"Knowledge acquired through fieldwork experience, alongside more experienced professionals."* *"With this knowledge, I requested a redo of everything, including the trench that was going to be operationalized. I insisted on shoring up according to the service's depth, and only then could the work begin. Without these measures, I would not approve the start of maintenance."*
Difficult and/or facilitating factors (resources):	*"Time pressure for executing maintenance/service, as it heavily impacts city traffic."* *"Emotional control, as everyone is experiencing adrenaline at that moment."* *"Lack of knowledge among some employees regarding the proper use of PPEs for that operation."* *"Established organizational culture with entrenched habits, making it difficult to change or correct."* *"Cost can also be a barrier, as financial resources are always limited and can impact operations."*

Source: authors, 2024

The focus of the second instrument is on identifying the knowledge flow, starting with the first question that reaffirms the critical knowledge identified in the previous instrument. Table 7 highlights the knowledge related to the work plan and company procedures.

Table 7: Main evidence of application of the knowledge flow identification instrument.

Block	Description
Ratify the critical knowledge identified	1. *"Knowledge of technical standards and regulations."* 2. *"Knowledge of the company's work plan and procedures."* 3. *"Knowledge acquired through fieldwork experience, alongside more experienced professionals."*
Knowledge origin	*"Knowledge of the company's work plan and procedures."* *"Based on technical standards (NBR), Standard Operating Procedures (SOPs) are developed by the company's management and made available in a digital repository for all employees involved in those procedures. Knowledge of SOPs primarily comes from training sessions and safety management workshops. It's worth noting that accessing this knowledge is easy, as with a smartphone on-site, any SOP or other necessary information can be consulted instantly."*
Knowledge destination	*"Knowledge of the company's work plan and procedures."* *"All employees involved in those procedures."*
Knowledge movement channel	*"Knowledge of the company's work plan and procedures."* *"This knowledge moves from its source (digital repository of SOPs) to the involved employees, mainly through digital means, but also through informal conversations among workers. Evaluating this knowledge from the perspective of absorptive capacity, it can be said to have a moderate absorption rate."*
Knowledge context	*"Knowledge of the company's work plan and procedures."* *"This knowledge can be utilized in various other sectors of the company, and it should be standardized across all operations of the organization to improve service quality."*
Barriers and/or facilitators to knowledge	*"Knowledge of the company's work plan and procedures."* *The main barriers in the knowledge flow are indeed the "Time pressure for executing maintenance/service, as it heavily impacts city traffic," and the "Established organizational culture with entrenched habits, making it difficult to change or correct."*

Source: authors, 2024

With the application of the instruments in this first interview, the importance of technical and regulatory knowledge for carrying out operations was evidenced. The interviewee emphasized the importance of possessing a deep understanding of technical standards and regulations relevant to working with sewage. This knowledge not only enabled them to identify potential risks during maintenance operations but also to take corrective actions to prevent serious accidents.

The interviewee also highlighted that knowledge flow in the company is essential to ensure the safety and effectiveness of operations. Access to Standard Operating Procedures (SOPs) through a digital repository facilitates knowledge dissemination among employees. However, it was mentioned that the absorption of this knowledge may only be at a moderate level, indicating the need for improvements in the effectiveness of knowledge transfer.

Several barriers hindering knowledge movement in the company were also identified, including time pressure, established organizational culture, and cost. Time pressure may lead employees to overlook proper procedures, while entrenched organizational culture may resist necessary changes and corrections. Additionally, financial constraints may limit the resources available to implement additional safety measures.

The second interview discussed the water reservoir rupture. Tables 8 and 9 highlight the main evidence resulting from it.

Table 8: Main evidence of application of the critical knowledge identification instrument.

Block	Description
Interviewee identification	*The professional, referred to as interviewee 02, has nine years of experience in the organization and works as a leak detection technician, meaning he carries out operations to find hidden leaks in the water network, usually working at night when water pressure increases and consumption decreases. He is currently the head of the city's Water Operations Center.* *"In the second semester of 2023, there was a rupture of a water reservoir in the city, and the force of the water caused significant damage to the neighboring community. As a result, the organization's management called all department heads to assist in support. This incident occurred in the early hours of the morning, and a few hours later, my team, consisting of about eight professionals, arrived to assist in the recovery efforts."*
ESO identification	*Rompimento do reservatório de água*
Diagnosis	*"The mission given by the organization's management to my team was to clean up the affected area. At first glance, it seemed like a war zone because there was debris, cars, swimming pools, fallen walls, and poles, all out of place and piled up. There was a lot of risk involved in this activity."* *"Looking at the whole situation, I realized there was a lot of risk involved. So, I first conducted a reconnaissance of the entire area, entering houses, analyzing the terrain, and talking to residents to determine the action plan. Because I had to ensure the safety of my team."*
Intervention	*"The entire action plan for the team involved in this activity is not documented in company standards, manuals, or SOPs. It was defined through discussions and past experiences of both myself and my team."* *"Knowledge gained through fieldwork experience."* *"Leadership skills and empathy."* *"From there, we organized the team and machinery to start the work. The focus was mainly on the position and path of the machinery because it had to remove the material and dispose of it."*
Difficult and/or facilitating factors (resources):	*"As factors that hindered the operation, we faced pressure from individuals seeking to take advantage of the situation, such as those who presented themselves as community leaders and exerted pressure."* *"As facilitators, we had the support of senior management for the actions undertaken."*

Source: authors, 2024

In Table 9, knowledge through fieldwork experience is highlighted.

Table 9: Main evidence of application of the knowledge flow identification instrument.

Block	Description
Ratify the critical knowledge identified	*"Knowledge gained through fieldwork experience."* *"Leadership skills and empathy."*
Knowledge origin	*"Knowledge gained through fieldwork experience."* *"The knowledge within my team is acquired through knowledge transfer, meaning we gather every fifteen days for an informal discussion to exchange experiences from the past days."*
Knowledge destination	*"All employees of the organization."*
Knowledge movement channel	*"This knowledge moves from its source to the involved employees, primarily through in-person meetings every fifteen days.*
Knowledge context	*"This experiential knowledge can be applied in other contexts; for example, there was a 180mm reservoir rupture in another neighborhood, destroying the entire street and forming a false bottom. When the team arrived there to diagnose the situation, they already utilized the knowledge from the previous experience."*
Barriers and/or facilitators to knowledge	*"As factors that hindered the operation, we faced pressure from individuals seeking to take advantage of the situation, such as those who presented themselves as community leaders and exerted pressure."* *"As facilitators, we had the support of senior management for the actions undertaken."*

Source: authors, 2024

Considering the reports from Interviewee 02, whose experience focuses on incident management, the crucial role of knowledge acquired through fieldwork experience, as well as leadership skills and empathy in conducting emergency response operations, becomes evident. In a crisis situation such as the rupture of a water reservoir,

practical knowledge and the ability to make quick and effective decisions play a fundamental role in minimizing damage and ensuring the safety of the team involved.

Furthermore, the transfer of this knowledge among team members through regular experience-sharing meetings highlights the importance of internal communication and collaboration for disseminating best practices and strengthening the organization's capacity to respond to emergency situations.

Finally, reaffirming that knowledge is a fundamental element to support resilient capabilities, as defined by Hollnagel (2011), Table 10 synthesizes the evidence of knowledge identified in the interviews of this study, which are potential contributions to support and enhance resilient capabilities.

Table 10: Identification of knowledge to strengthen resilient capabilities in both ESOs.

Identification of critical knowledge	Knowledge qualification through knowledge flow	nputs for organizational learning
Knowledge in technical standards and company regulations.	The knowledge is explicit, acquired through training, requiring a technical background as a prerequisite. It has been internally developed by the organization itself and presents a moderate level of difficulty for absorption.	Knowledge to review access to field work plans.
Knowledge of the work plan and company procedures.	The knowledge is explicit, acquired through safety training and seminars, requiring a technical background as a prerequisite. It has been internally developed by the organization itself and has a low level of difficulty for absorption. It is mainly accessed virtually and faces challenges in field accessibility.	Knowledge to review access to field work plans.
Knowledge gained through fieldwork experiences, alongside more experienced professionals.	The knowledge is tacit, acquired through interaction with experienced professionals within the organization, presenting a high level of difficulty for absorption. One of the main barriers is communication.	Formalization of this knowledge for sharing through training.
Knowledge acquired through fieldwork experiences.	The knowledge is tacit, acquired through interaction with experienced professionals within the organization, presenting a high level of difficulty for absorption. One of the main barriers is communication, while a facilitator is the support from senior management.	Formalization of this knowledge for sharing through training.
Leadership skills and empathy.	The knowledge is tacit and explicit, acquired through interaction with experienced professionals within the organization, presenting a moderate level of difficulty for absorption.	Formalization of this knowledge for sharing through training.

Following the presentation of potential contribution evidence, the conclusion of the research will be presented in the next section.

4. Conclusion

The main objective of the article was to investigate and identify critical knowledge and knowledge flows within complex sociotechnical systems, through interviews with professionals who witnessed risk situations and somehow managed to prevent a possible incident and/or accident, in order to contribute to resilient capacities.

The interviews yielded positive results, providing the organization with a valuable understanding of the critical knowledge identified, which has the potential to drive organizational learning and strengthen the resilience capabilities of the company. It is important to emphasize that knowledge is a fundamental resource for organizational resilience. According to the literature, as stated by Hollnagel (2011), knowledge is a determining factor for resilient capabilities, and through the interviews, this assumption was reaffirmed.

Based on these observations, it is possible to initiate a discussion on how the company can overcome the identified barriers and promote a culture of safety and efficiency through better transfer and utilization of available knowledge. This could involve investments in additional training, continuous review and updating of operational procedures, and a gradual change in organizational culture to prioritize safety as a fundamental priority.

The findings of this study corroborate the theories and concepts of renowned authors in the field of resilience and knowledge flow. Snowden and Boone (2007) identify the complexity of sociotechnical systems within the

complex domain of the Cynefin Framework, where resilience is essential, aligning with the operational safety events analyzed. Zhuge (2002) highlights crucial attributes of knowledge flow, reflected in the transfer of tacit and explicit knowledge observed in the study. Miranda et al. (2021) point out objectives of organizational improvement, management, and innovation, evidenced in the practical application of the critical knowledge identified. Woods (2015) discusses resilience as adaptation and recovery, exemplified by the effective crisis response documented in the study. Hollnagel (2011) emphasizes the importance of knowledge for monitoring, anticipation, response, and learning capabilities, confirming the central role of knowledge in organizational resilience found in the research.

As a next step, the aim is to investigate the visual representation of knowledge flows, evaluate its effectiveness, and provide specific guidelines to enhance knowledge management processes within organizations.

Configurations of Employee Assessments of Past Changes: Do Leadership and Learning Matter?

Irena Mladenova
Sofia University St. Kliment Ohridski, Sofia, Bulgaria

irenaml@feb.uni-sofia.bg

Abstract: Organisational change studies increasingly interpret the phenomenon as multiple change, and not a one-time occurrence. Even successful changes may have detrimental longer-term effects - change fatigue, resistance, and undermined cohesion. These might hamper the organisational capabilities needed to navigate current and future changes. Previous research highlights the importance of transformational leadership and learning culture for maintaining organisational capabilities to change sustainably. Employees' interpretations of past changes largely shape their (future) attitudes – were they involved in decision-making, were consequences personally (organisationally) beneficial, and did change break the team cohesion. This paper argues that learning organisation and transformational leadership practices are related to how employees experience and interpret past changes. A configurational approach is employed. The research aims to reveal the relationship between learning organisation (LO) and transformational leadership (TL) with three variables associated with how employees evaluate past changes – history with change (HC), valence (VA), and cohesion (CO). The study is quantitative and uses a standardised questionnaire. The level of research is individual, the sample consists of 188 respondents – managers and employees in firms in Bulgaria. Five composite variables measured by scales adapted from previous research are used. HC, VA, and CO are applied in cluster analysis which reveals three distinct clusters. Cluster 1 consistently shows the highest scores on all three variables, and Cluster 3 – the lowest. The three clusters are profiled using demographic variables, TL and LO. Of all demographic variables, only job position has a statistically significant correlation to cluster membership, suggesting that management and employees experienced past changes differently. Respondents in Cluster 1 gave the highest scores on TL and LO at their workplace, while Cluster 3 had moderate scores. The main conclusions support the argument that transformational leadership and learning organisation are related to how employees interpret past changes. There are several theoretical and practical implications. The research provides empirical evidence on the five variables' relationships thus adding to organisational change studies' advancement. The results highlight the importance of monitoring how employees internalise change consequences. Failing to do so might be detrimental to the organisational change capabilities.

Keywords: Organisational Change, Learning Organisation, Transformational Leadership, Cohesion, Valence, History With Change.

1. Introduction

Changes in organisations are the rule rather than the exceptions and require organisations to focus on building the necessary capabilities to navigate successfully change imperatives. New change initiatives are often started before previous ones are completed, putting a strain on people, processes, and resources in the organisation.

Organisations being open systems are temporary structures of relationships and interactions between individuals and the environment. Organisations are better equipped with the capabilities to change faster than individuals or societies (Laurent, 1990). It might be thus relatively easier to change structures, processes, and procedures within the organisation. When and how employees adopt the new behaviours, though, is more problematic. Heracleous and Bartunek (2021) stress that change outcomes cannot be adequately assessed from the short-term, linear time perspective, focusing on the present – which typically considers deadlines and budgets.

Narratives and sensemaking can help motivate the organisation to pursue a change and connect the past to the future. Shipp and Jansen (2021) stress the importance of accounting for subjective time – how people interpret past, present, and future changes and add meaning to what has changed and what will change. Individuals' interpretations of past changes provide the context for the way they approach current and future changes. Suddaby and Foster (2017) identify four distinct models of organisational change based on the implicit models of history involved – history as fact, as power, as sensemaking, or as rhetoric. The prevailing assumptions of history have a major impact on how change is managed, what exactly changes, and how past, current, and future changes are interpreted.

Subjective time reflects both social construction and individual perception and stresses the important role of interpretation (Shipp and Jansen, 2021). Individuals' interpretations of change (past-present-future) interact with how their group jointly co-creates the experiences and social norms, and thus impacts (individual and

shared) attitudes and behaviours. A current (or future) change is rarely evaluated on its own. It is rather interpreted based on past experiences and future expectations, individual and shared within the group.

Stepping on the concepts of subjective time and multiple change could help explore some important relationships and add to our understanding of organisational change. This study aims to reveal individual-level interpretations of organisational change and seeks answers to the following research questions:

RQ1. How do individual interpretations of past changes relate to organisational change success factors?

RQ2. Can these individual interpretations distinguish between different groups of organisational members (clusters)?

RQ3. What are the different clusters' characteristics?

The rest of this paper is organised as follows. The next section provides an overview of the theoretical background. The third section presents the methodology and sample. The fourth section describes the analysis and results. The fifth section discusses the findings and limitations of the study. The last section concludes.

2. Literature Review

2.1 Organisational-Level Factors

2.1.1 Learning Organisation

Learning has a crucial role in the adaptability of organisations to increasingly dynamic environments. The organisation seen as an open system employs learning and knowledge to interpret the internal and external environment signals, formulate (proactive or reactive) responses and implement them to ultimately improve its chances to survive (and prosper). Marsick and Watkins (1999) define the learning organisation as characterised by (1) systems-level, continuous learning (2) that is created in order to create and manage knowledge outcomes (3) which lead to improvement in the organisation's performance, and ultimately its value.

A learning approach to strategy, structure and culture enables the development of a learning organisation, and this highlights the importance of leadership (Alerasoul *et al.*, 2022). A learning organisation has an adequate climate, culture, systems, and structures that influence and create a proper environment in which individuals learn; it results in intentional improvement in knowledge performance (Marsick and Watkins, 2003).

A learning organisation builds a capacity to support, encourage, and apply knowledge on an organisational, not just an individual level. This means integrating learning into systems, structures and relevant climate and culture while considering learning on individual, team, and organisation-wide levels (Marsick and Watkins, 2003).

2.1.2 Transformational Leadership

Transformational leadership is associated with change-oriented behaviours, adaptation to external stimuli, innovation, and learning at the individual, team, and organisational levels (Mladenova and Davidkov, 2023). Many authors point to leadership as one of the key success factors of organisational change (Burke, 2011; Cameron and Quinn, 2011; Peng *et al.*, 2021). Transformational leadership is characterised by charisma-inspiration, intellectual stimulation, and individualised consideration (Bass, 1999).

Transformational leadership fosters employees' positive attitudes towards organisational change (e.g. commitment, openness, and readiness) and reduces negative reactions (e.g. resistance and cynicism) (Peng *et al.*, 2021). Transformational leadership increases employees' perceptions of attractive change consequences (valence) (Faupel and Süß, 2019) and correlates with learning on the organisational level (Lundqvist *et al.*, 2023).

2.2 Individual-Level Interpretations

2.2.1 History with Change

In this study, history with change reflects the participation in the planning and implementation of previous changes. These are often cited as key success factors in change literature. Participation is among the most prevalent change process dimensions that are found to be change antecedent (Oreg *et al.*, 2011). The way employees evaluate their experiences with previous changes may be key to the realisation of future changes (Lauzier *et al.*, 2020). Positive assessment of previous changes may help instil openness to change and reduce

change cynicism, increase self-efficacy (Lauzier *et al.*, 2020), and encourage employees to participate actively and share their opinions and concerns (Mladenova, 2022). Previous experience refers to the collectively developed change processes and perceived legitimacy of change (Klarner *et al.*, 2008) and is positively related to organisational adaptability and performance (Mladenova, 2022). The success or failure of a past change is manifested in the retrospective narratives of the organisational members and may also be controversial (Hay *et al.*, 2021). It relates to learning and suggests the active participation of employees in planning and implementing changes. Transformational leadership is expected to encourage – and correlate with – participation.

2.2.2 Valence

A key determinant of acceptance of or resistance to changes is whether these are perceived as beneficial or not (Oreg *et al.*, 2011). Personal valence in this study refers to the extent to which one feels that he or she benefitted or not from the implementation of previous changes (Holt *et al.*, 2007). Valence is one of the beliefs of change recipients that plays a key role in the success or failure of change initiatives (Armenakis *et al.*, 2007).

Armenakis et al. (2007) see valence as crucial in developing readiness for change – i.e. when the organisation plans an upcoming change initiative employees will seek a motivating answer to the question "what is in it for me?". Similarly, assessing past changes and their outcomes on a personal level might influence the open attitude to future changes. If one benefitted from previous changes, he or she would more likely expect that future changes would be also beneficial. Such a conclusion, however, is highly dependent on the scope of previous and upcoming change initiatives, and a direct relation cannot be assumed. Transformational leadership is expected to demonstrate the change benefits, work to prove its fairness, and motivate employees. If successful in past changes, transformational leadership is expected to correlate to valence.

2.2.3 Cohesion

This study borrows the definition of cohesion used by Bouckenooghe et al. (2009). It reflects the perception of togetherness and sharing, as well as the cooperation and trust in team members' competence. Trust in colleagues is one of the internal context antecedents of change (Oreg *et al.*, 2011). Cohesion is one of the climate-of-change dimensions and plays an important role in defining the background against which a change unfolds. Climate-related dimensions reflect individuals' description of their own perceptions (Koys and DeCotiis, 1991) of interconnected experiences with organisational policies, practices, and procedures, such as leadership (Schneider *et al.*, 2017) or change processes.

High levels of cohesion would mean employees would be more willing to support each other, expectedly also during challenging times such as when the organisation undergoes changes. Perceiving one's work environment as generally unsupportive, on the other hand, is more likely to lead to cynical reactions and rejection of changes (Oreg *et al.*, 2011). Climate is delicate and impacted by various organisational life events and management actions. Leadership has been widely agreed upon as a major driver of climates of all kinds (Schneider *et al.*, 2017). Transformational leadership is expected to correlate with cohesion.

2.3 Hypotheses Formulation

This study selects three dimensions of individual interpretations of past change and their effects on personal and group levels. They represent the process of change (history with change reflects whether the individual participated in the process of designing and implementing previous changes), the climate of change (cohesion reflects whether the individual trusts and cooperates with peers), and outcomes of change (valence reflects whether the individual evaluates previous changes as personally beneficial or not). Their correlation with two organisation-level success factors is assessed – transformational leadership and learning organisation. Transformational leadership is expected to largely influence employees' interpretations of changes and their results and impact. Learning organisation is expected to be influenced – and influence employees' interpretations of organisational changes.

Based on the above review, this study posits the following hypotheses:

H1: Transformational leadership correlates with individual-level interpretations (previous experience with change, valence, and cohesion).

H2: Dimensions of the learning organisation correlate with individual-level interpretations (previous experience with change, valence, and cohesion).

3. Method

3.1 Sample

This study uses data from a larger research project. The sample acquisition was conducted via an online self-administered questionnaire distributed to employees and managers in firms operating in Bulgaria. Data collection used a convenience approach in line with previous empirical research (Rahi *et al.*, 2022). This sampling approach has its limitations but can be beneficial in preliminary research (Stratton, 2021) and thus is found applicable for the purposes of this study. The inclusion criteria are ease of access and willingness to participate, as well as previous experience with organisational changes. The government sector is excluded. The level of research is individual (micro level). The demographic characteristics of the sample are presented in Table 1.

Table 1: Demographic characteristics of the sample (n=188)

Respondents profile	Number	Percentage
Age (M=34.94, SD=9.292)		
up to 30	76	40.4
31-40	64	34.0
41-50	35	18.6
51-60	10	5.3
above 60	3	1.6
Gender		
Female	109	58.0
Male	79	42.0
Education		
High school	11	5.9
Bachelor	44	23.4
Master	124	65.9
PhD	9	4.8
Tenure (M=6.85, SD=7.633)		
up to 5 years	122	64.9
6-10 years	27	14.3
11-15 years	18	9.6
16-20 years	6	3.2
above 21 years	15	8.0
Job position		
Employee	105	55.9
Middle management	69	36.7
Top management	14	7.4

The largest share of the respondents work in the Services sector (56.4%), followed by Manufacturing (28.2%). Commerce (11.7%) and Construction (3.7%) are less represented. Similarly, the largest share of the respondents work for large firms, as measured by the number of employees, i.e. 250 or above (58.6%), followed by medium-sized with 50-249 employees (20.2%), small with 10-49 employees (12.2%) and micro firms with up to 9 employees (9%).

The respondents' composition is balanced adequately according to the demographic and firm characteristics to justify their use in subsequent analyses. Some deviations from the national structure of sectors and employment should be mentioned – i.e. employees in large enterprises are overrepresented in this study sample, while micro-enterprises are underrepresented.

3.2 Composite Variables and Measures

This study uses five composite variables measured by scales adapted from previous research. All indicators were translated into Bulgarian language and transformed to a uniform 5-point Likert scale (1=completely disagree, 5=completely agree). In line with methodological recommendations (Weijters and Baumgartner, 2012) some reverse items were transformed to reduce possible issues related to psychological mechanisms employed by respondents. The final set of indicators and sources are presented in the Appendix.

4. Analytical Procedure

Data was analysed with SPSS v.25. First, the construct reliability, convergent validity and discriminant validity were examined. All constructs were found to have acceptable reliability and validity (Cronbach's alpha>0.7, item-total correlation >0.3, inter-item correlations>0.2) (Clark and Watson, 2016; Everitt, 2002; Hair *et al.*, 2010; Nunnally, 1967) (Table 2).

For the purposes of further analyses, the composite variables were calculated as mean values of their indicators.

Table 2: Composite variables - reliability and convergent validity

Composite Variable	Number of items	Corrected item-total correlation	Range of inter-item correlations	Cronbach's alpha
CO: Cohesion	4	0.720-0.808	0.582-0.794	0.895
VA: Valence	3	0.373-0.630	0.325-0.651	0.708
HC: History with Change	3	0.430-0.553	0.319-0.472	0.667
LO: Learning Organisation	7	0.354-0.716	0.200-0.643	0.848
TL: Transformational Leadership	7	0.755-0.877	0.643-0.843	0.952

Results of Kolmogorov-Smirnov and Shapiro-Wilks tests showed that data is not normally distributed. Thus, Spearman's rank-order correlation was applied. Descriptive statistics and correlations are presented in Table 3 and show that all composite variables are correlated ($p<0.01$).

Table 3: Descriptive statistics and factors correlations (n=188)

Composite variable	M	S.D.	CO	VA	HC	LO	TL
CO: Cohesion	4.4149	0.72857	1				
VA: Valence	3.0355	0.89624	.199**	1			
HC: History with Changes	3.2411	0.93953	.326**	.416**	1		
LO: Learning Organisation	3.8480	0.77188	.605**	.269**	.476**	1	
TL: Transformational Leadership	4.1223	0.93620	.473**	.283**	.392**	.658**	1

**. Correlation is significant at the 0.01 level (2-tailed).

Hierarchical and non-hierarchical cluster analyses were performed along the three individual-level composite variables (CO, VA, HC) to assess possible similarities within and dissimilarities between the groups. The other two (LO, TL) were then used to describe the clusters, and thus to verify the hypotheses.

Hierarchical cluster analysis with Ward's method was applied to assess the possible cluster solutions. The decision to proceed with a three-cluster solution was based on the assessment of the dendrogram and agglomeration schedule. The agglomeration matrix shows that a three-cluster solution is appropriate.

Then, K-means cluster analysis was performed, specifying three clusters. The resulting mean values per cluster are presented in Table 4. The F-values indicate that the means of all three variables are significantly different. The non-hierarchical cluster analysis results suggest that the three-cluster solution is adequately discriminating the observations.

Table 4: Composite variable means per cluster

Composite variable	Final Cluster Centres				
	Cluster 1	Cluster 2	Cluster 3	F	Sig.
Cohesion	4.66	4.53	3.11	134.5979	0.000
Valence	3.72	2.47	2.48	88.94436	0.000
History with Change	3.91	2.87	2.04	222.7495	0.000
Cluster size	85	80	23		
% of total	45%	43%	12%		

The three clusters' profiles are illustrated in Figure 1 and clearly point to the differences in values for each cluster. The three factors' mean values are highest in Cluster 1 and lowest in Cluster 3.

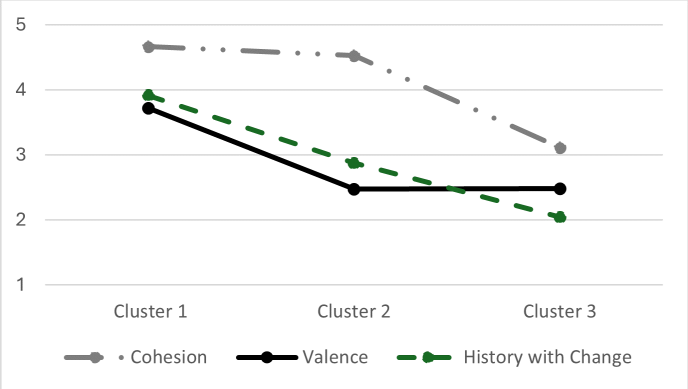

Figure 1: Clusters profiles – mean values per variable

Examining cluster stability and validity allows for further analysis and deriving conclusions of practical significance (Hair *et al.*, 2010). To assess cluster stability, data was reordered by another factor (respondent's age) and non-hierarchical analysis was performed again. The four-cluster solution is stable, with 37 of the observations (19.7%) assigned to a different cluster.

To assess predictive validity, a multivariate test was performed using three additional variables. These are three indicators of firm performance - capacity utilisation (financial performance), process improvements (market performance) and secure jobs (stakeholders). A MANOVA model was estimated where the above three variables were entered as dependent variables, and the cluster membership as an independent variable. The overall model is significant (Wilks' Lambda for cluster membership=0.814, F=6.604, Sig.=0.000). The individual F-statistics are also significant ($p<0.05$), as presented in Table 5. The results demonstrate that the cluster membership can predict other variables thus providing evidence for validity.

Table 5: Three criteria validity variables and cluster membership

Variable	Cluster number	Mean	F	Sig.
Capacity utilisation	1	4.082	9.234	0.000
	2	3.638		
	3	3.348		
Process improvements	1	4.024	18.575	0.000
	2	3.263		
	3	3.043		
Secure jobs	1	4.365	8.921	0.000
	2	3.925		
	3	3.696		

The profiles of the clusters are first assessed using the demographic variables of the respondents (age, gender, education, tenure, and job position). Then, to test the hypotheses, the additional two composite variables are used – learning organisation and transformational leadership. The relationships are tested with cross-tabulation (Table 6). Of the demographic variables, only job position has a statistically significant relationship with cluster membership. Both LO and TL show statistically significant relationships to cluster membership providing support to confirm the hypotheses. and can be used to define the clusters' profiles. The two organisation-level variables (transformational leadership and organisational learning) correlate with the individual-level interpretations (previous experience with change, valence, and cohesion).

Table 6: Cluster Profiles

		Cluster Number of Case			Total
		Cluster 1	Cluster 2	Cluster 3	
Job position	Employee	38	51	16	105
	Middle management	36	26	7	69
	Top Management	11	3	0	14
Total (χ2=11.556; df=4, Asympt. Sig.=0.021		*85*	*80*	*23*	*188*
Learning organisation	Low	0	0	2	2
	Rather low	0	0	1	1
	Average	3	13	8	24
	Rather high	32	42	10	84
	High	50	25	2	77
Total (χ2=53.049; df=8, Asympt. Sig.=0.000		*85*	*80*	*23*	*188*
Transformational leadership	Low	0	0	2	2
	Rather low	0	2	4	6
	Average	5	11	3	19
	Rather high	17	19	11	47
	High	63	48	3	114
Total (χ2=51.297; df=8, Asympt. Sig.=0.000		*85*	*80*	*23*	*188*

5. Results and Discussion

In response to the first research question, the results show that the composite variables HC, VA, and CO can be used to describe some of the individual-level interpretations of organisational changes. These variables and the organisational-level factors (LO, TL) are correlated. The cluster analyses respond to the second research question and show that these individual-level interpretations can be used and discriminate well between the groups of organisational members. Profiling of the clusters responds to the third research question and demonstrates that the three clusters have different characteristics.

Several conclusions could be made based on the analysis results. In all clusters, cohesion has the highest scores among the three composite variables. Even the lowest mean value in Cluster 3 (M=3.11) points to a rather high assessment of cohesion by the respondents. In view of the interpretations of past organisational changes and their consequences for the self and the cohesion climate, one of the possible explanations would be that past changes had positive effect on the cohesion climate, as suggested by the correlation between HC and CO. Active participation in previous change initiatives may be interpreted as a mechanism that pulls together and guides the organisation and its members; focuses their attention on the change events and the belief that they are part of something important; gives direction and enthusiasm (Bamford and Forrester, 2003). VA scores also align with such interpretation. Individuals who were actively involved in previous changes (HC) are likely to give a higher assessment of the consequences for the self (VA) and give a high assessment of the climate for cohesion in their organisation. The subjective time lens might have an impact on how respondents interpret past changes and their consequences (HC, VA) and relate to the assessment of the present climate (CO). The presence of a climate of cohesion could serve as an important ingredient for the successful implementation of upcoming changes.

Second, the composite variables used to describe two organisational-level factors (TL and LO) are correlated. The correlation between TL and LO aligns with previous research findings (Lundqvist *et al.*, 2023).

Third, this study finds evidence to support the two hypotheses raised – that the two organisational-level variables (TL and LO) correlate with the individual-level interpretations (HC, VA, CO). It suggests that the firms who worked to develop the dimensions of learning organisation and transformational leadership are characterised by more favourable individuall-level interpretations of past changes.

Fourth, this study reports a positive relationship between cluster membership and three firm performance measures – capacity utilisation, process improvements and secure jobs. This suggests that in dynamic times and environments, positive individual-level interpretations of changes might support the organisation's endeavours to improve performance. The subjective time lens could point to the relationship between the way employees internalise past changes' consequences and their interpretations of and behaviours during current and future change initiatives.

Several limitations of this study need to be mentioned. The level of analysis employed is individual. The study uses cross-sectional data. An organisation-level quantitative analysis combined with a qualitative data collection method could enrich the understanding of the studied factors and their relationships. A longitudinal study could allow for the analysis of multiple changes thus providing empirical evidence for the conclusions suggested here.

6. Conclusion

The goal of this study was to explore the relationship between two organisation-level variables (transformational leadership and learning organisation) with three individual-level variables that describe personal assessments of changes and their consequences for the self and the organisation (history with change, valence, and cohesion).

A configurational approach resulted in confirming correlations between all five composite variables (TL, LO, HC, VA, and CO). Three distinct clusters were identified, with Cluster 1 consistently scoring highest and Cluster 3 – lowest on all variables. The study finds a relation between cluster membership and three firm performance indicators – capacity utilisation, process improvements and secure jobs. The study finds evidence to support two hypotheses raised regarding correlations between two organisational-level variables (TL, LO) and three individual-level interpretations (HC, VA, CO). It thus promotes the argument that transformational leadership and learning organisation dimensions are related to the way organisational members experience and interpret past changes.

Appendix

Construct, (source)	Items used
Cohesion, (Bouckenooghe *et al.*, 2009)	When I need help, I can always ask my colleagues
	We cooperate well in my department
	My colleagues are sufficiently competent
	I have confidence in my colleagues
Learning Organisation (DLOQ), (Marsick and Watkins, 2003)	In my organisation, people are rewarded for learning
	In my organisation, people spend time building trust with each other
	In my organisation, teams/groups revise their thinking as a result of group discussions or information collected
	My organisation makes its lessons learned available to all employees
	My organisation recognises people for taking initiative
	My organisation works together with the outside community to meet mutual needs
	In my organisation, leaders continually look for opportunities to learn
Transformational Leadership, (Carless *et al.*, 2000)	My leader communicates a clear and positive vision of the future
	My leader treats staff as individuals, supports and encourages their development
	My leader gives encouragement and recognition to staff
	My leader fosters trust, involvement and cooperation among team members
	My leader encourages thinking about problems in new ways and questions assumptions
	My leader is clear about his/her values and practices what he/she preaches
	My leader instils pride and respect in others and inspires me by being highly competent
Valence, (Armenakis *et al.*, 2007)	Previous changes usually increased my feeling of accomplishment
	In general, after previous changes I earned higher pay
	As a result of previous changes, I had better opportunities for self-fulfilment
History with Change, (Coyle-Shapiro, 1999; Daly and Geyer, 1994)	People like myself had input into the decisions for previous changes
	Management did not give me a chance to express my concerns before they made the decision to move (R)
	I personally participated in the implementation of previous changes in the organisation

Stories as the Tool of Knowledge Sharing: How Does it Work

Ludmila Mládková
Prague University of Economics and Business, Prague, Czech Republic

mladkova@vse.cz

Abstract: Our minds use stories as an instrument of interaction with our external and internal world. Stories are essential communication and knowledge-sharing tools. They help to create trust and participate in the creation of communities. This paper aims to explain the neurobiological aspects of storytelling. It summarises the results of research on what happens in human bodies on the neural and neurochemical levels during storytelling. The theoretical part provides a theoretical background of the topic based on the keyword search. The application part discusses how neurobiological aspects of stories work on examples of two types of stories proposed by Steven Denning: the negative and the positive. The paper enriches the theory of storytelling by explaining the biological roots of storytelling and demonstrating how they impact the listener.

Keywords: Stories, Storytelling, Knowledge Sharing

1. Introduction

"For over 27,000 years, since the first cave paintings were discovered, telling stories has been one of our most fundamental communication methods. If we listen to a Powerpoint presentation with boring bullet points, certain parts in the brain get activated. Scientists call these Broca's area and Wernicke's area. Overall, it hits our language processing parts in the brain, where we decode words into meaning. And that's it, nothing else happens. When we are being told a story, though, things change dramatically. Not only are the language processing parts in our brain activated, but any other area in our brain that we would use when experiencing the events of the story are too" (Widrich 2012). Therefore, whether real or fictional, the rich and diverse experiences embedded in narratives are integral to how we learn about our environment and how we come to understand, process and memorise information (Bruner 1991; Gretter, Yadav and Gleason 2017). "By giving meaning and personal importance to narrative content, stories also allow the emergence of emotions essential in building a sense of belonging with others in the community" (Dal Pian, Dal Pian and Dal Pian 2019, p. 10073)

Stories are perceived as "key instruments of mind … with ability to disseminate knowledge about or ways of engaging with the world" (Herman 2013, p. 162). They provide "a society of mind, suprapersonal systems for sense-making" (Herman 2013, p. 192) and are "equipment for navigating the world and solving problems" (Armstrong 2019, p. 406).

Traditional ideas of a dualism of body and mind were challenged "by empirical facts and findings amassed in the last 15 years or so by cognitive science and neurobiology "(Aldama 2015, p. 91). These are based on "an ever more accurate knowledge of the anatomy and physiology of the brain and have empirically dissolved the so-called mind/body problem in favor of a monist (or materialist) approach. The brain is a very specialized organ of the body that reacts to stimuli from the body itself (internal stimuli) and from the outside world (external stimuli), and this material reaction, according to its specific origin and outcome, is termed emotion, thought, intention, planning, etc. " (Alama 2015, p. 91).

These findings change "understanding of the relation between language, cognition, and narrative, poised between formalist models of schemes, scripts, and preference rules inherited from structuralism and pragmatically oriented theories of narrative as embodied, intersubjective interaction. Understanding the neurobiological bases of narrative may help solve this problem by showing how the ability to tell and follow stories aligns with how the brain processes language" (Armstrong 2019, p. 396).

The researches show that "experiencing a story alters our neurochemical processes, and makes assertions about memory and mirror neurons (brain cells that fire not only when we perform an action, but when we observe someone else performing the same action), the brain activity of both storytellers and consumers starts to align thanks to mirror neurons" (Dal Pian, Dal Pian and Dal Pian 2019, p. 10080). "As we become involved with a story, fictional things come to seem real in our bodies" (Smith 2016, p. 3).

This paper aims to summarise some of the most important ideas on how this works and demonstrate them using the example of two types of stories. "The ability to tell and follow a story requires cognitive capacities that are basic to the neurobiology of mental functioning. Neuroscience cannot, of course, reveal everything we might want to know about stories, but it is also true that our species would probably not produce narratives so

prolifically if they weren't somehow good for our brains and our embodied interactions with the world "(Armstrong 2019, p. 395).

The research objective of the research discussed in the paper was to explain what happens in human bodies on the neural and neurochemical levels during storytelling. The research enriches the theory by explaining the biological roots of storytelling. We demonstrate the theoretical findings of what happens during storytelling in our bodies and how it impacts the listener on two types of stories: positive and negative.

2. Background - Stories, Storytelling

"Narrative is a huge territory that encompasses numerous phenomena "(Aldama 2015, p. 88). The story is a set of symbols, "a narrative that links a set of events in some kind of casual sequence" (Denning 2004, p. 2); “it is everything told or recounted in the form of a causally-linked set of events, account, tale, the telling of a happening or connected series of happenings, whether true or fictitious” (Denning 2013, Some definitions). It is "an account of events that are causally connected in some way" (Denning 2011, p.13), a sequence of interlinked events (Snowden 1999). "A story describes a sequence of actions and experiences done or undergone by a certain number of people, whether real or imaginary" (Ricoeur 1990, p. 150).

Humans are "homo narrans", (Fisher 1984, p.6), "essentially storytellers" (Fisher 1984, p.7). Stories are the key cognitive coping mechanism (Hevern 2008). They "give events meanings and significance" (Polkinghorne 1988, p. 18) and are "the preferred sense-making currency of human relationships" (Boje 1991, p. 106). Stories provide a virtual environment for knowledge sharing and identity development (Gibbons and Prusak 2020). "Storytelling gets inside the minds of the individuals who collectively make up the organisation and effects how they think, worry, wonder, agonize, and dream about themselves and in the process create - and re-create- their organization" (Denning 2012, p. xiv). It is natural for people to share their knowledge and experience through story "because the process of creating the story also creates the memory structure that will contain the gist of the story for the rest of our lives" (Shank 1990, p. 115).

As Armstrong (2019 p. 396) writes, "Stories help the brain negotiate the never-ending conflict between its need for pattern, synthesis, and constancy on the one hand and for flexibility, adaptability, and openness to change on the other".

"The story had created a context in which the message is inescapable or at least unarguable. This contrasts with most corporate communications, where the message is delivered at the start and then explained/justified. The fable structure prevents the problems associated with starting a communication with the message, where the audience makes up their mind early in the process and decide upfront whether they will accept the message "(Snowden 2001, p. 4).

3. Objective and Methodology

The objective of this paper is to explain the neurobiological aspects of storytelling, e.g. what happens in human brains on the neural and neurochemical levels during the storytelling. The brain response to storytelling is discussed from the perspective of the listener. We did not research the storytelling brain processes of the teller, though it is possible to conclude that the teller brain response is similar.

As for the methodology, the data used in this paper are secondary data from the literature. The theoretical background, e.g. the literature on neurobiological aspects of storytelling was collected by keyword search in WOS. In WOS we searched for words: story and physical aspects of storytelling, storytelling and brain endorphin system, storytelling and neurobiology showed that the topic is underdeveloped as the search led to the identification of only a few topic-relevant articles. The same happened when Google searched for the same keyword combinations. Still, these papers became the foundation for further snowball searches, which led to the identification of other materials. We also used literature (Merzenich, Zak, Doidge) previously known to the author.

To show how the neurobiological aspects of stories work, we demonstrate them using the example a negative and the positive story (Denning 2004). As for the methodology of this part of the paper, we analysed two types of stories (Denning 2004) from the perspective of neurobiological aspects of storytelling. We applied knowledge presented in the theoretical background to elements of negative (connectedness, strangeness, comprehensibility) and positive story (introduction of the problem, solution of the problem, I into we change,

repetitions). E.g., we combined two different pieces of explicit knowledge (explicit knowledge on neurobiological aspects of storytelling and knowledge on different types of stories) to explicit knowledge of higher quality.

In this paper, we use the words story and narrative as synonyms. We use the term story in the most general and broad way as a set of symbols, "a narrative that links a set of events in some kind of casual sequence" (Denning 2004, p. 2). From this perspective, stories are not only what is told but also various types of art, like pictures, pieces of music, etc. This approach allowed us to capture the ideas of authors from different fields. The literature shows that the human brain responds to stories performed in different forms in the same way.

4. Findings

4.1 How Does it Work – Brain and Body

One of the most exciting questions concerning stories and storytelling is "how is it possible that we learn from objects we know do not exist and how we can do this" (Aladama 2015, p. 82). We can explain this miracle by an explanation of neural circuits as action-perception circuit and by so-called neural synchronicity.

The neurons in the brain create new synapses and organise them into networks. This synaptogenesis develops new knowledge and is "experience dependent" (Merzenich 2015, p. 20). It is "the formation of synaptic connections in response to our experiences and environment" (Merzenich 2015, p. 20). Or, as Hebb (2005, p. 70) writes, "The general idea is an old one, that any two cells or systems of cells that are repeatedly active at the same time will tend to become associated: so that activity in one facilitates activity in the other".

The brain is plastic. New incentives create new connections, and connections (knowledge) that is not used are dying (Doidge 2007; Merzenich 2015). "The brain knows the world by forming and dissolving assemblies of neurons, establishing the patterns that through repeated firing become our habitual ways of interacting with the environment, even as ongoing fluctuations in these syntheses combat their tendency to rigidify and promote the possibility of new cortical connections. The brain's ceaseless balancing act between the formation and dissolution of patterns makes possible the exploratory play between past equilibria and the indeterminacies of the future that is essential for successful mental functioning and the survival of our species" (Armstrong 2019, p. 397).

"Contemporary neuroscience suggests that the biological basis of these connections is an action-perception circuit that makes action fundamental to many cognitive processes that might seem unrelated to the control of

various body parts by the motor cortex" (Armstrong 2019, p. 401). Various studies proved that reading or thinking about the action reveals the activity in the relevant part of the motor cortex, which coordinates body movements (Paul 2012; Doidge 2007). "Imagining a movement relies on the same mechanisms as actually performing it, (Jeannerod 2006, p. 28)" and that "imagined actions are indeed actions in their own right: they involve a kinematic content, they activate motor areas almost to the same extent as executed actions, they involve the autonomic system as if a real action was under way" (Jeannerod 2006, p. 39). "Learning a motor task by using motor imagery induces a pattern of dynamic changes in cortical activation similar to that occurring during physical practice" (Jeannerod 2006, p. 41). Armstrong (2019, p. 402) concludes, "If the motor cortex and even muscle tissue can be excited by mental rehearsal of an action, that should also be true of linguistic simulations of actions, and there is experimental evidence that this is so".

When we see somebody else perform the action or hear about the action in the story, "the brain activity of both storytellers and story listeners starts to align thanks to mirror neurons, brain cells that fire not only when we perform an action but when we observe someone else perform the same action" (Smith 2016, How stories unfold in our bodies). "The synchronization of brain waves across the cortex makes possible the formation of neuronal assemblies and coordinates the workings of different regions of the brain" (Armstrong 2019, p. 399).

This is called neural synchronicity. This neural process allows the other person to feel like the other one motoric sensation via his own kinaesthetic memory and knowledge (Bolens 2012). Therefore, the life experience transformed into the story works the same way.

"The story activates the neuronal connection in the brain of the listener and allows him to live the experience via his own memory and knowledge. "Different brain regions track different aspects of a story," Speer concludes, "such as a character's physical location or current goals," and "some of these regions mirror those involved when people perform, imagine, or observe similar real-world activities" (Speer et al 2009, p.990). As we become involved with a story, fictional things come to seem real in our bodies" (Smith 2016, How stories unfold in our

bodies). Through this mechanism, "the brains of the person telling a story and listening to it, can synchronize" (Widrich 2012; Stephens, Silbert and Hasson 2010, p. 14425).

"This process changes the patterns of listener reception and as such support cooperation among people therefore are a valuable source of collective knowledge and social cohesion "(Armstrong 2019, p. 406).

"Plots can play a central role in structuring our understanding of the world because action is thoroughly implicated in perception and cognition" (Armstrong 2019, p. 401).

Said differently, "readers' representations of word meaning are grounded in visual and motor representations. The brain regions involved in tracking different dimensions of a reader's situation model should correspond to regions that have a role in seeing and acting out similar activities in the real world." (Speer et al 2009, p. 2).

Forming and dissolving assemblies of neurons based on imagined actions and synchronicity represents just one of the processes related to storytelling. Storytelling is also related to changes in neurochemical processes responsible for emotions.

Zak (2015, p. 6-7) notes, "If you pay attention to the story and become emotionally engaged with the story's characters, then it is as if you have been transported into the story's ". Telling and listening to stories raises emotions, which are "the response of dedicated neurobiological systems to concrete experiences" (Hogan 2010, p. 255). Eslocker (2023) writes that our brains respond to different story elements by transmitting oxytocin, endorphins, cortisol, dopamine, and other neurotransmitters.

"The narrative with the dramatic arc caused an increase in cortisol and oxytocin" (Zak 2015, p. 4). "Oxytocin was associated with concern for the characters in the story "(Zak 2015, p. 6) as it increases trust (Zak 2017). As for cortisol, its release is stimulated by a hormone called ACTH. Zak (2015) found out that "the change in ACTH correlated with the amount of attention people paid to the story. If we do not attend to a story, it will not pull us into its narrative arc" (Zak 2015, p. 6). "Once we are attentive and emotionally engaged, our brains go into mimic mode and mirror the behaviors that the characters in the story are doing, or might do" (Zak 2015, p.9). Endorphins and dopamine are released as a result of resolving the problem in the story and happiness (Eslocker 2023).

Even more, Zak (2015) discovered that "emotionally engaging narratives inspire post-narrative actions" (Zak 2015, p.4). He writes, "The narrative is over, but the effects linger. It is as if the brain is lazy and is using a "monkey see, monkey do" approach to assess appropriate social behaviors. (Indeed, the brain seeks to conserve energy by using default pathways—a kind of "laziness)" (Zak 2015, p.6).

4.2 How Does it Work – Example of Negative and Positive Story

In this part of the paper, we would like to provide examples of how different types of stories work on the biological level. Even though all stories initiate knowledge sharing, "the purpose of telling a story might determine its form" (Denning 2004, p. 6). "Stories told in order to spur action need to make good on their promises and contain sufficient evidence of a positive outcome. But stories intended mainly to transfer knowledge must be more than true. Because their objective is to generate understanding and not action, they tend to highlight the pitfalls of ignorance; they are meant not to inspire people but to make them cautious" (Denning 2004, p. 6). We call the stories supporting the action the positive stories, the ones transferring knowledge the negative stories. The form of both types is different.

Negative stories are told in the form of the springboard story (Denning 2011). The negative story is built from three blocks: connectedness, strangeness and comprehensibility. The story starts with connectedness. Connectedness is the element of the story familiar to the listener. The protagonist has a typical role the listener understands and, therefore, can put himself into the shoes of the protagonist (Denning 2012). Feeling connected to the character leads to releasing oxytocin, the bonding hormone, which results in caring and increased empathy (Eslocker 2023). "The oxytocin response lags behind the attentional spike as the story begins. After about thirty seconds, vagal activity begins to increase as viewers get to know and then begin to empathize" (Zak 2015, p.8) with the protagonist. It is a factor that engages the listener's imagination and emotions (Denning 2012). From the biological point of view, connectedness is the factor that stimulates imagination. The imagination stimulates one's kinaesthetic memory and knowledge and activates the neuronal connections in the brain of the listener (Bolens 2012; Armstrong 2019), connections that represent his own experience, therefore, start the synchronicity.

Strangeness is the factor that interrupts the thought process of the listener and, therefore, violates this experience. There are two ways how to insert strangeness into the story: something expected does not happen, or something unexpected happens. It provides the shock of the unforeseen and raises fear or curiosity (Denning 2012). Getting information that violates one's own experience (the way how neurons fire) raises cortisol levels, which increases attention, focus and memory (Eslocker2023). It prepares the listener for the knowledge the story brings.

"As the cortisol that feeds attention mixes with the oxytocin of care, we experience a phenomenon called "transportation." Transportation happens when attention and anxiety join with our empathy. In other words, we're hooked" (Smith 2016, How stories unfold in our bodies).

Comprehensibility is the idea that should move the listener to a new level of understanding. Therefore, it is the knowledge embodied in the story (Denning 2012). In this type of story, comprehensibility usually provides the solution to the problem introduced by the strangeness. Recovery from solving the problem raises dopamine levels, resulting in pleasure, hope and increased focus (Eslocker 2023; Smith 2016).

Good stories release endorphins, which relieve stress, make people relaxed, and increase creativity.

Positive stories initiate action. They are objective-oriented and, as such, propose new objectives and visions. Their form can be explained by the specific examples of these stories, which are speeches that introduce vision statements. The purpose of such statements is to introduce the ideas and visions of the teller to the listener and motivate him to accept them. To do so, it is necessary to link the story with the listener's hopes, dreams, aspirations and values. The format of how to do it is the following.

The positive story (the speech) starts with an explanation of what is wrong. The storyteller (speaker) introduces the problem from his perspective as his problem. The stress from bad news releases cortisol, which increases the attention of the listener. The problem presented is usually some general problem that worries many people. This helps people to identify themselves with the teller, and as a result, the storyteller switches from I form to we form. The problem becomes the problem of listeners, too. Then, the teller offers the solution as his vision. He explains it in images and word pictures using traditional values and well-known examples in a positive and hopeful way, which raises levels of endorphins. The solution to the problem is to increase dopamine. He also uses repetitions. Repetitions help the audience have a common experience, increase the levels of oxytocin, and lead to trust and a feeling of human interconnectedness (Kouzes and Posner 2006; Eslocker 2023). As a masterpiece of positive stories may be mentioned two human rights-focused speeches, J. F. Kennedy's Address to the Greater Houston Ministerial Association ("I believe in America …", 12.9.1960, Houston) and M. L. King's "I Have a Dream" (28.8.1963, Lincoln memorial).

Telling the story (and listening to it) is the work with two stories. "This circuit entails an interaction between worlds the fictional worlds constructed by storytellers, and their re-creation in the imaginative worlds built by their recipients" (Armstrong 2019, p.219). The emotions of the listener reflect the emotions of the character, but "they are not the character's. They are our own. That's how empathy and identification work in fiction" (Oatley 2012, p. 29).

The storyteller and the listener have different experiences, e.g., different networks among neurons and these experiences may not match. "Following a story is a similarly paradoxical process, with both intersubjective and solipsistic dimensions, whereby my own resources for configuring the world are put to work to make sense of another, fictive, narrated world that may seem both familiar and strange and that may either reinforce or disrupt my sense of the world's patterns, since its figurations both are and are not analogous to mine "(Armstrong 2019, p. 404).

5. Discussion and Conclusion

In our paper, we intended to explain what happens in the brain of the listener when listening (reading, watching) to the story and demonstrate this mechanism through specific examples of two different types of stories. Our findings indicate that storytelling, the important tool of human communication, has deeper roots than generally perceived. These roots are biological and, as such, concern stories we tell in our personal lives or produce in the arts and the entertainment industry. The same rules also apply to stories shared in organisations, even though managers and employees may be sceptical about them (Snowden 2001).

Stories provide us with a virtual environment where we learn and share our knowledge (Zak 2015). "When we read or view a fictional narrative we know it is not real, yet we still experience it as if it were real. This stimulatory

approach is what allows to determine that fiction provides a place to experience emotions within a safe space. This can and does have an ameliorative effect: it helps us improve our mental models of others and ourselves" (Oatley 2012, p. 19) or as Aldama (2015, p. 82-83) notes, "we experience fleeting emotions and insights that leave residues that can over time change our selfhood."

The change of neurochemical processes that happens in our brains when we tell and listen to the story explains the emotions the story raises and their importance for the transfer of knowledge. "Emotion is a defining ingredient in narrative fiction. If we don't experience emotion we are less involved in the story" (Aldama 2015, p. 84).

On the other hand, the experience from practice and research shows that these mechanisms may fail. Stephens, Silbert and Hasson 2010 et al (2010, p. 14425) explain, "We used the speaker's spatiotemporal brain activity to model listeners' brain activity and found that the speaker's activity is spatially and temporally coupled with the listener's activity. This coupling vanishes when participants fail to communicate. Moreover, though on average the listener's brain activity mirrors the speaker's activity with a delay, we also find areas that exhibit predictive anticipatory responses. We connected the extent of neural coupling to a quantitative measure of story comprehension and find that the greater the anticipatory speaker–listener coupling, the greater the understanding."

The approach to storytelling adopted in this paper explains why people like stories regardless of their ethnicity and culture and why "recurrent configurations that develop" (Armstrong 2019, p. 218) in stories reflect "certain repeated characteristics of our species'. Shared experiences of birth and death, collaboration and competition, propagation and violence interact with biologically based cognitive proclivities to produce statistically discoverable regularities in cultural institutions, including the stories we circulate in our communities" (Armstrong 2019, p. 218). It also explains why stories can initiate profound behavioural changes, including costly acts of altruism (Smith 2016, How stories change behaviour).

Approaching storytelling from the biological perspective opens "new possibilities for addressing fundamental issues concerning the emotional, ethical, educative, and cognitive value of art" (Carroll and Gibson 2011, p. 2) and storytelling as such. These possibilities indicate potential research gaps.

Corporate Taxonomy Mapping for Performance-Supporting KM

Maayan Nakash
Department of Management, Bar-Ilan University, Israel

Maayan.Nakash@biu.ac.il

Abstract: Taxonomies are controlled vocabularies and multidimensional frameworks for organizing and classifying content. This study is the first to examine the meanings chief knowledge officers (CKOs) ascribe to corporate taxonomy mapping for enabling sustainable performance-driven knowledge management (KM). Utilizing a qualitative methodology, the research corpus comprised in-depth interviews, focus groups, participant observation, and cyber-ethnography. The findings underscore the essential role of investing resources in systematic taxonomy management as a cornerstone for attaining excellence in KM. Empirical evidence is provided for the critical importance of consistent taxonomies in establishing standardized terminology, facilitating systematic knowledge retrieval, and streamlining access within KM systems. Insight is provided into the constraints of contemporary technological advancements, including the capabilities of auto-tagging and classification through artificial intelligence (AI) and natural language processing (NLP) techniques. We underscore the nuanced interaction between human cognition and automated human-like capabilities in taxonomic classification, stressing the importance of embracing a balanced leadership socio-technical approach to the dynamic development of taxonomies. Furthermore, the study proposes promising avenues for future research to enhance the depth of inquiry into this subject matter.

Keywords: Taxonomy, Corporate Taxonomies, Controlled Vocabulary, Knowledge Management, Knowledge Management Systems, Knowledge Item

1. Introduction

Knowledge is a critical organizational asset that is vital for achieving strategic goals and maintaining sustainable competitive advantage. Knowledge management (KM) is a management discipline that emerged towards the end of the 20th century with the purpose of supporting the leveraging of existing knowledge and the development of new knowledge to enhance firm performance. Since its inception, KM has been enriched by an inexhaustible abundance of academic contributions and accumulated practical experience (Chang and Chuang 2011; Dalkir 2023; Mat Nor et al. 2020; Nakash and Bouhnik 2023). To successfully implement KM within an organization, strategic planning is required, including clear definitions of long-term goals, resources, and implementation plans (Bolisani and Scarso 2015).

In a sense, corporate taxonomy serves as a common language that connects knowledge workers to organizationally relevant knowledge. By moving from broad categories to increasingly specific ones, it provides a multidimensional framework for organizing and classifying content. Successful implementation of corporate taxonomy in the knowledge management system (KMS) can enhance the navigation of organizational resources (APQC 2019, 2021, 2023; Chaudhry et al. 2008; Fouché 2006). As such, the development of a corporate taxonomic framework has been identified as a key milestone for achieving KM excellence (Nakash et al. 2023).

Despite the considerable importance of developing corporate taxonomies to support performance-enhancing KM, this topic has received scant attention in the scientific literature to date, with a notable lack of recent empirical studies focusing specifically on this issue. An integral yet understudied component of KM, taxonomies are vital for structuring organizational knowledge and promoting the discovery and accessibility of useful information for employees. Substantial knowledge gaps persist regarding best practices for optimal taxonomy design and implementation that dedicated research could help address. The present study aims to fill this gap by examining the contemporary perspectives of chief knowledge officers (CKOs) on corporate taxonomy mapping, including the meanings they ascribe to this process as well as the perceived benefits stemming from well-constructed taxonomies. Furthermore, we seek to deepen understanding of emerging innovations and future directions pertaining to the development of automated solutions in this domain.

2. Theoretical Background

A taxonomy is a hierarchy of categories used to classify a body of knowledge (APQC 2021; Ihongo et al. 2021; Sisson et al. 2019). It is a controlled vocabulary that expresses hierarchical (broader/narrower) or equivalent (synonymous) relationships between terms (Whittaker and Breininger 2010). The term “taxonomy” originated in biology and was later discussed extensively in library science. In organizational contexts, a corporate taxonomy represents the collection of terms used within the organization and reflects relationships between

them. It serves as a foundation for the organization's knowledge architecture (Cruz 2004; Fouché 2006; Gilchrist 2001; Gilchrist and Mahon 2004; Whittaker and Breininger 2008; Woods 2004; Zhonghong et al. 2006).

Many firms face challenges in implementing and maintaining productive KMSs (Mat Nor et al. 2020). Organizing knowledge for reuse is a major difficulty (Sharma et al. 2016). To ensure efficient knowledge use, organizations are increasingly interested in categorization. Corporate taxonomies play a critical role in organizing business knowledge (Bolisani et al., 2016; Sharma et al., 2016; Wibbenmeyer 2015) thereby easing information overload for knowledge workers (Gilchrist 2001).

In many ways, taxonomy provides a system of labels forming a hierarchical navigation scheme (Fouché 2006; Gilchrist and Mahon 2004; Ihongo et al. 2021). When standardized taxonomies are lacking, problems like inconsistencies and inaccuracies in content emerge (Munkvold et al. 2006). A logical taxonomy enables users to effectively locate, access, and retrieve knowledge items (Knox and Logan 2003). A specific methodology for implementing corporate taxonomy was presented by Wibbenmeyer (2015). A taxonomy works within ontology structures outlining organizational term relationships in KMSs (Castillo-Barrera et al. 2013). The classification scheme layout differs across organizations based on scope, role, and characteristics (Chaudhry et al. 2008).

Defining taxonomy structure is preceded by determining content volume/type and identifying target users (Lambe 2014; Nakash et al. 2023; Whittaker and Breininger 2008). Corporate taxonomy is a living, expensive entity to maintain and create (APQC 2023), requiring significant time investments (APQC 2019). Differing content catalogs across departments hamper taxonomy development (Vom Brocke et al. 2011). As knowledge organization sets, intuitive taxonomies provide basic structures and controlled vocabularies that allow effective categorization, storage, retrieval, and access to information (Lambe 2014).

3. Materials and Methods

The research was conducted using a qualitative methodology, relying on interpretive foundations, and adopting an inductive approach. Fifty-two CKOs participated in a semi-structured in-depth interview and/or in one of two focus groups. The participants have an average of 12 years of experience in KM methodologies and technologies and they operate in various sectors in the local and global industry. As part of their roles, they are responsible for mapping corporate taxonomies in KMS. Each meeting lasted between an hour and an hour and a half and was recorded and transcribed with the knowledge and consent of the participants.

In addition, we conducted participant observation in KM units in organizations that differ from each other in size and business lines. The observations were designed to allow us to get an impression of the structure of the corporate taxonomies that were implemented in a variety of KMS, produced by different software providers.

Cyber-ethnography, also known as web ethnography, digital ethnography, and netnography, was used as a fourth data collection tool. This method applies an adaptation of ethnographic methods to the study of communities formed in computer-mediated social interaction (Kozinets 2015; Kulavuz-Onal 2015). We thoroughly reviewed 20,349 posts and comments from two public and visible Facebook groups dealing with KM in organizations that have over 7,500 people as members. During the systematic review, we marked 3,459 posts and comments as relevant. Analytical analysis was performed on every third posting, creating a broad database for in-depth analysis of 1,019 posts and comments. The materials collected in the network fieldwork were consistently documented and we recorded field notes.

Text analysis of the data collected both in the physical and virtual spaces was performed by the MAXQDA software according to the thematic analysis method's principles. This paper incorporates authentic testimonies obtained from informants. It should be noted that the results and insights presented here are part of a more comprehensive study we conducted to clarify the position, development, and future of the KM discipline.

4. Findings

4.1 Corporate Taxonomy in the View of CKOs

As part of the process of organizing the knowledge items in KMS, CKOs build a taxonomic schematic structure. The knowledge items are indexed and cataloged in a logical and consistent manner by implementing division into categories and sub-categories of key core business issues. The categories create the classification system – it is the taxonomic framework – which captures the interrelationships between knowledge items.

The taxonomy reflects the organizational glossary, which undergoes a process of *"classification and organization, in a hierarchical and related manner of various contents belonging to the same content world"* (F330). To prepare the taxonomic infrastructure, tagging operations and adding metadata are applied to the knowledge items during their creation. Constant maintenance accompanies the treatment of taxonomy, including an ongoing need to classify each new knowledge item. CKOs are also required to decide where to place items that may possibly fall into more than one category.

Based on corporate taxonomy mapping, a computerized hierarchical tree is built, in which knowledge items are associated in a balanced manner with its branches. This is how a CKO in a global management consulting firm described the process of taxonomy building:

> *"It is important to define a structured taxonomy, that someone sits down and defines that this* [the one content type] *belongs to this* [the other content type]*, and this is somehow related to this. ... I mean, we invest a lot of thinking in this construction* [of the professional content]*. ... In serious organizations, there is an organizational steering committee that meets once a quarter to approve entries for the taxonomy, download entries* [from the knowledge tree]*, and analyze the use* [in the contents]*. That is, manage the taxonomy"* (C2).

4.2 Benefits of Effective Taxonomy

The informants emphasized that, first and foremost, a good taxonomy creates a uniform language between the various officials in the organization. That is, it prevents an unlikely reality in which *"substantial differences exist in the way different units in the organization define the same product or the same process"* (F105).

The ambition of CKOs to create *"performance-supporting KM"* (C6) was a recurring motif in the four data collection tools. Specifically, an effective taxonomy is seen as assuming a solid foundation for effective orientation in knowledge bases. Furthermore, it helps employees understand the broader associative relationships of the knowledge item. One of the members of the KM virtual community on Facebook explained the importance of taxonomic mapping accuracy as helping to reduce the cognitive effort required of employees to locate the knowledge needed to complete their tasks:

> *"Most employees prefer that 'we spoon-feed them' (and rightly so...), because they are not measured by the way knowledge is consumed and used, but by the results and goals they have achieved. Knowledge is only the means* [for outputs]*. This is where taxonomy and the use of metadata come into play. ... The important principle here is mapping as accurately as possible. For example, it is possible to divide the professional subject into four levels of hierarchy – a kind of funnel from the macro to the micro. Any measurement of the taxonomy used will help us further refine the search terms, make them more precise, and adapt them to the end user"* (F8).

Moreover, the results reveal that a good taxonomic infrastructure will be able to support the search engine's success in quickly retrieving relevant content: *"Taxonomy is of enormous importance for locating the specific knowledge item in real-time and with minimal effort. ... All items must contain tags and keywords which will allow them to be cataloged and retrieved"* (F77). The close interrelationships between taxonomy and organizational search engines were well illustrated in the following parable: *"The search engine will allow us to find a needle in a haystack. The taxonomy will make sure that we have reached the right haystack and that we have not gone astray in the barn"* (F279).

One of the CKOs elaborated and compared this infrastructure to *"a backbone that helps the KM activity in the organization to stay upright. ... It* [the corporate taxonomy] *is what allows me to search, retrieve content and understand its contexts"* (C8). Another parable given to the importance of adequate mapping of the taxonomic structure came up in the following quote: *"Organizations tend not to devote enough energy to it, but it is the basis. It is like architecture, like the foundations of a building"* (C2).

4.3 Emerging Innovations and Future Directions in Taxonomy Automation

The informants reported that today a taxonomy practice almost always requires human intervention:

> *"Auto-tagging is certainly an existing capability which is currently realized in a few organizations, and it is essential to start realizing it in others, but it does not eliminate the need for people to label according to the context known only to them"* (F112).

This argument is explained in the following online response:

> *"The automated tools* [that exist today] *know how to base themselves on the content of a knowledge item, tag it, and formulate a corporate taxonomy automatically. It's a shame that too few firms examine this possibility, but it is necessary to implement human tagging as well. It should be remembered that people have the ability to tag according to context, even if the* [related and specific] *term is not even hinted at in the content"* (F239).

However, research participants anticipate significant automation developments in this area: *"There will be tools that will run over a million documents and say, 'this is your taxonomy.' It* [the KM discipline future] *is going there"* (C2). In fact, *"the auto-tagging will take the use of tags one step further and make the search smart, advanced and above all adapted to the user and his / her needs"* (F238). We found an interesting perspective in the following quote:

> *"It may be a favorable point in time to see what machines can do in the future (which is already here) (such as smart indexing and deeper taxonomy) and reconsider the CKOs' role in the emerging reality. Technological developments will allow CKO to deal less with technique, but more in essence"* (F489).

The forecast for future developments envisages automatic extraction of unstructured content from multi-page documents, as well as automatic taxonomy creation using techniques of natural language processing (NLP), pattern recognition, and sentiment analysis.

If the situation today is that *"no technological 'monster' can manage knowledge without a touch of a human hand"* (C14), it seems that according to the predictions, human involvement in KM will decrease and it will be replaced by machines. In many ways, the development of artificial intelligence (AI) technologies, which rely on robotic abilities to imitate human cognition, is nothing but perceived by the informants as *"inevitable"* (M8). As one of the focus group participants stated: *"AI will not replace KM but will change its face"* (C1).

5. Discussion and Conclusions

This study provides an integrative perspective on mapping corporate taxonomies for performance-supporting KM. The results empirically validate claims in the literature regarding the criticality of consistent taxonomies for standardizing terminology, enabling systematic knowledge retrieval, and facilitating access in KMSs (Munkvold et al. 2006; Vom Brocke et al. 2011; Milton and Lambe 2016; Wibbenmeyer 2015). This substantiates why taxonomy is a foundational KM element (APQC 2019, 2023). We find that KM excellence depends on systematic taxonomy mapping while advancing understanding of taxonomies' intrinsic value in ensuring effective organizational knowledge reuse to improve performance. Well-designed taxonomies can greatly reduce KMS search times. Decreasing time wasted searching may increase productivity and generate major financial savings (Nakash and Bouhnik 2024).

Although technology is becoming central to KM, it remains an enabling rather than a disruptive force. The participants indicate that continued improvements in cognitive computing, machine learning (ML), and AI will automate KM tasks. Specifically, auto-tagging and machine taxonomic classification are emerging. However, over-reliance on software solutions to create a corporate taxonomy has long been defined as involving risk (Gilchrist 2001). CKOs in our study confirm such concerns, noting limitations of existing software in inferring broad context compared to human cognition. Thus, monitoring, feedback, and supervision needs persist. A corporate taxonomy must be scalable (Cruz 2004). But more than that, it should be adaptable. Taxonomies should change as business lines shift, tracking contemporary content domains of interest to employees. Therefore, CKOs should continually reexamine classification schemes to align with strategic priorities.

To summarize, advances in AI, specifically ML and NLP, are poised to transform the creation and ongoing evolution of corporate taxonomies. leveraging ongoing exponential advances in AI for corporate taxonomy construction appears set to accelerate mapping of organizational knowledge architectures. However, a purely technology-centric approach discounting human guidance risks suboptimal structures. instead, an integrated socio-technical solution harnessing both algorithmic insights and expert assessment shows promise in improving taxonomy development and evolution to strengthen KMSs. This distributed development pathway will leverages complementary human and machine capabilities.

6. Implications

6.1 Theoretical Implications

This study makes several key contributions to KM theory regarding organizational taxonomies. First, it provides empirical validation of taxonomy's foundational role in enabling effective knowledge reuse, navigation, and access in KMS platforms. This confirms and strengthens theoretical perspectives on the intrinsic value of taxonomies for overall KM outcomes. Second, the findings reveal sophisticated, context-dependent aspects of taxonomy development, such as the need for human judgment in inferring implied content meanings. This advances conceptual thinking on taxonomy design, going beyond basic structural issues to complex cognitive challenges requiring blended human-machine input. Finally, identifying the adaptable, “living” nature of effective taxonomies makes a theoretical contribution, revealing that static classification schemes will likely fail. This insight can shape taxonomy models and best practices emphasizing flexibility and continual alignment with shifting organizational priorities.

6.2 Practical Implications

For industry practice, documenting the substantial productivity and financial benefits derived from streamlined taxonomy-enabled knowledge access provides tangible evidence for justified investments in taxonomy development and maintenance. Firms now have a greater rationale for allocating resources and leadership attention to taxonomy creation. Additionally, illuminating the gaps between human cognition and AI capacities regarding taxonomic classification cautions managers against over-dependency on software tools without ongoing human guidance and correction. A blended socio-technical approach balancing automated classification with expert oversight is recommended to mitigate risk.

7. Future Research Directions

Several productive avenues exist for further research on organizational taxonomies. As adopting NLP expands, researchers could examine how effectively these tools automate taxonomy mapping versus requiring supplemental human input. Studying taxonomy evolution across longer timeframes would also offer practical insights into sustainably managing “living” taxonomies. Additionally, comparative case studies on taxonomy approaches between high and low performing firms could uncover best practices for maximizing taxonomy value. Taken together, such research directions hold promise for uncovering best practices that enable high-performing organizations to leverage taxonomies as strategic drivers of competitive advantage.

Abstract: In the complex mosaic of the digital age, the tactical incorporation of artificial intelligence (AI) within knowledge management (KM) is revealed as a central business component of technology management. The current study aims to clarify the intersection between KM and AI in organizational contexts. Specifically, this paper represents a preliminary step to investigate the potential impacts of AI on KM research and practice. Building on a database we created from Scopus, we shine a spotlight on trends in pertinent peer-reviewed scientific articles published in the last decade (2013-2023) on the KM-AI nexus. In addition, the paper presents an extended systematic analysis of literature, which synthesizes theoretical and empirical works conducted to date on this topic. Through a review of the available studies, we strive to shed light on effective KM frameworks and strategies in the era of AI. As extant research in the literature is largely theoretical, we propose to conduct empirical research on AI technologies in core KM processes such as acquisition, documentation, sharing, and application of knowledge. In addition, we recognize that the challenges and barriers to implementing AI in KM systems are not in focus and deserve to ignite further research. The anticipated contributions from such inquiries promise not only to augment the corpus of knowledge within the discipline, but also to furnish KM practitioners with the insights necessary for the crafting of efficacious systems. This research marks the advent of a transformative scholarly epoch, wherein the harmonious integration of KM and AI emerges as the bedrock of organizational ingenuity and strategic acumen. It distinguishes itself from prior works by pinpointing knowledge gaps in the synergy between disciplines and underscores the imperative for future research to bridge these lacunae.

Keywords: Artificial Intelligence, Cognitive Computing, Machine Learning, Knowledge Management, Knowledge-Driven Organizations

1. Introduction

Knowledge management (KM) has been recognized for decades as a key component of business strategies for organizational success (Al Mansoori et al. 2020; Bolisani and Bratianu, 2018; Jallow et al. 2020). It is identified as “the process of creating value from an organization’s intangible assets” (Liebowitz 2004, p.4). Sometimes it is associated with a formal approach to governing the creation, transfer, retention, and use of a firm's explicit and tacit knowledge resources (O'Leary 1998) while other times it is simply an informal or “emergent” approach (Bolisani et al. 2016). KM is now a pervasive attitude that integrates concepts of information technology, computer science, organizational behavior, human resource management, strategic management, and more (Bolisani et al. 2023; Edwards and Lönnqvist 2023; Liebowitz 2001).

Technology is often seen as a key element of KM since it enables better knowledge flow facilitation (Nakash and Bouhnik 2022). For this reason, the rapid upsurge of widespread artificial intelligence (AI) applications can have a tremendous impact on how we see KM and KM processes (KMPs). AI leverages computational techniques for machine learning (ML) and has been widely adopted across various domains (Sanzogni et al. 2017). Simply put, AI refers to instilling intelligence into autonomous machines, aiming to enable the performance of tasks requiring human cognition. That is, AI attempts to mimic functions like human learning, decision-making, and problem-solving (Jallow et al. 2020; Sanzogni et al. 2017; Vadari and Desik 2021).

AI is considered one of today’s most disruptive technologies. Its benefits have been assessed in terms of improved outputs, amplified innovation, and greater profitability (Yigitcanlar et al. 2020). Moreover, AI is a powerful competitive tool (Jackson 2019) with significant business impacts (Malik et al. 2023). It can optimize diverse processes, reducing labor requirements and increasing efficiency (Mishra and Pani 2021). Consequently, AI can disrupt today’s KM landscape by providing an integration of the two extreme views of KM: one that sees KM as a substantial technological challenge, where the new systems can process structured explicit knowledge in a highly efficient way; and the other that describe the core KM challenge as that where humans need to create, handle, and effectively share their tacit knowledge components. Indeed, even in the history of companies that intensively use KM (Bolisani et al. 2016), there has often been a struggle to combine these opposite views that represent two sides of the same coin. Today, AI presents the opportunity to ultimately and conclusively integrate the technological and human viewpoints within the field of KM.

At the same time, effective KM can enhance the potential of AI to achieve better business performance compared to competitors (Leoni et al. 2022). In fact, AI has been deemed to "desperately need KM" (Edwards and Lönnqvist 2023, p.914). On the other hand, since the 2000s AI has been recognized as potentially catalyzing core KM tenets (Liebowitz 2001). Practitioners have predicted that it will shape knowledge creation and consumption, transforming the KM discipline (Nakash and Bouhnik 2021). However, the connections between KM and AI remain unclear in research (Jallow et al. 2020; Renukappa et al. 2020). In other words, as is affirmed in some recent papers (Zbuchea et al., 2019; Bencsik 2021), the literature is still poor in studies that deal with the theoretical and practical validity of the connection points between the two fields.

Acknowledging the lack of focus on the KM-AI nexus, our exploratory, techno-centric study aims to elucidate this intersection in organizational contexts and to reveal cross-disciplinary synergies. To provide significant insights on this subject, we have delineated two key objectives: (1) Identify trends in current peer-reviewed publications at the nexus of KM and AI; (2) Synthesize relevant theoretical and empirical works via a systematic literature review (SLR). These goals were accomplished through the utilization of popular scientific database, enabling us to identify knowledge gaps in the literature and propose promising avenues for further inquiry. The methodology is based on two steps: first, a quantitative bibliometric analysis of papers published in the last decade and indexed in the Scopus citation database, to reveal main trends and provide a basic classification of articles; second, a qualitative analysis of selected articles, to provide insights into the missing gaps and the directions of research.

The scope of this paper encompasses a comprehensive consideration of AI technologies. While AI has been a topic of discussion for decades, it is only recently that its pervasive potential in the business domain has begun to be fully realized; mainly due to the emergence of Gen-AI, large language models (LLMs), and related applications that are, today, readily available to a broad market. This emergence has prompted a closer scientific investigation of AI's relationship with KM. In any case, since there are still different categories of AI systems and applications, we prefer to adopt an inclusive approach that deliberately refrains from focusing on any singular technology or distinct AI implementation.

2. Materials and Methods

To address the first objective of elucidating publication patterns, we utilized the Scopus scientific database, which is a highly reputable digital database providing inclusive, extensive coverage and advanced search and filtering capabilities. Launched in 2004 by Elsevier, it is a worthy alternative competing with the monopoly established by Web of Science (WoS) (Abrizah et al. 2013; Meho and Yang 2007) and for this reason, is often used for a systematic analysis of the scientific literature. Scopus offers accessible and comprehensive coverage of lead journals across scientific disciplines, including in the management, organization, and technology fields.

An initial search for "knowledge management" AND "artificial intelligence" in titles, abstracts, or keywords yielded 4,029 records across books, reports, and conference papers. Our inclusion criteria specified only English, peer-reviewed journal articles, leaving 949 results. Specifically, we ran this Scopus query: TITLE-ABS-KEY ("knowledge management" AND "artificial intelligence") AND (LIMIT-TO (LANGUAGE , "English")) AND (LIMIT-TO (DOCTYPE , "ar")). To obtain a contemporary portrait, search results were limited to the past decade (2013-2023).

Regarding the second research objective, we aspired to provide a general perspective on previous works that discussed the application of AI technologies to KM in organizations. By accumulating theoretical and empirical publications, we implemented the SLR protocols that are often used in management and organizational research (Denyer and Tranfield 2009). The systematic review was performed without constraints on document types or publication timeframes, except for an English language filter.

Our search strategy was achieved in two sequential steps. First, we identified readily accessible scientific articles that were highly ranked on the list of most-cited publications in these subject areas. We also used relevant keyword combinations in title and abstract fields, harnessing Boolean operators and adjacency functions to optimize results. After that, we read the publications' abstracts and if the content was considered relevant, we reviewed the full text to consider its inclusion in the final qualitative analysis. That is, a text analysis methodology was employed to further refine the selection of pertinent literature. This expansive purview enabled a broad synthesis of conceptual models, existing frameworks, empirical findings, and analytical methodologies to thoroughly map the scholarly territory. By reviewing available studies, this paper elucidates effective KM frameworks and strategies in an era of AI.

3. Results

This section presents the core findings of our research, organized into two critical segments: The first, detailed in sub-section 3.1, refers to a bibliometric analysis, while the second, described in sub-section 3.2, to the results of a textual analysis.

3.1 Bibliometric Analysis

Limiting the analysis to the last decade, the results revealed that from 2013 to 2023, 572 articles were published at the KM-AI intersection, of which, as of February 2024, 534 were in the final version and 38 were articles "in press". Increased interest has been found in combining these fields, with an exponentially consistent upward trend in the last four years. Within a decade there was an acute increase in the number of articles (from 25 articles in 2013 to 136 in 2023). The results also reveal that between 2022 and 2023, when advanced AI applications (such as ChatGPT, Gemini, Midjourney, Leonardo AI, and Claude AI) burst into our lives, there was a tremendous increase of approximately 1.5 times in publications under KM-AI (see **Figure 1**).

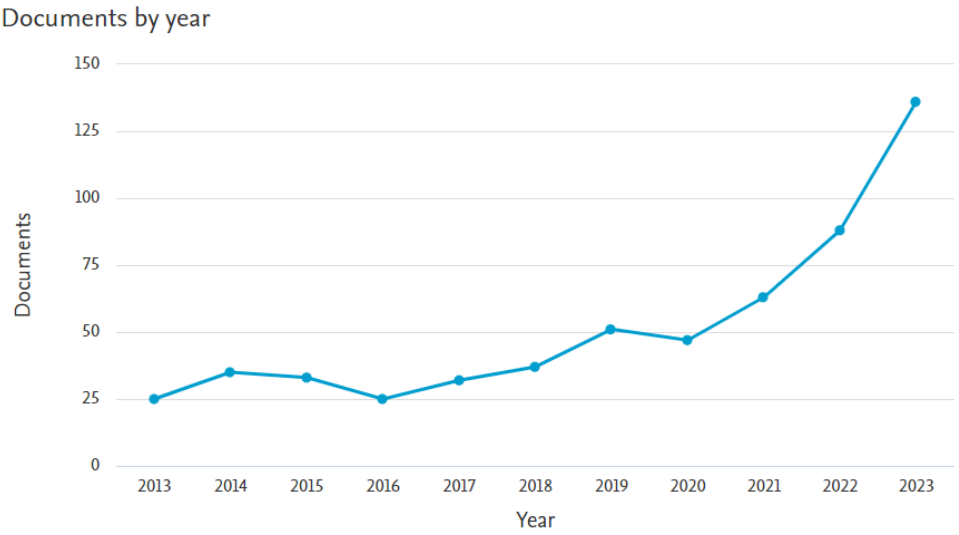

Figure 1: Segmentation of the articles dealing with KM and AI according to years

The two leading fields are "hard" sciences: computer science (n=363, 30.5%) and engineering (n=207, 17.4%). Articles classified under business, management, and accounting (n=117, 9.8%) ranked third (see **Figure 2**).

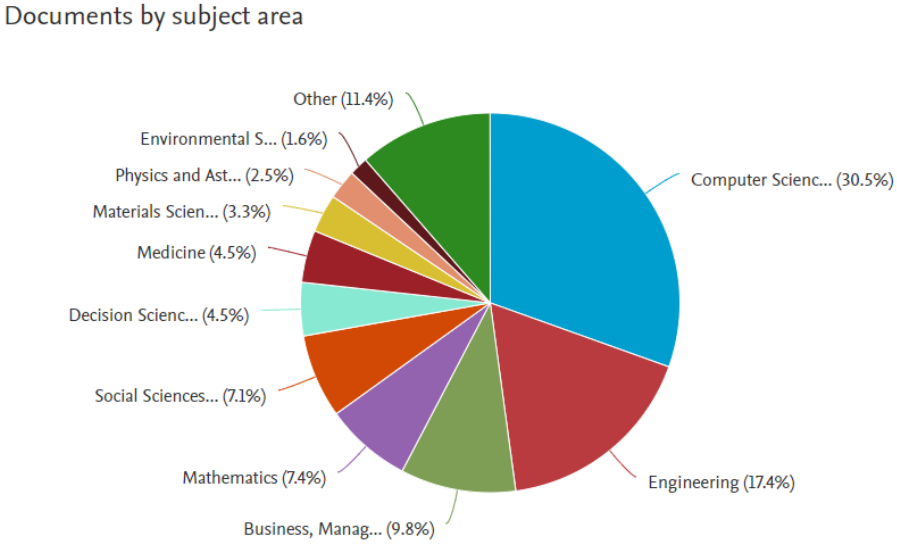

Figure 2: Segmentation of the articles dealing with KM and AI according to areas of expertise

Regarding the academic journals, the articles published in IEEE Access appear most often (n=19). The three journals, known for their specific focus on KM, which led in publications are “Knowledge-Based Systems” (n=9), “Knowledge Management Research & Practice” (n=6), and “Journal of Knowledge Management” (n=6).

The most cited article was published in “Knowledge-Based Systems” by Lu et al (2015) and deals with transfer learning using computational intelligence. An overview of the citations of the 572 articles retrieved on KM and AI revealed that throughout the decade there was a constant consistent increase, with the articles being cited 3,109 times in 2023 alone (see **Figure 3**).

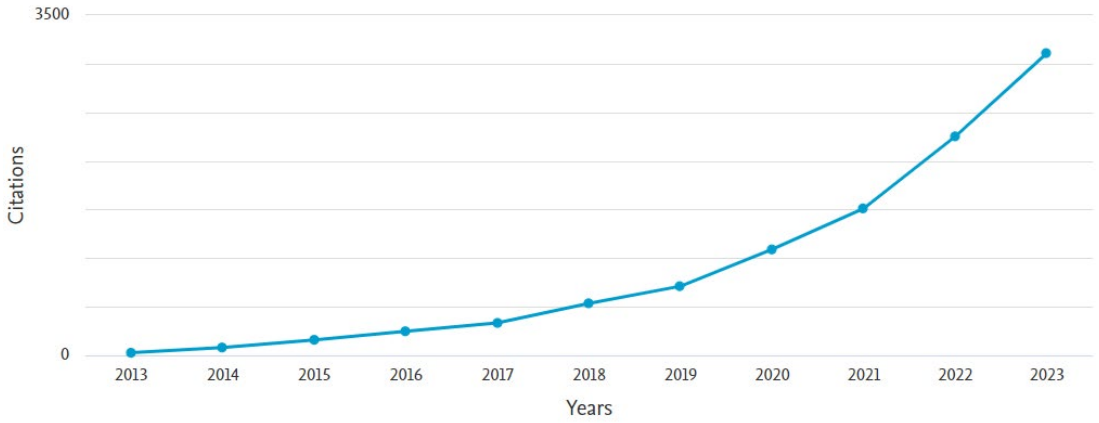

Figure 3: Segmentation of the articles dealing with KM and AI according to the number of citations

The main contribution to the body of knowledge on KM-AI in the last decade came through authors from China (n=120), the United States (n=109), and the United Kingdom (n=55) (see **Figure 4**).

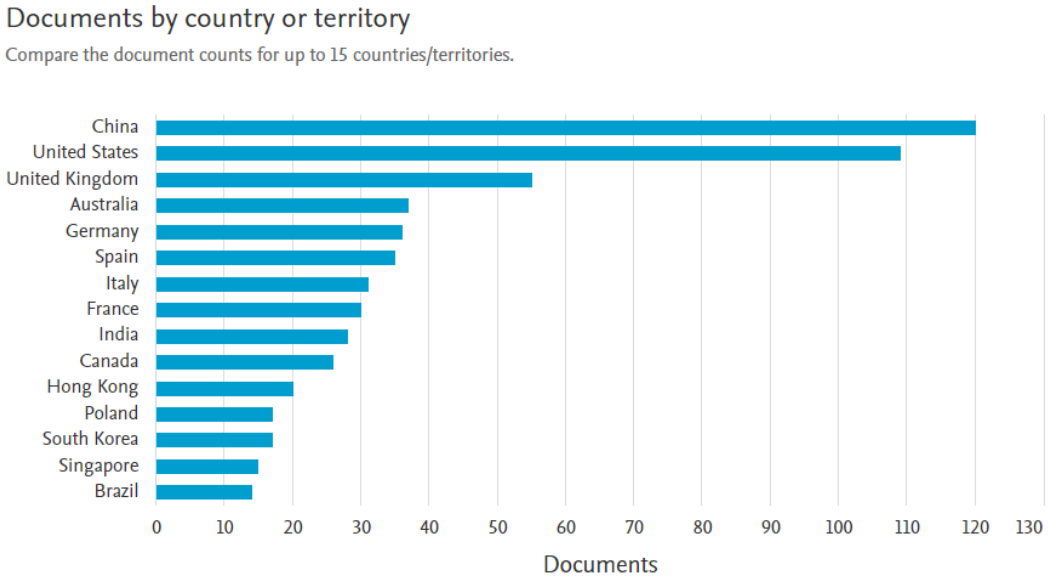

Figure 4: Segmentation of the articles dealing with KM and AI according to authors' countries

The top five keywords provided to the 572 articles in the last decade are “knowledge management” (n=494), “artificial intelligence” (n=407), “learning systems” (n=113), “machine learning” (n=94), and “decision making” (n=83) (see **Figure 5**). Not considering the two initial all-encompassing words (KM and AI), the first in the rank that directly refers to the typical KM keywords is “knowledge transfer”, only in the ninth place. In addition, few KM-related terms appear in the list. In general, based on the keyword analysis, it may be said that the majority of articles tend to adopt more of a technical perspective.

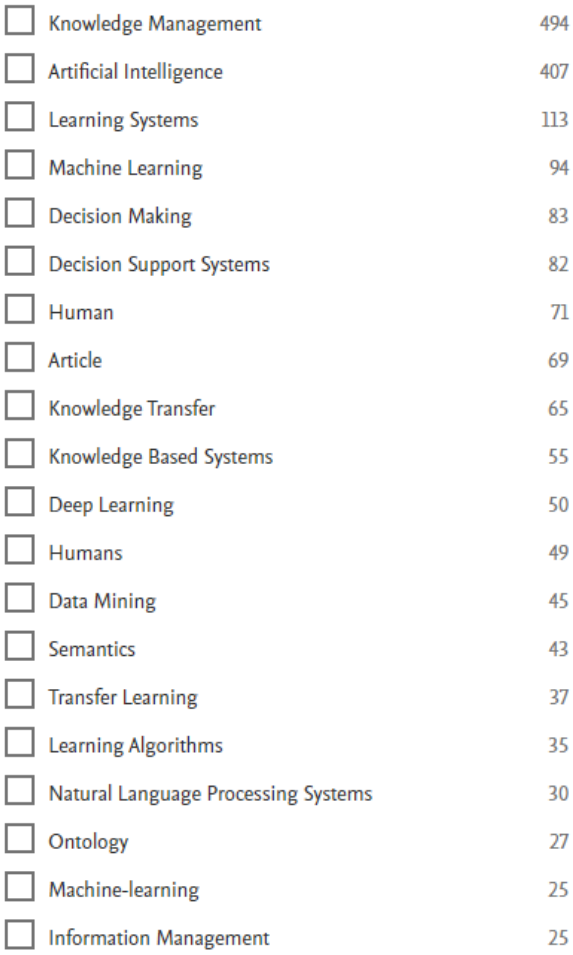

Figure 5: Segmentation of the articles dealing with KM and AI according to keywords

3.2 Textual Analysis: SLR Outcomes of Previous Works Discussing the Interplay Between KM and AI

In this section, we illustrate a classificatory analysis of key papers analyzed, to delineate the predominant perspectives at the intersection of AI and KM. This makes it possible to draw a picture of the state-of-the-art of literature on the selected topic and detect the current research directions.

3.2.1 Knowledge as an Interweaving Factor

The core concept of "knowledge" is the main linkage between the two fields of study, as can be expected. Considering that both are multidisciplinary in nature and intensively bound to knowledge, KM and AI are intuitively linked (Bencsik 2021; Cantu-Ortiz 2021; Jarrahi et al. 2023; Taherdoost and Madanchian 2023; Zbuchea et al. 2019). KM provides a conceptual platform for a better understanding of knowledge, while the second gives machines the ability to learn, create and use knowledge (Mohammad et al. 2022; Pai et al. 2022). Given that, since the revolutionary development of AI, humans are no longer seen as the sole source of knowledge in organizations (AlGhanem et al. 2022).

To enhance business competitiveness and organizational effectiveness, many companies still look for ways to improve their KM practices (Al Mansoori et al. 2020). The novelty is that AI is being presented as a key building block for the development of "advanced" KM (Kai and Yingxin 2022). Furthermore, it has been characterized as changing the way knowledge is handled (Taherdoost and Madanchian 2023). Various AI technologies, such as robotics, computer vision, and voice recognition, have a high potential to fertilize organizational KM (Cantu-Ortiz 2021). Their abilities may contribute to raising KM to the next level (Al Mansoori et al. 2020).

3.2.2 The Potential of AI to Improve KMPs

KMPs are one of the constitutional elements of the KM field. Although there are variations, four key KMPs can be identified in the literature: acquisition, documentation, sharing, and application of knowledge (Lei and Wang 2020; Scarso and Bolisani 2023). Previous studies examined how knowledge flow processes affect AI systems (AlGhanem et al. 2020). However, a minority of researchers have explored the inverse correlation in-depth. In a survey conducted in Italy with 120 senior executives, it was found that AI adoption has positive effects on the effectiveness of KMPs in manufacturing firms (Leoni et al. 2022). In a qualitative study conducted with 10 managers in the UK construction industry, the researchers concluded that AI technologies can be built and used to assist KMPs that businesses have already implemented (Jallow et al. 2020).

Thanks to the capabilities of AI to create new knowledge, integrate existing knowledge, determine relationships between contents, help in the search, and distribute knowledge to users, modern organizations can rely on AI mechanisms to enhance KMPs (Alghanemi and Al Mubarak 2022; Al Mansoori et al. 2020; Kovačić et al. 2022; Lei and Wang 2020; Leoni et al. 2022; Mohammad et al. 2022; Zhou 2022). A special case is the conversion of tacit to explicit knowledge. It has long been appreciated that smart technologies might close the gap between codification and collaboration (Sanzogni et al. 2017). Considering that the vast majority of a firm's intellectual assets is knowledge in the minds of employees (Nemati et al. 2002), the implementation of AI may provide new ways of knowledge sharing (Gurian et al. 2023).

3.2.3 Smart Systems for KM

A knowledge management system (KMS) is a platform for implementing KM (Zhou 2022), which includes a combination of information technologies to capture, organize, transfer, and distribute knowledge (Al Mansoori et al. 2020). KMSs are designed to support intra-organizational business processes based on KM. Their recent progress based on AI is of great interest, particularly the application of human-simulate cognitive computing capabilities (Nakash and Bouhnik 2022). The accelerated pace of technological progress dictates organizational practices to introduce these advanced contemporary technologies (Bencsik 2021). Applications such as user profile identification, pattern matching, and sentiment analysis have received high attention given the automation of KM practices (Al Mansoori et al. 2020).

One of the main goals of KM policies is to make corporate knowledge more available and accessible to employees. Therefore, businesses struggle to adopt efficient KMSs (Taherdoost and Madanchian, 2023). The AI-oriented KMS adds additional features to the traditional KMS approaches (Sundaresan and Zhang 2022). Based on the premise that AI can allow quick access to relevant and high-quality knowledge (Jallow et al. 2020; Pai et al. 2022), thereby supporting informed decision-making (Bencsik 2021), intelligent virtual agents are being proposed as support in search and retrieval of knowledge from KMS (Liebowitz 2001; Malik et al. 2023).

3.2.4 Adoption of AI in Terms of KM

AI includes a lot of different applications, ranging from expert systems to virtual reality (VR), from natural language processing (NLP) to visual recognition (Cantu-Ortiz 2021; Jackson 2019). However, it is the recent appearance of powerful generative AI tools that is leading to a new potentially disruptive era of organizational KM (Alavi et al. 2024). Gen-AI applications, built on LLMs, are becoming common in the daily activities of many people (Makridakis et al. 2023), although the real scope and usefulness of their adoption in the business environment have not yet been clarified (Mishra and Pani 2021; Zbuchea et al. 2019). AI can play a meaningful role in enriching and strengthening KMSs: these can be significantly enhanced with AI technologies (Vadari and Desik 2021) and thus facilitate knowledge work (Sundaresan and Zhang 2022).

There are, however, several criticalities. First, knowledge workers' perception of intelligent robots as a real occupational threat to their career path can lead to efforts of “knowledge hiding” by employees who can be afraid of sharing their precious knowledge (Arias-Pérez and Vélez-Jaramillo 2022). In addition, although the burgeoning transformation in this field hints at an immense opportunity for firms, there is still a lack of understanding of how to appropriate business value from the nascent technology – which explains the existing gap between potential and actual AI adoption (Mishra and Pani 2021). More specifically, the strengthening of AI for KM in organizations is relatively limited. AI algorithms are considered slow in their approach to providing KM support in industries. Furthermore, it has been recognized that AI-based technology alone does not necessarily solve the KM problems of companies (Pai et al. 2022).

4. Critical Issues and Future Directions

The bibliometric analysis and the findings of the SLR indicate that AI in the context of KM is a developing field of research. However, there is still a real need for joint and converging research work in both fields (Cantu-Ortiz 2021; Malik et al. 2023; Sanzogni et al. 2017). In fact, the comprehensive landscape review exposed critical blind spots in the meeting between KM and AI. By mapping the scholarly discourse, this paper identifies overlooked yet important directions ripe for future investigation. Based on the results, we outline below some high-potential avenues to spark progress in follow-up studies.

First, very few empirical studies have been conducted to date to deepen the understanding of the potential symbiosis between KM and AI. Specifically, the SLR shows that most works in these fields were mainly theoretical (e.g., Al Mansoori et al. 2020; Bencsik 2021). One gets the impression that even when empirical research has been done, it has a narrow perspective limited to specific industries (Jallow et al. 2020; Leoni et al. 2022; Renukappa et al. 2020). Furthermore, the usage of AI capabilities for KM tasks has only been examined in outdated reviews (Birzniece 2011). KM research on AI is required to keep pace with digital transformation. Integrating AI into KM strategies may improve business performance and support value creation, but researchers need to empirically explore this fruitful area using quantitative, qualitative, or mixed methods to enhance understanding of the KM-AI nexus.

Second, despite AI's clear potential for positive organizational change, little research examines how it can be practically linked to KM (Renukappa et al. 2020). While studies have analyzed how KMPs can affect AI systems (AlGhanem et al. 2020), the opposite relationship remains unexplored. A minority of works have highlighted AI's de facto impacts on organizational KM (Al Mansoori et al. 2020), even as its technologies are recognized to promote KM practices (Jallow et al. 2020). Mohammad et al. (2022) highlighted the need for research clarifying the connections between KM and AI techniques. Specifically, the literature lacks professional recommendations outlining supportive AI approaches (Bencsik 2021). Empirical research is needed to illustrate how AI can benefit the specific core KMPs which, being different in nature, can require different AI tools and approaches. Integrating AI with KMPs involves strategic themes like knowledge use, learning organizations, value generation from knowledge, and business process changes.

Third, while technology presents opportunities, it also poses considerable challenges (Makridakis et al. 2023; Malik et al. 2023; Mishra and Pani 2021; Nakash and Bouhnik 2022). There are still limitations to the application of AI to KM (Al Mansoori et al. 2020). Insufficient AI adoption can hinder organizational progress in an increasingly digitized world (Pai et al. 2022). As AI is expected to soon support KM across sectors (Taherdoost and Madanchian 2023), research on its usage scope is needed to benefit KM in diverse industries. Barriers like resource constraints, inadequate infrastructure, resistance to automation, and change difficulties can impede emerging technology adoption. Although AI would clearly benefit KM (Zhou 2022), it is vital to investigate hindrances from human, cultural, technological, financial, ethical, and regulatory perspectives.

5. Conclusion

We recognize the potential for bias inherent in our literature selection strategy for the bibliometric analysis and SLR. However, this paper, which represents a preliminary analysis on the topic, makes new contributions by mapping the scholarly landscape relating to the integration of KM and AI. We outlined the current and potential AI contributions to organizational KM to highlight the most promising research areas. Since AI disruptions in KM remain largely unexplored in corporate settings, some potentially fruitful future research directions emerge, which we have elaborated on in detail within this paper.

Especially, there is a need for empirical studies that deepen our understanding of AI benefits for KMPs in the real life of companies, as well as the challenges and implementation barriers. Gaining valuable insights into these areas is vital for designing AI technologies that facilitate, support, and promote organizational KM excellence. Building on this foundation, this article distinguishes itself from previous literature reviews by providing not only a pioneering synthesis of the integration of KM and AI, but also offering an updated and forward-looking perspective that serves as a beacon for subsequent empirical investigations.

Abstract: In supply chains, social attributes, such as trust, and commitment, are key drivers of efficiency performance. In the agriculture industry in developing countries like Vietnam, social capital may have a greater role when other formal systems are not in place. This study empirically tests the mediating role of supply chain absorptive capability as a complementary asset to leverage social, and cognitive capital to enhance innovation performance. This research examined small food producers using a standard questionnaire and captured 85 responses in Vietnam. The findings showed that social capital plays a more significant role in enhancing absorptive capability, highlighting the need for a structural resource network in developing regions. Food processing firms benefit from the direct and indirect influence of absorptive capability. Absorptive capability acts as a catalyst in enhancing cognitive, and social capital for improving innovation outcomes, such as new product development. The food producers should not just stop at sharing and capturing information, but move forward to deploy new ideas and learned knowledge. The results urge agricultural businesses to establish networks with supply chain partners, who can significantly impact the development of new ideas, and quickly exploit new knowledge to accommodate resources for sustainable agricultural strategies.

Keywords: Knowledge Management, Supply Chain Management, Innovation

1. Introduction

Organizations compete based on the capabilities they can accumulate across their supply chains. Although firms face resource scares, and knowledge deficits (Tunisini, Harrison, & Bocconcelli, 2023), however, some outperform others due to their abilities to absorb, transform, and apply external partners' knowledge in supply chains (Horvat, Dreher, & Som, 2019; Malhotra, Gosain, & Sawy, 2005). In operations, and strategic management research, efforts to understand the relationships between these performance improvements have typically focused on firm-based, and industry-based research. Due to the unpredictable and turbulent business environment, the dynamic of supply chain knowledge depends on the linkages between the knowledge network, and synchronization among members (Arenas, Díaz-Guilera, Kurths, Moreno, & Zhou, 2008; Simatupang, Wright, & Sridharan, 2002). This study argues that the interrelationship between social, and cognitive capital, and a firm's absorptive capability can leverage external knowledge from suppliers, and customers to enhance competitive advantage and innovation performance. It can serve as an alternative explanation that may inform an enhanced understanding of the dynamic of this phenomenon.

Social capital is captured from the goodwill that exists between SC partners highlighting trust, cooperation, friendship, respect, and reciprocity in interactions. Effective networking allows firms to build high-quality ties that enable the transfer of knowledge (Horvat et al., 2019), the building of new knowledge, and faster, and more comprehensive learning (Loermans, 2002). Cognitive capital represents alignments among organizational actors about business visions and shared cultural values (Tsai & Ghoshal, 1998). Literature suggests that cognitive capital can be developed when supply chain partners share a common understanding of business norms, and technical terminologies, align business visions, and conduct joint workshops to identify issues, and opportunities (De Carolis & Saparito, 2006).

This study posits that absorptive capability (APC) mediates the relationship between social and cognitive capital and performance based on congruence theory. The concept of the APC is an emergent dynamic capability that facilitates better capturing, disseminating, and utilizing external knowledge to support their operations and sustain firms' competitiveness. Supply chain absorptive capability refers to abilities to capture, disseminate, and apply knowledge of markets and know-how from supply chain partners, to apply in enhancing final product quality and reducing costs (Ramanathan & Gunasekaran, 2014).

According to the congruence theory, cognitive capital derived from supply chain collaborative efforts can enhance tangible social-economic satisfaction when supply chain partners align, and achieve common

objectives, culture, and business practices. Organizational goal congruence facilitates knowledge-sharing practices that mitigate opportunistic behaviors among supply chain partners (Dyer & Singh, 1998), thus leading to more collaboration. In this sense, goal congruence is a useful supply chain coordinating mechanism that leads to superior outcomes (Roh, Min, & Hong, 2011).

Vietnam's agricultural industry is less structured, characterized by high transaction costs, and poor public, and private institutions (Ba, de Mey, Thoron, & Demont, 2019). Social capital can emerge from a network of cooperatives and unstructured traders. The agricultural industry in Vietnam plays a fundamental role in the country's economic growth, contributing 13 percent of GDP, and 29 percent of employment in 2021 (Van Huong et al., 2021). Vietnam's policies are highly appreciated in motivating to promote potentials, and advantages of the agricultural sector, which turns Vietnam from a recipient of food aid to a food exporting country. Agri-food in Vietnam includes mainly SMEs, who act as elements of cohesion in agricultural processes in which the activity is carried out. The agri-food supply chains serve international, and local markets through innovation and the management of multiple value chains. Vietnamese consumer needs are not limited to food safety, and quality, but increasingly include innovation, sustainability, competitive pricing, and value for money.

This current study addresses the above, in the Vietnamese agricultural context, by examining relationships between social, and cognitive capital, and firms' absorptive capability, and its impacts on performance. While literature indicated that social capital can bring the focal company long-term benefits (De Carolis & Saparito, 2006; Phadnis, 2024), others assert that supply chain managers must examine the stage of development, and identify facilitating factors in designing their supply chain operations. This study investigates the following questions:

- To what extent do social, and cognitive capitals affect the supply chain's absorptive capability?
- How do these knowledge dimensions, and supply chain absorptive capability impact innovation performances?

This study provides a better understanding of how knowledge from supply chain partners in the agricultural context (e.g. farmers, and cooperatives) contributes to absorptive capability and innovation performance. For operations managers, this empirical study highlights the importance of leveraging suppliers', and customers' knowledge in enhancing innovation development, and performance. A comprehensive picture of facilitating factors associated with supply chain absorptive capability can help smaller food producers allocate resources to enhance innovation performance, thus staying competitive. Furthermore, by investigating the APC and social networks in an emerging agricultural context, this study shed different views on research and practice areas.

Theoretical background, and research hypotheses

The paper introduces the theoretical background, highlighting the mediating role of supply chain absorptive capability and social capital knowledge literature.

1.1 Absorptive Capability - APC

A firm's absorptive capability refers to abilities to recognize and obtain external knowledge (Aboelmaged & Hashem, 2019; Kurniawan, Hartati, Qodriah, & Badawi, 2020). From an economic stand, a firm can recognize the value of new, external information, assimilate it, and effectively apply it for commercial purposes (Cohen & Levinthal, 1990). Literature is divided into four basic building blocks: acquisition, assimilation, transformation, and exploitation. In a supply chain context, partners find and exchange knowledge from the internal, and external environment, such as their customers, and suppliers. Furthermore, accessing novel information about markets, and products/services encourages the organization to be involved more in supply chain collaboration, and partnerships, thus creating further knowledge (Ramanathan & Gunasekaran, 2014). In the context of agricultural supply chains, farmers often add complementary knowledge about materials, and processes that can be combined with the buyer´s knowledge for further processing foods.

When agri-food firms combine farmers' knowledge, and their expertise as a strategic resource, the nature of internal combination makes these resources a "hidden" competitive advantage that cannot be easily imitated. APC measures knowledge acquisition, assimilation, transformation, and knowledge exploitation (Jiménez-Barrionuevo, García-Morales, & Molina, 2011). This is particularly important when farmers use specialized or unique resources. The social capital created among farmers, and buying firms (food processors) represents collaborative activities and can transform, and implement new ideas, thus enhancing absorptive capability (Ye & Kankanhalli, 2013), and innovation performance. In the environmental context, famer usage of sustainable materials can be an innovative idea. Supply chain partners, like food producers, can utilize the farmers'

specialized know-how in such green projects to remodify their existing processes, leading to better innovation measures, such as frequencies of new products, reduced time to market, etc. Thus, this study proposes that:

Hypothesis H1. A supply chain absorptive capability has a positive influence on innovation performance.

1.2 Social Capital and Innovation Performance

Social capital theory suggests that an organization can generate benefits from the knowledge captured within an organizational network (Tsai & Ghoshal, 1998). Operations management literature contends that social capital among different partners in a supply chain represents stages and levels of capturing, dissemination, and using of such creative ideas as knowledge, and information. Social capital can emerge between customers and product designers. Firms nowadays pay attention to understanding customer experiences, perceptions, demands, expectations, and preferences (namely, customer knowledge) that can be effectively leveraged by R&D teams to enhance innovation performance. Customer insights have been a critical factor for many industries to keep up the trends, and meet dynamic customer needs. Customer insights enable Zara to replenish products rapidly driven by customer demand and also offer frequent assortment rotation of products within 2 weeks of fulfillment (Aftab, Yuanjian, Kabir, & Barua, 2018). In 2015, timely knowledge created from the network with customers innovated Zara's pink scarves. 500,000 pink scarves were dispatched, and sold within 7 days later, in more than 2,000 Zara stores globally (Roll, 2020). The social capital created by collocated designers, and other members of the supply chain like the buying team, merchandising team, pattern-makers, and suppliers enhances lead time and responsiveness. This capital is from co-locating them to enable cross-functionality, and high coordination, increase product knowledge, and streamline the product design decision-making process. The team can use standard frameworks, and process mapping which can quickly be communicated across the supply chain (Phadnis, 2024; Roll, 2020). These capabilities, in return, disseminate the newly obtained knowledge and provide opportunities for creating innovative processes resulting in future market share, and revenues. Accordingly, this study proposes that:

Hypothesis 2. A manufacturer's social capital has a positive effect on innovation performance.

1.3 Cognitive Capital and Innovation Performance

Cognitive capital emerges when supply chain partners align their visions, and develop shared cultural values. Congruency refers to "the degree to which the needs, demands, goals, objectives, and/or structure of one component are consistent with the demands, goals, objectives, and/or structure of another component" (Nadler & Tushman, 1980). Without a common understanding between these partners (e.g. quality, and technological concepts), or lack of business vision, and top management support. Toyota shares technological understanding with suppliers to enhance supply chain quality. When the company discovered that some suppliers did not understand its technological innovations, they quickly shared an information system to give the supplier access to necessary knowledge of Toyota's process. This shared understanding enabled Toyota and the supplier to collectively improve the process, thus enhancing performance and creating benefits for the supplier. It also allowed the supplier to become a valued knowledge partner of Toyota, rather than merely operating as a low-cost vendor (Dyer, 1996).

After COVID-19, farmers continue to command the deepest trust, driven by expertise, and demonstrating shared values around caring for the planet. A green, and sustainable environment can be the shared value, and visions that have deepened consumer trust in the food supply chain – retailers and food service operators have been the key beneficiaries (Berti & Mulligan, 2016). Ensuring sustainable food production systems, and implementing resilient agricultural practices become important drive plans for many actors in the agri-food supply chains. Collaboration in this sphere enhances mutual understanding, a shared vision of green, and safety in food production systems. Cognitive capital plays an important role in enhancing production and maintaining ecosystems, that strengthen capacity for adaptation to climate change, extreme weather, drought, flooding, and other disasters, and that progressively improve land and soil quality.

Furthermore, farmer's knowledge could facilitate the process of sensing the new niche market. Through its understanding of the product's nature and local niche market, thus creates new markets. Cognitive social capital is created when farmers and food producers share their understanding of the new product and new materials. This connection can emerge some collaborative ideas on new markets and potential demands, which directly influence performance such as market share. Therefore, this study proposes that:

Hypothesis 3. A supply chain cognitive capability exerts a direct positive effect on innovation performance.

1.4 Mediating Roles of Absorptive Capability (APC) Between Social, and Cognitive Capital, and Performance

The role of social, and cognitive capital, and knowledge created have been discussed in the above sections concerning innovation performance. Previous sections discuss the influences of social and cognitive capital on performances. This study suggests that the influence of newly created capital on innovation performance can be even greater when organizations enhance their absorptive capabilities. APC indicates the degrees or levels of implementation, and exploitation of new knowledge, and organizational resources. The accumulated knowledge from social networks and alignments with supply chain partners enhances organizations' ability to design more efficient and innovative products, and processes that contribute to improving quality, flexibility, and delivery, and reducing cost (Cousins, 2005; Ketchen Jr & Hult, 2007).

The APC could be a possible means to strengthen the relationship because the buying firm benefits from Absorptive capability such as quality improvements. With social capital gains from customer insights, Zara enhanced supply chain integration to support 2-week innovation delivery (Aftab et al., 2018). The intensive communication and joint workshops between designers and operations improve the quality of the final products. Literature shows that social capital creates pressures that can eventually enhance supply chain quality through better integration and more collaborations (Chu, Yang, Lee, & Park, 2017; Quibria, 2003). Cognitive capital gained from aligning corporate strategies and business cultures enhanced VW's supplier quality significantly in Brazil's automobile industry (Marx, Zilbovicius, & Sergio Salerno, 1997; Nguyen, Onofrei, & Truong, 2020).

Food producers often handle customers' innovative feedback, and suggestions to keep updated with the market trends. This capital and knowledge created will likely guarantee customer acceptance and market fit (Mansor, Yahaya, & Okazaki, 2016; Tarhini, El-Masri, Ali, & Serrano, 2016). On the other hand, customers who have been consulted and engaged in the designing and production stages can directly benefit from new or improved products or services, thus continuing the collaboration, and knowledge sharing. APC facilitates innovation and provides linkages to customers' and suppliers' knowledge, which will further influence the process and product innovation stages; thus enhancing quality improvements, and cost reductions on the buying firm's side (Malhotra et al., 2005; Saenz, Revilla, & Knoppen, 2014). Therefore, this study proposes the following hypothesis:

Hypothesis 4a,b. APC mediates the positive relationship between social (a), and cognitive (b) capital, and innovation performances

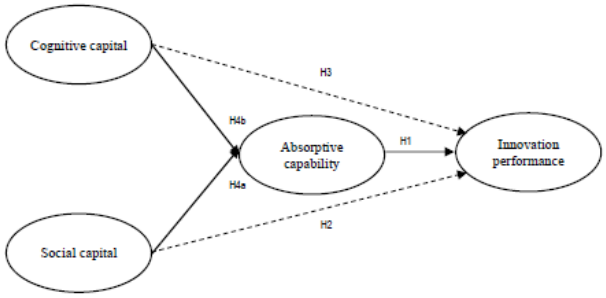

Figure 1: Research model

2. Research Methodology and Analyses

2.1 Research Design

This study employed a survey among food producers in Northern Vietnam. The original survey was in English, translated to Vietnamese using back-translation to ensure consistent use of the scales. Several changes have been adjusted to reflect better local practices after pilots with local experts in the Vietnamese Food Science and Technology Association. Table 1 indicates company profiles and characteristics. The questionnaire was sent via email to the members of the association and got 85 completed, and useable responses. The majority of the

samples were small, and medium-sized companies (90%). Firms included in the survey were mainly local (without foreign direct investment, FDI) and heavily import-oriented for their equipment and materials. These firms came from seven major agricultural products such as vegetables, fruits, cassava, meat, etc.

Table 1: Survey respondent profiles and characteristics

Industry	Frequency	Percent	**Size**	Frequency	Percent
Rice	5	5.9	Large	9	10.6
Vegetables and fruits of cultivation products	22	25.9	Medium	22	25.9
Meat and meat products	6	7.1	Small	54	63.5
Seafood and processed products	4	4.7	**Export Orientation**	85	100.0
Agricultural products (cassava, tea, cashew, coffee)	13	15.3	FullyExport	5	5.9
Drinks (juice, bottled water)	2	2.4	LittleExport	19	22.4
Sweet and candy	4	4.7	Local	41	48.2
Other processed foods	29	34.1	Significant	20	23.5
Foreign Direct Investment - FDI	85	100.0	**Import Orientation**	85	100.0
Dominant_FDI	2	2.4	FullyImport	5	5.9
Full_FDI	9	10.6	LittleImport	23	27.1
Local	67	78.8	Local	39	45.9
Small_FDI	7	8.2	SignificantImport	18	21.2
Total	85	100.0	Total	85	100.0

2.2 Research Constructs Development

Table 2 provides research constructs, questionnaire items, and their statistics. Supply chain absorptive capability includes questions related to the capability of obtaining, acquiring, and applying new knowledge (Cao & Zhang, 2011). Social and cognitive capital constructs were derived from existing literature (De Carolis & Saparito, 2006; Menor, Kristal, & Rosenzweig, 2007). Cognitive capital reflects firms' ability to share common language and codes; developing a common understanding of the same concepts such as quality, and delivery (Menor et al., 2007). Innovation performance was measured based on the number, frequency, and market share of new products (Chen, Lin, & Chang, 2009; Sadikoglu & Zehir, 2010).

This study employed several methods to check the reliability, validity, and consistency of the model. Cronbach's alphas indicated good results [0.82-0.89], which were above 0.60, the threshold value (Hair, Black, Babin, & Anderson, 2010). The confirmatory factor analysis indicated four unique constructs with good model fit indices ($\chi 2/df$ =1.46) and a moderate fit with RMSEA = 0.075. The CFA indicates in Table 3 acceptable discriminant validity.

Table 2: Constructs means, and reliability measures

Research construct measurements	**Estimate**	**Means**	**SD**
Coginitive capital - This organization and its partners have ...			
common understanding about what activities are best for our relationship.	0.680	4.81	1.19
shared objectives and visions.	0.758	4.60	1.16
share common language and codes (e.g. special vocabulary, abbreviation, and technical terms).	0.806	4.86	1.11
common understanding about the same concepts (e.g. good, fast, quality and safety).	0.899	5.11	1.24
similar behavioral rules and norms.	0.936	5.05	1.21
Social capital			
Establishing networks with suppliers and customers has had a significant impact on developing new ideas for our organization	0.885	5.36	1.17
I have an informal network among customers, suppliers and competitors	0.813	5.11	1.18
I consider that our future is related to other firms in the area	0.774	5.11	1.21
My organization has received considerable information about products and markets from local institutions	0.639	4.98	1.25
Absorptive capability			
Application of external information to our business contributes to our profitability	0.926	5.41	1.20
We convert external information directly into new business applications to be used on our business	0.991	5.32	1.16
Employees on our business record and store newly acquired knowledge for future reference	0.764	5.42	1.19
Our business regularly considers the consequences of changing market demands in terms of new products and services	0.537	5.42	1.25
Innovation performance			
Frequency of new products introduction.	0.921	4.59	1.17
Speed of introducing new products.	0.978	4.71	1.16
Number of new products.	0.881	4.81	1.17
Percentage of total sales stemming from new products.	0.773	4.76	1.13

Notes: χ2 = 152; df = 110; χ2/df = 1.38; CFI = 0.961; GFI = 0.931; RMSEA = 0.068. Note: SD: Standard Deviation; RMSEA=Root Mean Square Error of Approximation, GFI=Goodness-of-fit Index, CFI=Comparative Fit Index. The scale format for each of these measures was 1=strongly disagree to 7=strongly agree.

Table 3: Correlation matrix, and construct validity measures

Research measurements	CR	AVE	MSV	ASV	[1]	[2]	[3]	[4]
[1] Cognitive capital	0.90	0.70	0.14	0.09	**0.808**			
[2] Social capital	0.89	0.57	0.33	0.11	0.270**	**0.724**		
[3] Absorptive capability	0.88	0.64	0.59	0.18	0.220**	0.244**	**0.783**	
[4] Innovation Perf.	0.87	0.69	0.11	0.03	0.063*	0.068*	0.335**	**0.811**

Note: Diagonal elements in (bold-underlined) are the square root of the average variance extracted (AVE) between the constructs and their measures. Off diagonal elements are correlations between constructs. MSV – Max shared variance, and ASV – Average shared variance. For discriminate validity, AVE should be greater than off-diagonal elements. ** Correlation is significant at 0.001.

2.3 Hypothesis Testing

The model was tested using a structural equation model (SEM) in AMOS software. The sample size is slightly small compared to the rule of thumb around 100 cases for SEM analysis(Wang & Wang, 2012); however, considering the normally distributed data in this study, a ratio of 5 to 10 cases per variable may be sufficient. Besides, all the major indexes such as the Comparative Fit Index (CFI), Root Mean Square Error of Approximation (RMSEA) indicate good model fit, thus the model can be considered valid (Schermelleh-Engel, Moosbrugger, & Müller, 2003; West, Taylor, & Wu, 2012). Table 4 provides the results of the hypotheses among the research constructs. Supply chain absorptive capability has a positive impact on innovation performance measures (H1 accepted). Both social and cognitive capital influenced positively and significantly on APC.

Table 4: Results of the hypothesis testing

Research impacts		Estimate	S.E.	C.R.	P
Cognitive	=> Absorptive	0.306	0.138	2.21	0.027
Social	=> Absorptive	0.562	0.116	4.832	***
Absorptive	=> Innovation Perf	0.324	0.105	3.092	0.002

χ2 = 165.83; df = 113; χ2/df = 1.46; CFI = 0.95; NFI = 0.94; RFI = 0.84; RMSEA = 0.075. Note: S.E = Standard Errors;

P = *** Correlation is significant at 0.001.

2.4 Mediating Roles of APC

The influences of social, and cognitive capital can be directly, and indirectly via APC. This study employs structural equational models with boot-trapping procedures, recommended by (Mallinckrodt, Abraham, Wei, & Russell, 2006) to test for such mediation effects. Bootstrapping can be useful in this case with a relatively small sample size as it does not rely on assumptions of normality (Nevitt & Hancock, 2001). Table 4 provides outcomes of the direct effects with, and without the mediator. The test of the indirect effects between the Cognitive capital → APC → Innovation performances was significant (β = 0.058, p = 0.02). Since both direct and indirect relationships were significant, the mediation is partial. On the other hand, Social capital → APC → Innovation performances were significant (β = 0.205, p = 0.05), and fully mediated.

Table 4: Results of the mediating role of APC

Mediating factor - APC	Direct with mediator	Indirect	Mediation
Cognitive capital and InnPerf	0.215*	0.058*	Partial
Social capital and InnPerf	0.362	0.205*	Full

Note: ** significant at 0.01

2.5 Theoretical and Practical Implication

This research argued that supply chain absorptive capability, and innovation performance in an agricultural context can be influenced differently. Drawing upon the knowledge-based view, this study confirmed that both social and cognitive capital are important sources of developing supply chain absorptive capability. Development of social networks, and exchanging knowledge among supply chain partners may not be not enough for innovation performances. The results from this study show that managers should pay more attention to the application, and exploitation of newly learned knowledge. The accumulated capital created by the collaboration, shared business visions, and technological knowledge among farmers, producers, and customers become important resources for innovation development. In addition, supply chain partners, farmers, traders, and food processors should align their business vision, and goals to facilitate better collaboration, and innovation performance. The empirical results provide support to the argument of the importance of APC in enhancing social, and cognitive capital from supply chain partners to enhance agricultural innovation performance.

These results confirm the previous literature mainly in operations management that social, and cognitive capitals are key components for enhancing absorptive capability, and innovation performance (Ali, Hussin, Haddad, Alkhodary, & Marei, 2021; Aribi & Dupouët, 2015). It provides evidence that absorptive capability further enhances the impacts of social knowledge created by exploitations, and dissemination (Scuotto, Del Giudice, & Carayannis, 2017; Tortoriello, 2015). Recent literature indicates that food security and cleaner food supply chains are the top drivers for innovation in supply chains (Mehmood, Ahmed, Viza, Bogush, & Ayyub, 2021; Sharma, Mangla, Patil, & Liu, 2019). This study contributes to this important area of research by highlighting the mediating role of firm's supply chain absorptive capability in enhancing social and cognitive capital. This concept provides additional aspects of collaborative efforts among supply chain partners in jointly capturing, and applying knowledge in developing new products, and services, and improving processes (Cao & Zhang, 2011; Phadnis, 2024; Ramanathan & Gunasekaran, 2014). These results support previous research on social, and cognitive capital and their associated trust that facilitates higher absorptive capability (Ali et al., 2021; Malhotra et al., 2005). APC plays a significant role as "business intelligence" in connecting the dots and enhancing collaboration through organizational boundaries.

3. Limitations and Future Research

The results of this study are subject to several limitations. First, this study was conducted for small food producers, and cooperatives in Vietnam, thereby it has limited generalizability power. Therefore, it is recommended to explore findings in other types of industry sectors other than the agricultural processing industry.

Social Impacts of Digitalisation Through the Lens of Hungarian Experts

Nóra Obermayer, Tivadar Máhr and Zsuzsanna Banász
University of Pannonia, Faculty of Business and Economics, Veszprém, Hungary

obermayer.nora@gtk.uni-pannon.hu
mahr.tivadar@gtk.uni-pannon.hu
banasz.zsuzsanna@gtk.uni-pannon.hu

Abstract: Nowadays, we live in the fourth industrial revolution (the so-called digital revolution), which is fundamentally reshaping industry and business as well as the economy and civil society. Within the research activities of the National Laboratory for Social Innovation project, a research plan has been drawn up taking into account the quadruple helix model. The aim of this research is to map the social impacts of digitalisation based on the perspective of Hungarian experts. The research aims to map the social impact of digitalisation, whether the perception of the impact of digitalisation on society depends on the individual perceptions of the experts involved in the research (age, education) or organisational (sector of the organisation represented). The research seeks to answer the following research questions: Q1. How can the social impact of digitalisation be described? Q2. Do individual (age, education) or organisational (sector of the organisation represented) characteristics influence the experts' opinion? Q3. Are there any significant relationships between experts' responses to questions on the social impact of digitalisation and, if so, how strong are they? The data analysed are the results of a qualitative and quantitative, empirical survey carried out in 2021 with experts from academia, government, business and civil society. The former was conducted in the form of focus group interviews with invited experts (n=9) and the latter, in the form of an online questionnaire survey (n=78) using descriptive statistics and relationship analysis methods (Cramer's V and Kendall's Tau). The results show that the majority of experts consider the social impact of digitalisation to be rather positive, highlighting for example more efficient problem solving. It can be shown that the development of digitalisation requires a well thought-out but not over-regulated framework. As the transfer of knowledge improves, the opportunities for those who use digital technologies increase, but so does awareness of its harmful effects. The results can guide digital policy makers in identifying key areas for intervention.

Keywords: Digitalisation, Society, Experts, Focus Group, Questionnaire

1. Introduction

Throughout history, innovation has mostly taken the form of major industrial revolutions (Kagermann et al., 2013), aiming to both facilitate everyday life and increase the efficiency of production systems through new technologies (Horvath & Szabo, 2019). In the first three industrial revolutions, productivity growth was realised, driven by mechanisation, electricity and information technology (Kagermann et al, 2013). Nowadays, the fourth industrial revolution (also known as Industry 4.0) is considered to be the digital revolution, which is fundamentally transforming all aspects of life (Horvath & Szabo, 2019). Digitalisation has positive impacts on both society and economic development. Research shows that the spread of digitalization stimulates growth (Myovella et al., 2020), reduces income inequality and supports financial development (Ha, 2022). Thanks to the increasing use of the Internet and mobile phones, people around the world can connect with each other faster and more cost-effectively. Consequently, a new economic structure based on the use of information and communication technology (ICT) is of utmost importance (Lapatinas, 2019), especially for faster development (Donou-Adonsou, 2019). Digital technologies have become indispensable for a wide range of human, social and economic activities (Visser, 2019). The social distance constraints caused by the COVID-19 pandemic have inevitably increased the use of digital technology among the population (De, et al., 2020). A major consequence of the emergence of the viral pandemic is the rise of contactless technologies, which increasingly require people and technologies to interact (Manimuthu et al., 2021). Social actors have opened up to innovations that would not have been accepted in the ordinary circumstances before the epidemic. While its importance is unquestionable, few studies have examined the impact of digitalisation on society, and those that have, have tended to measure the environmental impact (Liu et al., 2019). An international survey examined whether digitalisation has an impact on the sustainable development of society. The results showed that the social components of the countries studied are positively affected by the process of digitalisation (Jovanović et al., 2018).

A national survey analysed the social impact of 21st century innovations in terms of generations. These impacts were examined from the perspective of older age groups in an ageing Hungarian society. It was found that the supportive power of the community and the efforts against loneliness are at the core of the social relevance of innovative solutions (Bene et al., 2020).

2. Theoretical Background

Some believe that robots may take over human work in the future. This belief is unfounded, seeing that robots are already carrying out tasks which human resources do not, or do not fully have the required capacities for. They are not taking over work done by people, but rather facilitate, accelerate problem solving. No jobs were lost to the emergence of the computer, the product of the third industrial revolution. It only created new ones, and the same future is expected from the fourth industrial revolution. However, this age will bring new challenges for both enterprises and employees (Kaasinen et al., 2020). Controlling new technologies requires new skills and competencies and a more flexible business environment, as corporate performance is still hugely impacted by the capability and dedication of managers and employees (Stachová et al., 2019). The human factor must be an integral part of the fourth industrial revolution. The future must be shaped so as to emphasize people, as the most dehumanized form of the fourth industrial revolution does “robotize” human beings. The impact of digitalization, the speed and scale of current changes, and the emergence of digital technologies have led to a radical transformation of workplaces and daily life, with a decreasing demand for workers performing routine, manual tasks (Bertani et al., 2020), while the demand for digitally skilled workers is steadily increasing (Kozanoglu & Abedin, 2020).

From a societal perspective, three other important factors can be identified: demographic change (the emergence of new generations), increasing virtual work (the impact of COVID-19), and increasing process complexity. The terms digital divide or digital inequality are used to illustrate the differences between social groups. These gaps can be demographic (age) (older generation lagging behind), geographical (lagging regions) or social (people living on the periphery). The state has a key role to play in closing the digital divide and in creating equal opportunities. The development of specific programmes should focus on developing the digital competence of disadvantaged people (Vinnai, 2020).

An adequate level of digital competence in the use of digital technologies is a key competence that all citizens need. Digital competence is *"the confident, critical and responsible use of, and engagement with, digital technologies for learning, at work, and for participation in society. It includes information and data literacy, communication and collaboration, media literacy, digital content creation, safety, intellectual property related questions, problem solving and critical thinking."* (European Commission, 2019:10). The DESI (Digital Economy and Society Index) measures the development of the digital economy and society. In 2022, 54% of Europeans had at least basic digital skills and less than a third had more advanced digital skills (26%), meaning that a large proportion of the EU population still lacks the digital skills required by most companies and positions. Hungary ranks 22nd and only around half of the population has at least basic digital skills (49%) (EC, 2022). The expected impacts of digitalisation have been investigated by national (Horváth & Szabó, 2019; Makó et al., 2018) and international research (Frey & Osborne, 2017; Li et al., 2019). In addition to academic research, consultancies have also addressed the issue (Bughin et al., 2018), but none of the studies have examined the social impacts.

3. Research Framework

The aim of this study is to explore the social impacts of digitalisation based on the opinion of national experts, and to answer the following three research questions:

- Q1. How can the social impact of digitalisation be described?
- Q2. Does the expert's opinion depend on individual (age, education) or organisational (sector of the organisation represented) characteristics?
- Q3 Are there significant relationships between the experts' answers to each question on the social impact of digitalisation and, if so, how strong are they?

3.1 Data collection - Quantitative

Before the quantitative research a qualitative survey was conducted to assess the social impact of digitalisation, using a focus group interview. The interviews were carried out by a research team within the framework of the research activities of the National Laboratory for Social Innovation (TINLAB). The research plan has been drawn up taking into account the quadruple helix model. This model is a further development of the triple helix model, where the fourth helix is the civil society, thus including the civil and public sectors in the university-industry-government nexus (Birkner & Máhr, 2016). The semi-structured interviews took place online on 26 March 2021 with 9 invited experts representing academia-government-business-civil society. Based on the results of the focus group interviews a questionnaire was compiled. This study is only focusing on the results of the

quantitative research. The online survey was carried out anonymously in compliance with GDPR rules. In line with the four-helix model, 80 professionals from the academic-government-business-civil sector were invited to complete the questionnaire. The invited respondents were well-known Hungarian actors in these fields, experts working as social innovators or in potential social innovation organisations, whose activities are related to digitisation with a social impact. The selection was based on the TINLAB network's connectivity and database. The full questionnaire survey used in the research consisted of 11 sets of questions. The present study examined demographic characteristics and the impact of digitalisation on society, as well as the influence of social media presence on individuals' social interactions. The research team chose to analyse these issues because the experts' opinions were the most divergent during the interviews.

Descriptive statistics and relationship analysis are used as research methods. The former is used to answer research question Q1, the latter for questions Q2, Q3. A total of (3·10=) 30 relationship tests are analysed between the answers to the 3 independent (X) and 10 dependent (Y) questions. The level at which the questions are measured determines the indicator used to quantify the relationship between them. All variables considered as dependent (Y) are measured on an ordinal scale. Two of the independent variables (X) (X1. age: 1: 30-49 years, 2: 50-64 years, 3: 65 years and over; X2. highest level of education: 1: secondary education, 2: higher education (university, college)) are measured on ordinal scale, and their relationship with the variables to be explained can therefore be explored using the Kendall tau (τ) indicator, which quantifies the rank correlation and ranges in the interval [-1, 1]. The questionnaire respondent's sector (X3: academic degree) can only be measured at the lowest level, the nominal scale. The Cramer indicator (V), which can take a value in the interval [0, 1], is used to determine the relationship of this sector with the variables to be explained (Y). All relationship tests are interpreted at 5% significance level using SPSS software. If the p-value for the test is < 0.05, then a significant relationship exists between the two criteria being tested. In the case of significant relationships, the absolute value of the indicator indicates the strength of the relationship (Sajtos & Mitev, 2007): below 0.2 is considered a weak relationship, from 0.7 a strong relationship, and between these two numbers a moderately strong relationship. The Cramer indicator can only take a positive value, so the sign of the indicator cannot be interpreted here. Since the indicator τ can be both positive and negative, the sign of this indicator, which indicates the direction of the relationship, is also interpreted here. A negative (positive) τ means that the higher the ranking of one variable, the more likely it is that the other variable will have a lower (higher) ranking.

4. The Results of the Questionnaire Survey

The questionnaire was completed by 78 of the 80 experts invited to participate. In terms of age, there were exactly half and half of respondents under 50 (39) and 50 and over (39). The majority (57) had the highest level of education (university or college), 14 also had a degree and 7 only a school leaving certificate. In terms of field of work, 36 people belong to the business sector, 17 to the academic sector, 15 to the civil or media sector and 10 to the public sector.

4.1 Descriptive Statistics (Q1)

Y1 asked respondents to choose between statements 'a' and 'b' on the societal impact of digitalisation, indicating negative or positive attitudes. On a scale of 1 to 4, 1 and 2 represent negative attitudes (a) and 3 and 4 represent positive attitudes (b). Experts agree most with the statement where the mode, the mean, is highest and, in addition, the relative dispersion of responses is low. The distribution of responses (%) between the 1-4 response options is shown in Figure 1. The black rectangles indicate the proportion of non-responders, for the other colours the darker colour indicates the proportion of more positive experts (agreeing with response option ‘b').

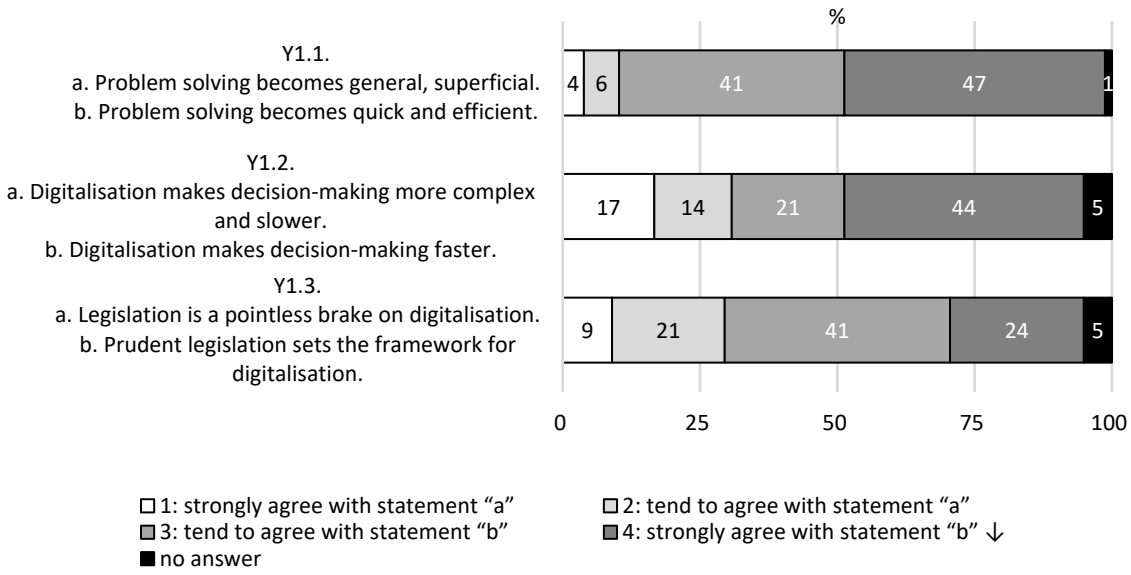

Figure 1: Y1. Which statement do you think is most representative of the social impact of digitalisation? (%)

88% think that problem solving is becoming faster and more efficient rather than generic and superficial (Y1.1). Apine and co-authors' (2020) research aimed to explore how leadership practices are changing in the digital age. Similar to the results of our research, they also concluded that digitalisation provides better, faster, simpler tools and channels for organising information and problem solving. 65% believe that digitalisation makes decision-making faster rather than more complex and slower (Y1.2). In his research, Hoßfeld (2017) investigated whether digitalisation will be a relevant topic to improve decision making. His results are in line with our findings that digitalisation (especially smart technology) speeds up decision-making. The use of smart technologies to speed up decision-making is becoming more and more common for companies. On the one hand, it can reduce human error and can therefore be important for decisions that rely heavily on data, and on the other hand, it can help automate certain decision-making situations.

65% believe that well-considered legislation provides a framework for digitalisation rather than pointlessly curbing it (Y1.3). The digital revolution is challenging traditional legislation, as legislation cannot keep pace with rapidly changing technologies (e.g. self-driving cars, drones, digital contracts), as the environment to be regulated is dynamically evolving (Kardos, 2020).

In question Y2, respondents had to decide how much they agreed with 7 statements. The statement where experts agree the most is the one with the highest mode, the mean, and also where the relative dispersion of responses is low. The responses are shown in more detail in Figure 2, which shows the distribution of responses (%) between the 1-4 response options. The order of the statements reflects the preference of the respondents.

98% of the participants thought that it is important to regulate the new world order created by digitalisation processes and the ethical issues that arise (Y2.1). This issue has been addressed by several researchers at the international level, for example Roša (2021) explores the role of ethics in the context of digital technologies through a systematic literature review. Among others, he finds that research such as Baldini et al (2018) argue that the legal framework alone cannot fully cover all privacy risks and that a model that addresses ethical issues is needed.

A new and previously untested finding is that 78% of respondents believe that the development of digitalisation has improved the transfer of knowledge between generations (Y2.2).

88% of the experts claim that larger companies can take advantage of the opportunities of digitalisation (Y2.3), and 62% also agree that smaller companies can also take advantage of the opportunities of digitalisation (Y2.4). A survey by Csizmadia and co-authors (2022) also found that the larger the size of the company, the higher the adoption of digital technologies, as highlighted by an international survey (Savastano, Amendola, Bellini, & Ascenzo, 2019). The OECD report also confirms that large companies are at the forefront of business digitalisation, and in Hungary this is mostly the case for foreign-owned subsidiaries (Éltető & Sass, 2021).

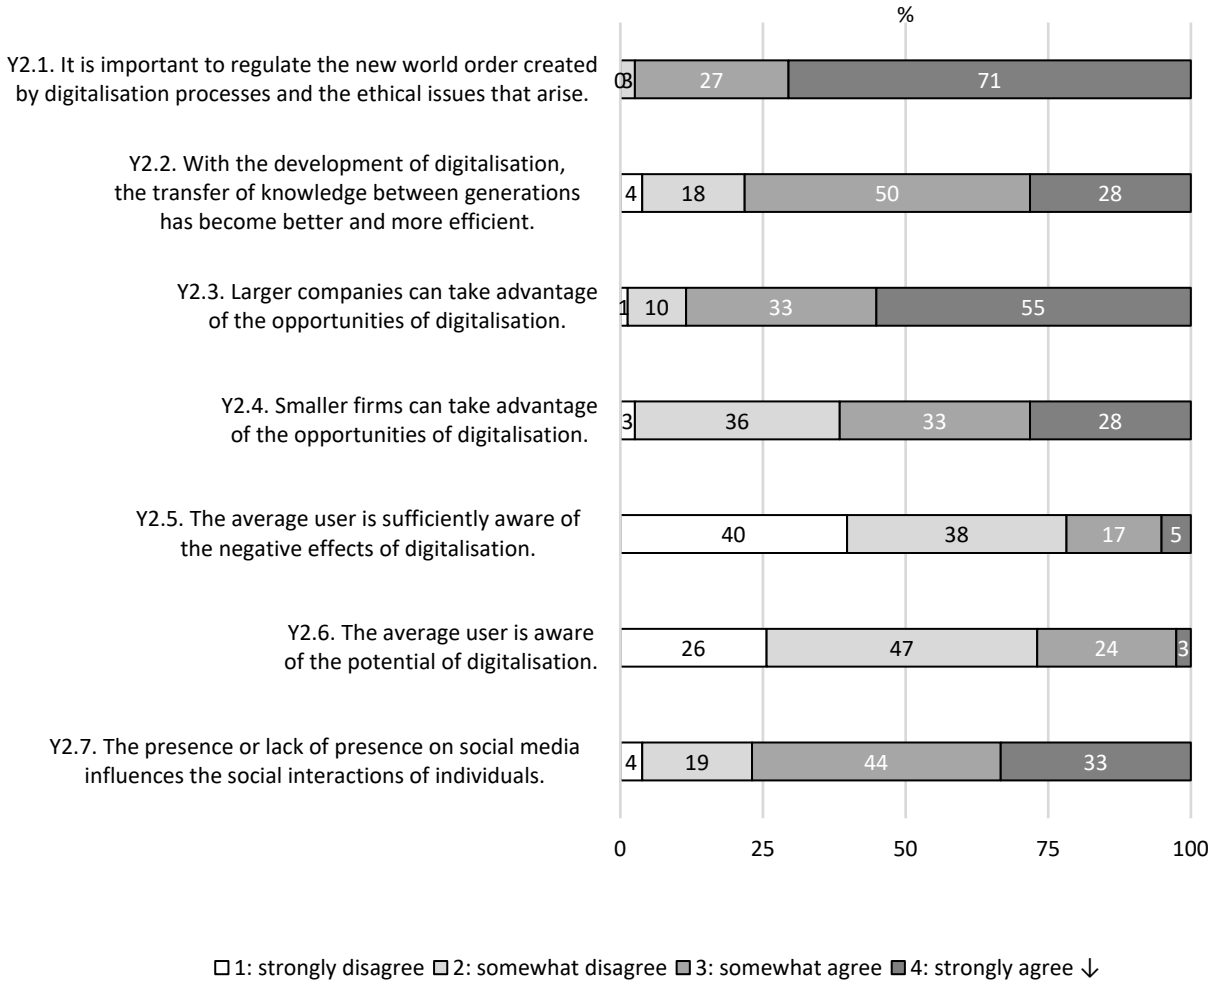

Figure 2: Y2. How much do you agree with the following statements? (%)

78% disagree that the average user is sufficiently aware of the negative effects of digitalisation (Y2.5) and 73% disagree that the average user is aware of the potential of digitalisation (Y2.6). The results were supported by Meggyesfalvi's (2021) research, as it is a serious problem that digitalisation and new algorithms increase the risk of exposure to harmful content, especially for younger generations.

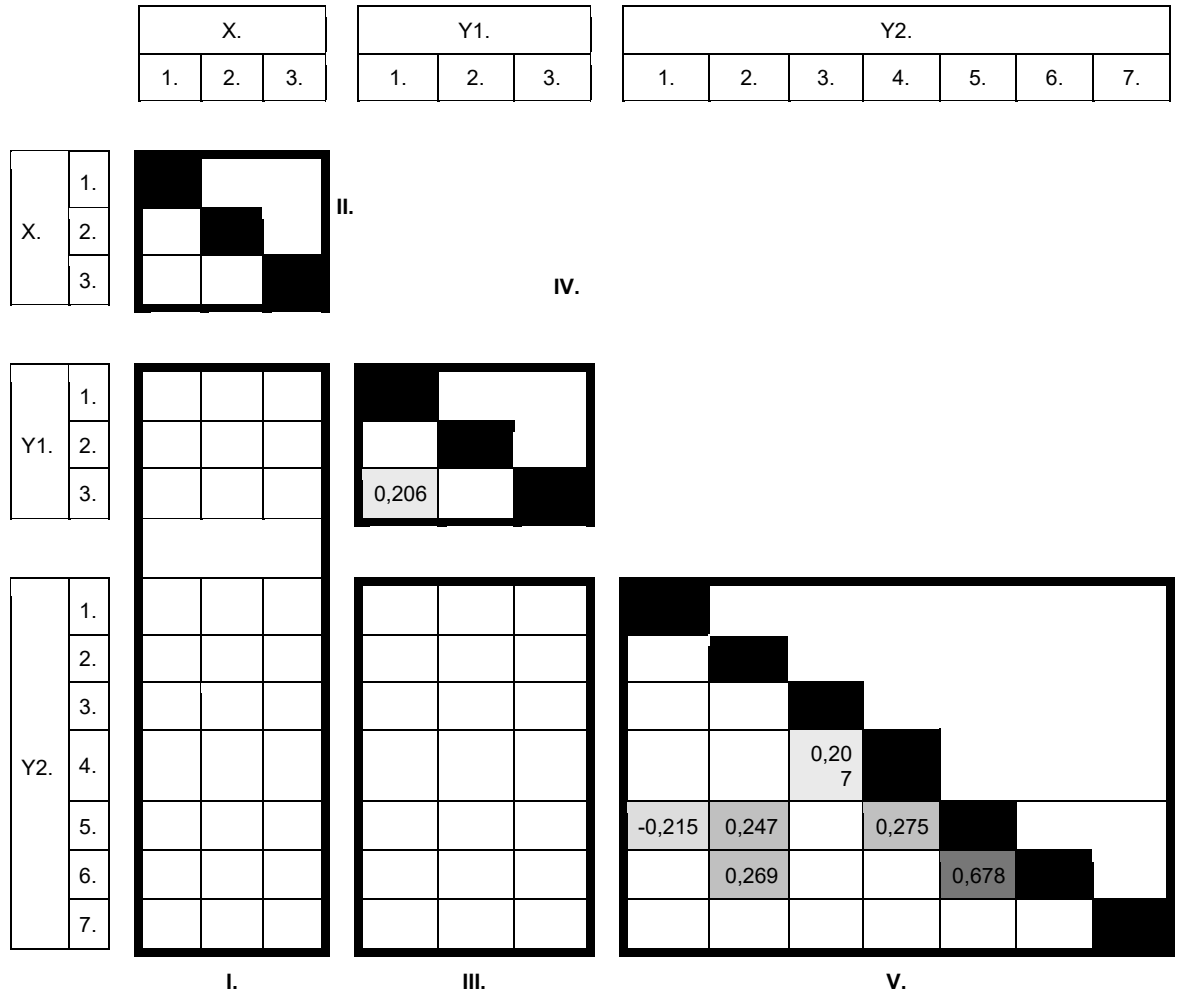
More than two thirds (77%) believe that the presence or absence of social media influences one's social interactions (Y2.7). Social media helps communication between generations, allowing people who are geographically distant from each other but have similar interests to find a way to connect. However, excessive use of social media has negative effects, for example, users often want to present a perfect image of themselves, or excessive use can take valuable time away from other activities.

4.2 Relationship Analyses: (Q2, Q3)

In the following, we move from descriptive statistics to relationship analyses in order to answer the second and third research questions mentioned in the introduction (Q2, Q3). The significant results of the relationship analyses are summarised in the relationship matrix in Table 1.

In the diagonal of the correlation matrix, cells with a black background indicate the relationship of each indicator to itself, on which diagonal the results are symmetrically duplicated, so only the part of the matrix below the black diagonal is examined.

Table 1: Significant results of relationships



The background colour of the cells indicates the strength of significant relationships: weaker stronger relationship

4.2.1 Relationship Analyses: Demographics and Digitalisation (Q2)

Q2 asked whether the experts' opinion on the social impact of digitalisation depends on the individual (age, education) or organisational (sector of the organisation represented) characteristics of the expert making the statement. The relevant relationship analyses aim to identify significant relationships between the answers (Y) to the questions on the social impact of digitalisation and the experts' characteristics (X) as potential explanatory variables. This section is shown in sub-matrix I of Table 1, which however does not contain any significant relationship. This means that our hypothesis that the individual and organisational characteristics of experts (age, education, sector) influence their opinions has to be rejected.

This result is interesting because it implies that the experts' opinion on the social impact of digitalisation does not depend on the age of the expert, the highest level of education or the sector in which the expert is classified as an expert. The analysis shows that the social impact of digitalisation is a phenomenon experienced by all adults in the same way, regardless of their level of education and employment. This leads to the conclusion that if the social impact of digitalisation is to be communicated to experts, it is not necessary to use segmented communication elements, as the demographic characteristics of these groups can be interpreted as a single target group. This is also true for marketing, social or corporate communication.

Part II shows the relationships between the characteristics (Xs) of the experts, where there is also no significant correlation. This is not surprising, because it means that the age of the expert does not affect his/her education or sector, nor does education affect the sector in which he/she works.

4.2.2 Relationship Analysis: Digitalisation (Q3)

More interesting, however, are the relationships between the variables (Y's) to be explained (Part III-V), which answer the third research question (Q3), whether and how strong significant relationships can be detected between experts' responses to questions on the social impact of digitalisation. For the answers to questions Y1 and Y2 (Part III), we also find that there are no significant relationships, thus the experts think similarly. There was a significant relationship ($\tau = 0.206$) between the responses to the Y1 questions (Part IV), which was moderately strong and positive. This can be interpreted as the more experts agree that the societal impact of digitalisation is to make problem solving faster and more efficient (rather than general or superficial) (Y1.1), the more they agree that legislation should frame (rather than constrain) digitisation (Y1.3). The results of the relationship analysis therefore suggest that the faster and more efficient solution to a problem requires, according to respondents, a careful legislative process. This may be related to the fact that the rapid and rapid development of digitalisation - to the benefit of society - can only be envisaged within a well thought-out but not over-regulated - legal - framework.

The most significant relationships were found between the answers to the Y2 questions (Part V): 6 out of the 21 relationships concerned. All of these relationships are moderately strong. The direction of the relationships is positive in five cases and negative in one case. The almost strong relationship ($\tau = 0.678$) relates to the experts' opinion of the average user. The more they believe they are sufficiently aware of the harmful effects of digitalisation (Y2.5), the more they believe they are aware of the opportunities of digitalisation (Y2.6). Experts believe that as users perceive the opportunities of digitalisation to increase, they also recognise its harmful effects. This may be related to the fact that experts, who have more and deeper professional knowledge, think the same about the average user.

Four of the other five medium-strong relationships can be linked to one of the responses to these two statements. The more the expert agrees that the average user is aware of the opportunities of digitalisation (Y2.6), the more the development of digitalisation has improved the transfer of knowledge between generations (Y2.2) ($\tau = 0.269$). The experts' opinion shows that the increase in opportunities for digitalisation also increases the opportunities for knowledge transfer. This may be related to the fact that experts, who are more aware of the potential of digitalisation, are better able to use its achievements in knowledge transfer and feel the same about ordinary users.

The more the expert agrees that the average user is sufficiently aware of the harmful effects of digitalisation (Y2.5),

- the less they agree that it is important to regulate the new world order created by digitalisation processes and the ethical issues that arise (Y2.1) ($\tau = -0.215$),
- on the one hand, the more he agrees that the development of digitalisation has made the transfer of knowledge between generations better and more efficient (Y2.2) ($\tau = 0.247$),
- on the other hand, that smaller firms can take advantage of the opportunities offered by digitalisation (Y2.4) ($\tau = 0.275$).

The experts argue that the average user who understands the adverse effects of digitalisation - but also its potential - does not need to be constrained by over-regulated processes, as the world has become faster, we communicate more efficiently, we share knowledge more quickly. The same is true of the business opportunities for small businesses, which are typically fast, change-ready and dynamic, and can take advantage of the rapid opportunities offered by the digital world.

The last almost weak relationship ($\tau = 0.207$) can be interpreted as the experts who agreed more that larger firms can take advantage of digitalisation (Y2.3), had similar views about smaller firms (Y2.4). This correlation shows that the flexibility and speed of small firms helps them in the field of digitalisation: the success of larger firms in exploiting the opportunities of digitalisation naturally goes hand in hand with the success of smaller firms in exploiting the opportunities of digitalisation.

5. Discussion

Based on our research, we found that the majority of experts consider the social impact of digitalisation to be positive rather than negative. Several factors of this positive impact are worth highlighting: problem solving has become more efficient, which needs to be further strengthened, as users are not sufficiently aware of the potential of digitalisation. Contrary to our assumption, the experts' opinion on the social impact of digitalisation is not significantly influenced by their age, education or the sector in which they work. On the one hand, this

implies that there is convergence among experts, they are well prepared, and regardless of their demographic characteristics, it is safe to use their opinions in decision-making. On the other hand, communication to them on the social impact of digitalisation can be uniform, there is no need to use different communication methods and channels, no need to define specific target groups.

Finally, there were only a few significant relationships between the answers to the questions on the social impact of digitalisation, but it should be pointed out that the development of digitalisation requires a well thought out, but not over-regulated framework. As the transfer of knowledge improves, so the opportunities for those using digitalisation increase, but so does awareness of its harmful effects. The success of businesses through digitalisation is primarily a credit to small businesses, but it also has an impact on larger firms.

5.1 Practical Implications

Businesses are able to take advantage of the opportunities offered by digitalisation, but as digitalisation processes evolve, the ethical issues that arise need to be regulated, and this is also true of social media: the presence or lack of presence on social media has an impact on the user, which ultimately has an impact on socio-economic processes. These processes have brought cybercrime to the forefront and this social problem needs to be addressed, as users are not sufficiently aware of the harmful effects of digitalisation. It is worthwhile to raise the awareness of the average user through training and better information transfer, as they are the main victims of the negative effects of digitalisation, while businesses, the media, academia and NGOs can be the shapers of these effects. It is worthwhile to launch practical programmes and developments to address these issues in the future. Our results can provide food for thought for decision-makers on where to allocate resources and where to develop reinforcement/prevention programmes when allocating scarce resources. EU countries, including our own, already have frameworks in place that can be used effectively to improve digital inequalities in society, both for the population and for workers. The digital divide can be tackled through training and development. In addition to developing the digital competences of the younger generations in a school setting, there is a need to provide free educational opportunities for adults to develop the digital competences that are increasingly essential in the labour market.

5.2 Limitations and Future Research

One of the limitations of our research is that the surveys were only conducted in Hungary. We consider it worthwhile to repeat both the qualitative and the quantitative survey in English in the near future, with foreign professionals working in Hungary. In this research, we asked experts to assess the social impact of digitalisation. It would also be interesting to examine the views of average users, not experts, and compare the results with those presented here.

Prepared in the "National Laboratory for Social Innovation" project (RRF-2.3.1-21-2022-00013), within the framework of Hungary's Recovery and Resilience Plan, with the support of the Recovery and Resilience Facility of the European Union.

A Comparative Study of ECKM Academic Papers 2017-23

Johan Olaisen and Birgit Helene Jevnaker
BI Norwegian Business School, Oslo, Norway

Johan.olaisen@bi.no
Birgit.h.jevnaker@bi.no

Abstract: The purpose of this paper is to analyze and compare all the academic papers in the proceedings of ECKM in 2017 (Barcelona), 2018 (Padua), 2019 (Lisbon), and the digital conferences in Coventry 2020 and 2021. In 2022, the conference was arranged in Naples, and 2023, in Lisbon, both as hybrid conferences. The study classifies the papers according to methodology, analysis, discussion, and conclusion regarding their contribution to the four paradigmatic boxes. The approach uses the five philosophy of science framework and compares this to the content of the research papers. We will use the findings in four representations of knowledge, two typologies of concepts, four paradigmatic classifications, and the concluding framework for knowledge management research. The seven conferences heavily emphasize knowledge-itis and instrumental itis and much less on problem-itis. The papers are mostly centered around existing knowledge and accepted methodology and are less related to new problems. The results indicate a conference based upon as-is knowledge and less upon new and often unsolvable issues. The ECKM academic papers in 2017, 2018, and 2019 have relatively low complexity and are presented in an empirical and materialistic paradigmatic framework through definitive concepts representing a form of atomistic research. The papers in 2020, 2021, and especially 2022 and 2023 are delivered within a more robust, clarified subjectivity and action research-based framework through definitive and sensitizing concepts. What would ECKM have been with more complexity in action and subjective paradigmatic framework through sensitizing concepts representing holistic research? A more creative, engaged, and relevant conference. It will also be a more scientific conference discussing what is acceptable or not acceptable and what is adequate. Studies concerning sustainability, digitalization, and globalization might require another research approach. The more critical and green papers in the 2020 and 2021 conferences are open to new perspectives on methodology, problems, and knowledge. The 2022 and 2023 conferences represent a turning point for critical sustainability and digitalization papers that clarify subjectivity through action-based research. The 2022 and 2023 papers represent the turning point of ECKM into improved relevance through more critical and constructed studies based on the societal climate crisis and sustainable strategies and business models.

Keywords: Paradigms, Concepts, Perspectives, Knowledge Creation, Knowledge Accumulation, Sustainability

1. Research Justification

We have experienced knowledge management (KM) as a research field developed from Information systems (IS), Information Resources (IRM), Information management(IM), Intellectual capital (IC), and Information and communication technology (ICT) management. KM has been concerned with theoretical and practical implications, while the other fields have been mainly concerned with practical implications(Jevnaker & Olaisen, 2022 b). The other fields have eroded as disciplines while KM keeps stubbornly on. Artificial intelligence (AI) has been the hot spot for the last two years and has yet to be convincing as an own research discipline. KM might be a part of AI, or AI might be a part of KM. There are many KM journals, but the main outlet for reflections and discussion of KM is the ECKM conference going on for more than 30 years with more than 110 reviewed academic research papers yearly.KM is a broader discipline, including business models for sustainability, equality, digitalization, globalization, climate issues, and AI. The contributions include anthropology, art, aesthetics, philosophy, psychology, scenario learning, pattern studies, biology, neuroscience, and traditional business studies(Jevnaker&Olaisen, 2021). KM is at a crossroads, either eroding as its own discipline or developing further as its own research domain(Jevnaker and Olaisen, 2022 a). Where is KM heading, and why is KM heading in this direction? Are there other directions in which to look? The most valid and trustworthy way to investigate KM is to evaluate the ECKM academic papers. We have used five conceptual and theoretical frameworks from the philosophy of science to do the evaluation. The strength of the evaluation is the pluralism of using five different frameworks.

2. Conceptual and Theoretical Framework

Tornebohm (1983) conceives social science as a sequence of partly cumulative and partly non-cumulative transformations of Knowledge (K), problems (P), and instruments(I). Tornebohm (1983) argued that if the sciences and social sciences progress, there must be a balance between K, P, and I. An overemphasis on any of them will hinder a free scientific discourse and the development of any scientific field. For instance, a central notion from the compound (K1, P1, I 1) to (K2, P1, I2) occurs when the problems P1 are solved to increase the stock of Knowledge from K1 to K2. In problem-solving, new instruments may be developed or borrowed from

other disciplines, changing I1 to I2. If one of the three aspects dominates the other two, the domain becomes less relevant. Overemphasis on knowledge ("knowledge-itis") may result in empirically empty structures irrelevant to the problems.

The initial KPI maps the aspect of interest (in this case, a feature of knowledge structures or processes). The KPI compound in this process filters through what is called the "researchers' orientation and worldview" or perspectives in Tornebohm's words (1983) or paradigms in Kuhn's words (1970) or research domains in Olaisen's words (1985). These authors are all referring to the fact that there are alternative ways of approaching the social sciences and, by that, also knowledge management research. The aspects studied are not given once and for all. New knowledge widens the boundaries, as might happen after broadening knowledge management research. Thornebohm believes that pluralism is needed in any discipline to accumulate knowledge.

Galtung's (1972) idea was to identify four ways of approaching the social sciences in a triangle of theory, data, and values:

1. Empiricism – is what we are presenting true or false (if true consonance, if false dissonance)
2. Criticism – is what we are giving acceptable or not acceptable (if acceptable consonance, if not acceptable dissonance)
3. Constructivism – is what we are presenting as adequate or inadequate (if adequate consonance, if not adequate dissonance)
4. Pluralism – a triangulation of empiricism, criticism, and constructivism (if congruence consonance, if not congruence dissonance)

Galtung (1972) assumes that a common goal of all social sciences is to establish what are called sentences dichotomizing their "world space" by including some defining the empirical world by having some "world points" and excluding others. Hence, data sentences explain the empirical world by including what they observe and eliminating what they do not see or imagine. On the other hand, theory sentences (hypotheses or propositions) define the foreseen world, including aspects predicted by the underlying theory. Finally, value sentences refer to the preferred world, including what is accepted and excluding what is rejected. Galtung proposed that all social sciences needed criticism, constructivism, and pluralism in addition to traditional empiricism. Constructivism might be constructing our data or practice to develop new alternatives. The constructed worldview is dependent upon our judgment and interpretation. The constructed story demands great imagination and creativity to tell an excellent relevance. Galtung believed all the social sciences could be analyzed according to this framework. Our research paper is the first time Galtung's and Tornebohm's approaches are used to analyze a research discipline.

Blumer (1969) argued that research concepts in any social science might be divided into definitive and sensitizing concepts. Definitive concepts are empirical concepts defining what is accurate or not true while sensitizing concepts look for new directions and ask about what is adequate or inadequate. The concepts have an essential role in any scientific inquiry. They are usually the anchor point in the interpretation of findings.

The purpose of the definitive concept is to:

Describe-Explain-Predict and Control and Rule (A definitive and objective process). Bunge (1967) named this process "the process of all serious systematic research."

The sensitizing concepts have another purpose:

Describe-Explore-Reflect-Participate and Change (A subjective and relative process). Glaser and Strauss (1967) named this process "Grounded-theory-research."

Olaisen (1985) divided any Knowledge into four types of knowledge:

1. What we know about defining
2. What we do not know implying
3. What we do not know that we know as a part of
4. What we do not know that we do not know

According to Olaisen(1985), to get a scientific, intuitive, and creative movement between these four types of knowledge to represent the essence of representable and non-representable knowing modes in any science and social science. The known directs us to the known unknown and further to the unknown known together with the unknown.

Olaisen (1985) divided the social sciences into four paradigms in a quadrate of harmony versus conflict and objectivity versus subjectivity:

1. The empirical paradigm
2. The materialistic political paradigm
3. The clarified subjective paradigm
4. The action paradigm

According to Olaisen, any social science paper could be placed within these four paradigms.

These are the five scientific philosophy frameworks used as analytical tools for analyzing academic papers.

3. Methodology

This paper analyze and compare all the academic papers in the proceedings of ECKM in 2017, 2018, 2019, 2020, 2021, 2022, and 2023. A total of 770 double-blind-reviewed academic documents were reviewed, each 5000 words and ten pages long. The approach uses a philosophy of science framework and compares this to the content of the research papers.

We have used five philosophy of science frameworks to analyze all the papers:

1. Tornebohm's knowledge, problem, and instrument description (1983)
2. Galtung's scientific perspective triangle (1972)
3. Olaisen's four kinds of knowledge identification (1985)
4. Blumer's two types of scientific concepts (1969)
5. Olaisen's four types of paradigms identification (1985)

This paper combines (4) and (5) as pluralistic proposals for future knowledge management research progress.

Each paper has been classified according to the following:

1. Problem
2. Methodology
3. Theoretical foundation
4. Propositions or hypotheses
5. Analyze
6. Discussion of results
7. Conclusions
8. Theoretical and practical implications

A decision has been made for each of the five frameworks according to which format the paper fits within each academic writing. The decision is based on the reading of the article. For two-thirds of the documents, placing them into a category was clear. We had to decide which type we set them within for one-third of the papers. The decision is based upon our notes from each piece; if in doubt, we reread the article.

After reading each section of the paper, we classify within each of the eight criteria. When the session is missing, our decision is based on our classification. The subject classification is done according to the keywords in the documents, the abstract, and the introduction. The exactness of the category has continuously been approved. Therefore, we have reclassified 2017, 2018, and 2019 for our 2024 paper.

4. Knowledge-Itis, Instrument-Itis, and Problem-Itis

The papers are suffering from "instrument-itis" and to some extent from "knowledge-itis," but they are indeed not suffering from "problem-itis." Problem-oriented research demands systematic and logical argumentation (Lawrence, 1992). Problem-orientated research might need to be improved for knowledge management researchers. The researchers do the statistical tests well, presenting the data in "nice" total packages as a form of scholarly truth. However, only some results conflict with existing marks. 2 of 3 hypotheses are correct, and 1 of 3 needs to be corrected. There are many similar hypotheses/propositions (54%) in papers dealing with knowledge sharing and knowledge management, while 61% reach the same result and 39% reach a different outcome for similar propositions and hypotheses. The Popperian falsification process (1973) is used for both explicit and tacit knowledge processes even if 82% in 2017, 84% in 2018, 83% in 2019, 68% in 2020, 57% in 2021, 52% in 2022, and 48% of the papers in 2023 do not make any distinction between tacit and explicit knowledge

processes. The inability to distinguish between tacit and explicit knowledge might represent a lack of theoretical sophistication. Two-thirds of the papers need a definition of knowledge, information, management, leadership, or the situations included in these concepts. The lack of definitions presents a kind of storytelling where a story exemplified by statistics is told. The scholarly and scientific storytelling is what Kuhn (1970) defined as a pre-scientific situation where anything might be equal in importance or what Popper (1968) described as the situation for psychology as a field. Kuhn (1970) called this "something less than research." The lack of problem-itis makes it challenging to make progress and accumulate knowledge; as Nonaka (2018) noted, there had yet to be any progress in understanding and performing tacit knowledge(Olaisen&Revang, 2018). There is, however, a greater degree of sophistication in the 2021, 2022, and 2023 papers regarding problem formulations and the knowledge content, making the papers more relevant at a business and societal level. The sustainability and green leadership questions have increased the imagination and creativity of solving several problems that have yet to be solved or even pure speculation as a band wagon effect (Merton,1967).

More than 60% of the papers write about the need for new ways of sustainability and knowledge leadership, management, and organizing. The documents, however, are centered around traditional leadership, management, and organizational issues. The paper's label and marketing propose new leadership, management, and organizing ways. However, they neither define today as the situation nor how we will take us tomorrow. The papers are promising the "promised land," but in the end, tomorrow's management is the same as today's management. The papers' problems are centered around solvable matters and seldom relate to unsolvable problems. In knowledge management research, we define "instrument-itis" and "knowledge-itis" as a misdirecting striving for respectability. Eighty-three of 770 papers (11%) discuss our ecological systems' problems and what we need to do to solve the climate crisis through sustainable businesses. These green ecological papers ask several questions they cannot answer and are thus speculative and are all conceptual papers without any empirical basis. The 2022 and 2023 conferences doubled the number of such papers and increased the conference's relevance for our actual and future business situation. The bearing, creativity, and scientific quality are enormously improved from our earlier analyses of these aspects (Jevnaker & Olaisen, 2021). The 2022 and 2023 papers confirmed the trend toward critical papers discussing sustainability, the climate crisis, and moral issues of what is morally adequate and morally inadequate for businesses. AI is addressed from the angle of what is good for our civilization versus what is suitable for AI businesses. Human control is compared to machine control according to consequences. The 2022 and 2023 papers are more pluralistic in their problem formulation, choice of methodology, and discussion of findings.

5. The Aspects of the World Studied

We are making a distinction between four areas of knowledge in management research: "What we know" (1), "What we know that we do not know" (2), and "What we do not know that we know (3) and What we do not know that we do not know" (4). Area (1) will define area (2), while there will be a misinterpretation and bias towards area (3) and area (4).

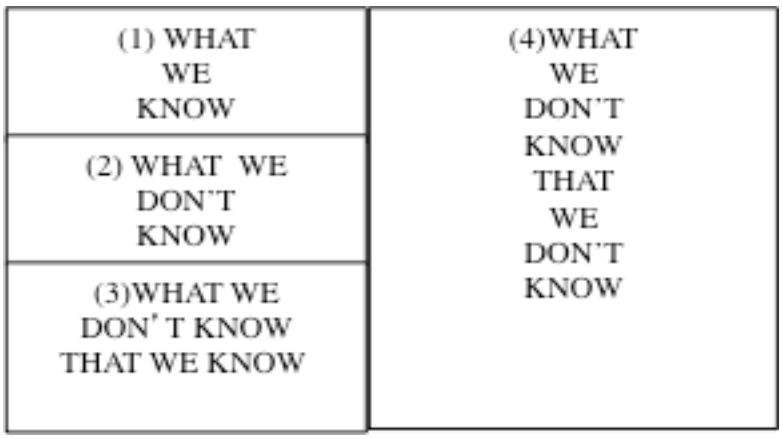

Figure 1: Knowledge representations (Olaisen, 1985).

For areas (3) and areas (4), will imagination and intuition be necessary for the creativity needed to make a scientific movement in knowledge management in zones 3 and 4? If we expand only into area two, it will be limited knowledge research emphasizing instruments and knowledge while the problems will be defined by what

we know. We distinguish between the known, the known unknown, the unknown known, and the unknown. The exciting part is the dynamics between the known and unknown and how we make a part of the unknown known in our research process. The papers have progressed from 2016 to 2023 in defining what is unknown and discussing why tacit knowledge remains unknown in most situations. There is also a beginning discussion of the need to approach the unexplored areas and the challenges looming in the unknown domains.

If we want to move between areas one and two, logical, empirical studies ("secure and clean studies") will be ideal. However, the source of bias and misinterpretations starts as soon as we move into what we do not know anything experienced. We will here begin to involve imagination and intuition. Experience-based intuition is the starting point of any essential research effort. Simultaneously, the movement from area one to area two is only instrumental puzzle-solving, often without knowledge accumulation (Minzberg, 1979; Morgan, 1980). “The way to improve our technique is not to attempt to analyze things into their elements, reduce them to measure and determine functional relations but to educate and train our intuitive powers to make the unimaginative and the unknown known” (Knight, 1936, p. 103). Suppose our role is only to produce some publishable or travelable research. In that case, we are reduced to mechanical puzzle-solving, demonstrating that we can master the techniques we learned in our Ph. D's. Between 50 and 60% of the research papers at ECKM represent this kind of mechanic puzzle-solving (Morgan, 1980). The empirical ECKM researchers are sending out a questionnaire to a large sample, getting a 5-20% response rate. Applying statistics and getting a research classification results in nice tables, diagrams, and figures, getting more of the same trivial already known knowledge. The 2020 and 2021 papers are based on qualitative, in-depth interviews, constructed datasets from several studies, and theoretical foundations. Primarily, the 2022 and 2023 papers represent an improvement with more problem-oriented papers and more speculative papers, including imagination and speculation as a part of the research process. The unknown and unknown areas have gotten more interest, including a few papers (5) in 2021 based upon a constructed empirical basis where the authors discuss unexplored areas to see solutions for sustainability for discussing what green leadership and a green organization represent. The ECKM academic papers at their best in 2021 represent the societal issues addressed later at the Cop 26 conference in Glasgow (Olaisen, 2022). The papers of 2022 and 2023 follow up on these critical issues, wondering if knowledge management represents the problem or the solution.

6. Scientific Orientations

Galtung (1972) assumes that a common goal of all social sciences is to establish what are called sentences dichotomizing their "world space" by including some defining the empirical world by having some "world points" and excluding others. Hence, data sentences explain the empirical world by including what is observed and excluding what is non-observed. On the other hand, theory sentences (hypotheses or propositions) define the foreseen world, including aspects predicted by the underlying theory. Finally, value sentences refer to the preferred world, including what is accepted and excluding what is rejected. We developed Galtung's approach into our research model (Figure 2).

Most of the papers (65%) in 2017, 63% in 2018, 61% in 2019, 52% in 2020, 46% in 2021, and 41% in 2022 and 2023 do not develop hypotheses but only describe the theory's findings without concluding them into hypotheses for testing (Bunge, 1967). However, the research compares data sentences with theory sentences without using Popper's falsification principle (Popper, 1972). The increasing number of papers using hypotheses or propositions increases the discussion of verifying and falsifying the findings. The testing of hypotheses and propositions is making the ECKM conferences more scientific. Dissonance does not produce new theory sentences, while consonance notes that the research results align with mainstream knowledge management research. Criticism is a scientific activity where data sentences are confronted with value sentences. By the tenets of this orientation, consonance is created by producing new data sentences by changing reality into an acceptable condition. Criticism is an increasing part of the ECKM 2017, 2018, 2019, 2020, 2021, 2022, and 2023 papers (15% versus 16% versus 18% versus 23% versus 26% versus 28% versus 30%). The trend is clearly towards more criticism-based pieces. Criticism is needed through values, speculations, and ad hoc methods to advance a field, even if the validity and reliability are lower.

Constructivism implies comparing theory sentences with value sentences to see to what extent the foreseen world is preferred. Consonance refers to what is adequate, and dissonance to what is inadequate. In dissonance, theory and value sentences are prioritized equally, and both might be changed in knowledge management research. Constructivism represents 33% of the papers, increasing from 15% in 2017 to 33% in 2023. The business reality is today complex, sustainable, digital and global. A combination of understanding wholisms and atomisms is needed in a good research strategy (Minzberg, 1979) and actionable puzzle solving (Morgan, 1980).

Imagination and intuition are required for this process (Bunge, 1967; Alvesson & Skjoldberg, 2009). The intuitive powers are less trained among the ECKM researchers even if the number of papers, including a constructed empirical basis through speculations and intuition, increases to meet a higher degree of complexity, like the solutions of future sustainability problems. Papers concerned about sustainability and a circular economy must construct a reality we neither have tried nor have an empirical basis for. To be Marxist, we need a new superstructure for the economic basis, which has to be constructed as adequate for a sustainable business and society.

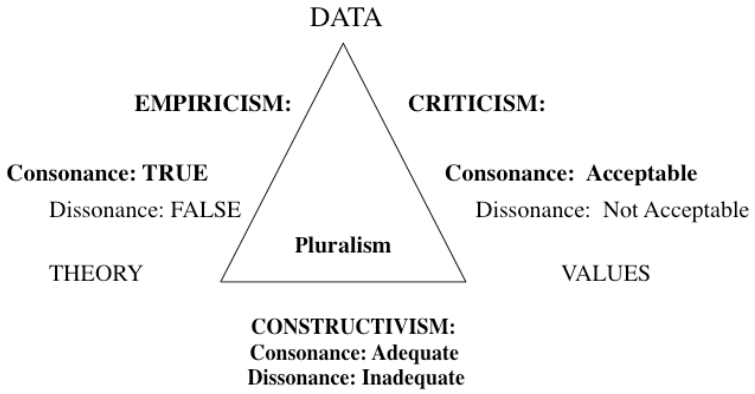

Figure 2: Empiricism, Criticism, and Constructivism

7. The Rise and Fall of Paradigms

Kuhn's position (1970) is that paradigms serve a normative and conserving function. When a standard prevails in a discipline, "normal" science practice evolves as a puzzle-solving activity. During normal science, the scientific community works under the assumption that "it knows what the world is like" and is prepared to defend this assumption "at any cost." (Kuhn, 1970, p. 5). Normal science often suppresses "major novelties, conceptual or phenomenal" (Kuhn, 1970, p. 36). Thus, scientists are only preoccupied with solving problems/puzzles according to accepted rules according to traditional viewpoints or preconceptions. With such anomalies built up and scientists losing faith, the field enters the crisis stage.

Kuhn writes that "there can be a sort of scientific research without paradigms, schools, perspectives"… (1970:11); in such research, "… though the field's practitioners were scientists, the new findings of their activity were something less than science or social science" (1970, p.13). He further notes that "… every individual researcher starts over again from the beginning" (1970, p.13), "… that some competing schools are directing their publications where they may be published. A continued discussion over the same fundamentals and no scientific progress is made at all" (1970, p.159). In the KM papers at ECKM, we have not found any schools of KM or any clearly defined KM research domain. There are no competing schools or paradigms, but mainly papers repeating more or less the same findings. There are new perspectives but not an accumulation of knowledge or defined scientific progress. Feyerabend (1974,p.103) summarized such a situation as scientific storytelling.

We may sum up Kuhn (1970) in this way:

1. Only readily available facts are collected.
2. At this stage, all points seem equally relevant.
3. To get "false" respect the instruments are overemphasized and often presented in "quasi-fanciful" ways to get "false" respect.

Looking at knowledge management research at ECKM, we conclude that this is the situation for more than 63% of the papers. The 2020, 2021, 2022, and 2023 papers were more scientific than the 2017, 2018, and 2019 papers – 63% versus 83%. In 2020-2023, progress was made in making knowledge management more scientific and robust. We found that Feyerabend's and Kuhn's descriptions fit the situation in KM research well. Every researcher starts over again from the beginning with an easily collected survey, and case data are assembled and presented in fancy scientific ways. The papers in 2021, 2022, and 2023 (24%) focused on sustainable businesses, greener businesses and societies, and the future of knowledge work, representing a positive change. The 2022 and 2023 conferences might illustrate a turning point for making knowledge management research more relevant and scientific.

8. Alternative Concepts

The concepts have an essential role in any scientific inquiry. They are usually the anchor point in interpreting findings (Blumer 1969 and Baugh 1990). The concepts are the glasses we have used since our Ph.D. We discuss two different worlds of ideas. The definitive concept is based on empirical data or "evidence" and often searches for causal relationships. Blumer(1969:52) wrote, "… to do robust research is defining and handling your concepts … research without concepts is not researching, but something else….". "Defining the concepts are the start point for any serious research discipline" (Bunge, 1969, p. 97) and "… the only way to get progress" (Feyerabend, 1973, p. 9)."When concepts are not defined there is not a scientific clarification process"(Kuhn 1971, p.87).

In knowledge management studies, the definitive concepts are taking over the ground of the sensitizing concepts(directions along which to look). Taking all the papers and dividing them into one of these ideas, around 65% of the studies rely on definitive deductive theories, while 35% rely on inductive sensitizing concepts. In the ECKM 2020, about 55% depend upon definitive concepts, while 45% rely upon inductive sensitizing concepts compared to 50/50 in 2021-23. The induction process described as "directions along which to look and use intuition and curiosity" (Blumer 1969,p.18) instead of facts or data is less used. Intellectual curiosity might be the path to choose for creative scholars. The papers are becoming more inductive and sensitizing in the 2021,2022, and 2023 conferences than in 2017, 2018, 2019, and 2020). The papers regarding sustainability and green leadership are more complex, focusing upon internal business models as drivers for an external greener and more innovative market and a sustainable societal environmentOlaisen&Revang,2017). Sensitizing concepts are used to find directions to walk in an undefined new, brave, sustainable world. The opening up into new directions, including AI, might strengthen KM or erode KM into conceptual fragments.

9. Alternative Research Paradigms

It is here proposed to analyze knowledge management research from four main perspectives. These alternative realities are different meta-theoretical assumptions about the nature of social science. The empirical paradigm, where its explanatory power establishes causal relationships between variables. The knowledge systems and the knowledge technology relations have a concrete, actual existence and systematic character, producing quantitative and qualitative findings according to the needs of societies and businesses. The business world is considered primarily conflict-free and harmonious at a higher level of aggregation. 50% of the studies in 2018 versus 45% of the 2019 papers belong here, compared to 38% in 2020, 36% in 2021, 31% in 2022 and 29% in 2023. The trend is towards fewer traditional empirical papers and more subjective and exploring papers. We explain the change towards more articles about green, sustainable business models and a new class of younger European researchers and consultants. Today's green reality is a higher external complexity met by clarified subjective and action-based business models. The modus is explorative versus explaining business models. ECKM is in 2021,2022, and 2023, starting to complete this change in the content of their academic papers.

In the materialistic political paradigm, physical events and behavior are the surface manifestations of underlying mechanisms. The materialistic paradigm relies on the assumption of predictable uniformities in the knowledge systems. The world of knowledge systems exchanges is defined by concrete, measurable, ontologically fundamental structures and interdependencies in knowledge systems. 20 % of the studies in 2018 are here versus 21% in the 2019 conference, 16% in 2020, 15% in 2021, 13% in 2022 and 11% in 2023. The importance of the measurable fundamental structures in KM is of lesser importance.KM moves from slow, large samples of definitive quantitative measurements to fast-sensitizing qualitative facts. AI and digitalization require fast decisions.

The clarified subjectivity paradigm holds that social reality does not exist in any concrete sense but is the product of individuals' and organizations' subjective and inter-subjective experiences(Berger&Luckmann, 1966).According to this paradigm, knowledge behavior must be understood from the employee and organization's viewpoint rather than the outside observer. We can only get such understanding by direct, give-and-take interaction with the employees and organizations. We can get surveys as questionnaires, but then we define the questions and the business situation. 25% of the studies in 2018 are here versus 27% in 2019, 32% in 2020, 35% in 2021, 36% in 2022, and 40% in 2023. The action paradigm (5% of the studies in 2018 and 7% of the studies in 2019 compared to 14% in 2020,15, % in 2021, and 20% of the 2022 and 2023 studies) also assumes that what passes for reality is socially determined. The move towards clarifying subjective and action-based paradigms in 2021, 2022, and 2023 is significant. Most ECKM studies are now found within the clarified subjectivity and action paradigm. The change is impressive over a concise period. The change represents a movement from explaining to exploring and exploiting studies. Most studies are empirical, but the findings are

discussed through open-sensitizing glasses rather than definitive glasses. The implications and interpretations are drawn much further, representing complex issues like sustainability, digitalizing, globalization, robotics, and AI. The empirical part is constructed to grasp future survey implications in increasing studies within the clarified paradigm. The teams have a more significant variation of knowledge, experience, and attitudes designed for taking action-driven change decisions based on subjective clarification basics. Academic research is based on slow facts, while business is based on fast facts. The action-driven paradigm then conflicts with academic research, but understanding the paradigm might strengthen KM's relation to practice(Jevnaker and Olaisen, 2022).

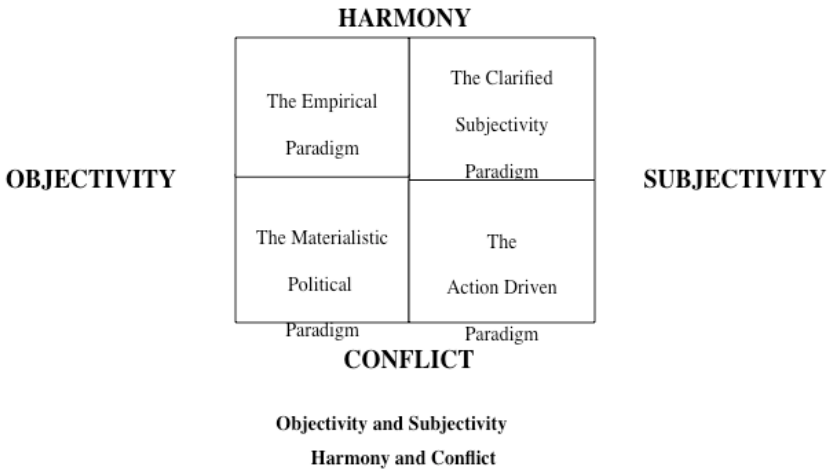

Figure 3: Research paradigms (Olaisen. 1985)

10. The Fall of Knowledge Management as Objective Research?

The action-driven and the clarified subjectivity paradigms represent a different degree of complexity and subjectivity. They represent both harmony and conflict. Various levels of complexity require different research paradigms; Pluralism is demanded to catch other aspects of reality. Subjectivism is necessary to capture complexity. The greener and more sustainable business models, the higher complexity and internal focus to get green action-driven business models. Traditional business models reduce complexity and uncertainty through a higher external market focus. The reality offers inductive exploring versus deductive explaining business models. The driving force for the explorative models is to be ahead of the market, offering new sustainable solutions.

In contrast, they explain that business models are already existing market needs in the traditional industrial way. Disruption, efficiency, and connectivity versus scale economics and effectiveness. Explorative inductive models versus deductive explaining models. Kuhn(1971) will describe it as different paradigms. The standard business science paradigm is under attack, not explaining a new societal and business reality. More and more academic papers at ECKM explore the sustainable and new green reality using more subjective and action-based business models, criticizing existing models and constructing new models. The times are 'changing, and the research methodology with new problems demands other instruments to be helpful in another reality (Jevnaker & Olaisen, 2022).

Consequently, we will have to define this discipline as a subjective multidiscipline, and we will have to explore, innovate, simulate, and experiment to a much higher degree. We need more subjectivity conflicts and less harmony and objectivity in our research. Leadership and organizational methodology movement toward phenomenon research takes research from the iron jacket into a flexible and soft jacket, opening up for alternative realities (Doh, 2015; Schwartz & Stensaker, 2014; von Krogh et al., 2012). The driving force for the future might be green climate business models, giving KM research new possibilities for understanding the green corporation. A green vision, strategy, and business models were nonexistent in the 2017,2018 and 2019 conferences but appeared as fashion in the 2022 and 2023 studies. The first AI studies appeared in 2023

11. Synthesis and Conclusion

Figure 4 presents a synthesis of our reflections. One of the axes represents the degree of complexity, and the other the level of subjectivity. The definitive concepts represent a small degree of subjectivity (i.e., a high degree

of objectivity, if possible), while the sensitizing concepts express a high degree of subjectivity. The four paradigms might be subjective or objective. The problematic question is: if we choose one model, will it be possible to move on from a low degree of complexity to a higher level of complexity (i.e., can we generalize from a tiny part of reality to a more substantial portion) of the reality)? Corporations with green business models, management, and organizational systems will drive societal and market changes. Societies and needs are changing too slowly, and the green knowledge-creating corporation is changing faster and might be the driving force for societal changes. The question is: How does KM's research contribute to green business models and green public strategies and alterations? There may be a new era for KM research.

Are the models interchangeable? It might be impossible or desperate to move up the line from origo to a higher degree of complexity and from the top to Origo (Alvesson & Skjolberg, 2009; Bunge, 1967). The knowledge research reality in AI, digitalization, sustainability, and climate conflicts offers global complexity. To understand this, we must apply subjective paradigms combined with empirical investigations for theory building (Eisenhardt & Grabner, 2007). We have to use sensitizing concepts coupled with actionable, definitive ideas. We have a field like KM research to understand whether applying it is subjective, but it is systematic and logically rigid. Future green business models will move from high complexity and subjectivity (i.e., more explorative and exploiting internal models) to more definitive and objective ones. Today, politics demand green models, solutions, promises, and concrete green business deliveries.

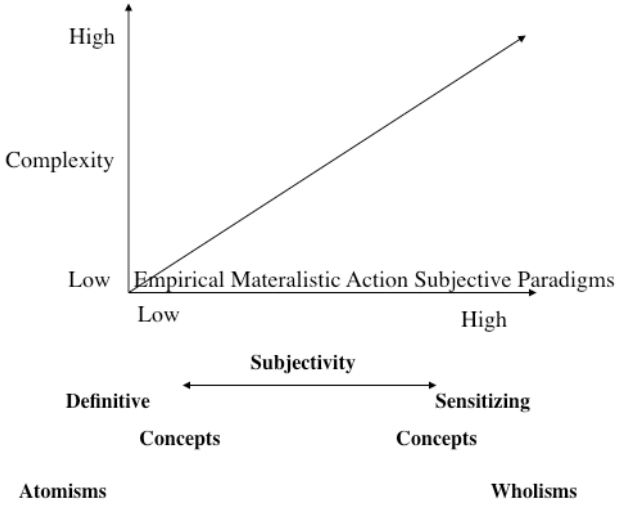

Figure 4: Complexity and subjectivity versus paradigms and concepts

Will KM erode and disappear as a discipline? Interpreting Feyerabend(1987), any storytelling discipline will erode, and we will get a new AI storytelling discipline. Our study reports remarkable adjustments in 2022-23 and changes in all the conceptual and theoretical frameworks used. KM has developed into a pluralistic discipline describing and analyzing the making of a fast-changing reality, including constructions of the future.KM has also kept the notion of understanding tacit knowledge(Olaisen&Revang, 2018). We conclude that KM will remain, and AI will instead become a part of KM rather than the opposite.IS, IRM, IM.IC and ICT are eroded as diciplines(Jevnaker and Olaisen, 2022a) and KM might be the remaining discipline.

Abstract: As the diversity and complexity of Artificial Intelligence (AI) systems increase, there is a growing need for advanced knowledge representation methods to enhance decision-making capabilities. Existing research indicates a gap between AI and Knowledge Management (KM), emphasizing the necessity of coordinating learning and knowledge creation processes between humans and machines. Despite the widespread use of generative AI, as seen through the growing popularity of conversational AI tools like chatbots powered by Large Language Models in recent years, the absence of a theoretical framework for effectively managing the knowledge they generate could mean missing out on significant opportunities. This work seeks to bridge this gap between KM and IA through an integrated framework that aims to apply KM to support IA chatbot applications, adapted from the Internet of Everything Integrated Knowledge Management Model (IoE IKM Model). The IoE IKM Model's original goal is to support knowledge creation in IoE applications, but here, we show how it can be adapted to bring KM to the context of AI. We accomplish this by explaining the development process of the IoE IKM Model, identifying shared aspects between IoE and AI general applications, and adapting necessary elements to establish our integrated KM framework tailored for supporting AI chatbot applications. The resulting framework is then discussed, and examples of how it can be applied to enhance human interaction with a chatbot, namely Open AI's ChatGPT. Research has been conducted to demonstrate the advantages of applying AI in KM. However, we aim to take a different approach by showing how KM can contribute to AI applications. We expect this work to be helpful for those whose professional activities may involve the usage of AI systems by providing them with the necessary tools to manage the knowledge generated by these same AI systems and by offering a Knowledge Manager's perspective on how to boost human-machine interaction.

Keywords: Artificial Intelligence, Knowledge Management, Internet of Everything, Chatbots, ChatGPT

1. Introduction

Artificial Intelligence (AI) has become an important and vast field with fast-growing usage recently (Liu *et al.*, 2018). Its applications range from natural language processing to predictive analytics, image recognition, etc. Nonetheless, as AI systems become more diverse and complex, they continuously require more sophisticated knowledge representation and management methods to support their decision-making competencies. The more AI studies and technology expand, the more it interacts with humans (Real de Oliveira and Rodrigues, 2021), thus increasing the need to coordinate human and AI systems' learning and knowledge-creation processes.

Research on Knowledge Management (KM) has focused on understanding the complex relationships between data, information, and knowledge creation, how they are impacted and benefited by the sources of data and information, and the contexts in which they are analyzed and shared (Philip, 2018). Research in the AI and KM fields of studies suggests a gap between those two, which needs to be filled so studies can continue (Jallow, Renukappa and Suresh, 2020). This work proposes an integrated framework to apply KM to support chatbot applications, adapted from the Internet of Everything Integrated Knowledge Management Model (IoE IKM Model) (Costa and Souza, 2022).

The original purpose of the IoE IKM Model was to assist in knowledge creation within the context of IoE applications (Costa and Souza, 2022). However, in this case, we will demonstrate how the model can be adjusted to incorporate KM (Knowledge Management) in the context of AI (Artificial Intelligence). We will achieve this by elucidating the development process of the IoE IKM Model, highlighting the commonalities between IoE and

general AI applications, and customizing the necessary elements to create our integrated KM framework, specifically designed to support AI chatbot applications.

2. Methodology

Design Science Research (DSR) is a research paradigm that employs the principles of Design Science to create artifacts, i.e., objects intentionally created by humans to solve practical problems. Within the domain of information systems design, the Soft Design Science Research (SDSR) methodology serves as an approach for artifact development. It encompasses the formulation of hypotheses, the construction of artifacts through experimentation, and the evaluation of results within a continuous iterative loop that iterates between the development of artifacts and the evaluation of these artifacts until their usefulness and validity are achieved and verified (Baskerville, Pries-Heje and Venable, 2009).

However, developing a new artifact from scratch is only sometimes necessary. Dresch (2021) suggests that, first, searching for an existing artifact that solves the overall problem is necessary. In this work, the practical problem could be summarized as follows: the lack of a framework that assists in managing the knowledge generated by artificial intelligence applications. Suppose an existing artifact has characteristics that identify it as a potential solution. In that case, this artifact should be addressed to ensure that the research is well-developed and will offer a relevant contribution to a specific class of problems (Dresch, Lacerda and Antunes Júnior, 2021).

Initially, we conducted a brief literature review on possible interactions between KM and AI. The practical problem to be solved was the potential need for a framework guiding the application of KM to AI applications. The research question was, "What are the possible theoretical models that integrate KM with AI applications?" This step is necessary to raise awareness of the problem. We were presented with some key concepts summarized in Section 3. The research returned an ideal ready-made artifact: the IoE IKM Model could solve our stated practical problem. Thus, Section 4 is dedicated to showing how the model can be effectively applied to solving the knowledge management problem of AI applications.

3. Key Concepts

Before introducing the framework that will ground this work, we shall discuss the nature of knowledge and its classification. Knowledge is divided into five categories: Explicitness, Structure, Trust, Outcome, and Act. For this work, only Explicitness will be addressed. The Explicitness category has three subcategories: Tacit, Explicit, and Implicit (Ein-Dor, 2008).

Tacit knowledge in AI refers to individuals' expertise, intuition, and skills in AI development and application. It is often difficult to express. It includes insights gained through experience, an understanding of complex patterns, and the ability to make intuitive decisions based on expertise. This tacit knowledge plays a crucial role in designing AI models, selecting appropriate algorithms, and making informed decisions during the AI development (Ein-Dor, 2008).

Explicit knowledge in AI refers to the knowledge that can be articulated, codified, and shared formally and systematically. It includes documented information, algorithms, models, datasets, and best practices that others can easily communicate and understand. It is typically stored in knowledge repositories, documentation, and technical specifications. It can be easily accessed, shared, and transferred between individuals and AI systems (Ein-Dor, 2008).

Implicit knowledge in AI refers to the knowledge embedded within the AI system or the data it processes. It is not explicitly expressed or documented but is derived from the patterns, correlations, and relationships discovered through AI algorithms and machine learning techniques. It is often hidden within large volumes of data and can be extracted through data analysis, pattern recognition, and machine learning models. It may involve insights and information that are not readily apparent or explicitly stated (Ein-Dor, 2008).

Next, we present the two main KM models that influenced the development of the IoE IKM Model: the SECI model (Nonaka and Toyama, 2003) and the SERI cycle (Kim, 2019). Their significance in KM studies cannot be overstated, as they, along with the Hierarchical Model for Knowledge Management proposed by Prat (2006), form the foundation of much of the KM methodology.

The knowledge-creation model expresses the SECI process (Nonaka and Konno, 1998), consisting of four knowledge conversion processes: Socialization, Externalization, Combination, and Internalization (Nonaka and Toyama, 2003). Socialization involves creating opportunities for individuals to interact, collaborate, and engage

in face-to-face or direct communication; Externalization involves articulating and expressing tacit knowledge in a form that can be captured and shared with others; Combination involves collecting, organizing, and synthesizing explicit knowledge from various sources to create new insights, perspectives, and ideas, and Internalization involves the absorption, assimilation, and internal adoption of explicit knowledge by individuals.

According to Kim (2019), the SERI cycle defines the evolution of products and services as a spiral trajectory encompassing four evolution quadrants: Servitization, Establishment, Reinforcement, and Infrastructure:

- *Servitization* represents the initial phase of the product or service evolution. In this stage, the focus is on shifting from a product-centric approach to a service-oriented approach. Companies have started to offer value-added services alongside their core products. For example, a manufacturing company may begin offering maintenance, repair, and training services related to their products.
- *Establishment* is characterized by the growth and consolidation of the service offerings. At this stage, companies refine their service capabilities and develop expertise in delivering the added services. They establish processes, frameworks, and service standards to deliver consistent, high-quality service. This quadrant is about solidifying the foundation of the service-oriented business model.
- *Reinforcement* is when the focus shifts towards strengthening the integration between the product and service components. The goal is to create a seamless and mutually beneficial relationship between the product and the associated services. This quadrant may involve enhancing product features to support better service delivery or adapting services to take full advantage of the product's capabilities. The reinforcement quadrant aims to maximize the synergy between products and services.
- *Infrastructure* represents the final stage of the SERI cycle. In this stage, companies develop the necessary infrastructure and systems to support the delivery of integrated products and services at scale. Infrastructure also includes implementing advanced technologies, establishing robust service management frameworks, and creating efficient service delivery and customer support processes. The infrastructure quadrant ensures the long-term sustainability and scalability of the integrated product-service system.

Finally, the Hierarchical Model for Knowledge Management proposed by Prat (2006) provides an effective conceptual representation of knowledge management from a strategic point of view and proved to be adequate for distinguishing knowledge management processes between strategic processes and operational processes, making it possible to abstract the concepts of value and trust (more strategic point of view regarding knowledge identification and evaluation), from the way knowledge is managed, shared and stored. The evaluation process guides the evaluation of knowledge, knowledge systems, and projects.

4. The IoE IKM Model

Gao et al. (2017) reviewed the definitions of KM. They concluded that despite the vast amount of definitions and descriptions of KM, the essence of KM is to support learning efficacy and integrate different information resources to improve competitiveness advantages. This work suggests using an integrated KM model to support the effective governance of AI applications and help managing the knowledge generated by them. The Internet of Everything Integrated Knowledge Management Model (IoE IKM Model) proposed by Costa and Souza (2022) will be adapted to harness the insights gained from intelligence sources in AI applications, considering AI enablers and observation capabilities, supporting governance and knowledge creation in the AI ecosystem.

The IoE IKM Model was developed by integrating service science and knowledge management research. It leverages awareness of intelligence sources in IoE applications, considering IoE enablers, observation capabilities, supporting e-governance, and knowledge creation (Costa and Souza, 2022). The model integrates the knowledge creation model (SECI process) and service evolution cycles to support the design of intelligent services centered around creating knowledge and value in the IoE context (Costa and Souza, 2022). Figure 1 shows a visua representation of the IoE IKM Model.

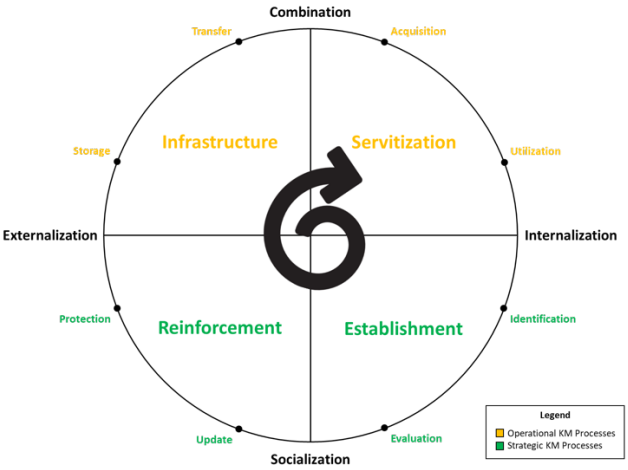

Figure 1: The IoE IKM Model, adapted from Costa and Souza (2022).

The purpose of the IoE IKM Model is to provide a specific knowledge management model that supports knowledge creation in IoE applications (Costa and Souza, 2022). As the model aims to facilitate KM by designing and implementing strategies that consider collaboration between machines, people, and processes, it appeared as a good choice for solving the practical problem stated before.

To adapt the work to AI applications, the focus should be on integrating AI algorithms into the existing knowledge-based strategy for machine-to-machine, human-to-human, and machine-to-human interactions in IoE applications. This integration would enhance the intelligent services provided by the applications by leveraging AI capabilities to process and analyze data more efficiently. Table 1 below shows the adaptations necessary in the defined contextual recommended activities that guide the application of the IoE IKM Model in order to create our AI-adapted IM Model.

Table 1: AI-adapted IKM Model. Adapted from Costa and Souza (2022).

AI-adapted IKM Model			
Service Design	**Knowledge Management Strategy**		
Service Cycle Process	**Knowledge Conversion Process**	**Knowledge Management Process**	**Contextual recommended activities**
Servitization	Combination and Internalization	Acquisition	Analyze data generated by various sources and devices, analyze generated social data to achieve collective intelligence, maintain context-awareness of social relationships from users and devices, maintain context-awareness of infrastructure capabilities as well as information semantic perspective, and support contexts for different individuals to internalize tacit knowledge using the explicit knowledge communicated through the AI applications.
		Utilization	Offer personalized services and customized content according to the user's social context, use of artificial social agents to generate and manage actionable social knowledge within the application environment, allow devices in the execution of automatic tasks without the involvement of the humans, support collaboration and cooperation between AI applications, maintain context-awareness and record the resulting interactions between humans and machines and learn by doing, and interact with analytical software to gain experience.
Establishment	Internalization and Socialization	Identification	Support intelligence orchestration in interactions between humans and machines, understand the AI contexts and customize services and applications accordingly, and foster human-to-machine interactions in a shared time and different places.

AI-adapted IKM Model			
Service Design	**Knowledge Management Strategy**		
Service Cycle Process	**Knowledge Conversion Process**	**Knowledge Management Process**	**Contextual recommended activities**
		Evaluation	Maximize the system knowledge about the social dimension of the users, maximize context-awareness of knowledge in AI applications, computational capability perspective as well as information semantic reasoning perspective, and evaluate knowledge sources, knowledge systems, and KM strategy for service evolution.
Reinforcement	Socialization and Externalization	Update	Develop machines' thinking abilities side-by-side with their social integration abilities, maintain tight coupling of AI techniques merged with the humans' and machines' social context, and cultivate a serendipitous environment through the collaboration of users of AI applications.
		Protection	Evaluate the trust level of AI-generated content, implement a social privacy preserving scheme to support trust, protect the social properties of users as sensitive information to support the customization of offered services, and provide a knowledge protection strategy on behalf of critical knowledge identified for AI applications.
Infrastructure	Externalization and Combination	Storage	Support data management activities at every application, involving pre-processing and filtering tasks, such as data aggregation and data compression, support data acquisition for future training of AI models and AI-generated content.
		Transfer	Use social networks to solve AI-related issues, support service recommendation system to leverage the social relationships between AI applications users, support a socially connected community of users, integrate communication and processing technologies near end-user devices, improve AI application performance and foster information exchange between users, and provide state-of-the-art technologies, software, databases, and repositories.

5. Evaluation

Many AI systems could have been used in this evaluation. A quick Internet search could find examples like BARD, Copilot, SciSummary, AI Lawyer, Dall-E, Midjourney, and Stable Diffusion, to name a few. For now, and for convenience, we will focus on the Large Language Models chatbot applications, which have Open AI's ChatGPT as the most popular. One of the various generative AI, i.e., AI capable of generating new content, such as text, images, or music, based on patterns learned from large datasets, the GPT-3.5 (Generative Pre-trained Transformer 3.5), a transformer-based language model capable of generating coherent and context-relevant texts. GPT-3.5 is trained using a large amount of textual data for translation, text summarization, and dialog generation, among other applications. ChatGPT is a specific implementation of the GPT-3.5 model focused on conversation. It can answer questions, provide information, assist with problem-solving, and engage in natural language dialogues.

The emergence of ChatGPT signifies the advancement of technologies facilitating processing, inference, and dissemination in the realm of information and knowledge. In the field of KM, which encompasses continuous processes such as acquisition, audit, organization, dissemination, value creation, and application of knowledge to achieve business goals, intelligent processing and communication technologies are particularly crucial (Hassanzadeh, 2022). Using these technologies will make access to specific knowledge faster and tailored to individual needs, solving problems related to content, language, and search skills. Dynamic and intelligent systems improve knowledge applicability, bridging the knowledge gap and promoting acquisition. Auditing and replacing outdated information enhances knowledge application (Hassanzadeh, 2022). ChatGPT presents an innovative opportunity for designers to acquire knowledge by providing a comprehensive and integrated platform for knowledge retrieval. Within this centralized system, designers can access a wide range of knowledge, including common sense, domain-specific, engineering, and technical knowledge (Hu *et al.*, 2023).

Integrating AI and KM can potentially boost innovations in diverse sectors such as wireless networks, education, healthcare, businesses, and organizations. Research indicates that AI has already made significant advancements in enhancing the quality and effectiveness of KM. It has proven beneficial in various areas, including knowledge acquisition, problem-solving strategies, knowledgeable tutoring, optimal solution systems, organization, and modeling (Taherdoost and Madanchian, 2023).

Thera are yet many more examples of contributions that ChatGPT in particular can make to the field of KM. Jarrari et al. (2023) highlight potential AI application in different KM processes such as sifting through organizational data and discovering relationships in knowledge creation processes, harvesting, classifying, organizing, storing, and retrieving explicit knowledge in knowledge storing and retrieving, and promoting equitable access to knowledge without fear of reprisal or social cost in knowledge application. Other authors state that organizations ma adopt ChatGPT to store, transform, and distribute organizational data (Korzynski *et al.*, 2023). However, we aim to take a different approach by showing how KM can contribute to AI applications.

The effectiveness of KM is increasing and fostering connections between knowledge and business tasks within organizations. AI agents assist in creating comprehensive conceptual networks, improving the understanding and utilization of organizational knowledge. We asked ChatGPT about how it could be used together with KM. More particularly, we started from the hipotetical existence of an implemented KM system that could benefit from ChatGPT. The question posed was “Imagine I already have a well-established Knowledge Management System (KMS) in my organization. Instead of using ChatGPT to improve it, I want to use it to enhance my interactions with ChatGPT. What would you suggest?” The suggestions given by ChatGPT and their relationship with our proposed AI-adapted IKM Model are shown in Table 2.

Table 2: How KM can benefit ChatGPT?

How KM can benefit ChatGPT?		
Suggestion	**Description**	**Relation with AI-adapted IKM Model**
Integration of ChatGPT with KMS	Integrate ChatGPT directly with your KMS so that it can access relevant information and provide more accurate and up-to-date responses based on the stored data.	Acquisition, Utilization and Identification processes.
Use of Plugins or APIs	If your KMS offers plugins or APIs, explore ways to connect ChatGPT to these resources so it can fetch real-time information and provide contextualized responses.	Transfer process.
Training ChatGPT with Data from the KMS	Feed ChatGPT with data from your KMS during training so that it can learn to interpret and respond to queries more accurately and relevantly.	Update and Storage processes.
Feedback and Continuous Learning	Use interactions with ChatGPT as an opportunity to provide feedback on the quality of responses compared to your KMS. This will help improve the model over time.	Utilization, Identification, Update and Storage processes.
Personalization of Responses	Configure ChatGPT to personalize responses based on specific information from your KMS, such as policies, procedures, or relevant documents.	Utilization, Identification, Update and Storage processes.
Monitoring and Performance Analysis	Track and analyze interactions with ChatGPT to identify areas for improvement and opportunities to optimize the KMS.	Update, Evaluation and Protection processes.
Integration with Workflows	Integrate ChatGPT with existing workflows in your KMS to automate tasks and improve operational efficiency.	Transfer process.

6. Discussion

As can be seen in Table 2, chatbot applications can benefit directly from specific KM processes taking place. The research showed relationships between contextual activities recommended by our AI-adapted IKM Model and the suggestions given by ChatGPT itself. The first one is that knowledge acquisition can enhance integration

between chatbots and a KMS, fostering human-to-machine interactions and helping Interternalization processes. If there are well-structured knowledge transfer processes, integrating a KMS using plugins and APIs to search for contextualized responses is possible. Knowledge transfer practices can also guarantee a good integration with existing workflows in a KMS to automate tasks. Knowledge storage processes can have multiple uses: stored knowledge can be used to train chatbots to give better answers and provide personalized responses. Knowledge storage itself can help make new knowledge generated by AI enduring. Knowledge evaluation and knowledge update processes have the potential to make the performance of AI systems even better. Even though the application of AI seems to be all beneficial, there are still some ethical discussions regarding the use of AI solutions.

Responsible AI entails the ability of AI to provide ethical and legally compliant guidance from a human-centric perspective. The research and development of natural language models significantly emphasize their reliability (Jang *et al.*, 2021). This reliability directly impacts the accuracy of the generated content, which in turn influences the acceptance and effectiveness of the AI. However, the presence of false and outdated information that carries inherent biases can lead to incorrect output, ultimately undermining the reliability of the AI system and eroding user trust.

Also, promoting transparency in AI is a crucial aspect of responsible development. As AI technology advances, the community has a growing consensus to prioritize transparency in decision-making systems. Transparency enables users to understand the underlying basis and sources of their responses, allowing them to verify the accuracy of the provided information (Felzmann *et al.*, 2020).

To address the lack of empirical evidence, we suggest that future research include an empirical study to validate and refine our AI-adapted IKM Model. This empirical study could involve implementing our model in various organizations, ranging from small businesses to large enterprises, ensuring broad applicability. Over six to twelve months, data could be collected on performance metrics such as response time, accuracy of responses, user satisfaction, and the efficiency of knowledge transfer and storage processes. Additionally, user feedback could be gathered through surveys and interviews to gain insights into the human-centric perspective on AI and KM integration.

Detailed case studies of these implementations could be documented, highlighting specific challenges, solutions, and the overall impact on organizational knowledge management and AI performance. These case studies would provide rich qualitative data and practical insights. Ethical considerations would be a key focus, assessing transparency, reliability, user trust in AI systems, data usage, and privacy.

Based on the empirical data, the effectiveness of our model could be evaluated, and areas for improvement could be identified, refining the model to enhance its practical applicability and address any shortcomings. This comprehensive empirical study would provide robust evidence supporting our theoretical framework and demonstrate its real-world effectiveness, contributing significantly to the broader field of knowledge management and artificial intelligence integration.

7. Conclusion

Artificial Intelligence (AI) has grown significantly in recent years. However, there is a gap between this rapid growth and our ability to harness the full potential of knowledge generated by AI-based systems. The field of Knowledge Management (KM) can not only benefit from the application of AI but also provide the theoretical framework and best practices necessary to bridge the existing gap between the two areas. Thus, if correctly applied, KM processes can also enhance AI-based systems and applications.

This work has contributed to the effort to strengthen the relationship between AI and KM by suggesting the adaptation of a KM model initially developed for Internet of Everything applications. This model can be easily adapted for AI application KM, with the necessary adaptations presented and discussed. An evaluation of how appropriate this adaptation was has also been made, specifically for chatbots.

The objective was to pinpoint an effective framework that could seamlessly integrate KM principles into AI applications. Amidst the vast literature, the focus was on finding a holistic framework that clearly merges KM with AI. This endeavor was motivated by the need for a structured method that ensures the efficient use of knowledge assets in AI systems, thereby enhancing their functionality. The aim was to fill the existing knowledge gaps and offer organizations a definitive, actionable guide for incorporating KM in their AI initiatives, effectively enhancing AI's capabilities through the strategic management of knowledge.

When it comes to AI applications such as chatbots based on Large Language Models like ChatGPT, we evaluated the suitability of our adapted KM model for AI by asking ChatGPT itself what possible contributions knowledge management—or an already implemented knowledge management system—could bring to the use of applications like ChatGPT. We concluded that each suggestion would be related to a KM process in the model and to the contextual recommended activities freely adapted from the original IoE IKM model.

The evaluation of the model was limited and represents only a suggestion for the application of our AI-adapted IKM Model. Further testing must be done for the model to prove helpful in incorporating KM practices into the development of AI applications. It would be interesting for the KM field to obtain evidence that the application of KM techniques does indeed bring tangible and measurable benefits in terms of AI system performance. Confirmation of this point could renew interest in the area of KM applied to knowledge generated by AI. Another possible future work would be the development of strategies to externalize the implicit knowledge in algorithms and already trained systems.

In conclusion, integrating knowledge management processes with artificial intelligence applications, particularly chatbots, presents significant potential for enhancing technological and organizational efficiencies. Our AI-adapted IKM Model's theoretical framework offers a structured approach for this integration, detailing the benefits of knowledge acquisition, transfer, storage, and evaluation in AI contexts. Although our study primarily focuses on theoretical insights, future empirical research could provide concrete validation of these concepts. By implementing our model in diverse organizational settings and collecting performance data, we could offer robust evidence of its practical applicability and effectiveness. This empirical work would substantiate our theoretical claims and contribute to refining the model, ensuring it addresses real-world challenges and optimizes AI functionalities. Ultimately, this dual theory and empirical validation approach would provide a comprehensive understanding of the relationship between knowledge management and artificial intelligence, paving the way for more efficient, transparent, and user-centric AI systems.

We expect this work to be helpful for those whose professional activities may involve the usage of AI systems by providing them with the necessary tools to manage the knowledge generated by these same AI systems and by offering a Knowledge Manager’s perspective on how to boost human-machine interaction.

Abstract: The ability to support both strategic and operational management with data-informed insight can generate significant benefits for organizations. Industries continue to become increasingly data-driven, and organizations continue to develop their business analytics capability to seize the value potential embedded in data. Consequently, organizations are investing in data and technology resources and, to leverage these investments, also in human and intangible resources, such as technical skills, managerial skills, and data-driven culture. While the integral role of human skills in an organization's business analytics capability is widely acknowledged within the extant research literature, there is much less discussion and evidence on how organizations develop these skills. However, such investigation would help provide organizations with new perspectives on maximizing the business value of their business analytics capability investments. Using 36 semi-structured interviews, this study explores what kind of measures organizations apply to develop the skills of their analytics professionals. Building on the extant business analytics capability literature and the resource-based view of the firm, this study contributes by deepening the current understanding of the development of human skills in building a well-functioning business analytics capability. Our findings show that, besides technical and managerial skills, organizations should also proactively develop the collaboration skills of their analytics professionals. The practical examples of skills development measures described in this study, such as job rotation, mentoring and role overlaps, provide new ideas for analytics professionals and decision-makers to enhance their business analytics capability development.

Keywords: Business Analytics, Capability Development, Technical Skills, Managerial Skills, Data-Driven

1. Introduction

Business analytics capability (BAC), defined as an organization's ability to effectively leverage its data, technology, and talent to generate data-driven insight (Kristoffersen et al, 2021) is a widely discussed concept among information systems and management science scholars. Since the first conceptualizations (see, e.g., Cosic et al, 2012; Cosic et al, 2015; Gupta and George, 2016), it has been leveraging the resource-based view (RBV) of the firm (Barney, 1991; Penrose, 1959) to elaborate those resources the organizations should possess and combine to form a well-functioning BAC that helps them create value.

As part of the discourse on human and intangible business analytics (BA) resources, several scholars have been seeking to identify what kind of human resources are essential for forming a successful BAC, as well as what is the role of intangible resources, such as the intensity of organizational learning and data-driven culture. The extant literature on human BA resources has extensively focused on listing various human BA skills (see, e.g., Cosic et al, 2015; Qin et al, 2023) and emphasizing the importance of developing those skills (see, e.g., Shao et al, 2023). While such research has helped scholars and managers to understand the significance of human BA skills when forming BAC, it does not offer many practical examples of how organizations develop their human BA skills.

In this study, we explore what kind of measures organizations apply to develop their human BA skills. First, we describe the current literature on BAC and especially the human BA skills and their development. After this, we introduce our research approach, followed by the empirical findings on the observed measures for human BA skills development. Finally, we discuss how this study relates to the extant literature on human BA skills, and how our findings can support both scholars and organizations to increase their understanding of human BA skills development.

2. Theoretical Background

2.1 Business Analytics Capability

This study draws on the resource-based view of the firm (RBV), especially its sub-streams of resource combination (Penrose, 1959), complementarity (Harrison et al., 1991), relatedness (Dierickx and Cool, 1989, and co-specialized resources (Lippman and Rumelt 2003), as well as the emerging discussion on BAC (e.g., Cosic et

al. 2015; Gupta and George, 2016). As per the theoretical underpinnings, firm resources could be far more valuable if they are combined and used together instead of in isolation (Penrose, 1959). By combining complementary, related, and co-specialized resources firms can establish capabilities that help them undertake productive activities through simultaneous deployment of their resources (Lockett et al., 2009; Teece et al., 1997).

In essence, BAC is conceptualized as a multidimensional third-order formative construct, comprising three BA-specific dimensions (i.e., resource categories), including: tangible resources, human resources, and intangible resources (Gupta and George, 2016; Kristoffersen et al, 2021; Mikalef et al, 2020). These dimensions are conceptualized as second-order formative constructs, encompassing seven first-order constructs (Figure 1): tangible resources include data, technology, and financial investments, human resources consist of technical and managerial skills, and data-driven culture and intensity of organizational learning are considered intangible resources, whereas BAC itself is an outcome of an organization-specific combination of these resources (Gupta and George, 2016; Mikalef et al, 2020).

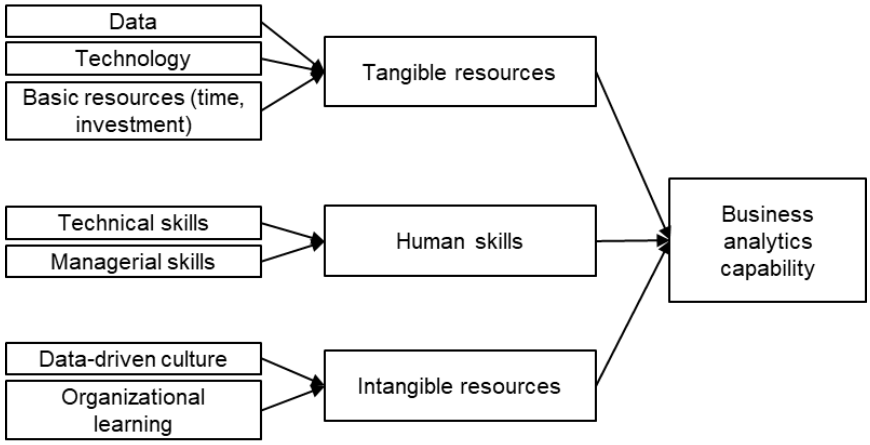

Figure 1: Business analytics capability as construct of tangible, human and intangible resources (e.g., Gupta and George, 2016)

The formative nature of BAC indicates that a firm-specific combination of data, technology, basic resources, technical skills, managerial skills, data-driven culture, and organizational learning are required to establish the capability (Gupta and George, 2016). Having a suitable combination of tangible (also called infrastructure), human, and intangible BA resources is touted as a crucial feature for establishing a well-functioning BAC (Mikalef et al, 2020; Morimura and Skagawa, 2023).

2.2 Human BA Skills

The role of human resources and especially human BA skills is pronounced in the previous literature. For instance, Fosso Wamba et al (2017) conclude that the expertise of analytics personnel is more important for organizations than analytics infrastructure or analytics management in general, and it should be managed dynamically. Further, Kristoffersen et al (2021) warn firms not to focus too much on tangible resources (i.e., data and infrastructure), as the investments targeted on human talent and data-driven culture are equally important for establishing BAC and reaping business benefits.

Human BA resourcesarerequired not only to operate and use BA but also its output. This requires people involved in BA-related activities to possess adequate technical and managerial skills (Gupta and George, 2016; Shamim et al, 2019). Technical BA skills refer to the ability to use BA technology to produce the intended outputs (Gupta and George, 2016; Mikalef et al, 2019), such as skills related to data management and utilization, modeling, and improving the performance of analytical models (Cosic et al, 2012; Srivastava and Dixit, 2023). The technical skills required from the analytics professionals highly depend on the data and technology resources they have at their disposal, but also on the intended use of analytics (Qin et al, 2023; Srivastava and Dixit, 2023). Managerial BA skills are described as a combination of the individual's business acumen and an adequate level of understanding of data and analytics processes, as these help them to understand how BA output is generated and what are those decision-making situations it can be applied in (Carillo, 2017; Mikalef et al, 2019; Shamim et al, 2019; Srivastava and Dixit, 2023). Certain coordination skills, such as resource

management skills (Srivastava and Dixit, 2023) and setting goals and monitoring analytics performance (Cosic et al, 2012) are also required from those who run and develop BA.

Whereas the extant literature seems to agree on the importance of technical BA skills and managerial BA skills as crucial elements of BAC, also skills that facilitate collaboration between business and analytics professionals are important for well-functioning BAC (Carillo, 2017). People leveraging BA should also be endowed with a certain attitude that promotes the collaboration and innovative use of BA (Cosic et al, 2012). Analytics professionals should be able to enhance analytics understanding within the organization, e.g., when they communicate and present their findings to business managers (Carillo, 2017). To be able to collaborate with business managers, analytics professionals should also understand the business they are supporting (Cosic et al, 2012; Ghasemaghaei et al, 2018). For this study, we have combined these skills into one category, describing the collaboration skills needed for operating BAC. A summary of the three categories of human BA skills identified in the extant literature can be found in Table 1.

Table 1: Summary of the three human BA skill categories described in the extant literature.

Category	Description	Related literature
Technical BA skills	Ability to use data and analytics technology to produce intended BA outputs	Cosic et al, 2012; Gupta and George, 2016; Mikalef et al, 2019; Qin et al, 2023; Srivastava and Dixit, 2023
Managerial BA skills	Ability to understand how BA output is generated and where it can be applied Ability to manage BA work and monitor BA performance	Cosic et al, 2012; Gupta and George, 2016; Carillo, 2017; Mikalef et al, 2019; Shamim et al, 2019; Srivastava and Dixit, 2023
Collaboration skills	Communication skills, presentation skills, business understanding, proactive attitude	Cosic et al, 2012; Carillo, 2017; Ghasemaghaei et al, 2018

The extant literature provides various listings of human BA skills that would support organizations in establishing a well-functioning BAC. However, the actual measures that organizations could apply to develop their human BA skills have received significantly less attention. Therefore, it is worthwhile to take a closer look at how organizations develop their human BA skills in practice to ensure a well-functioning BAC.

2.3 Developing Human BA Skills

Organizations' growing need to develop their BAC has increased the demand for human BA skills in the job market (Qin et al. 2023). Possessing a set of human BA skills, however, does not alone guarantee that an organization could be able to leverage these skills to establish a well-functioning BAC (Srivastava and Dixit, 2023). Recent studies have continued to emphasize that organizations should pay increasing attention to continuously develop their employees' BA skills to enhance their performance on individual level (Shao et al, 2023) but also to improve data-driven decision making on organizational level (Srivastava and Dixit, 2023). While the extant management literature contains excellent examples of potential measures for skills development in organizations, it has not been examined, how these measures are applied when developing human BA skills.

Learning takes place continuously and on different levels within organizations, and a large share of individual-level skills that are relevant to conducting organization-specific work tasks are learned as part of everyday work practices and interaction at the workplace (see, e.g., Brown and Duguid, 1991; Tynjälä, 2008). It should be acknowledged that the human BA skills introduced in the extant literature are already based on empirical data, and thereby can be considered as a solid representation of skills that are relevant for operating and leveraging BA in practice.

To enhance the learning of individual employees, organizations can support skills development with various measures (Huselid, 1995; Manuti et al. 2015), including, e.g., job rotation, specific training programs, mentoring programs, talent management programs, or communities of practice for knowledge sharing purposes. Each organization differs in what kind of measures they prefer to apply (Tynjälä, 2008). In this study, we address the question of what kind of measures organizations apply to intentionally support and foster their human BA skills development. Next, we explain how we approached such an endeavor in this study.

3. Methodology

3.1 Data Collection

While the extant literature has mostly focused on identifying the required human BA skills for building a well-functioning BAC, how these skills are developed is a rather unexplored phenomenon. This study pursues to commence this discourse by sharing the observations on measures applied in organizations. To enable collecting novel insight on this topic, we chose to conduct a qualitative inquiry (Timmermans and Tavory, 2012).

The empirical context of this study was informed by the framing of an ongoing research project that had been established to investigate BA usage and development in large Finland-based organizations. To identify suitable informants, we asked these organizations to name informants they considered capable of providing input on BA usage and development (an approach complying with criterion sampling, see, e.g., Patton, 1990). For data collection, we decided to use semi-structured interviews, as this enabled us to adjust the interview themes depending on the role of the interviewee (Qu and Dumay, 2011). Our data was collected between September 2022 and January 2023, and it consisted of 36 interviews that were transcribed with the help of a third-party service provider.

3.2 Data Analysis

The focus of our data analysis was to identify those measures that organizations have applied to develop their human BA skills. Our analysis proceeded through three phases described in Figure 2.

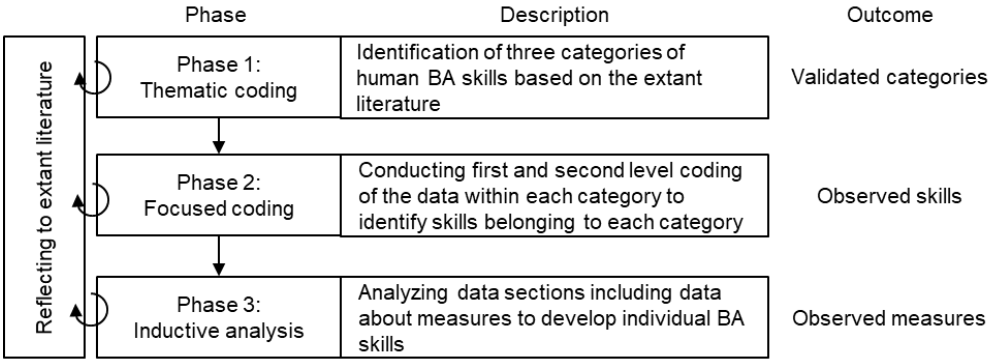

Figure 2: Three-phase analysis approach applied in this study.

Phase 1 had an objective to understand which of the human BA skills observed in previous literature were observable in our data. Hence, we chose to start our analysis by reflecting our data on human BA skills identified in the extant literature in a deductive manner (Fereday and Muir-Cochrane, 2006; Timmermans and Tavory, 2012). This was done as thematic coding, using the three human BA skills categories identified in the extant literature as a starting point (see Table 1).

For Phase 2, we moved into focused coding to further identify the individual skills under each of the three categories we had already used to categorize our data during Phase 1. During this phase, we also continuously returned to extant literature to validate our coding. As a result of the second phase, the structure consisted of three levels of coding (see, e.g., Saldaña, 2013): 1) aggregated third-level codes to describe the categories identified in extant literature (Technical BA skills; Managerial BA skills; and Collaboration skills); 2) thematic second-level codes describing skills within these categories; and 3) focused first-level codes to describe the more granular sub-areas under each skill.

After examining our data from the perspective of human BA skills, we moved on to Phase 3, where we applied a more flexible inductive analysis approach (Timmermans and Tavory, 2012) to identify, what kind of skills development measures we were able to observe from those sections of our data where any of the human BA skills were discussed. Through cross-comparison of our findings, triangulated both between the authors as well as between the data from individual informants (see, e.g., Shenton, 2004) we identified measures that we were able to link to developing specific skills. A summary of these findings is included in Table 2.

Finally, we used our data structure and inductive observations as a basis to form a narrative report of our empirical findings (see, e.g., Krippendorff, 2019) regarding the development of each of the identified categories of human BA skills: technical skills, managerial skills, and collaboration skills.

4. Empirical Findings

4.1 Development of Technical BA Skills

Technical BA skills consist of various skills that are required to leverage an organization's tangible BA resources, such as data and technology (Gupta and George, 2016). According to our informants, the needs for technical BA skills are mostly connected to analytics technologies and tools that the organization has invested in. Examples of such skills identified in our analysis include using various analysis and modeling tools; ensuring analytics output quality; building and maintaining analytics-related tools and services; and – as a skill enabling the other technical BA skills – the ability to identify and apply suitable methods and approaches. Skills related to data management and utilization were emphasized by most of the informants, independent of how they had described the role of other technical BA skills.

Based on our observations, the analytics professionals develop their technical BA skills mainly by attending trainings arranged by external vendors. Analytics professionals also attend analytics-related communities inside and outside organizations to learn from other analysts. Additionally, analytics team managers seem to enable learning at the workplace by offering opportunities for job rotation and to some extent, allowing overlaps in the roles of individual analysts to support peer-to-peer learning. Senior analytics professionals also intentionally get engaged as sparring partners with their more junior colleagues, which we interpreted as a form of workplace mentoring. Our data also indicate that organizations that consider having major gaps in their existing technical BA skills tend to either recruit new analytics professionals with these skills or contract external consultants to temporarily fill in the need for such skills, instead of assuming their existing analytics professionals to develop these skills for themselves.

4.2 Development of Managerial BA Skills

Regarding managerial BA skills, we observed three types of skills that were directly related to BAC. First, analytics professionals are expected to be able to plan, manage, and deliver analytics projects and initiatives. Second, they also need to monitor the value generated through these projects and communicate it to various stakeholders in their organization. Third, our data suggest that individual analysts are often expected to work rather independently, and to organize and manage their own work.

Senior analytics professionals support their more junior colleagues to help develop their skills and improve their readiness to start managing analytics projects and initiatives and monitoring and communicating the value resulting from these projects and initiatives. However, managerial skills, and especially the self-organizing skills in general do not seem to be supported with other development measures. Instead, we paid attention to some of our informants explaining that certain managerial skills and proactive attitude are used as criteria when selecting new members for the team.

4.3 Development of Collaboration Skills

In contrast to technical and managerial BA skills, collaboration skills are not an established concept within BAC-related literature, yet it has been discussed in earlier research. Our data show that analytics professionals collaborate with various intra-organizational stakeholders, such as business managers and their team members, business controllers, other analysts in their own team and across other teams, as well as information systems professionals. They are also involved in inter-organizational collaboration with external consultants and to some extent fellow analytics professionals from other organizations, such as technology vendors. Based on the extant literature, however, skills that can be linked to collaboration with relevant analytics stakeholders are facilitation and presentation skills, business understanding, and a set of skills that form what we have named a “proactive attitude” (see Table 1).

Based on our data, facilitation, and presentation skills are important in many aspects. Whereas presentation skills often manifest through the ability to document and visualize analytics outcomes, analytics professionals are often also expected to present their output to decision-makers and facilitate the discussion during the presentation. Such activities assume them to be able to adjust the level of details in their presentation according

to the audience, as well as apply a conversational approach that enables their audience to understand how the output has been formed and what it means from decision-making perspective. Our data also suggest that an effective measure for developing these skills is to involve more junior analysts into situations where they can learn such skills by shadowing their more senior colleagues.

We also found a strong indication that facilitation skills are required to establish a longer-term collaboration with different analytics stakeholders. Ability to facilitate continuous collaboration and dialogue seems to help analytics professionals to adjust their work based on the business needs and thereby increase the relevance and value delivered by analytics. Additionally, analytics professionals are expected to share analytics-related knowledge and educate their stakeholders, such as business managers and information systems professionals, on analytics-related matters. While these skills emerged through our analysis, we did not identify any evidence in our data of intentional measures to develop these skills, and unlike facilitation and presentation skills concerning the presentation of analytics output, these facilitation skills are not highlighted within the extant BAC literature.

In addition, business understanding is an enabler of collaboration, especially between analytics professionals and business decision-makers. Understanding the internal and external business logic, such as internal processes or industry and market dynamics, combined with the ability to identify business side needs, helps analytics professionals create analytics models that produce the intended output. Therefore, it is connected to the ability to document and visualize analytics outcomes on shorter term but also to the ability to establish a longer-term collaboration with business stakeholders.

Business understanding develops as part of collaboration between business and analytics, and organizations also expect their analytics professionals to proactively accumulate their business understanding as part of their work. To develop business understanding of their analytics professionals, organizations involve them in business meetings and forums on a permanent basis, allow analytics professionals to move between analytics and business roles as part of career development plans, and offer them opportunities to work with various business stakeholders. We also found some indication that business experience and understanding may be valued when recruiting new analytics professionals.

Lastly, we observed a group of "skills" that can be described as individual characteristics or behaviors expected from analytics professionals. These include, e.g., willingness to learn, ability to think critically and to challenge the status quo, creative mindset, and proactive approach to networking and communication. While these characteristics may not be categorized as skills, they may represent the attitude described by, e.g., Cosic et al (2012), and we decided to include them into this category. What comes to achieving such a proactive attitude, our data suggest that this – similarly to the managerial BA skills – is a criterion when hiring new analytics professionals.

Table 2: Summary of empirical findings.

Category	Observed Skills	Observed Measures
Technical BA skills	Managing and utilizing data; Using analysis and modeling tools; Ensuring quality of analytics output; Building and maintaining analytics-related tools and services; Identifying and applying suitable methods and approaches	Participating in externally organized trainings Intra- and inter-organizational analytics communities Job rotation between analytics roles Role overlaps Mentoring Recruitments, temporary hires (consultants)
Managerial BA skills	Planning, managing, and delivering BA-related work and projects; Monitoring and communicating value through analytics; Organizing own work	"Assumed" from new hires Mentoring
Collaboration skills	Facilitation and presentation skills	Job shadowing
	Business understanding	Permanent roles of analytics professionals in business meetings and forums Job rotation between analytics and business roles Offering opportunities to collaborate with various business stakeholders Recruitments
	Proactive attitude	"Assumed" from new hires

5. Discussion and Conclusions

Building on the extant literature on the RBV (e.g., Barney, 1991), resource combination as means to achieve competitive advantage (Lockett et al. 2009; Teece et al. 1997), and the emerging BAC (see, e.g., Gupta and George, 2016) and human BA skills (see, e.g., Srivastava and Dixit, 2023) literature, our study goes beyond the state-of art by offering the first glimpse on the measures that organizations apply to develop those skills.

Our study contributes to extant research in three ways. First, it helps validate the suggested scope of technical BA skills and managerial BA skills already outlined in the extant literature (see, e.g., Gupta and George, 2016; Mikalef et al, 2019; Srivastava and Dixit, 2023). Our analysis shows that the existing high-level descriptions of the technical and managerial BA skills form a solid basis for examining BA skills in organizations and can be applied deductively in qualitative data analysis. On more detailed level, the technical BA skills also seem to vary between organizations, depending on the data and technology resources as well as the intended scope of BA in each organization (Qin et al, 2023; Srivastava and Dixit, 2023). For organizations that aim to develop and improve their BAC, this indicates that they are likely to achieve good results by aligning their BA strategy and technical BA skills, instead of following, e.g., industry trends in terms of talent acquisition.

Second, it combines the various collaboration skills mentioned by, e.g., Cosic et al. (2012), Carillo (2017), and Ghasemaghaei et al (2018), and extends this skill category with additional findings on facilitation skills that promote longer-term collaboration and education of analytics stakeholders, as well as a proactive attitude that represents the individual characteristics expected from analytics professionals. While the human BA skills discussed by our informants were mostly consistent with those human BA skills recognized in the extant literature, collaboration skills received significantly more attention from the informants than the technical and managerial BA skills. Therefore, while our study encourages organizations to continue developing their human BA skills with a wide scope, it highlights the key role of collaboration skills in a well-established BAC and points out the facilitation skills and a proactive attitude as potential new focus areas that could help organizations reap more benefits from their BAC.

Third, it goes beyond the extant BA literature by introducing a set of measures applied in organizations to achieve and develop human BA skills, providing BA scholars and practitioners with a new layer of actionable knowledge on the top of BAC frameworks. Based on our findings, organizations hire analytics professionals mainly when they need to add completely new technical BA skills. As part of the recruitment process, organizations also evaluate candidates based on their collaboration skills, such as business understanding and attitude. Organizations may also fill in the skill gap temporarily by using consultants. Human BA skills are also developed using several measures, such as enabling job rotation within analytics and between analytics and business, offering opportunities for job shadowing, mentoring and peer-to-peer learning, involving analysts in business meetings and forums, and allowing analytics professionals to attend specific (mainly external) trainings to develop their technical BA skills.

The observations made during this study also generated some future research ideas. The extant research already includes manifestations about how business managers should be interested in learning about analytics processes and the potential benefits of using BA to support their decision-making (Carillo et al, 2019; Chen and Nath 2018; Peterson et al, 2023), and thereby understanding the BA skills required from business managers, as well as how to develop them would increase understanding on how to establish a well-functioning BAC. Also, the significance of organizational learning as a crucial element of BAC indicates the dynamic nature of this capability, and organizations should nurture their organizational learning culture to continuously develop their human BA resources and skills (Mikalef et al, 2019; Shao et al, 2023). Thereby, understanding organizational learning mechanisms (see, e.g., Argyris and Schön, 1996) and applying them to identify innovative mechanisms for human BA skills development might help organizations to create a BAC that enables them to achieve competitive advantage.

Simultaneously, the limitations of this study should not be ignored. While the number of interviews forming the empirical data of this study can be considered to provide an adequate basis for conducting a qualitative analysis (Saldaña et al, 2011), our data is collected among large Finland-based organizations and is thereby geographically and contextually limited. We have also aimed at reporting our analysis approach in a transparent manner. However, we also see that further examination of the topic within other contexts (e.g., different geographies, different company sizes) and conducted by other scholars would further support forming an understanding of potential measures for developing human BA skills in organizations.

Study of the Level of Innovation in the European Union: Poland Compared to the Leading Countries

Zuzanna Ostraszewska and Agnieszka Tylec
Czestochowa University of Technology (CUT), Częstochowa, Poland

zuzanna.ostraszewska@pcz.pl
agnieszka.tylec@pcz.pl

Abstract: Knowledge and innovation are key resources of modern economies. The ability to transform knowledge into new products, technologies, marketing methods and organizational solutions (and thus into broadly understood innovations) is not only the basis of entrepreneurship, but also the foundation for building competitive advantage. Thus, supporting innovation remains the main challenge for managers and staff in power, and the very concept of innovation in enterprises, regions and countries is rightly considered an important area of research. Innovation is therefore an economic category that is measurable. The theory and practice of economic life have allowed the development of a number of metrics for measuring innovation, enabling the assessment of not only its level, but also the source of the innovative potential of individual entities. Taking into account the above, the article presents the results obtained by the EU and its individual countries, based on short theoretical considerations regarding the essence of innovation and the methodological basis for its measurement by the European Commission (in the annual European Innovation Scoreboards EIS using the Summary Innovation Index - SII). The basis for the study is the data contained in the EIS from 2016-2023. The article uses the method of analysis, synthesis and graphical presentation of data. The research focused on Poland and Denmark, which was the leader in innovation in the last study, overtaking the long-term front-runner Sweden.

Keywords: Innovation, Summary Innovation Index

1. Introduction

Innovations are currently treated as one of the most progressive factors of competitiveness, growth and development. Supporting innovation therefore remains the main challenge for managers and staff in power, and the very concept of innovation in enterprises, regions and countries is rightly considered an important area of research (Szklarz et al, 2021; Bielińska-Dusza and Hamerska, 2021; Stojanović, Puška and Selaković, 2022). Innovation is therefore an economic category that is measurable. The theory and practice of economic life have allowed the development of a number of metrics for measuring innovation, enabling the assessment not only of its level, but also the indication and assessment of the sources of innovation potential of individual entities (Krawczyk-Sokołowska, Pierscieniak and Caputa, 2021). Without a doubt, a special area of interest in this matter is human capital: knowledge, entrepreneurial attitudes and appropriate resource management. The above may be confirmed by the fact that the above-mentioned categories were included in the structure of the Summary Innovation Index, a measure used by the EU to monitor the innovation of its countries.

The aim of the article was to conduct an analysis of the level of innovation in Poland compared to EU countries, with reference to nations that have been innovation leaders for years. The study was based on the latest European Innovation Scoreboard (EIS 2023) data. The countries, to which the results obtained by Poland were referred, are Sweden (the leader in previous years) and Denmark, with the best results among all EU countries in 2023. Indirectly (due to the interdependence of knowledge and innovation) this will allow us to determine how Poland uses knowledge and the potential of its resources compared to other countries. In the era of globalization and the race of economies, innovation and knowledge - as their sources - have become particularly important. Therefore, conducting dedicated research and showing the results, as presented in the article, is important due to the need to monitor this phenomenon. This allows us to determine the level of innovation in individual countries and the factors determining it (developing and inhibiting it). They can thus become a contribution to identifying the directions of necessary changes and optimizing decision-making processes in this area.

To achieve the indicated goal, first of all, short theoretical considerations were presented in the field of the essence of innovation and knowledge as its basis. Then, the methodological assumptions for measuring innovation in the EU using the Summary Innovation Index and the data taken into account when determining the level of innovation in individual countries and the entire EU are presented. The essential part of the presented considerations is a descriptive and graphical presentation of the level of innovation in the EU and member states, with particular emphasis on the comparison of the results obtained by Poland with the results of countries placed on the innovation map in the Innovation Leaders group. The presented data will allow for the identification and preliminary comparisons to other EU countries of Poland's innovative potential, based, in

the authors' opinion, mainly on knowledge and financial resources. At the same time, it is an introduction to further work, in which Poland's innovation profile will be determined based on the decomposition of the SII index. The results of this work will be presented in the publication: "Analysis of Poland's innovation profile based on the decomposition of the Summary Innovation Index (SII)".

2. Knowledge as the Basis for Innovation - Outline of the Issues

Innovation and knowledge are basic components of the development of enterprises, countries, economies and various organizations. Innovation-oriented entities are modern knowledge enterprises. These entities recognize its power and see it as a key factor in shaping competitive advantage, resulting from the ability to transform knowledge into new products, services, technologies, marketing techniques and organizational solutions, i.e. into innovations. When analysing the issues of knowledge and innovation, it is impossible not to notice a certain interdependence. Without appropriate knowledge potential, it is difficult to plan and implement any changes and innovations. On the other hand, innovations create demand for new areas of knowledge (Kokot-Stępień and Krawczyk, 2023; Chomać-Pierzecka, 2018). Going further, the greater the knowledge in the field of innovation processes, the more productive are human resources, which translates directly into an increase in knowledge capital and innovation capital (Myjak, 2022).

It is obvious that the scale of innovative activity is determined by the innovative potential of organizations, the use of which in an effective manner means having innovative capacity (including the creative creation process). Managerial and employee competencies are assumed to be the key determinants of building and developing innovative capacity - in particular "inside" knowledge (creativity and knowledge of employees, databases held by the enterprise/organization) and knowledge obtained from outside. Other elements include: modern infrastructure, work organization, cooperation in knowledge management (i.e. building knowledge alliances with clients and other entities and using open sources of knowledge, purchasing technology (Karaś, 2021; Haberla and Kuźmińska Haberla, 2013). The process of converting external knowledge into internal knowledge and back into external knowledge - materialized in innovations - is also considered particularly important in the innovation process (Baruk, 2016; Castaneda, and Cuellar, 2020).

Innovation and innovativeness are identified with novelty, or more precisely, with beneficial novelty that will not exist without scientific and technical knowledge. Innovation is a category with a large semantic capacity. This results in numerous definitions and taxonomies (Ostraszewska and Tylec, 2017; Kogabayev and Maziliauskas, 2017; Taylor 2017), with particular importance given to the interpretation contained in the Oslo Manual (2018), which allows for distinguishing individual types of innovation, as well as its important feature indicating that the innovation must find practical application. Thus, the term "innovation" means "a new or improved product or process (or combination thereof) that differs significantly from the entity's previous products or processes and which has been made available to potential users (product) or put into use by the entity (process)". According to this definition, there are two main types of innovations, i.e. product innovations (new or improved product/service) and business process innovations. In the previous edition of the Manual (2005), four of them were distinguished, i.e. product, process, marketing and organizational innovations (OECD, 2018). Quoting the above definition here is important because the Oslo methodology is used by Eurostat (including the EIS) and is the basis for developing the Summary Innovation Index (SII), which is a set of sub-indicators grouped into dimensions and categories (Onea, 2020; Janoskova and Kral, 2019).

3. The Essence of Measuring Innovation with the Summary Innovation Index (SII)

The analysis of the literature on the subject allows us to conclude that various and extensive tool sets and measures have been developed that can be used to assess the level of innovation of countries or enterprises. At the same time, methodological problems are identified in the construction of the measures themselves, which makes it difficult and sometimes impossible to conduct analyses and make comparisons (Podstawka, 2021; Szuper, 2021). Therefore, there is no ideal model of the innovation research system. The SII Summary Innovation Index used by the EU - despite its limitations - allows for a synthetic assessment of the innovativeness of EU countries and for making appropriate comparisons (Mikołajczyk, 2016). The SII index is a composite index calculated (since 2001) on the basis of sub-indexes, grouped within categories and dimensions. Tables 1-3 present the categories and dimensions of the indicator, divided into the last 3 periods in which its significant modifications were made. The last major revision took place in 2021. As a result, the SII indicator from 2021 is a set of 32 sub-indexes grouped into 4 main categories and 12 dimensions of innovation (European Commission, 2022; European Commission, 2023).

Table 1: Categories and dimensions of SII sub-indexes in 2010-2016

	Categories and dimensions of SII sub-indexes (2010-2016)		
	Catalysts	**Firm activities**	**Outputs**
Innovation dimensions	Human resources	Firm investments	Innovators
	Open, perfect and attractive research systems	Relationships and entrepreneurship	Economic effects
	Finance and support	Intellectual assets	
25 indicators

Table 3: Categories and dimensions of SII sub-indexes in 2021-2023

	Categories and dimensions of SII sub-indexes (EIS 2021-2023)			
	Framework conditions	**Investments**	**Innovative activities**	**Impacts**
Innovation dimension	Human resources	Firm investments	Innovators	On employment level
	Attractive research systems	Finance and support	Linkages	On sales level
	Digitalisation	Use of information technologies	Intellectual assets	Environmental sustainability
32 indicators				

Source: own elaboration on European Commission, 2022; European Commission, 2023.

In previous years, the SII index included (European Commission, 2016, European Commission, 2018, European Commission, 2020):

- 25 indicators, 3 categories, 8 dimensions (2010-2016),
- 27 indicators, 4 categories, 10 dimensions (2017-2020).

The SII index ranges from 0 to 1. The closer to 1, the higher the level of innovation of a given country. Currently, this indicator is calculated based on 32 sub-indicators (Crisan and Stanica, 2022; Šofranková et al, 2022). Based on the value of the indicator and its level in relation to the EU average, belonging of a given country to one of the four groups of innovation efficiency for EU Member States is determined. The following classification scheme was adopted in EIS 2023:

1. Innovation Leaders - countries for which the SII value was above 125% of the EU average,
2. Strong Innovators - countries for which the SII value was between 100% and 125% of the EU average,
3. Moderate Innovators - countries for which the SII value was from 70% to 100% of the EU average,
4. Emerging Innovators - countries for which the SII value was below 70% of the EU average.

These thresholds and the names of individual groups have also been modified compared to previous editions (Preda et al, 2019). Even a superficial analysis of the data allows us to conclude that Poland is classified in the fourth category, i.e. countries with the lowest level of innovation.

4. Innovation of the European Union According to the SII index value

The 2023 Innovation Scoreboard (EIS 2023; European Commission, 2023a), based on eight years of data, provides a comparative assessment of the research and innovation performance of EU Member States and selected third countries and the relative strengths and weaknesses of their research and innovation systems. It helps countries assess where they need to focus their efforts to improve their innovation performance. The EIS 2023 report is the third edition published using the new measurement framework introduced in 2021 and, as this report shows, in 2016-2023 the European Union improved its innovation performance (expressed by the SII index) by approximately 8.5 percentage points. Over this period, the innovation performance of most EU Member States has improved, confirming that the Union is a favourable environment for innovation. However, the innovation gap between countries persists because countries with weaker innovation systems are developing at a slower pace than the European Union.

	2022			2023	Ranking change	Performance change 2016-2023 (pp)
INNOVATION LEADERS	Sweden	SE	1	2	-1	10,4
	Finland	FI	2	3	-1	18,3
	Denmark	DK	3	1	2	16,0

*since 2023 Hungary's performance group is Moderate Innovators

where:

Innovation leaders; Strong innovators; Moderate Innovators; Emerging innovators

Figure 1: Development of innovation performance in EU member states according to the value of the Summary Innovation Index (SII) in 2022 and 2023 (as a percentage of the EU average)

Source: own elaboration on Eurostat data.

The analysis of research results contained in subsequent European Commission reports on innovation proves that over the years both the level of innovation in individual countries and the share of countries within the four groups characterizing the categories of innovators change. The modification of the methodology for 2021-2022 and the percentage range of classification of innovators also had a significant impact on these changes. Figure 1 shows the division of European Union countries into groups of innovators, corresponding to the results included in EIS 2022. This data is compared with the latest results from EIS 2023. The purpose of this graphical presentation was to show changes in the ranking on the innovation map of EU Member States over the course of the last two years of analysis and to present the evolution of innovation by comparing the results from 2016 with the latest results.

Between 2016 and 2023, differences in performance between Member States decreased, most significantly in the groups of strong and moderate innovators. However, the distribution of innovation performance groups still shows a geographical concentration - innovation leaders and most strong innovators are located in Northern and Western Europe, and most moderate and emerging innovators are located in Southern and Eastern Europe. As mentioned earlier, the EU's innovation performance has increased by 8.5 percentage points since 2016, driven by an increase in innovation in 25 EU Member States (except Luxembourg and France). The Member States that increased innovation the most are: Cyprus, Estonia, Greece, Czech Republic (by 20 percentage points or more; grey in the last column of the table). Generally speaking, the greatest improvement was recorded in the case of indicators included in the Innovative activities and Investments dimensions, i.e.: business process innovators (SMEs), venture capital expenditures, international scientific co-publications, job-to-job mobility.

In the latest edition of the European Innovation Scoreboard (EIS 2023), the distribution of Member States by performance groups remains largely unchanged compared to the previous year (Figure 1). It is worth emphasizing that Denmark is a new innovation leader with the best results in the EU, outdistancing Sweden after several years of its leadership position. According to the results of the latest Commission report, taking into account that the average SII innovation index for the European Union for 2023 was 0.54761, the group of other innovation leader countries included Sweden, Finland, the Netherlands and Belgium with innovation results significantly above-mentioned average. The SII index for this group of countries ranged from 0.6888 to 0.7535. Figure 1 presents the percentage of each country's SII index to the EU average, which was treated as a base value (100%). Its analysis shows that the percentage results of the strongest innovators significantly exceed the EU average - by a minimum of 25.79pp (Belgium) and a maximum of 37.59pp (leader - Denmark). Countries with decreasing SII index values, approaching the EU average (0.5766-0.6563; 105.29% and 119.85%, respectively), are included in the group of strong innovators and include, in descending order: Austria, Germany, Luxembourg, Ireland, Cyprus and France. By far the largest decline in the ranking of EU countries (and strong innovators) was recorded by Ireland, which dropped from 6th position in the ranking in 2022 to 9th in 2023. In turn, in France and Luxembourg, as the only European countries, there was a slight decline in results compared to the results in 2016. This highlights the need for continued efforts to increase innovation capacity, regardless of past performance.

The largest group, consisting of 10 members, comprise moderate innovators, i.e.: Estonia, Slovenia, the Czech Republic, Italy, Spain, Malta, Portugal, Lithuania, Greece, as well as a new member of this group - Hungary. In this group of innovators, Estonia showed the level of innovation closest to the EU average, differing only slightly from the EU average with a score of 98.64%. Hungary made significant progress and moved up to the better performing group, moving up the rankings from Emerging innovators. However, they still remained in 21st place among European countries (22nd including the average for the entire EU), so qualifying for the Moderate innovator category was due to the increase in the percentage of Hungary's SII in the EU average from 69.81% in 2022 to 70.35% in 2023. The results achieved by Croatia, Slovakia, Poland, Lithuania, Bulgaria and Romania with SII index values in the range of 0.1810-0.3809 place the above-mentioned countries well below the EU average, which resulted in their classification in the last group - Emerging innovators. In this group, the greatest progress in increasing innovation compared to 2022 was made by Bulgaria (increase in the share of the SII index in the EU average by 6.0pp) and Poland (increase in the share of the SII index in the EU average by 5.2pp), and taking into account the eight-year period - Croatia (increase in the SII share by 14.8pp) and again Poland (increase in the SII share by 13.3pp).

5. Poland's Innovativeness Compared to the European Union Leader Countries - Analysis of SII and Dimensions of Innovation

Poland, with an innovation index of 62.8% of the EU average, ranks in the last group of innovators - emerging. With the change in the methodology for calculating the SII index, starting from 2021, its innovation standing on the European Union results map deteriorated - from the position of a moderate innovator to the level of an emerging innovator. Figure 2 presents the evolution of Poland's results in the field of innovation, measured by the level of the SII index in 2016-2023, taking 2016 as the base year and presenting the annual pace of change. Poland's innovativeness has improved significantly over time, with this improvement occurring cyclically every second year of analysis. The largest declines in innovation were recorded in two years: in 2018 compared to the previous year (by 0.20%) and in 2020 compared to 2019 (0.89%). In the comparison of data from 2021/2020 and 2023/2022, the growth dynamics of the SII index was the highest, which ultimately translated into an overall improvement in Poland's innovativeness by 24.28% compared to 2016. The fastest pace of change was recorded in 2023 - the level of innovation measured by the SII index increased by 8.31% compared to the previous year.

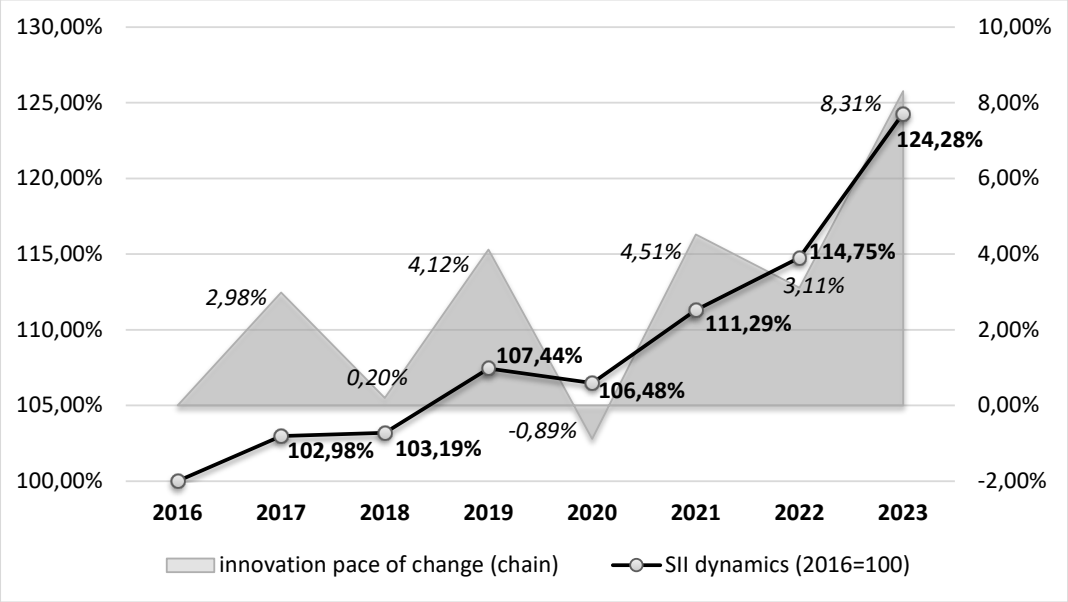

Figure 2: Evolution of Poland's level of innovation in 2016-2023

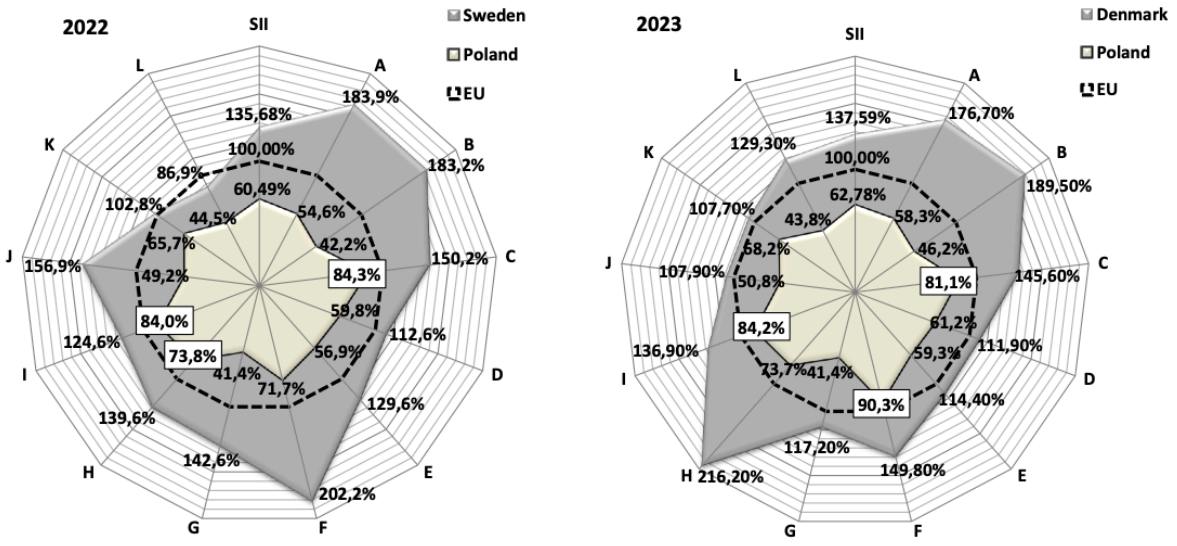
Source: own elaboration on Eurostat data.

In the further course of the analysis, the results of Poland, the innovation leader from 2022 - Sweden, and the innovation leader from 2023 - Denmark, were assessed in terms of the dimensions of innovation, which are presented in Figure 3. Similarly to Figure 1, reference was made to the EU average, and the aim was to show the strengths and weaknesses of both the 24th country in the innovation ranking of European countries - Poland, as well as to illustrate the results achieved in the field of innovation by countries considered the best in this matter over the last two years.

Despite a significant increase in innovation over the last year, Poland performs worse than the EU average in all 12 dimensions of the EU Summary Innovation Scoreboard (marked alphabetically), as presented in Figure 3. The distribution of Poland's innovation dimensions (light grey) also allows stating that progress is gradual and the results for 2023 do not differ significantly from the results from the previous year. In 2022, the average values for Poland in the twelve components of the indicator ranged from 41.4% of the EU average of the Innovators (G) dimension to 84.3% for Digitization (C), and in the case of the contemporary innovation leader - Sweden - in the range of 86.9% determined by the Environmental Sustainability (L) and 202.2% for the Use of Information Technology (F). In 2022, Sweden exceeded the EU average in 11 out of 12 dimensions of innovation, including in six cases by a minimum of 40.0pp (a maximum of 102.2pp).

In 2023, the Innovators (G) dimension was again the one in which Poland achieved the weakest results (41.4% of the EU average), while innovation measured in dimension F - Use of information technologies - came closest to the EU average. It was this dimension that developed the fastest in Poland, which resulted in an increase in the indicator, calculated as a percentage of the EU average compared to 2022, by 18.6pp - the highest for all

dimensions. The next result concerned Attractive research systems (B), but here the increase in the indicator was not so significant - only by 4 percentage points. Decreases were recorded for these dimensions: Digitization (-3.2pp), Environmental sustainability (-0.7pp) and Linkages (-0.1pp).



A - Human resources	**D - Finance and support**	**G - Innovators**	**J - Employment impacts**
B - Attractive research systems	**E - Firm investments**	**H - Linkages**	**K - Sales impacts**
C - Digitalisation	**F - Use of information technologies**	**I - Intellectual assets**	**L - Environmental sustainability**

Figure 3: Dimensions of innovation and the level of the Summary Innovation Index (SII) for Sweden, Denmark and Poland in 2022 and 2023 (as a percentage of the EU average)

Source: own elaboration on Eurostat data.

It is worth paying attention to the results achieved by the new (2023) European innovation leader, i.e. Denmark. This country, overtaking Sweden and Finland in 2023, became the innovation leader thanks to the SII index value of 137.6% of the EU average. This was partly due to significantly improved indicators for non-R&D innovation spending and sales of innovative products, and partly due to a decline in Sweden's innovation performance in 2022-2023. Denmark's innovation performance has been growing at a rate of 16pp since 2016, which is higher than the EU average (8.5pp; last column in Figure 1). In 2023, Denmark exceeded EU values in all 12 dimensions of innovation, although this result was not uniform. In 5 cases, the dimension values exceeded the EU average by 25.50pp, in three - by more than 50.0pp (including a maximum of 116.2pp). Both Denmark and Sweden were undisputed leaders in terms of Human resources (A), achieving 176.70% and 183.50% of the average EU indicator value in 2023, respectively (second and first place in the EU). Denmark's progress is particularly visible here, as it moved up from third place in the ranking to second, outclassing Finland. These countries are therefore distinguished by a high share of labour resources with appropriate skills and qualifications that are necessary to build a knowledge-based economy.

6. Conclusions

Innovation is the engine of development. The driving force of innovation is people and their knowledge. Man, thanks to his knowledge, skills and actions, is responsible for most of the processes taking place in modern organizations, including countries and their associations, such as the European Union. The ability to create and implement innovative solutions, and thus the ability to develop himself and the above-mentioned organizations, depends on a person's knowledge, ingenuity and creative involvement. In the literature on the subject one can find statements about the philosophy of development through innovation as a combination of knowledge and experience (Chomać Pierzecka, E 2018).

Innovation, knowledge and creativity are also familiar to Polish enterprises, but despite human resources (often indicated as a strong point of the Polish economy), it cannot be said to be innovative, especially when compared to other EU countries. Research on Poland's innovative performance based on 32 sub-indicators conducted in 2023 shows that the innovativeness of the Polish economy measured by the dynamics of the SII index, despite an almost 8.31% increase compared to 2022 and a 24.28% increase from 2016, is still very weak. Poland is most lagging behind in the area of innovative activities (in the Innovators dimension), expressed in the scope of introducing innovations to the market or within its organizations (41.4% of the EU average), Environmental sustainability (43.8% of the average) and Attractive research systems (46.2% of the EU average). Only three of the 12 dimensions come close to the EU average, i.e. the Use of information technologies (90.3% of the EU average), Intellectual assets (84.2% of the average) and Digitalization (81.1% of the average) and the rest of the analysis is devoted to these areas in the next publication, titled "Analysis of Poland's innovation profile based on the decomposition of the Summary Innovation Index (SII)". The elements undoubtedly influencing the results of innovation should include those regarding geopolitical variants, which have a decisive impact from at least February 2022 on the Polish economy. On the one hand, turmoil in supply chains that occurred much earlier (2020) in connection with the COVID-19 pandemic led to reduced profitability or even bankruptcy of many economic entities in Poland. On the other hand, the war started by Russia in Ukraine determined the need to quickly adjust the policy of energy supply and commodity exchange, which still has a significant impact on the country's economy. Despite these factors unfavourable for the competitiveness of the Polish economy, the Polish industrial system, in which small and medium-sized enterprises operate, forces them to be innovative as one of the conditions for staying on the market and to make strategic changes within enterprises, requiring the application of knowledge and the employment of qualified employees.

The presented data also confirm that the European Union is an organization bringing together countries with different economic profiles and - as can be seen from the presented data - a strongly differentiated level of innovation. The process of building and increasing the innovativeness of such different countries is a difficult and multi-stage task, therefore there is a need to constantly monitor progress in this area. The results of this monitoring and comparison allow for the optimization of decision-making processes, both at the EU level and in individual Member States. This article, through the analysis and systematics of data, contributes to the assessment of this process and can constitute a basis for further research.

Analysis of Poland's Innovation Profile Based on the Decomposition of the Summary Innovation Index (SII)

Zuzanna Ostraszewska and Agnieszka Tylec
Czestochowa University of Technology (CUT), Częstochowa, Poland

zuzanna.ostraszewska@pcz.pl
agnieszka.tylec@pcz.pl

Abstract: Knowledge and new technologies, and thus the innovation created based on them, determine the development opportunities of countries, regions and enterprises. Innovation built on the basis of human resources and their knowledge (and all activities aimed at its development) define the competitive position of the indicated entities and their place on the map of knowledge-based economies. The aim of the article was to analyse Poland's innovative profile against the background of EU countries, based on the latest data. To achieve this goal, first of all, the total Summary Innovation Index (SII) was decomposed and the indicators and data taken into account when determining the level of innovation in individual countries and the entire EU were presented. Then, the considerations focused on the dimensions in which Poland has achieved the most favourable results in recent years, i.e. closest to the EU average, as well as those in which there are the greatest delays. The basis for the research process, during which the method of graphical data presentation and analysis with elements of comparison was used, is the data contained in the European Innovation Scoreboards (EIS) during years 2016-2023. This article is an extension of the study submitted for publication, entitled: "Study of the level of innovation in the European Union - Poland compared to the leading countries". It is an attempt to answer the questions: where is the Polish economy located on the innovation map of the European Union?, what dimensions of innovation have a positive impact on its innovative position, and in which areas do they differ significantly from the EU average? It has cognitive value for the development of knowledge, science, and further improvement of the level of innovation in Poland, thanks to highlighting problem areas and sources of innovative advantage of the innovation leader countries.

Keywords: Innovation, Summary Innovation Index, Innovation Dimensions, Knowledge-Based Economy.

1. Introduction

Innovation is becoming more and more important and is a necessary condition for the survival and development of every organization. It also determines the strength of economies and their competitive advantage and is positively related to them (Kim and Koo, 2017; Edghiem and Mouzughi, 2018; Rajapathirana and Hui, 2018). The key factor in the innovativeness of enterprises and economies is access to knowledge (sharing it) and other intellectual resources. The use of existing knowledge, as well as the creation of new knowledge (in the innovation process), in turn determines the strength and direction of competition (Kokot-Stępień and Krawczyk, 2023; Karaś, 2021; Castandea and Cuellar, 2020).

Innovation, understood as an organization's ability to engage in innovative activities, is key to ensuring organizational survival, improved performance, and growth. The key to innovation, in turn, is knowledge and its management including promoting a culture of innovation and developing innovative teaching programs (Mohamad, Ramayah, and Chiun Lo, 2020; Mondal, Al-Kfairy, and Mellor, 2023; Simeoni, Caballero and Lepez, 2024). The importance of knowledge and intangible resources in modern (knowledge-based) economies is also visible in the way of measuring the innovation of EU countries, including the construction of the basic measure for its assessment, i.e. the Summary Innovation Index (SII). The decomposition of an indicator consisting of sub-indicators allows us to conclude that the knowledge and quality of human resources are incorporated into its construction. Thus, the analysis of its components and the results obtained by Poland should make it possible to answer the questions posed by the authors of the article, i.e. where is the Polish economy located on the innovation map of the European Union?, what dimensions of innovation have a positive impact on its innovative position, and in which they differ significantly from the EU average? An attempt to obtain answers to the indicated questions was the main goal of the undertaken considerations. During the work, an additional question also arose: if the innovative economy is based on knowledge, can it be said that it is/is becoming a knowledge-based economy based on Poland's innovation profile (examined based on the decomposition of the SII index)? In the article, in search of answers to the questions asked, an analysis of Poland's innovative profile against the background of EU countries was carried out. The presentation of the dimensions of innovation in which Poland achieves the most favourable results (based on the European Innovation Scoreboard (EIS) from 2016-2023) was preceded by short theoretical considerations in the field of innovation and knowledge (as the foundation of knowledge-based economies). Methodological aspects of the EU's innovation research were also presented. Due to the limitations of the text's volume, only a brief description of the dimensions of innovation that make

up the Summary Innovation Index is presented. For the same reason, only indicators from those dimensions are presented for which Poland achieved the most favourable results in the last study (EIS 2023). The article uses the method of analysis, synthesis and graphical presentation of data.

2. Innovation in the Times of Knowledge-Based Economies – Chosen Aspects

Organizations are constantly looking for ways to stay ahead of their rivals, and one way to stay competitive is to equip themselves with knowledge, knowledge management, innovation and innovativeness. Innovation is understood as a process in which existing knowledge is acquired, shared and assimilated to create new knowledge that includes products and services, methods and processes, and social and environmental contexts (Castandea and Cuellar, 2020). The importance of knowledge is obvious because it is an introduction to the company's innovation (Abubakar, et al., 2019; Haberla and Kuźmińska Haberla, 2013). Therefore, knowledge and innovations are the subject of interest for theoreticians and practitioners of socio-economic life, as well as various organizations (including the European Union).

The importance of knowledge and innovation is also visible in one of the interesting phenomena observed in the modern world, i.e. the reorientation of the economy consisting in a gradual transition from an economy consuming materials to an economy based on knowledge and information. Competition between countries and regions based on material resources was replaced by competition based on human resources (knowledge and new technologies). The development opportunities of countries and regions are increasingly influenced by human intellectual potential and knowledge related to the latest achievements of modern science. A knowledge-based economy, in which innovations play a key role, is a fundamental challenge in the 21st century for countries whose goal is to achieve a high level of development and competitiveness (Mosbah, 2020, Dolińska, 2009; Milewska, 2018).

The knowledge-based economy (as well as the knowledge management process) is becoming more and more important for developing countries. This is caused by several factors. First, it enables such countries to participate in the global economy and leverage their strengths in technology, education and innovation. Secondly, the shift towards a knowledge-based economy can help address some key challenges such as poverty, inequality and unemployment. This is possible by creating new opportunities for economic growth, innovation and jobs, especially in the technology and services sectors. Moreover, the knowledge-based economy can also help create a better educated and skilled workforce, which is crucial for sustainable economic growth and competitiveness in the global market (Kulkarni, 2023; Ode and Ayavoo, 2020; Trivedi and Srivastava, 2022). These phenomena are not only the domain of developing countries. The prospects for social, economic and technological development, also in the economically developed countries of the European Union, increasingly depend on the ability to initiate, disseminate and implement innovations in all spheres of life, especially in new sectors oriented on knowledge and high technologies (Melnikas, 2012).

1. Dimensions and Sub-Indexes of the SII Index - Methodological Basis

The Summary Innovation Index ranges from 0 to 1. The closer to 1, the higher the level of innovation in a given country. Currently, this index is calculated based on 32 sub-indexes grouped into four categories and twelve dimensions (Crisan and Stanica, 2022; Šofranková, et al., 2022).

The first category included in the SII is "Framework Conditions", which allows you to identify the main factors influencing innovation performance. They consist of the following dimensions (European Commission, 2023):

- Human resources, which measures the availability of a highly skilled and educated workforce,
- Attractive research systems that measure the international competitiveness of the science base,
- Digitalisation - the dimension within which the level of digital technologies is measured.

"Investments" is a category covering investments made in both the public and private sectors, defined by 3 consecutive dimensions (European Commission, 2023):

- Financing and support - includes three indexes, including private financing (venture capital investment), research and development spending in universities and government research organizations, and direct government financing and government tax support for enterprise research and development),
- Corporate investment - includes three indexes on research and development and non-R&D investments, investments that companies undertake to generate innovations, including expenditure on R&D, expenditure on innovation other than R&D and innovation expenditure on employed person,

- Use of information technologies - a dimension that includes two indexes: enterprises actively improving the information and communication skills of their staff and employed ICT specialists.

The next category is: "Innovative activities" analysed in dimensions (European Commission, 2023):

- Innovators, including SMEs introducing innovations,
- Connections – indexes used to measure cooperation between the public and private sectors,
- Intellectual assets illustrating patent activity.

The last category of innovation included in the SII structure is "Impact". This category includes the effects of innovative activities of enterprises in three dimensions (European Commission, 2023):

- Impact on employment - indexes illustrating the level of employment in innovative sectors,
- Impact on sales - sub-indexes relating to the level of sales of innovations on the domestic and foreign markets,
- Environmental impact - indexes of this dimension focused on improvements aimed at reducing the negative impact on the environment.

Table 1 highlights the dimensions for which the EIS 2023 results for Poland are the most favourable, i.e. most similar to those of EU countries.

Table 1: Dimensions of innovation for which Poland achieved the most favourable results in EIS 2023

SELECTED INDEXES OF INNOVATION IN EU COUNTRIES CALCULATED UNDER SII		
Dimensions of innovation	Components of the SII index/ (Year of "availability" of the latest data)	Data source
FRAMEWORK CONDITIONS		
Digitalisation	1.3.1 Broadband penetration (2022) 1.3.2 Individuals who have above basic overall digital skills (%share) (2021)	Eurostat Community Survey of ICT Usage and E-commerce in Enterprises EU survey on the ICT usage in households and by individuals
INVESTMENTS		
Use of information technologies	2.3.1 Enterprises providing training to develop or upgrade ICT skills of their personnel (2022) 2.3.2 Employed ICT specialists (2022)	Eurostat, Community Survey of ICT Usage and E-commerce in Enterprises
INNOVATION ACTIVITIES		
Intellectual assets	3.3.1 PCT patent applications per billion GDP (in PPS) (2019) 3.3.2 Trademark applications per billion GDP (in PPS) (2022) 3.3.3 Design applications per billion GDP (in PPS) (2022)	Eurostat Patent data from the OECD EUIPO

Source: own elaboration on European Commission, 2023; European Commission, 2023a.

The SII calculation methodology includes several basic steps, presented in Table 2.

Table 2: Stages of calculation of the SII index

STAGE	ACTIONS
Setting reference years	For each indicator, a reference year is identified for all countries based on data availability for all those countries for which data availability is at least 75%. For most indicators, this reference year lags one or two years behind the year in which the EIS is published.
Imputing for missing values	Reference year data are then used for “2023”, etc. If data for a year-in-between are not available, missing values are replaced with the value from the previous year. If data are not available at the beginning of the time series, missing values are replaced with the next available year. If data are missing for all years, no data will be imputed (the indicator will not contribute to the Summary Innovation Index.

STAGE	ACTIONS
Identifying and replacing outliers	Positive outliers are identified as those country scores which are higher than the mean across all countries plus twice the standard deviation. Negative outliers are identified as those country scores which are smaller than the mean across all countries minus twice the standard deviation. These outliers are replaced by the respective maximum and minimum values observed over all the years and all countries excluding the identified outliers. With replacing positive (or negative) outliers, more countries can share the highest (lowest) normalised score of 1 (0).
Transforming data that have highly skewed distributions across countries	Most of the indicators are fractional indicators with values between 0% and 100%. Some indicators are unbound indicators, where values are not limited to an upper threshold. These indicators can be highly volatile and can have skewed data distributions (where most countries show low performance levels, and a few countries show exceptionally high levels of performance). For these indicators where the degree of skewness across the full eight-year period is above one, data have been transformed using a square root transformation, i.e. using the square root of the indicator value instead of the original value.
Determining Maximum and Minimum scores	The Maximum score is the highest score found for the eight-year period within all countries excluding positive outliers. Similarly, the Minimum score is the lowest score found for the eight-year period within all countries excluding negative outliers.
Calculating re-scaled scores	Re-scaled scores of the country scores (after correcting for outliers and a possible transformation of the data) for all years are calculated by first subtracting the Minimum score and then dividing by the difference between the Maximum and Minimum score. The maximum re-scaled score is thus equal to 1, and the minimum re-scaled score is equal to 0. For positive and negative outliers, the re-scaled score is equal to 1 or 0, respectively.
Calculating composite innovation indexes	For each year, a composite Summary Innovation Index is calculated as the unweighted average of the re-scaled scores for all indicators where all indicators receive the same weight (1/32 if data are available for all 32 indicators).
Calculating relative-to-EU performance scores	Performance scores relative to the EU are calculated as the SII of the respective country divided by the SII of the EU multiplied by 100. Relative performance scores are calculated for the full eight-year period compared to the performance of the EU in 2016 and for the latest year also to that of the EU in 2023. For the definition of the performance groups, only the performance scores relative to the EU in 2023 have been used.

Source: own elaboration on European Commission, 2023.

The method of calculating the SII index and the thresholds for membership of individual countries in innovation efficiency groups were presented by the authors in the article "Study of the level of innovation in the European Union - Poland compared to the leading countries", which is an introduction to the data presented in this study. On their basis, it can be concluded that Poland is among the countries with the lowest level of innovation.

2. Poland's Position in the European Union in Terms of the Use of Information Technologies, Intellectual Assets and Digitalisation Against the Background of the Summary Innovation Index (SII)

While in previous years the EIS data indicated dimensions such as Human Resources, Intellectual Assets and Enterprise Investments as sources of the innovative potential of the Polish economy, in the latest edition of the EIS Poland achieved results most similar to those of EU countries in the following dimensions (European Commission, 2023a; European Commission, 2022; European Commission, 2022a; European Commission, 2018):

1. Use of information technologies (dispersion of the percentage of the SII sub-index between the EU average and Poland in this category is the smallest: SII_{EU27}-SII_{PL}=9,7pp),
2. Intellectual assets (SII_{UE27}-SII_{PL}=15,8pp),
3. Digitalisation (SII_{EU27}-SII_{PL}=18,9pp).

The Use of information technologies dimension is an element included in the Investments category, covering investments made in both the public and business sectors. It contains two indicators determining the degree of use of information technologies, i.e.:

- 2.3.1 Enterprises providing training to develop or upgrade ICT skills of their personnel,
- 2.3.2 Employed ICT specialists.

Poland's result in the above-mentioned dimension was the best of the 12 dimensions considered. Therefore, first of all, it was analysed and the results on a European scale are graphically presented in Figure 1, assuming the division of countries into groups of innovators in accordance with the classification included in EIS 2023. The EU average was used as the cut-off point, which divided the chart into four parts, at the same time showing the

distribution of European countries according to the results achieved under the SII and the Use of information technologies dimension (as a percentage of the EU average). The same way of presenting the results was used in Figures 3 and 5 for the Intellectual assets and Digitalisation dimensions.

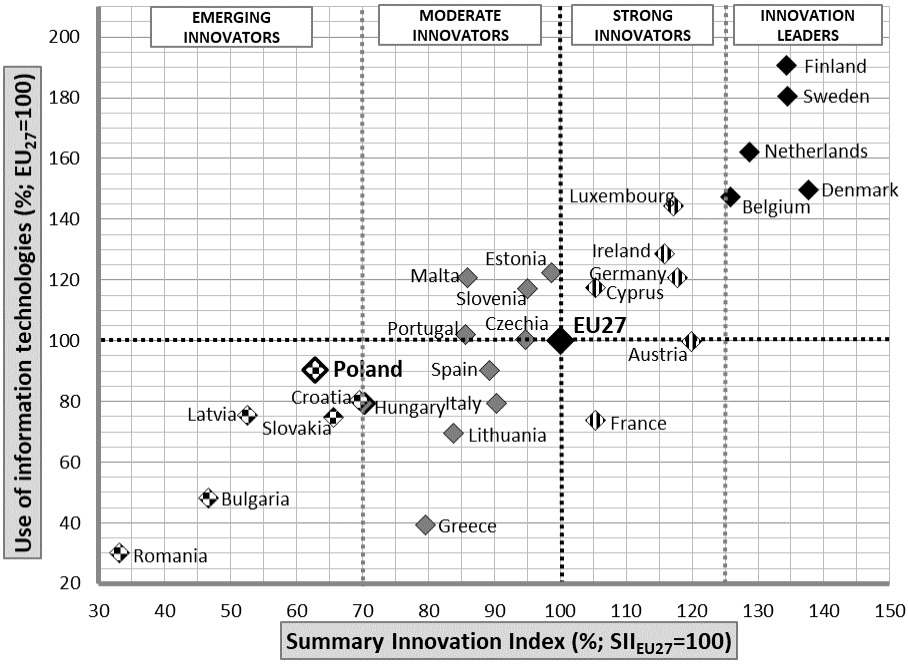

Figure 1: Poland's profile on the Use of information technologies dimension matrix compared to the innovative position of EU member states in 2023 (as a percentage of the EU average)

Source: own elaboration on Eurostat data.

The undisputed leaders in the Use of information technologies are Finland and Sweden. The analysis of Figure 1 also shows that 9 out of 11 countries whose results differ significantly from the EU average (both on the X and Y axis) come from groups of countries that are strong innovators and innovation leaders. 14 out of 27 European Union member states achieved results in the Use of information technology dimension above the EU average. Poland's position in this dimension has strengthened the most out of all twelve dimensions of innovation calculated under the SII index compared to 2022, which allowed it to rank 16th among European countries (an increase in the index from 71.7% of the EU average in 2022 to 90.3% in 2023). The weakest country in this area was Romania.

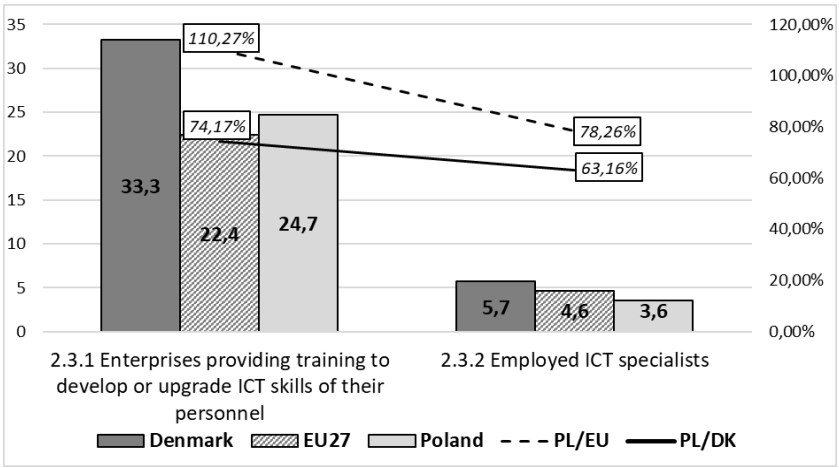

Figure 2: Sub-indexes included in the Use of information technologies dimension for the EU, Denmark and Poland in 2023

Source: own elaboration on Eurostat data.

ICT skills are particularly important for innovation in today's increasingly digitized economic realities. Eurostat defines ICT professionals as "workers who have the ability to develop, operate and maintain ICT systems and for whom ICT constitutes a core part of their work" (European Commission, 2022). The growing share of enterprises providing training in this area is also an indicator of the overall development of employee skills. The values of both sub-indexes - components of the Use of information technologies dimension - for Poland, the innovation leader - Denmark and the entire European Union in 2023 are presented in Figure 2. Additionally, the values of these indexes achieved by Poland were calculated and shown in relation to the results of Denmark and the EU. According to the analysis of the presented data, in Poland in 2023, for every 100 enterprises, there were nearly 25 entities that undertook to improve the digital competences of their employees. Thus, Poland's result was 74.17% of the result achieved by Denmark (33 enterprises out of 100) and 110.27% of the EU average (22.4 enterprises out of 100) and was the 11th best result in the EU. Unfortunately, this did not translate into the number of ICT specialists employed in companies - in Poland, out of 100 employees, only 3.6 employees had such competences, while in Denmark almost 6, and in the case of the leader - Sweden - 8.6.

The second dimension of innovation, in which Poland achieved the best results, includes Intellectual assets. This dimension is one of three areas of innovative activities, including: Innovators (two indexes, including SMEs introducing innovations), Connections (three indexes illustrating cooperation between the public and private sectors) and Intellectual assets (three indexes illustrating patent activity). The indexes that make up the Intellectual assets group include:

- 3.3.1 PCT patent applications per billion GDP (in PPS),
- 3.3.2 Trademark Applications per billion GDP (in PPS),
- 3.3.3 The number of industrial designs submitted per billion GDP (in PPS),

The results of the European Union member states for the Intellectual Assets dimension are presented in Figure 3, assuming the same assumptions as for Figure 1. According to its analysis, the countries that lead in the Intellectual assets dimension are Ireland and Austria, respectively (1st and 2nd place in the hierarchy). It is noteworthy that very good results in this dimension are achieved not by innovation leaders (Denmark, Finland, Sweden), but by countries classified as strong innovators (the above-mentioned Ireland and Austria, Germany) and moderate innovators (Malta, Estonia). Poland, with the results of indexes within this dimension presented in Figure 4, qualified in 18th place, taking into account the EU average (14th place). This result was most significantly influenced by the value of index 3.3.3, regarding the number of reported industrial designs per billion of GDP. Achieving over 150% of the EU average for registered industrial designs allowed Poland to rank fourth among the 27 EU member states. In turn, the European leader in innovation - Denmark - achieved much better results in the case of registered trademarks (per billion GDP). On average, in the European Union, there are 3.28 registered patent applications per billion GDP, over 7 registered trademarks and approximately 4 registered industrial designs.

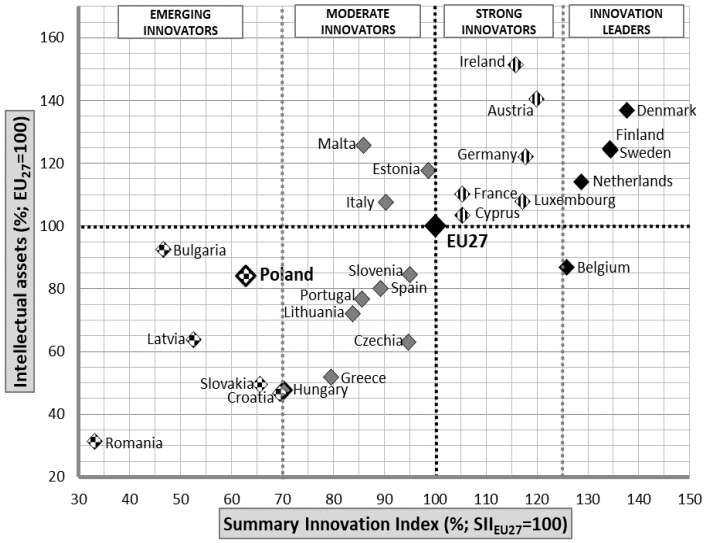

Figure 3: Poland's profile on the Intellectual assets dimension matrix compared to the innovation position of EU member states in 2023 (as a percentage of the EU average)

Source: own elaboration on Eurostat data.

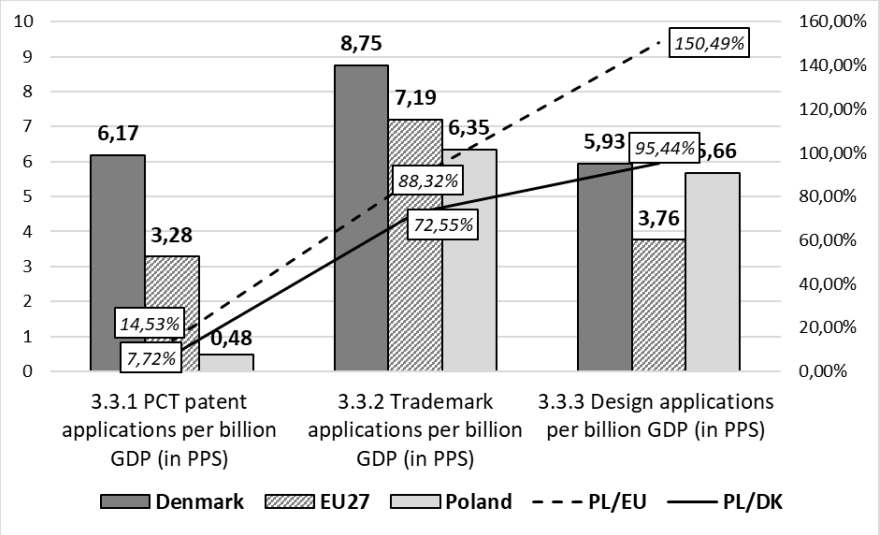

Figure 4: Sub-indexes included in the Intellectual assets dimension for the EU, Denmark and Poland in 2023

Source: own elaboration on Eurostat data.

The last dimension in which Poland achieved the best results as a percentage of the EU average was the Digitalisation dimension. This dimension falls within the SII category called "Framework conditions" and includes two indexes:

- 1.3.1 Popularization of broadband connections among enterprises (% share),
- 1.3.2 People with post-basic general digital skills (% share).

Framework conditions capture the main factors influencing the innovation performance of countries' economies. They consist of the following dimensions: Human resources, Attractive research systems and the above-mentioned Digitalisation. Digitalisation measures the level of digital technology through the spread of broadband connections among businesses and the supply of people with post-basic general IT skills.

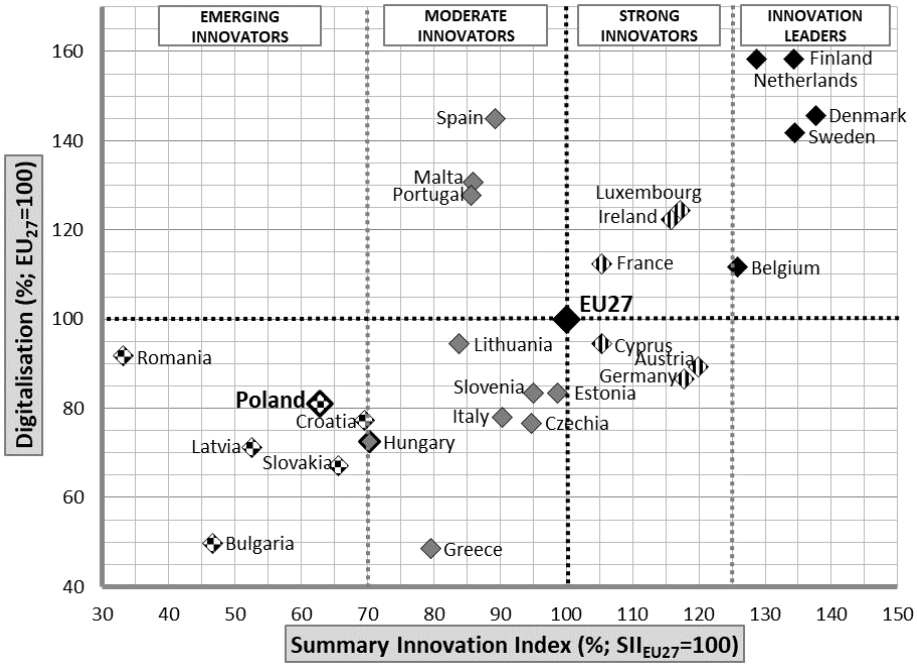

Figure 5: Poland's profile on the Digitalisation dimension matrix compared to the innovation position of EU member states in 2023 (as a percentage of the EU average)

Source: own elaboration on Eurostat data.

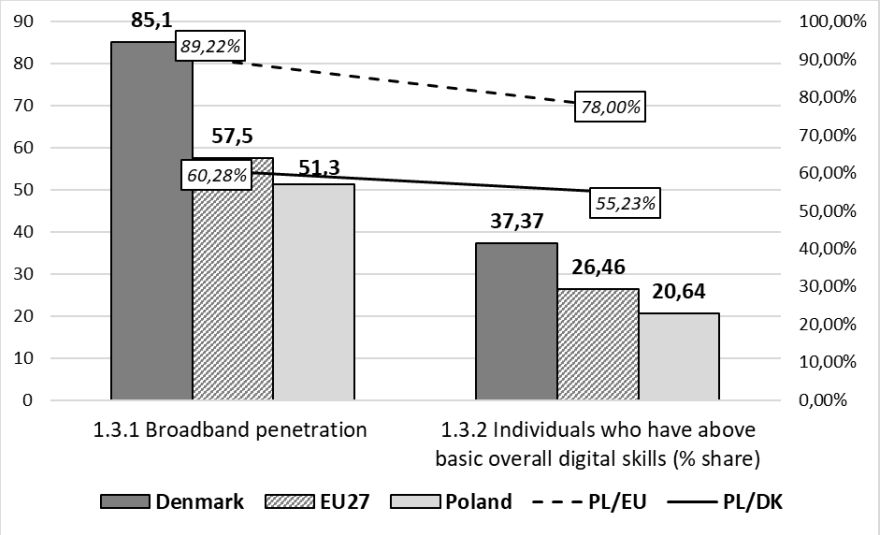

Figure 6: Sub-indexes included in the Digitalisation dimension for the EU, Denmark and Poland in 2023

Source: own elaboration on Eurostat data.

In Figure 5, Digitalisation (as a percentage of the EU average, which was assumed to be 100%) is compared on the X-axis with the percentage of the SII indicator (assuming that SII_{UE27}=100%). The results obtained indicate that the leaders in the European Union in the area of digitalisation are two countries - the Netherlands and Finland, with results of 158.3% and 158.2% of the EU average, respectively. Denmark - as a leader in innovation on a European scale - was in third place. The level of digitalisation of 81.1% of the EU average allowed Poland to rank 19th out of 27 member states. The EU average was 12th in the ranking of EU member states.

When decomposing the Digitalisation dimension into the above-mentioned two sub-indexes (Figure 6), it should be noted that Poland's results do not differ significantly from the EU average in this respect, constituting 89.22% and 78% of the EU average, respectively. This means that over 51% of enterprises in Poland have access to broadband Internet, and every fifth Pole has above-average IT skills (every fourth EU citizen). In the case of Denmark, these shares are correspondingly higher - 85% of enterprises use broadband connections, and 37% of the population has above-average IT skills. However, the decomposition of this dimension into component indexes leaves no doubt that despite Poland's good result against the background of 12 dimensions of innovation, this area is not the country's strongest point. The use of Poland's full e-potential depends on creating conditions for the development of e-commerce and the Internet, as well as on constantly improving the basic general digital skills of citizens aged 16-74 on the Internet, covering the areas of information, communication, problem solving and content creation. Considering that - according to the EIS 2023 report - within these two sub-indexes of the Digitalisation dimension, Poland is in 17th and 23rd position in the EU, respectively, it can be confidently stated that the country's innovative position is weak and requires intensification of financial outlays from the government.

3. Conclusions

Knowledge and innovation are the pillars of the knowledge-based economy. Without knowledge there is no innovation, information society and knowledge-based economy. The emergence of innovations, economic development, progress in scientific and technical knowledge, and the creation of an information society are considered important social problems, both in individual countries and in the entire European Union. Therefore, special attention should be paid to creating innovation, including through the development of knowledge - the potential to create a knowledge-based economy. The development prospects of the European Union and its role in the global system depend on the use of innovation potential, including the dissemination of humanitarian and democratic values, in order to create a new society which, among other things, through innovation in the field of technology, will create a knowledge-based economy. It should also be emphasized that human and intellectual resources provide enormous opportunities for activating innovation in the European Union. Their diversity, highly developed infrastructure for activating and developing education, science, experience in creating and developing high technologies and maintaining international connections are sources of innovative potential and gaining a competitive advantage (Melnikas, 2012; Rynio, 2010; Kucznik, 2019).

The European Union is an organization of culturally, socially and economically diverse countries. Even a cursory analysis of the level of innovation and the innovation potential of individual countries allows us to observe many differences and disproportions. However, the analysis of EU innovation research results indicates innovation leaders who have been setting the direction for innovation for several years, constantly increasing expenditure on research and development and promoting the development of the economy whose basic pillar is knowledge. The dominant role of the Scandinavian countries can be seen here, and with the change in the methodology of monitoring innovation, the position of countries such as Luxembourg and Germany has decreased. Poland belongs to the group of countries with a level of innovation that differs unfavourably from the average calculated for the 27 European Union countries - indexes in all dimensions of innovation for Poland were below the EU average, and Poland itself was in 24th position on the EU innovation map, measured by the value of the SII index.

In response to the research questions posed in the introduction of the article, it should be noted that when analysing Poland's position, based on the dimensions included in the SII index, it was found that the Polish economy achieves the best results for three dimensions: Use of information technologies, Intellectual assets, Digitalization. Unfortunately, the term "best results" does not mean that these are the results that justify calling Poland an innovative or knowledge-based economy. Poland's innovativeness in these three best areas gives it only 16th, 17th and 19th place in the ranking of 27 European countries and is always lower than the EU average. The Polish economy performs worst in the area of attractive research systems, as an innovator - with a low percentage of SMEs introducing innovations in products and business processes, as well as in the field of environmental sustainability. Of course, the dimensions include indexes whose results clearly indicate a good or very good position of Poland in the examined area (for example, Poland's high, 4th position is given only by one measure included in the Intellectual assets dimension, i.e. the number of registered industrial designs per billion GDP, and the 11th place is due to the high percentage of enterprises that have undertaken to improve the digital competences of their employees, included in the dimension of the Use of information assets). This gives rise to the claim that the Polish economy is moving towards a knowledge-based economy, but time, effort and many resources are still needed to reduce development backwardness and minimize arrears based on access to funds co-financing various types of development projects, including innovative ones. Changes are also needed in the country's innovation policy, focusing on increasing expenditure on research and development.

Business Transformation Powered by Knowledge Management in the Context of Corporate Sustainability

Krystian Pawlowski
Poznan University of Technology, Faculty of Engineering Management, ul. J. Rychlewskiego 2, 60-965 Poznan, Poland

krystian.pawlowski@put.poznan.pl

Abstract: The economic objectives in the different stages of the development of industrial era enterprises were operationalised by changing paradigms. After the industrial revolution and mass production stages, the economies of scale paradigm was followed by the waste elimination paradigm initiated by Toyota, based on the assumption that it is possible to reduce the costs of producing a car without employing the economies of scale. Lean companies improved their ability to meet individual customer needs but continued to be equipped with capital-intensive fixed assets with limited flexibility, thus seeking to extend product series and life cycles. The development of technology accompanying the above organisational changes aimed at increasing the agility of enterprises and the concept of KM 4.0 concluded the fourth stage of industrial production development. A new market objectives of enterprises was the customisation of a product to the individual requirements of a specific customer, characteristic of engineering-to-order production, but with the guarantee of low prices and short delivery cycle times typical of mass production. This paper addresses the issue of the relationship between the level of incorporation of KM 4.0 methods and tools allowing for transformation from Mass production to Mass Customization and the possibility of achieving objectives in terms of economic, human resources and environmental aspects. The empirical research covered 150 medium-sized and large enterprises operating in Poland in various industries. In summary, it can be concluded that there is a correlation between the implementation level of chosen KM 4.0 methods and tools supporting product customisation and the level of efficiency in terms of achieving "triple bottom line" goals in the aspect of economics, the aspect of human resources and the aspect of ecological goals. The methods indicated above largely concern operational and production processes and allow flexible delivery of highly customised products at a price comparable to that of mass products. The conditions and developments in the knowledge economy mean that modern organisations need to build an organisational strategy based at an operational level on KM methods and tools.

Keywords: Knowledge Management 4.0, Mass Customisation, Lean Management, Agile Enterprise, Modern Manufacturing Practices, Industry 4.0

1. Introduction

Mass production initiated at Cadillac Motor Car with the implementation of interchangeable parts technology led to significant price reductions through economies of scale, but at the same time reduced the manufacturer's ability to meet individual customer needs. Companies following the lean organisational strategy pioneered by TOYOTA Motor Company (based on the assumption of waste elimination) while managing to increase their ability to meet individual customer needs, continued to be equipped with capital-intensive fixed assets with limited flexibility, thus seeking to extend product series and life cycles (Trzcielinski, 2011), (Trzcielinski, Włodarkiewicz-Klimek, Pawlowski, 2013), (Jasiulewicz-Kaczmarek, Legutko, Kluk, 2020), (Pawlowski, 2020). The waste elimination paradigm proved to be insufficient in view of the increasing volatility and unpredictability of the environment. The ability to succeed in a competitive environment characterised by constant unpredictable changes creating market opportunities became the paradigm of the fourth stage of industrial production development. The development of technology accompanying the organisational changes aimed at increasing the agility of enterprises and the concept of Industry 4.0 concluded the fourth stage of industrial production development. Industry 4.0 has become an accepted reality, which affects the way companies operate (Jasiulewicz-Kaczmarek, Legutko, Kluk, 2020). A new market objectives of enterprises was the customisation of a product to the individual requirements of a specific customer, characteristic of engineering-to-order production, but with the guarantee of low prices and short delivery cycle times typical of mass production.

2. Research Problem, Literature Review

This paper addresses the issue of the relationship between the level of incorporation of Industry 4.0 methods and tools allowing for mass customisation and the possibility of achieving the company's goals in terms of economic, human resources and environmental aspects. The empirical research covered 150 medium-sized and large enterprises operating in Poland in various industries.

The literature on the subject provides numerous typologies of mass customisation forms, where customisation means adapting a product to the individual requirements of a specific customer (Bednarz, 2010), (Gilmore, Pine,

1997). Gillmore, J.H. and Pine B.J. organised this concept and proposed a general typology, distinguishing forms of mass customisation based on changes in the product itself, and changes in the customer's perception of the product. They also introduced the important concept of customer sacrifice, defining it as "the difference between what the customer accepts and what the customer actually needs, even if he or she cannot clearly name it" (Gilmore, Pine, 1997). By addressing the issue of customer sacrifice, the company can decide on the extent of the changes in the functionality of the product or the perception of the product. The aim of using mass customisation is to tailor the product to the individual requirements of a specific customer, characteristic of engineering-to-order production, but with the guarantee of low prices and short delivery cycle times typical of mass production. A narrower definition describes the concept of mass customisation as a system that uses information technology, flexible processes and organisational structures to enable the delivery of a wide range of products that meet specific customer requirements (often by selecting predefined options from a set) at costs comparable to those typical of mass production (Bednarz, 2010). Duray was the first researcher to use the notion of modularity of the product itself as well as the manufacturing process to identify the various forms of mass customisation. In the case of mass customisation, modularity guarantees low costs. The typology put forward by Duray (2002) identifies between two dimensions: the point of customer involvement and the type of modularity employed. However, the developed classifications do not answer the question of what changes are necessary in operational processes to effectively deliver customised products in an efficient manner (Bednarz, 2010), (Duray, 2002). In Industry 4.0, one of the market objectives of companies is to tailor the product to the individual requirements of a specific customer. The literature on the subject does not offer a single widely accepted definition of Industry 4.0. nor principles of adapting companies to its requirements (Herman, Pentek, Otto, 2015), (Mrugalska, Wyrwicka, 2017), (Alcácer, Cruz-Machado, 2019). The main ideas of industry 4.0 were first published in Germany in 2011 (Kagermann, Lukas, Wahlster, 2011), (Kagermann, Wahlster, Helbig, 2013). A broad analysis of the issue was developed by M. Hermann, T. Pentek, B. Otto, who provided an overview of the definitions and key principles of Industry 4.0 (Herman, Pentek, Otto, 2015). The authors defined four core elements of Industry 4.0: Cyber- Physical Systems, Internet of Things, Internet of Services, and Smart Factory. They also developed six principles to support a company's adaptation to the requirements of Industry 4.0. These include: interoperability, virtualization, decentralization, real-time capability, service orientation, and modularity. With regard to the issue of Knowledge Management 4.0, a wide range of possible research topics has been developed by Ribeiro at all (2023). While Ansari (2019) proposed the following definition of KM 4.0 "as a strategic and operational function comprising exploration and exploitation processes. KM 4.0 is responsible to accomplish the following tasks, namely i) continuously support value generation through enhancing and balancing need- or opportunity-driven knowledge generation and knowledge utilisation capacities, and ii) persistently facilitate developing and protecting human-machine collective intelligence across manufacturing enter-prises and in particular smart factories". With regard to the above this paper focuses on two issues:

1. The issue of operationalisation of mass customisation through the application of Industry 4.0 methods and tools. Salvador et al. identified three key areas of mass customisation (Salvador, Holen, Piller, 2009), (Doligalski T. 2009):

- defining the area of customisation **(solution space development)**,
- designing an efficient process **(robust process design)**,
- and customer selection process **(choice navigation).**

To each of these areas they assigned a so-called core competence (fundamental capability) and a set of methods and tools to develop them. And so:

- As a core competence in terms of defining the area of customisation, the authors identified the selection of product elements that can be customised by the customer. The authors assigned to this competence a set of innovation tools, (*innovation tool kits*), such as virtual product tests (*virtual concept testing*) and customer experience monitoring (*customer experience inteligence*). This paper, referring to the methods and tools of Industry 4.0, analyses the aspects of the level of tracking changes by the companies examined in the customer market, in the economic segment, in the socio-demographic segment of the environment, and in the natural environment, as a way of searching for areas of product customisation. Companies must use new product development as a strategy for remaining competitive in the market place in response to changing consumer demands (Miranda at all, 2019).
- The authors identified the use and configuration of the resources of the organisation or its partners in the value chain to meet the diverse needs of a large number of customers as a core competence for designing an efficient process. Among the methods and tools conducive to the development of this

competence such aspects as flexible automation, process modularity and adaptable human capital were identified. With regard to the above competence, the author asks questions about the level of application of the toolkit supporting the process of adaptation to the requirements of Industry 4.0 pointed out, among others, by Herman, Pentek and Otto (2015). The toolkit covered by this study includes:

- Internet of Things.
- Artificial Intelligence.
- Cloud computing.
- CAD, CAM, CAE.
- Reverse engineering.
- 3D printers.
- Transport robots(Automated Gaided Vehicle).
- SCADA.
- MES (Manufacturing Execution System).
- e-Kanban.

- In terms of the customer selection process, the authors identified support in identifying the customers' needs while reducing the complexity of their choices as a core competence. With regard to this competence, the authors identified three tools: assortment matching trial and error (*fast cycle, trial-and-error learning*) and embedded configuration. With reference to the above, the authors have posed questions about the level of application of such tools as: artificial Intelligence (computer algorithms process large databases and make decisions without human intervention). Cloud computing (computing is carried out by a service provider without the need to install and administer own software).

2. The second issue addressed in the paper is the effectiveness of the applied methods and tools of Industry 4.0 in relation to corporate sustainability goals (Elkington, 1997). The paper asks questions about the trend of the company's development in business terms, and the level of achievement of the objectives in terms of human resources and environmental aspects in relation to the level of applied methods and tools of Industry 4.0 employed for the purpose of product customisation.

3. Objectives

The aim of the paper is to answer the following question: Is there a correlation between the level of application of Industry 4.0 methods and tools for product customisation and the level of achievement of corporate sustainability goals.

4. The Research

4.1 Research Sample

The research sample comprised 150 medium and large industrial companies (including 60 large ones) operating in 19 different industries in Poland. The respondents were persons directly involved in the management of the production and engineering area (president/managing director; technical director; other persons with similar competencies). The surveys and interviews were conducted through an external company on 28 December 20223.

4.2 Scope of Research

The scope of the research included the level of product customisation, the level of application of Industry 4.0 methods and tools, and the effectiveness of achieving the triple bottom line objectives in the economic, human resources aspect and environmental aspect.

4.3 Research Methods

As part of this study, a questionnaire survey was conducted on a sample of 150 medium and large industrial companies in Poland. The survey was conducted in the form of an interview. Respondents answered on a 1–5 (Likert) scale. In addition, data was partially processed using the Spearman's rank correlation test.

4.4 Data Processing Methodology

The following methodology was used to process the collected data:

- Stage 1 – A group of companies offering products with a high degree of customisation was selected from the research sample.
- Stage 2 – From the companies offering highly-customised products, a group of companies A – characterised by high performance in terms of the triple bottom line objectives - and a group of companies B – characterised by low performance in this respect.
- Stage 3 – For the research samples of companies A and B, indicators of the implementation level of Industry 4.0 management methods and tools were determined, analysed and synthesised. In order to calculate the implementation level of each method, fully implemented methods were identified (response scale 3,4,5 – for solution space development; and scale 4,5 – for robust process design, and choice navigation) in each research sample. Then, the number of fully implemented individual methods and tools was divided by the size of the respective sample (A and B). This yielded an indicator of the implementation level of the respective method (but fully implemented) in each group of companies A and B. In addition, as part of the synthesis, the average total indicator of the implementation of the methods was determined according to the areas of mass customisation: solution space development, robust process design, and choice navigation separately for groups A and B.
- Stage 4 – Spearman's rank correlation tests were carried out for some of the features.

4.4.1 Stage 1 – Product Customisation Level

The following question (E1) was asked in order to identify the group of companies offering highly customised products:

Customisation (personalisation) of the product:

1. none (no customisation of the product and no personalised communication with the customer);
2. narrow scope (standard product + additional services selected from catalogue; no personalised customer contact);
3. medium scope (multiple product variants offered + additional services determined through personalised contact with the customer);
4. extensive scope (customer co-creates the product via personalised contact);
5. very extensive scope (customer co-creates the product via an online service).

Responses 3,4,5 on the scale were rated as high levels of product customisation. 69 companies from the entire research sample of N=150 offered highly customised products.

4.4.2 Stage 2 – Level of Achievement of Triple Bottom Line Objectives – Identification of Group A and B Companies

In order to assess the effectiveness in terms of the achievement of the triple bottom line objectives in the economic, human resources and the environmental aspect, the following questions were posed:

- In terms of the economic aspect, question E2.1 was posed about the trend of the company's development in business terms, starting from the pre-pandemic periods.

1. negative (leading to business closure);
2. stagnant (no growth);
3. acceptable but not satisfactory;
4. good – satisfactory;
5. very good.

Responses 4, 5 on the scale were deemed to reflect a high level of efficiency in terms of economic objectives and a basis for classifying a given company to Group A. Responses of 1,2,3 on the scale, in turn, were deemed to reflect low efficiency in that respect and a basis for categorising the company in question to Group B.

- In terms of the human resources aspect, questions were posed about the degree of implementation of the following measures according to the following scale: (1 – not implemented at all; 2 – implemented to a very low degree; 3 – implemented to a moderate degree; 4 – implemented to a high degree; 5 – implemented to a very high degree)

(E2.2) An analysis of risks to human health and life is carried out in the design stage of products or services.

(E2.3) An analysis of risks to human health and life is carried out in the design stage of manufacturing systems/organising services.

Responses 4, 5 on the scale were deemed to reflect a high level of efficiency in terms of human resources objectives and a basis for classifying a given company to Group A. Responses of 1,2,3 on the scale, in turn, were deemed to reflect low efficiency in that respect and a basis for categorising the company in question to Group B.

- In terms of the environmental objectives, questions were posed about the degree of implementation of the following measures according to the following scale: (1 – not implemented at all; 2 – implemented to a very low degree; 3 – implemented to a moderate degree; 4 – implemented to a high degree; 5 – implemented to a very high degree)

(E2.4) Technologies harmful to the environment are replaced with environmentally-friendly alternatives.

(E2.5) Waste is neutralised to render it harmless to the environment.

Responses 4, 5 on the scale were deemed to reflect a high level of efficiency in terms of environmental objectives and a basis for classifying a given company to Group A. Responses of 1,2,3 on the scale, in turn, were deemed to reflect low efficiency in that respect and a basis for categorising the company in question to Group B.

10 companies with a high level of efficiency in terms of the triple bottom line objectives in all three aspects combined were classified as group A companies. On the other hand, group B included 5 companies with a low level of efficiency in terms of the triple bottom line objectives in all three aspects combined.

4.4.3 Stage 3 – Indicators of the Implementation Level of Industry 4.0 Management Methods and Tools in Groups A and B

In order to determine the implementation degree of methods and tools supporting processes in the solution space development area, the following question was posed: In order to identify market opportunities, changes are tracked according to the following scale: (not tracked at all; 2 – tracked only to a limited extent; 3 – tracked to a moderate extent; 4 – tracked to a large extent; 5 – tracked to a very large extent)

- (E3.1) In the economic segment of the environment.
- (E3.2) In the socio-demographic segment of the environment.
- (E3.3) In the natural environment.
- (E3.4) In the technological segment of the environment.
- (E3.5) In the customer market.

Responses of 3,4,5 on the scale were considered to reflect a high degree of implementation of methods and tools supporting solution space development. In group A companies, the total indicator of the level of implementation of methods was 46%. The detailed distribution of the levels of implementation is shown in Figure 1.

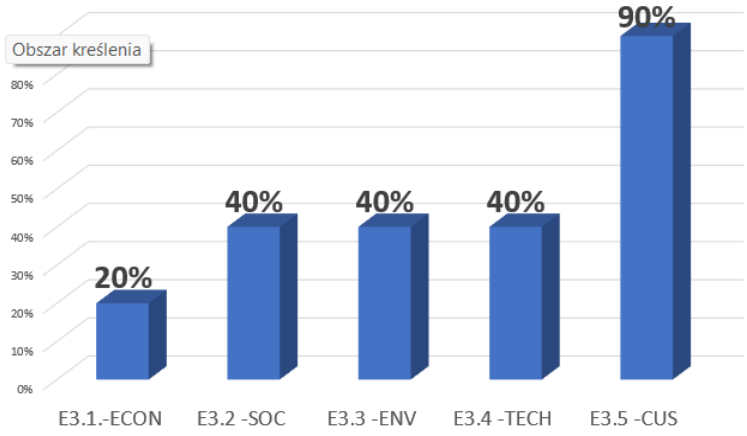

Figure 1: Chart 1. Detailed distribution of the level of implementation of methods supporting solution space development in group A companies.

On the other hand, in group B companies, the total indicator of the level of implementation of the methods was 72%. The detailed distribution of the levels of implementation is presented in Figure 2. These values were not in line with expectations, while the very fact of a considerable use of methods for tracking changes in the environment of group B companies results from high product customisation in the whole segment of enterprises with high customisation level.

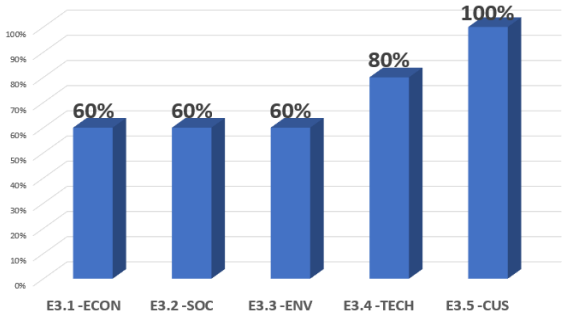

Figure 2: Detailed distribution of the level of implementation of methods supporting solution space development in group B companies.

In order to identify the group of companies supporting robust process design (questions a to j) and choice navigation (questions from b to c), the following questions were posed: The extent of application of the following technologies: (1 – not used, 2 – used to a very small extent; 3 – used to a small extent; 4 – used to a large extent; 5 – used to a very large extent)

- (E3.6) Internet of Things.
- (E3.7) Artificial Intelligence.
- (E3.8) Cloud computing.
- 9E3.9) CAD, CAM, CAE.
- (E3.10) Reverse engineering.
- (E3.11) 3D printers.
- (E3.12) Transport robots (Automated Gaided Vehicle).
- (E3.13) SCADA.
- (E3.14) MES (Manufacturing Execution System).
- (E3.15) e-Kanban.

Responses of 4,5 on the scale were considered to reflect a high degree of implementation of methods and tools supporting robust process design and choice navigation. In group A companies, the total implementation level of methods supporting robust process design was 60%, while the total implementation level of methods supporting choice navigation was 50%. Figure 3 shows a comparison of the implementation levels of methods supporting robust process design (questions from a to j) and choice navigation in groups A and B.

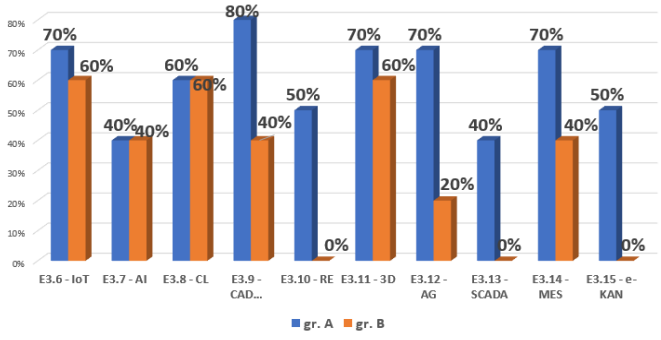

Figure 5: Comparison of implementation levels of methods supporting robust process design (questions from a to j) and choice navigation in groups A and B.

Detailed analysis of the distribution of implementation levels of methods supporting robust process design in group A indicates the highest level of implementation of CAD, CAM, CAE methods, which is most likely due to the wide availability of the above technologies. High implementation level of 70% was also identified for such methods as: a – Internet of Things, f – 3D Printers, g – Automated Gaided Vehicle and – MES. The lowest

implementation level for group A companies was identified for such methods as: b – Artificial Intelligence ora h – SCADA. In contrast, in group B companies, the total implementation level of methods supporting robust process design was 32%, while the total implementation level of methods supporting choice navigation was 50%. The detailed analysis of the distribution of the implementation levels of methods supporting robust process design in group B companies shows the highest scores for such methods as IoT, Cloud Computing and 3D printers. In contrast, three groups of methods: Reverse Engineering, SCADA and e-Kanban had zero implementation levels.

4.4.4 Stage 4 – Spearman's Rank Correlation Tests.

In order to verify whether there is a statistical correlation between the implementation level of Industry 4.0 management methods and tools and the performance of enterprises in terms of triple bottom line objectives, a correlation analysis was conducted. Since the variables take values on an ordinal scale, Spearman's rank correlation was used. Statistical analyses were performed using Statistica 13.1 software. Spearman's rank analysis was performed assuming a significance level of $p<0.05000$. The strength of the correlations was assessed based on the classification presented below in Table 1. The interpretation of the correlation coefficient does not provide a clear answer on the causal relationship, but indicates the existence of a certain statistical relationship between the variables examined, which is one of the conditions for the existence of a cause-and-effect relationship (Małkowska-Borowczyk, 2011).

Table 1: The strength of the correlations.

Correlation coefficient value	Interpretation
r ≤0.2	Virtually no relationship
0.2< r ≤0.4	Low but clear linear correlation
0.4< r ≤ 0.7	Moderate correlation
0.7< r ≤0.9	Significant correlation
0.9< r ≤1	Very strong correlation

Elaboration based on Ostasiewicz, Rusnak, Siedlecka, (2000) .

Table 2 presents the results of Spearman's Rang correlation between the implementation level of Industry 4.0 methods and tools supporting the processes of solution space development robust process design and choice navigation and the level of achievement of triple bottom line objectives.

Table 2: Spearman's Rang correlation.

Objectives/Methods		Human Resources aspect		Environmental aspect		Economic aspect
		E.2.2	E.2.3	E2.4	E2.5	E2.1
solution space development	E3.1	0,232510	0,055048	0,026032	0,092053	-0,007062
	E3.2	0,306320	0,067530	0,085222	0,053806	0,001929
	E3.3	0,409306	0,015822	0,073348	0,040235	0,063563
	E3.4	0,177733	0,075493	0,040583	0,058790	0,138388
	E3.5	0,051646	0,151659	0,229805	0,162892	-0,002757
sobust process design and choice navigation	E3.6	0,232510	0,055048	0,118231	0,184938	0,195864
	E3.7	0,306320	0,067530	0,088012	0,128992	0,178924
	E3.8	0,409306	0,015822	0,019361	0,186947	0,246889
	E3.9	0,177733	0,075493	0,068499	0,080334	0,116630
	E3.10	0,051646	0,151659	0,148908	0,096759	0,160551
	E3.11	0,279472	0,046321	0,094857	0,153698	0,160796
	E3.12	0,083694	0,190714	0,135461	0,205505	0,305156
	E3.13	0,131735	0,153927	0,201914	0,190439	0,339416
	E3.14	0,140805	0,128516	0,138452	0,176396	0,320284
	E3.15	0,332559	0,143282	0,209248	0,265239	0,217790

Analysis of Table 2 leads to the following conclusions:

- Figures highlighted indicate all significant correlation coefficients in the ranges between $0.2< r \leq 0.4$ and $0.4< r \leq 0.7$ which indicates a low but clear linear correlation in the first case and a moderate correlation in the second case.
- All significant correlation results are positive, which means that an increase in the implementation level of individual methods and tools supporting the solution space development robust process design and choice navigation processes is accompanied by an increase in the efficiency in terms of achieving triple bottom line objectives.
- The achievement of higher goals in the economic aspect is accompanied by an increase in the level of implementation of methods supporting robust process design, in particular (E3.12) Automated Guided Vehicles, (E3.13) SCADA, (E3.14) MES, (E3.15) e-Kanban, and (E3.8) Cloud computing. These methods and tools are related to the operational manufacturing of products.
- The achievement of more ambitious environmental targets is accompanied by an increase in the implementation level of methods: (E3.5) related to tracking changes in the customer market supporting solution space development processes and (E3.12) Automated Guided Vehicles, (E3.13) SCADA, and (E3.15) e-Kanban, which are conducive to robust process design.
- The achievement of more ambitious human resources objectives is accompanied by an increase in the implementation level of such methods as:(E3.1) tracking changes in the economic segment of the environment, (E3.2) in the socio-demographic segment of the environment, (E3.3) in the natural environment, to support solution space development processes, as well as (E3.13) SCADA, and (E3.15) e-Kanban conducive to robust process design.3. Results
- This section may be divided by subheadings. It should provide a concise and precise description of the experimental results, their interpretation, as well as the experimental conclusions that can be drawn.

5. Results and Discussion

The aim of the paper was to explore the question of a potential correlation between the implementation level of KM 4.0 methods and tools supporting product customisation and the level of corporate sustainability goals achieved. Exploring future directions in perspectives for stakeholders the following areas of using KM 4.0 methods and tools could be distinguished:

- Replace human labour with automated work.
- Increase resource flexibility through the use of network solutions.
- Support the identification and outsourcing of processes that do not meet best practice requirements.

Currently, the Polish market (as well as the entire EU market) is facing declining labour resource in all areas of business processes. The application of new emerging technologies not only improves the process of delivering a customized product at mass prices, but in many cases makes it possible to realise the process at all by replacing human labour with automated work. With reference to future directions in group A companies, highly efficient in terms of achieving triple bottom line goals, the implementation level of KM 4.0 methods and tools supporting robust process design and choice navigation was significantly higher compared to group B companies. The methods indicated above largely concern operational and production processes and allow flexible delivery of highly customised products at a price comparable to that of mass products. The result of applying the modern methods of Industry 4.0 in these areas is an increased efficiency in terms of achieving objectives in economics, human resources and environmental aspects. With regard to the implementation level of methods supporting solution space development processes, group B had higher scores than group A. Although the result differs from expectations, this is due to the high product customisation in the entire segment of the companies surveyed.

Abstract: The research examines technological competencies from the perspectives of both human and technical components, emphasizing their significance in responding to corporate management challenges. Recent global changes have triggered significant technological transformations, presenting new challenges for corporate management. In this context, technological competence – encompassing both qualified human resources and technical innovations – plays a crucial role in the success of the responses provided by companies. The objective of the study is to demonstrate how technological competencies affect a company's economic performance and strategic adaptation capabilities. Data collected within the research framework included economic information provided by companies, such as revenue and staff numbers, as well as specific data related to technological forecasting methods. The analytical methods employed enabled the creation of a comprehensive understanding of the role technological competencies play in the economic context. The research underscores how the development of technological competencies can assist companies in successfully navigating through the challenges posed by technological changes. The findings indicate that the development of human resources and the integration of technological innovations are indispensable for strengthening corporate success and market position. Expert-type companies, which facilitate knowledge-based development and the introduction or marketing of new technologies, particularly benefit. In these companies, not just the technical equipment, but also human capabilities are decisive in successfully responding to technological challenges. This supports the importance of combining human resource development and technological innovations. The application of technological forecasting methods enables companies to better anticipate and manage market and technological trends, further strengthening their adaptive and innovative capacity. In summary, the research concludes that the harmony between technological competencies, knowledge, and corporate strategy enhances organizational competitiveness, highlighting the importance of knowledge-based development and the expansion of qualified human resources. To successfully adapt to the dynamics of technological changes, companies need to integrate technological competencies at a strategic level, thereby promoting knowledge-based economic growth and long-term success.

Keywords: Technological Competencies, Economic Performance, Corporate Management, New Technologies

1. Introduction

In recent years, the business landscape has undergone significant transformations due to rapid technological advancements and shifting global dynamics. These changes have not only redefined the market conditions but also reshaped the way companies operate and compete. Central to navigating this evolving environment is the development of technological competencies which encompass a blend of qualified human resources and advanced technical innovations.

Understanding and harnessing these competencies have become pivotal for companies aiming to maintain a competitive edge and respond effectively to management challenges. While it may seem intuitive that technical competency positively influences economic performance, empirical evidence is mixed. Some studies, such as Oztemel and Ozel (2019), highlight the substantial role of technological infrastructure in enhancing company performance, whereas others, like Ainin et al. (2010), emphasize the importance of technical capability, firm innovativeness, and e-business practices. These mixed findings indicate the need for further research to gain a deeper understanding of how technological competencies affect business performance across different contexts. This study seeks to explore the intricate relationship between technological competencies and corporate management, emphasizing how these elements contribute to a company's economic performance and strategic adaptation. Through a comprehensive analysis of various data sources, including company-provided economic information and technological forecasting methods, this research aims to provide insights into how organizations can leverage these competencies to foster sustainable growth and long-term success in a dynamic global market.

Wolff (2021) discusses the complexities and interconnectivity of modern technologies, such as artificial intelligence and the Internet of Things, emphasizing the challenges they pose for governance and social control.

She highlights the increasing difficulty of understanding and managing these technologies due to their sophisticated nature. Wolff (2021) argues for a more nuanced understanding of technological impact, stressing the need for scholars to explore both the positive and negative effects of technological advancements on society. Also, underlines the importance of developing social, political, and legal tools to guide the evolution of technology in beneficial directions.

The analysis by Ellingrud et. al (2020) highlights the significant impact of automation and digitization on the workforce in operationally intensive sectors. As technologies advance, up to 58% of operational tasks could be automated using existing technologies, dramatically shifting skill requirements. The future demand will focus increasingly on technological skills, with a projected rise of over 50%, and a similar increase for complex cognitive skills. However, many leaders are unprepared for these changes, hindered by a lack of clarity on future skill impacts and insufficient tools to manage the transition effectively.

Considering these global changes and technological advancements, it becomes clear that companies must not only focus on developing human resource competencies but also pay close attention to their strategy formulation processes to successfully adapt and thrive in the rapidly changing business environment.

Hunger and Wheelen (2020) outline that strategic management typically evolves through four phases: from basic financial planning and forecast-based planning to externally oriented strategic planning, and ultimately to strategic management, which incorporates implementation, evaluation, and control into strategy formulation. This evolution reflects the need for organizations to adapt to dynamic environments and transition from rigid, bureaucratic structures to flexible, learning organizations. Such adaptability is crucial as it enables organizations to maintain competitiveness by continually reassessing their strategies and responding quickly to environmental changes.

The novelty of the study lies in its comprehensive examination of how structured technology management and forecasting practices influence a company's technological competence, particularly focusing on both economic performance and strategic adaptability. Additionally, the authors introduce a specific approach to defining and measuring technological competencies using two key indicators: knowledge intensity and technical intensity. Through a comprehensive analysis of various data sources, including company-provided economic information and technological forecasting methods, this research aims to provide insights into how organizations can leverage these competencies to foster sustainable growth and long-term success in a dynamic global market.

Given the significant shifts in the business landscape, it is essential to investigate this area further. The study is based on interviews with representatives from 62 companies to gain deeper insights into their strategic practices and viewpoints. Publicly available business data were also analysed to assess the economic performance of these organizations, comparing them with their systematic approach to developing technological competencies. This comprehensive method enables an examination of how effectively organizations are using their technological competencies to improve their strategic and operational effectiveness amidst ongoing global and technological transformations.

2. Literature Review

Nowadays in the business landscape, the influence of new technologies on organizational strategy, management methods, and corporate performance is profound. The literature review synthesizes findings from various studies that explore these dynamics, offering insights into how businesses are adapting to the technological era.

Marinkovic et al. (2022) stress the critical role of corporate foresight in enabling organizations to anticipate and adapt to rapid technological changes and market dynamics. Their study highlights how effective foresight activities help companies maintain competitiveness by preparing for future scenarios and mitigating potential risks. Also, advocate to integrate corporate foresight into strategic management to enhance responsiveness and strategic flexibility. Zhao et al. (2022) discuss the distinction between corporate foresight and technology foresight in the context of strategic planning and technology management. The authors highlight that while both concepts involve anticipatory functions, they serve different strategic roles within organizations. Corporate foresight is identified as a broader process that encompasses not only technological insights but also environmental scanning, societal changes, and economic shifts, making it integral to overall strategic management. In contrast, technology foresight is more narrowly focused on emerging technologies and their potential impacts on sectors and markets, specifically aiding in technological planning and innovation management.

Ilyina et al. (2020) emphasize the necessity for organizations, particularly within scientific sectors, to adapt rapidly to market changes. They propose a unified digital platform that integrates scientometric indicators and Technology Project Readiness Levels to enhance the management and visualization of scientific and technological competencies, fostering collaboration and innovation across industries. Tronina et al. (2020) suggest a methodological approach to mapping key technological competencies within regions, advocating for "smart specialization" to leverage regional strengths and drive innovation. This strategy aims to align regional capabilities with emerging opportunities, enhancing strategic planning and promoting sustainable economic growth. Oztemel and Ozel (2019) discuss the importance of technological competency assessments in SMEs, particularly in the manufacturing sector. They introduce a model that evaluates essential technological capabilities, providing a roadmap for SMEs to enhance their competitive advantage by aligning their technological infrastructure with contemporary standards. Zoia et al. (2018) examine factors influencing the technological status of Italian firms, finding that firm size, internationalization, and cooperation significantly impact innovation capabilities. The study points to the importance of geographic location and the propensity of technologically capable firms to engage in innovative cooperation. Fuertes et al. (2020) analyse the strategic management literature, noting a lack of theoretical frameworks to guide the formulation and evaluation of strategies in the context of technological advancements. They advocate for a balance between systematic planning and adapting to the organic, often chaotic nature of strategic processes. Belas et al. (2020) investigate management practices within SMEs, noting the critical role of human resources and participative management styles in adapting to changing business environments. Their findings suggest that a strategic integration of human resources is essential for corporate adaptability and performance. Toborek-Mazur and Partacz (2023) delve into how technological development impacts corporate management methods, highlighting the increasing significance of knowledge and technology management as critical components of modern business practices. Hamdani et al. (2018) discuss the impacts of AI, blockchain, and data analytics on corporate structures, predicting a future where traditional hierarchical structures may become obsolete due to the decentralizing power of these technologies. Tanushev (2022) focuses on the strategic adaptation required for businesses to thrive in the digital age, using Kaplan and Norton's strategy maps to outline the influence of digital processes on enhancing customer value and developing sustainable business models. Agolla (2018) presents a model aligning innovation, strategy, and strategic human resource management, positing that integrating these elements enhances organizational competitiveness by fostering an innovative capacity through strategic HR practices. Singla et al. (2018) analyse the transition between technology push and demand-pull strategies in manufacturing, supporting the view that market needs are crucial drivers of innovation. Fettig et al. (2018) explore the impact of Industry 4.0 on organizational structures, showing how the integration of Cyber-Physical Systems necessitates a re-evaluation of corporate strategies to maintain competitiveness in a digitally transformed economy.

The significance of technological competencies has increased substantially in recent years, as demonstrated by numerous studies showing that technological innovations and the associated development of human resources directly impact the economic performance of companies.

This review underscores the importance of technology foresight in equipping organizations to navigate and adapt to rapid technological and market changes. It highlights how integrating foresight into strategic planning and management is crucial for anticipating future challenges and seizing opportunities, thereby enhancing organizational agility and competitive edge in the global marketplace.

3. Research Question

The main research question of the paper seeks to examine the link between management approaches in technology and a firm's ability to develop and maintain technological competencies as a critical factor in today's fast-paced business environment:

- How do structured technology management practices and the use of technology forecasting impact the technological competence of the companies?

Technological competence: The ability of a company to effectively utilize technological resources to achieve competitive advantage. This includes the capacity to integrate, build, and reconfigure internal and external competencies to address rapidly changing environments. (Teece et al., 1997)

Technology management practices: These refer to the systematic approaches and processes that companies use to manage their technological resources and capabilities. This includes planning, implementation, and control of technological activities within the firm. (Gregory, 1995)

Technology forecasting: The process of predicting future technological developments and trends. This involves using various methods and tools to anticipate changes in technology that could impact the company's strategic planning and innovation efforts. (Watts and Porter, 1997)

Emerging from the identified need in the literature to understand the strategic integration of technological advancements, this study aims to:

- Assess the extent to which technology management practices are adopteded by companies.
- Analyse the relationship between the application of technology forecasting methods and technological competence levels.
- Determine the impact of these practices on a companies' capacities to innovate and compete.

Given the rapid evolution of technology and its disruptive impact on markets, the study is bounded by the examination of current technology management and forecasting practices, focusing on their direct correlation with measures of technological competence. It intends to contribute to the strategic management literature by offering empirical insights into the effectiveness of these practices, potentially guiding corporate leaders in optimizing their strategic responses to technological challenges.

4. Methodology

Data were gathered through structured interviews with representatives from 62 technology-intensive companies of varying sizes, including small, medium, and large enterprises. The selection of companies was based on identifying technology-intensive sectors. According to the research findings of Pekk et al. (2021), the telecommunications and electronics industries, as well as the machinery and automotive sectors, were selected for their high technology intensity. As a result of the interviews, two main areas were highlighted:

1. Technology Forecasting Application: Companies were asked about their use of technology forecasting methods, evaluated on a scale of 1 to 4, where:

- 1- indicates no use of technology forecasting,
- 2- acknowledges the importance of forecasting and its integration into decision-making,
- 3- signifies the use of simplified forecasting methods,
- 4- reflects the employment of comprehensive technology forecasting methods.

2. Technological Management Methodology: Companies were also rated on their systematic approach to technology management on a scale of 1 to 4, where:

- 1- Represents a non-systematic approach, where companies that apply technological forecasting and management methods on an ad-hoc or irregular basis.
- 2- Shows little evidence of a structured application of these methods.
- 3- Indicates that companies apply these methods consistently and moderately systematic approach.
- 4- Denotes a highly systematic and integrated technological management systems.

The evaluation of the Technological Management Methodology for the companies is based on several key factors: the systematic application of forecasting methods, the integration of strategy with new technologies, and the presence of systematic management practices. The Technological Management Methodology was classified and assessed accordingly by the authors.

Based on these assessments, a 4x4 matrix was constructed to classify companies according to their methodology in both areas, allowing for the identification of organizations with their systematic approaches in technology forecasting and management.

3. Technological competence was evaluated based on calculated values derived from public financial reports between 2012 and 2022. The calculation encompassed two components:

- Knowledge intensity: added value, derived from the average gross salary can reflect the skill level and knowledge of the workforce),
- Technical intensity: determined by the ratio of technology asset value to total revenue.

Knowledge intensity refers to the degree to which a company's operations and competitive advantage rely on specialized knowledge and skills. Higher knowledge intensity is linked to better innovation outcomes and higher productivity. For example, research by Ainin et al. (2010) demonstrates that companies with a more knowledgeable workforce are better positioned to implement advanced technologies and processes, leading to

sustained competitive advantages. Additionally, studies by Doloreux and Melançon (2008) emphasize the importance of knowledge-intensive industries in driving economic growth and innovation.

Technical intensity can also include other metrics such as the proportion of R&D expenditure to sales, the number of patents per employee, or the extent of technological equipment and infrastructure investments. This indicator measures the extent to which a company invests in technology relative to its overall size and is a key metric for understanding a company's commitment to maintaining and advancing its technological infrastructure. For example, studies like those by Hollenstein (1996) and Falk (2004) use similar measures to assess technical intensity in their respective analyses of innovation activities.

A 62x62 matrix was prepared, ranking companies according to these calculated values to position them based on their level of the two components of technological competence.

The final stage of the methodology involved a comparative analysis between the two matrices to investigate potential relationships or patterns between the companies' structured technology management practices, use of technology forecasting methods, and their overall technological competence. Figure 1 presents the interpretation of the two matrices and the way of examination of the correlations between them.

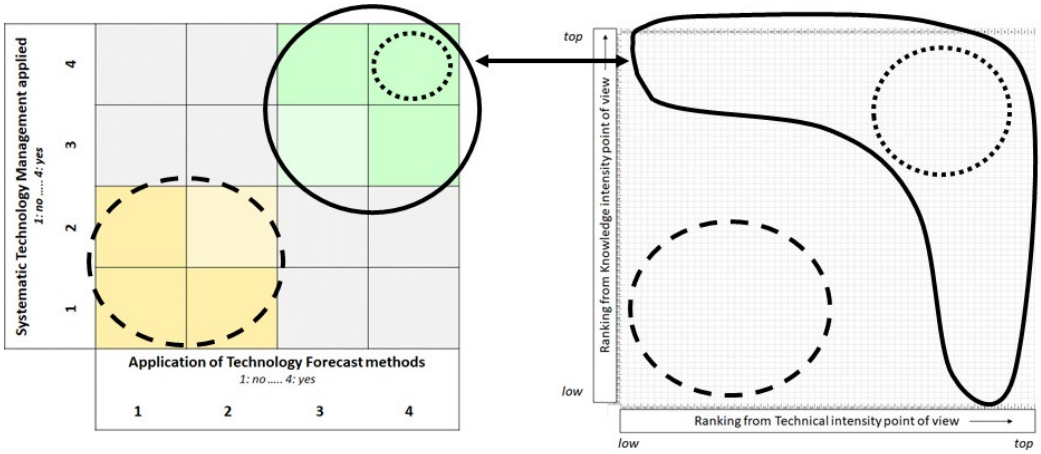

Figure 1: Display and expected relations of 4x4 and 62x62 matrices

This analysis aims to identify whether a systematic approach in these domains is indicative of higher technological competence, thereby providing valuable insights into effective management strategies for adapting to technological advancements.

5. Results and findings

This section highlights the findings derived from the analysis of the 4x4 and 61x61 matrices, which collectively represent the systematic application of technology management and forecasting alongside the calculated technological competence within the sample of the interviewed companies. The analysis aimed to explore how technological competencies - both human and technical - contribute to corporate success. Key observations include:

A. Contribution to corporate success: The study underscores that nearly 80% of the more systematic companies excel in either knowledge intensity or technical intensity, indicating that strong technological competencies in either dimension significantly contribute to corporate success.
B. Distinction in competence: Among the firms with more systematic approach, 3 out of every 7 exhibit strong competencies in both knowledge and technical intensity. This dual strength indicates that these companies, which excel in both dimensions of technological competence, are likely to achieve superior performance and adaptability in their respective industries.
C. Variability in approaches: Conversely, companies with less systematic approaches to technology management and forecasting tend to rank lower in both dimensions of technological competence. This suggests a correlation between the systematic application of technology strategies and higher levels of technological competence.

Figure 2 depicts the distribution of 62 companies based on the application of technology forecasting methods and the systematic nature of their technology management. The lower left quadrant, where both aspects score

low, is the most populated, indicating that majority of the companies do not employ systematic methods in either domain. Contrary, the upper right quadrant represents companies that score high in both, signifying a systematic approach in both technology forecasting and management. For the quadrants where companies have low technology forecasting but high technology management scores, it suggests these firms might prioritize internal processes and day-to-day operations over strategic foresight. This could imply a focus on current operational efficiencies rather than future-oriented planning, which may impact their long-term adaptability and innovation potential.

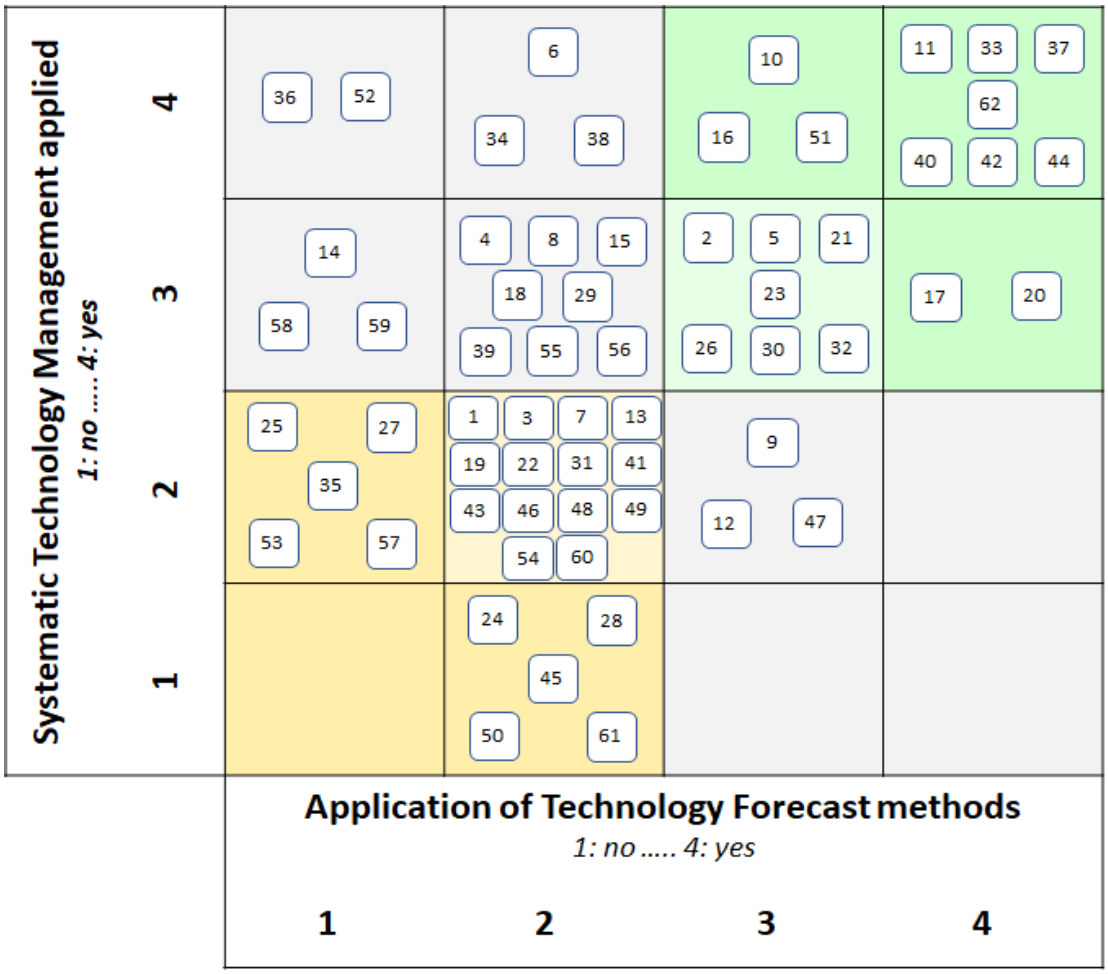

Figure 2: 4x4 matrix in the light of systematic Technology Management and Technology Forecasting methods across the analysed companies

Figure 3 illustrates a 62x62 matrix plotting the Knowledge Intensity and Technical Intensity of 62 companies, calculated from their business data. The marked 'L-shaped' area encloses companies that are strong in either or both dimensions, with those in the upper right quadrant excelling in both areas, indicating robust competencies. The green squares denote companies that were identified as methodical in both technology management and technology forecasting methods in the 4x4 matrix. Notably, three companies highlighted within the greens demonstrate high technical and knowledge intensities, pointing to their substantial capabilities in both domains.

The red squares indicate companies ranked as less methodical in the 4x4 matrix; these generally show weaker intensities in this matrix as well.

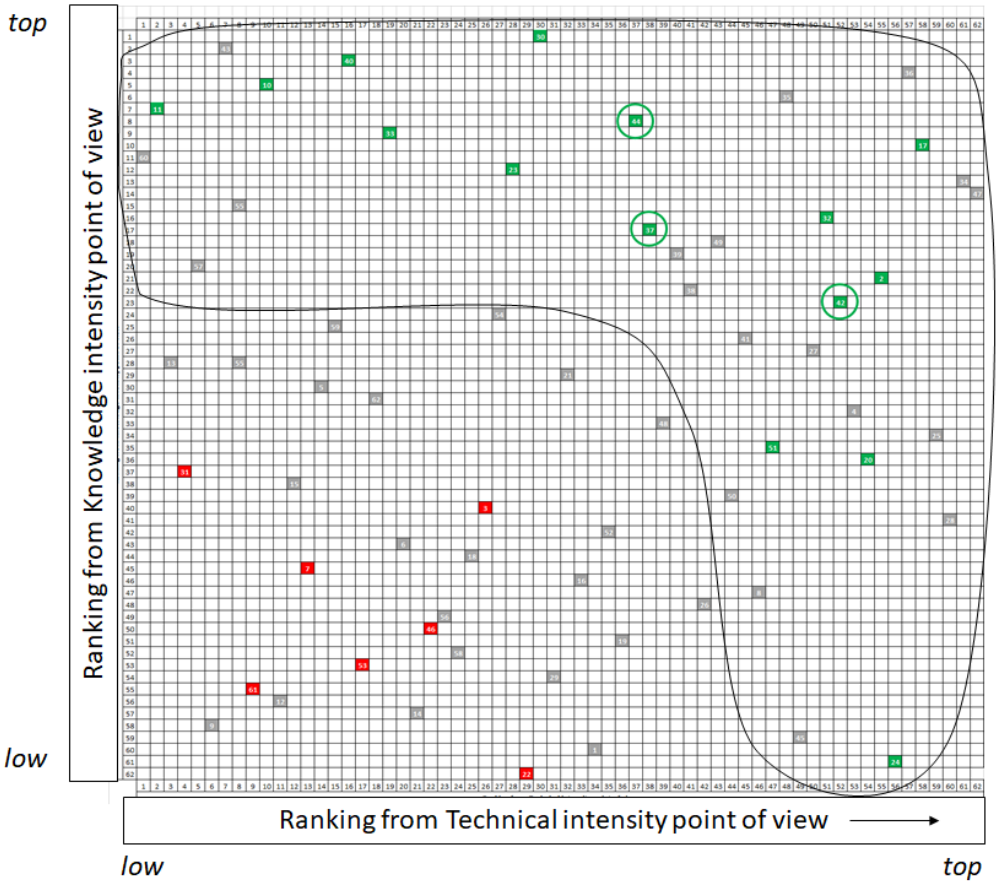

Figure 3: 62x62 matrix in the light of Knowledge intensity and Technical intensity across the analysed companies

The analysed companies do not necessarily show high scores in both dimensions to be successful. High Knowledge Intensity, derived from the added value or average gross wages, suggests that a higher wage is associated with higher-skilled personnel. On the other hand, Technical Intensity, calculated as the ratio of technological costs to revenue percentage, indicates investment in technology. There are successful companies that do not rely on expensive technology for added value, demonstrating that high performance can be achieved through various paths of technological competence.

The analysis of interview data and collected information has led to the following additional conclusions, providing deeper insights into specific trends and correlations observed among the companies:

- Profitability trends: The collected data indicates significant variability in the profitability of companies over the years. For example, "Company 17" experienced exceptionally high profitability in certain years, while in other years, it did not show significant profits. This suggests that some companies achieve periodic or project-based success, driven by specific technological developments or large-scale projects.
- Technology management systematic nature: Following the comprehensive evaluation of the companies' technology management practices, it was found that companies such as "Company 10" and "Company 11" both of which received a high rating (4), generally exhibit better technological intensity and profitability.
- Correlation between systematic technology management and profitability: The analysis reveals that the systematic application of technology management practices is positively correlated with profitability. Companies that more consistently apply these methods, such as "Company 11" (rated 4), generally achieve higher profitability compared to those that are less systematic in their approach, such as "Company 1" (rated 2).
- Impact of human/tech cost index: The analysis shows that companies with a higher human/tech cost index, such as "Company 5" (rated 3), generally achieve higher technological intensity and better long-term performance. This suggests that investments in technology tend to pay off in the long run.

- Sector-specific trends: The differences between sectors are also notable. For example, companies operating in the manufacturing sector, such as "Company 3" and "Company 4", generally exhibit higher technological intensity and productivity. However, their technology forecasting methods are rated lower (2), and their technology management systematic nature scores are (2) and (3), respectively. This suggests that while these sectors benefit from technology management and forecasting, there is still space for improvement in their systematic application to achieve even better performance.

6. Limitations and Future Research

While the study reveals insights into the relationship between technological management practices and corporate success, its scope is limited by several factors. The sample, consisting of 62 companies, provides a focused glimpse but may not reflect the broader industry landscape. Moreover, the research's cross-sectional design captures a single moment in time, which might not encompass the evolving nature of technological competencies and forecasting practices. Self-reported data from interviews could also introduce a degree of bias, as companies may present themselves in a more favourable light.

Further research could delve into how companies with high technical intensity approach innovation versus optimization. This research could explore the strategic decisions that lead companies to prioritize one over the other and how this affects their competitive advantage in the market. It would be insightful to examine if companies with both high knowledge and technical intensities are more innovation-oriented compared to those with high technical intensity but lower knowledge scores, which may focus on optimizing current processes. A more granular analysis of industry-specific trends could provide a detailed understanding of how different sectors adopt methodical technology management and forecasting practices. Investigating sectoral distributions of companies in the matrix may identify patterns that suggest certain industries are inherently more inclined towards systematic technological strategies. This line of research could uncover industry benchmarks and best practices that drive technological competence.

7. Conclusion and Discussion

This research has undertaken a comprehensive examination of how structured technology management and forecasting practices influence a company's technological competence. The findings from the analyses of both the 4x4 and 62x62 matrices provide insightful answers. Nearly 80% of companies with methodical orientations demonstrate excellence in either knowledge or technical intensity, indicating that a strong presence in at least one of these dimensions is pivotal to corporate success. Moreover, a significant portion of the - companies with systematic management show strength in both dimensions, underscoring the dual significance of robust knowledge and technical capabilities for superior industry performance and adaptability.

Contrary, companies with less structured approaches tend to exhibit lower levels of technological competence, as indicated by their positions in the lower left quadrant of the matrices. This alignment suggests that systematic practices in technology management and forecasting are correlated with enhanced technological capabilities.

The examination of the distribution of companies with systematic and less systematic approach within the 62x62 matrix has yielded additional insights. The green squares, representing the companies identified as methodical in the 4x4 matrix, are predominantly positioned within the 'L-shaped' area, reinforcing the notion that methodical practices correlate with higher technological competencies. Notably, the three companies that excel in both knowledge and technical intensities affirm that excellence in both areas can coexist within highly systematic frameworks.

The novelty of this research lies not only in examining the structured practices of technology management and forecasting but also in defining and measuring technological competencies using specific indicators: knowledge intensity and technical intensity. This approach provides a deeper understanding of how these competencies are developed and maintained within companies.

Practically, these findings suggest that companies should consider investing in systematic technology management and forecasting as part of their strategic planning. This does not negate the effectiveness of high technical intensity or the value of skilled personnel; rather, it emphasizes the additional competitive edge that structured foresight can provide.

In conclusion, as businesses continue to navigate the ever-changing technological landscape, it is evident that those who adopt structured and well-established strategies in their management and forecasting efforts are better positioned to exploit their technological competencies for economic and strategic gains.

The research highlights the importance of structured technological practices in enhancing both economic performance and strategic adaptability, providing insights for companies aiming to achieve long-term success in a dynamic global market. Furthermore, it contributes to the existing body of knowledge by providing empirical observations on the effectiveness of these practices, thus contributing to the understanding of the strategic integration of technological advancements.

Abstract: Most state-owned enterprises (SOEs) in South Africa face serious challenges with tacit knowledge loss risks, largely due to a lack of alignment and integration points for human resource management (HRM) practices in knowledge management to effectively manage such knowledge loss risks. This study was interdisciplinary in nature, presenting empirical evidence of a strong connection between HRM and knowledge management (KM), especially its knowledge risk management (KRM) sub-domain. The research paper employed a qualitative research design, which involved collecting in-depth qualitative data through interviews with 20 human resource (HR) managers in 9 SOEs. The qualitative data extracted through the interviews were analyzed thematically using Atlas.ti software. The research results revealed that HRM practices are not aligned, integrated and focused on mitigating enterprise tacit knowledge loss risks in most South African SOEs. A lack of HRM alignment and integration was a serious issue across the board, irrespective of whether the participating SOEs had knowledge management structures, roles and strategies in place. However, on a positive note, HR managers acknowledged the need for the integration and alignment of HRM strategies regarding effective knowledge loss risk management. The study highlights a deficiency in HRM alignment and integration for effective knowledge loss risk management. The researcher infers that HRM alignment and integration in KRM has a critical strategic and operational role to play in the mitigation of enterprise knowledge risks, as well as in developing the required knowledge management capabilities. The study sought to close a knowledge gap in the existing body of knowledge by presenting empirical evidence identifying alignment and integration points of HRM strategies into KRM for SOEs to effectively reduce knowledge loss risks. Furthermore, the study presents a strong link between HRM and KRM in building KM capacity for the reduction of the risks associated with tacit knowledge loss.

Keywords: Tacit Knowledge Loss; Human Resource Management; Knowledge Risk Management; Knowledge-Based View; Resource-Based View; State-Owned Enterprises; South Africa.

1. Introduction

Human resources and knowledge assets are key drivers of organisational performance, innovation and sustainability in the current global knowledge economy. State-owned enterprises (SOEs) are key instruments wholly or partially owned by the state to drive the economic development agenda in many developing and developed nations across the globe. In South Africa, SOEs are considered as catalysts for economic growth, employment and the sustainability of the economy. Phaladi (2023a) observed that SOEs are facing a number of knowledge loss-related risks due to voluntary, involuntary and the absence of knowledge-driven human resource management practices (HRMPs) that are aligned and integrated to mitigate knowledge risks. The Resource-Based View Theory (RBVT) of the business considers knowledge workers as drivers of competition, organisational effectiveness, innovation and productivity (Barney 2001). Similarly, the Knowledge-Based Theory (KBT) of the firm prioritizes organisational intangible assets such as knowledge, expertise and skills as drivers of organisational performance, innovation and sustainable competitive advantage (Grant 1996). Extant research demonstrates that the role of human resource management (HRM) in knowledge management (KM) is certainly unavoidable (Gürlek 2020). SOEs across the globe, including South Africa, are experiencing some serious tacit knowledge risks as a result of a lack of high employee attrition, knowledge-driven HRMPs and retention strategies. Such tacit knowledge risks threaten the economic development, innovation capacity and sustainability of these SOEs. The situation is worse in most developing countries because their economic performance and viability are much dependent on well-run SOEs. However, it remains unknown as to whether HRMPs in South African SOEs are well-aligned and integrated in knowledge risk management (KRM) strategies. In an organisational context, knowledge, competencies and skillsets are enterprise-specific intangible assets that are strategically linked or contingent on human resources. However, the extant corpus of research observes that these organisational intangible knowledge assets could place companies at risk as and when carriers of such knowledge decide to terminate their relationships with their employers (Phaladi and Ngulube 2024). KM research characterises such potential risks as knowledge loss risks that require management interventions (Durst and Zieba 2019).

Emerging research characterizes such a required management approach as knowledge risk management (Durst, Lindvall and Bruns 2020). KRM is a novel research niche area within the broad KM field of practice that seeks to

assist companies to predict and respond to knowledge-related risk occurrences. Phaladi (2023a) opines that HRMPs could play a crucial role in mitigating such knowledge-related risks. This is largely due to the fact that the effective management of organisational knowledge-related risks are contingent on firm-specific knowledge workers (Phaladi and Ngulube 2024). Nevertheless, extant literature points to the significant role of HRMPs for organisations such as state-owned enterprises to mitigate such knowledge-related risks. The role of HRMPs in the management of enterprise-specific knowledge assets is undisputable. Phaladi, Mhlongo, Omarsaib and Mpungose (2024) point to very limited empirical research in the global literature directly linking, aligning and integrating HRM practices for the effective management of knowledge loss risks and knowledge risk management. These authors lament the dearth of literature linking HRM systems to KRM in SOEs globally. This is despite the fact that the role of HRM and its practices in the mitigation of enterprise knowledge risks is inevitable. Phaladi et al (2024) indicate that such a relationship remains blurred in the current body of KRM research and practice. Much of the extant research on tacit knowledge loss risks is silent on the alignment and integration of knowledge-driven HRM systems with the management of such risks in both private and public enterprises. The study explores the alignment and integration of HRMPs in managing organisational tacit knowledge loss in SOEs. It also explores the need for such integration, its implementation, and the effectiveness of HRMPs in managing and mitigating knowledge loss risks. The research also proffers strategies for implementing such alignment and integration in the organization.

2. Literature Review

2.1 Human Resource Management Practices

Researchers have argued that tacit knowledge is heavily dependent on firm-specific workers, and that HRMPs such as recruitment, career management, learning and development, performance management, compensation and rewards, as well as the facilitation of a knowledge-driven organisational culture and behaviours, are crucial for managing knowledge and mitigating its potential loss within organisations (Le 2024; Phaladi et al. 2024). Proponents of the RBVT argue that HRMPs are key drivers of a sustainable competitive edge, innovation capacity and superior enterprise performance in knowledge-based competition (Murali and Kumar 2014). Recruitment as an HRM practice is considered an important activity within organisations and provides a direct link between KM and HRM. Phaladi (2023a) argues that the HRM recruitment process is by nature knowledge-driven, largely because it is tasked with the responsibility of sourcing much-needed firm-specific human resources. Thus, recruitment practices serve as a facilitator for the acquisition of required knowledge, competencies and skillsets. As such, it is the genesis of the nexus between HRM and KM in organisations. Learning and development is also an important knowledge-driven HRM practice that facilitates the acquisition of knowledge and absorptive capacities in organisations (Sarfraz et al. 2023). Kianto et al (2017) assert that retention practices such as compensation, rewards and incentives could be playing an important role in ensuring that organisations retain and protect firm-specific employees and their much-needed knowledge, competencies and skillsets to survive in knowledge-based competitive markets. Scholars have established that retaining highly experienced workers who are at the top of their performance and productivity levels remains a serious problem area for the HRM establishment and executives (Allen and Vardaman 2021). Phaladi (2023b) posits that knowledge-driven retention practices help to facilitate the retention and protective capacity of company-specific knowledge assets and, as result, such practices serve to enhance knowledge sharing, retention and protective capacities. Scholars concur that HRMPs that are knowledge-driven in character will serve to facilitate and develop knowledge-driven cultures, activities and behaviours (Le 2024; Phaladi 2023a). Consequently, such knowledge-driven practices will directly or indirectly facilitate the effective mitigation of knowledge loss risks in state-owned enterprises.

2.2 Knowledge Management

The knowledge-based view of the firm argues that knowledge assets such as knowledge, skillsets and abilities to perform organisational duties will provide companies with sources of superior performance and a sustainable competitive edge over their competitors (Grant 1996). Knowledge management involves the use of resources to create an environment where knowledge is easily accessible, thereby enabling firm-specific employees to develop their own knowledge and apply it for the benefit of the organization, encouraging the sharing and utilization of knowledge (Murali and Kumar 2014). Knowledge-intensive companies such as SOEs require a strong nexus between HRM and KM, which can enhance performance and lead to its success (Phaladi 2021). Within SOEs, individual employees are sources of organisational knowledge. Ideally, in order for knowledge to be acquired, created, shared and retained, HRM establishments should develop their practices in such a way that

they help facilitate the effective management of knowledge in order to lessen the risks of losing organisational tacit knowledge to their competitors. Phaladi (2023a) opines that a majority of the SOEs in South Africa are lacking key knowledge-driven HRMPs, which adversely affects the management, sharing and retention of organisational tacit knowledge. El-Farr and Hosseingholizadeh (2019) assert that HRM plays a significant role in supporting and facilitating the management of knowledge within organisations. It is for this reason that HRMPs should be aligned and integrated into knowledge management processes. Ideally, beyond this alignment and integration point, HRMPs should be knowledge-driven and integrated enough to effectively play a meaningful role in the management of tacit knowledge loss risks in SOEs.

2.3 Knowledge Risk Management in SOEs

In relation to KRM, extant literature defines it as the application of a set of tools and techniques used to identify, measure, prevent and lessen the risks related to the creation, use, sharing and retention of enterprise knowledge (Durst and Henschel 2020). In other words, KRM presents researchers, practitioners and business executives with the strategic tactics to use knowledge as a valuable firm-specific resource so that they are in a better management position to predict, measure and mitigate the risks associated with organisational knowledge. However, scholars lament the fact that conceptual and empirical research on the topic of knowledge risk management in private and public enterprises is still very rare (Durst et al. 2023). Phaladi (2023a) further notes that this also applies to empirical papers linking HRMPs to knowledge risks and its management in SOEs. Phaladi et al. (2024), in their global systematic literature review linking and integrating the role of HRM in KRM in SOEs, illustrate the scarcity of scholarly contributions in this research strand, despite the fact that knowledge risks are considered serious enterprise risks affecting knowledge-intensive business enterprises such as SOEs (Kumar 2020). The few existing studies in this research strand, especially in SOEs, indicate that these enterprises are quite vulnerable to serious knowledge loss risks given the fact that they are resource-intensive, knowledge-intensive learning organisations (Kumar 2020; Phaladi 2023a). Internationally, SOEs are key instruments in driving and shaping the economies of the world, in both developed and developing nations. Scholars observe that they are no exception to the great resignation and knowledge exodus affecting private and public companies in the current knowledge economy (Serenko 2023). High turnover (voluntary and involuntary) and the lack of strategies to retain knowledge workers and their much-needed intangible assets (knowledge, competencies and skills) threaten SOEs' ability to deliver on their developmental mandate, especially those operating in the developing economies of the world (Phaladi and Ngulube 2024). Nevertheless, it remains unclear as to whether the HRMPs in these public enterprises can be considered to be knowledge-driven, aligned and integrated to identify, predict, measure, respond to and mitigate such tacit knowledge risks associate with resignations and retirements.

3. Methodology

The research paper deployed a qualitative research approach which involved collecting in-depth qualitative data through interviews in South African state-owned enterprises. The researcher conducted interviews with twenty managers (20) in the human resource management departments of nine SOEs that were purposively selected for the purpose of gathering answers to the research questions, as illustrated in Figure 1 below. The researcher ensured ethical considerations, including obtaining permissions, maintaining anonymity and confidentiality, obtaining informed consent, and using the interview method in selected SOEs. The sample size of 20 managers in HRM was deemed adequate for the purpose of gathering in-depth data and developing a rich picture about the phenomenon under study. According to Creswell (2014), a few cases or interviewees, ranging from 1 to 40, are considered adequate for qualitative research for scholars to formulate a rich picture of the research phenomenon. The qualitative data collected through the interviews were analyzed thematically using Atlas.ti software.

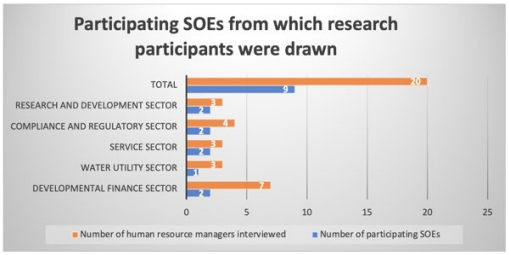

Figure 1: Participating SOEs from which research participants were drawn

4. Research Findings

Regarding the research question on whether HRMPs are aligned and focused on lessening tacit knowledge loss in SOEs, the research shows that 50% of participants think that their processes are aligned, while 50% disagree, indicating a lack of focus on managing organisational knowledge loss. Pertaining to whether there was a need for the integration of HRMPs in KRM, all the participants agreed that there was indeed such a need. Similarly, they articulated the need for a better understanding of KM vocabulary and tools in order to better reflect on their processes. Such an understanding would help HR managers to align themselves and their practices effectively in dealing with knowledge loss risks. In three cases, where KM structures and roles were well-defined, the participants postulated that they work in harmony with the KM practitioners in the SOEs to identify and mitigate knowledge-related loss risks. Nevertheless, their functions were not aligned and integrated to ensure the better management of such risks.

The issue of alignment and integration, regardless of the presence of KM roles and processes, was identified as significant. The HR manager in SOE1 put into words the lack of synergy in the following manner:

> *At the moment, the knowledge management people are there and we are here as the HR people, we still live like that, that is one of the things we need to bring together. We work together with knowledge management unit, but I cannot claim it to be an integration. It is not an integration that happens automatically (HR Manager #1).*

Regarding the follow-up research question on how such integration should be approached and implemented, HR managers in SOEs without knowledge management strategies, systems, structures and processes suggest that strategies, structures, roles or resources for knowledge management should be a starting point for the integration process, as there was no existing integration at the time of the study. One HR manager explained the state of affairs as follows:

> *What more can be done is for us to realise the value of knowledge management in an organisation, and not for our own good as individuals, but for the company good. In the same manner, that we are seeing that need to formal processes on knowledge management. We actually see the significance of strategy on that (HR Manager #17).*

Finding the gaps in one's knowledge is the first step towards developing a plan and procedures to close them. In those state-owned businesses with established KM strategies, structures, rules and procedures, the alignment scenario was different. In order to mitigate the effects of voluntary turnover and the loss of enterprise knowledge, their HR strategy places a high priority on the management and retention of mission critical skills. One participant narrated the science behind their HR strategy as follows:

> *Yes, we are implementing talent management; it was there but we are making it more formal. Therefore, that talent management is all-inclusive, including retaining critical knowledge it will include making sure that we keep our critical resources (HR Manager #1)*.

Based on the data analysis, it is evident that HRM departments were, in certain instances, re-aligning themselves to address the intricacies of knowledge in a knowledge-driven economy by using integrated people management approaches that consider talent holistically. More of such will help to reduce possible knowledge loss in these state-owned firms by promoting enterprise knowledge-driven activities and behaviours.

Regarding the overall effectiveness of HRM processes in enabling or easing the management and minimization of tacit knowledge loss in SOEs, in response to this study question, all the participants expressed concern about the gaps and areas in which their procedures for ensuring retention and minimizing organisational knowledge loss needed improvement. They articulated their opinions on this study issue as follows:

4.1 Effectiveness of HRMPs

Thirty percent of the participants indicated that their practices work well for helping their SOEs to effectively manage and retain much of their organisational tacit knowledge. Their answers did, however, also highlight shortcomings and potential areas for improvement. An SOE1 respondent, who discussed how KM is integrated into organisational life, stated the following:

> *Very effective. I think we are holding our space. However, there are areas for further development. On a scale of one is to five. I will give us four. As I said, we have systems, we have structures and we have policies that are highly effective (HR Manager #1).*

Even if, in some instances, the retention of human resources and their knowledge was achieved through deliberate acts of management and efforts aimed at minimising potential enterprise-specific tacit knowledge loss, there was also a need to continuously identify integration points for alignment and further improvements.

4.2 Partial or Average Effectiveness of HRMPs

Thirty percent of the HR managers found their practices to be neither effective nor ineffective, with some being partially effective but not very effective in reducing involuntary turnover and knowledge loss. They identified gaps and areas for further alignment and integration points between their HRMPs and KM strategies to ensure the proper management of knowledge loss risks in their SOEs.

The participant in SOE9, where the KRM and KM philosophy was not institutionalised, explained the situation as follows:

> *I think we have not been deliberate enough to be effective. In some cases, we have done well, in some cases we have not done well. Those pockets of excellence are here and there, but not necessarily calibrated well to a point where we can say we are effective. Therefore, there is still lots of gaps from one practice to the other (HR Manager #17).*

The aforementioned case highlights the lack of coordinated strategies and practices in knowledge management, and gaps in HRMPs for employee recruitment and retention. HR managers were not intentional in managing enterprise-specific knowledge, mainly because of the informal nature of how it manifested in their public enterprises. Therefore, in some instances where KM was not institutionalised as part of the organisational processes, there was a gap. On the other hand, there was also a need to perfect the science and embrace certain KM principles.

4.3 Ineffectiveness of HRMPs

This study established that 40% of HR managers found their practices in retaining and managing organisational knowledge ineffective. Even HR managers who had institutionalized knowledge management in their SOEs admitted that their processes were not yet effective. This situation was exemplified by the participant from SOE2, who stated:

> *I am tempted not to say that we are not there yet, we are not very effective, as we would like to be because of those gaps and then the loss of opportunities for those synergies for us to be able to work together. You know, they started harvesting knowledge many years ago, I think as early as 2013 or so, but we started becoming very involved and get to know what they are doing in recent times. That is why I am saying there has been that lack of working in silos, yet we are trying to achieve as a common goal (HR Manager #9).*

In certain SOEs, HR managers struggled with working in silos due to a lack of collaboration with relevant units for knowledge management. Many SOEs (67%) had not formalized knowledge management, resulting in ineffective HRMPs in managing and retaining company-specific knowledge. Their practices were not designed to support knowledge management and, therefore, the mitigation of inherent firm-specific knowledge loss risks.

5. Discussion of the Findings

This research explored the alignment and integration of HRM practices in managing and lessening tacit knowledge loss in selected SOEs in South Africa. Extant research highlights the significance of the interface, alignment and integration of HRMPs into KM for ensuring the mitigation of tacit knowledge loss (Murali and Kumar 2014; El-Farr and Hosseingholizadeh 2019; Gürlek 2020). However, the research findings point to a lack of alignment and integration as a serious issue facing a majority of South African SOEs. Regardless of whether SOEs have KM roles, functions or processes in place, this remains the case. The research suggests that streamlined HRMPs can improve knowledge absorptive capacity, KM capability and retentive capacity by supporting knowledge management. Moreover, HR recruitment and staff training practices are crucial for developing knowledge absorptive capacity in SOEs.

Furthermore, the study argues that if companies can invest in staff retention interventions such as retention strategies; rewards and recognition systems; and in other knowledge-based practices such as coaching and mentoring, job rotation and job shadowing, then knowledge protective capacity will be enhanced. The research also suggests that investing in staff retention interventions, rewards and recognition systems, as well as

knowledge-based practices like coaching, mentoring, job rotation and job shadowing, can enhance knowledge protective capacity.

All twenty HR managers in this qualitative study concurred that there was a need for the alignment and integration of HRM systems in KM for the successful mitigation of firm-specific knowledge loss. Furthermore, HR managers need to have a better understanding of knowledge management vocabulary and the tools to better use these techniques. In those SOEs where KM functions, practices, structures and resources were not institutionalised, the research found that there was nothing much to align and integrate as such. However, in order for these public enterprises to align and integrate their KM and HRM practices, the best starting point is to develop an understanding of the science behind knowledge management, strategy, function, roles and resources. A lack of awareness and education on the philosophy behind KM is a significant challenge. Hence, creating awareness of what is missing in terms of the strategies and procedures to close the gap will serve to advance the discourse. Consequent to this lack of awareness and education, the retention of critical skills and expertise will remain a challenge.

An overwhelming majority of HR managers concurred that their practices were ineffective in mitigating and managing tacit organisational knowledge loss, largely due to a lack of alignment and integration in support of KM. The majority of the HR managers concur that the loss of enterprise tacit knowledge is due to a lack of knowledge-driven retention strategies, which can decrease the survival chances of many SOEs. Recent studies have shown that knowledge loss in SOEs leads to knowledge risks negatively impacting organisational performance, innovation and sustainability (Durst and Zieba 2020; Kumar 2020; Phaladi and Ngulube 2024). Their practices were not designed to support KM, and consequently the mitigation of inherent firm-specific knowledge loss risks.

5.1 Limitations and Directions for Future Research

The study is an empirical contribution qualitatively exploring the alignment and integration points of HRM systems into KRM in South African SOEs. Future studies will benefit from quantitative surveys testing the alignment and integration of HRMPs to mitigate knowledge loss risks in organisations. On a global scale, whilst using South African SOEs as a case, the paper points to the scarcity of scholarly contributions linking, aligning and integrating HRM strategies into knowledge loss risk management. The picture of such alignment and integration points remains blurred in the extant research, both conceptually and empirically. Large portions of the current research dedicated their efforts to establishing the inevitable role of HRM and its practices broadly in facilitating KM processes and capacities, but with limited focus on KRM in research and practice. Furthermore, current research in KRM still dedicates such efforts to exploring KM practices to mitigate knowledge loss risks, not paying much attention to integrating HRM systems into KRM research. Therefore, future research will benefit the research community and practitioners by exploring this distinct area further, both in private and public enterprises. The current study also points to a need for future scientific explorations in SOEs on a global scale, investigating the role of various HRMPs in knowledge risk management for the effective mitigation of knowledge loss risks interdependently from HRM and KM standpoints.

6. Conclusion and Recommendations

Based on the findings of the study, it is apparent that there is a need to close the gaps to ensure a better alignment and integration of HRMPs to support the management of organisational knowledge and to mitigate against its potential loss. SOEs without a knowledge management strategy should develop one and implement it. The strategy should then be followed by structure. HRMPs should be streamlined to KM processes in order to enhance knowledge creation, absorptive and protective capacity, whilst reducing knowledge stickiness and knowledge loss-related incidents. HR managers and leadership within SOEs should enhance their understanding of KM vocabulary, strategies and tools to bridge gaps in knowledge management. In addition, knowledge managers in SOEs should also focus on understanding HRMPs, as this directly impacts their strategies and helps manage and mitigate tacit knowledge loss risks. Understanding the science behind these two management disciplines is crucial for their success in managing organisational knowledge loss. KM practices alone cannot create significant success in reducing and mitigating knowledge loss unless they are in alignment with and supported by HRMPs. For KRM strategies to be effective, it is important that HRMPs are integrated into KM strategies and processes. Leadership, management, HRM and KM practitioners should establish strategic partnerships; raise awareness of the importance of their relationship; and urgently address the removal of existing silos between these fields, as the success of these practices depends on their joint collaborative efforts.

A more integrated approach to management and retention is needed, with HR managers playing a central role in all KM processes. The findings suggest that KM practices can be better managed if they are structurally incorporated within HR organisational structures. Moreover, SOEs should embed KM into their organisational culture, with HR leading practices. HR managers should also reflect on their practices in the context of organisational knowledge loss, whilst knowledge managers should do the same. Collaboration between HR managers and KM is crucial to manage the knowledge risks associated with the loss of firm-specific human and knowledge resources. Regular interactions and reporting on key knowledge management issues can help avoid such loss.

Appendix A: Interview Protocol for Collecting Data From HR Managers in the SOEs

Do you consider HRM practices to be aligned and focused on managing organisational knowledge loss?

Is there a need for such an integration of human resource management practices in knowledge risk management?

How should such integration be approached, facilitated and implemented in the organisation?

Overall, how effective are HRM practices in facilitating the management and reduction of organisational knowledge loss?

Capability Development for Within-Organization Distinctiveness in Sub-Brand Products: A Case Study in the Media Industry

Amanda Piepponen, Päivi Maijanen, Ari Jantunen and Paavo Ritala

Abstract: Digital transformation necessitates firms to continuously innovate their product and service portfolios, which drives firms to develop their capabilities accordingly. While adapting to the evolving environment, incumbent firms develop new digital offerings that both seek novelty but also build on the existing brands and capabilities. Using a single case study design with 27 interviews from a media company, this study explores the capability development in the context of an incumbent creating a new, digital sub-brand and seeking a within-organization optimal distinctiveness. This study examines how an incumbent firm develops its capabilities and what organizational factors and practices facilitate and hinder the development of the new sub-brand and its associated capabilities. The findings show that developing capabilities for internal distinctiveness is a complex, organizationally embedded challenge that requires consideration of distinctive skills, professional norms and values, and how managerial and technical structures and systems are set up.

Keywords: Capability Development, Within-Organization Distinctiveness, Sub-Brand, Case Study, Media Industry.

1. Introduction

Digital transformation often materializes toward customers in the form of new digital value propositions and value proposition elements (Piepponen et al., 2022). Often, a value proposition is communicated to customers through brands and, in the case of new digital products and services, through new sub-brands. According to Payne et al. (2017), value proposition is "a strategic tool facilitating communication of an organization's ability to share resources and offer a superior value package to targeted customers" (p. 472). A sub-brand, on the other hand, refers to a product brand that is associated with a main brand but has its own name and identity to differentiate it from the main brand (Jo, 2007). The main brand plays a primary driver role, while the sub-brand can complement or modify the associations of the main brand and provide access to new important segments (Aaker, 2004; Zelenskaya & Elkanova, 2021). While the main brand creates synergies, its heritage, assets, capabilities, people, and values can also represent an important role in the sub-brand product (Aaker, 2004).

While the literature has a great deal of understanding of brands and sub-brands, as well as of digital value proposition development, it is less clear what consequences developing a new digital sub-brand has on organizational capabilities. When an organization develops a within-organization sub-brand, the co-existence of the new and main brand creates new "variables" for the organizational transformation; in particular, to what extent are existing capabilities utilized, and when and how are new capabilities built? We portray this challenge of capability development when an organization is seeking within-organization optimal distinctiveness (Bu et al., 2022). In other words, when sub-branding, the new brand must be aligned with the main brand while being distinctive to external audiences. A similar challenge is likely to arise inside the organization as well. However, the literature has studied intraorganizational distinctiveness challenges and dynamics relatively little, which represents a challenge to our understanding of how incumbent organizations can manage new sub-brand development internally.

These issues are also relevant for the media industry, where digitalization has shaped consumption patterns and customers' value perceptions and, consequently, the way organizations innovate and manage their businesses (e.g., Lischka, 2019; Malmelin et al., 2022). This necessitates a more comprehensive and multidisciplinary understanding of the strategic transformation of media organizations, integrating insights from fields such as corporate strategy, dynamic capabilities, and firm performance (Oliver, 2018). As several empirical and conceptual papers exploring dynamic capabilities in the context of the media industry (e.g., Ellonen et al., 2011; Maijanen & Jantunen, 2016; Murschetz et al., 2020; Oliver, 2014) have demonstrated, dynamic capabilities provide a useful lens for exploring the challenges faced by media organizations and explaining how they adapt to radically changing environments.

To bridge the abovementioned research gap, this study explores how an incumbent develops its capabilities and which organizational factors and practices facilitate and hinder the development of the new sub-brand and

related capabilities. We use a single case study approach to analyze new capability development in the context of creating a new distinctive digital news media product. The new sub-brand operates under the main brand but has a differentiated value proposition and, for example, its own editorial staff and customer segments. In line with the demands of digital transformation, the development of this new sub-brand necessitated the acquisition of new resources and the adoption of new ways of working and thinking, providing a rich real-world context for exploration. The media industry offers an exemplary environment for studying innovative practices, as media organizations must continuously innovate to meet the needs of multiple stakeholders across multiple strategic dimensions. Moreover, this case is not only necessitated by digitalization, as is often the case in traditional news media, but is also driven by it, proactively seeking to build and implement practices and capabilities that reduce path dependencies and facilitate the creation of a distinctive sub-brand within the organization.

We contribute to the literature on capability development in the context of creating a sub-brand that has to be, at the same time, detached from and integrated into an existing organization and product portfolio. The company meets a need to balance old and new in order to reach within-organization optimal distinctiveness. Optimal distinctiveness has usually been studied at the industry level (Zhao et al., 2017), but we show that the concept can also be applied to a within-organizational context, which is an important driver for the company to renew its business models and value propositions. In particular, our study unbundles capability development through four dimensions that create a core capability (Leonard-Barton, 1992). It shows what kinds of capabilities are needed in a context in which an incumbent creates a within-organization sub-brand and from which elements they constitute. Moreover, the findings discuss the main brand's different roles in capability development, enlightening the dynamics of capability development and management. By doing this, the study advances our theoretical understanding of the strategic renewal of media organizations.

2. Theoretical Background and Research Objectives

In a volatile business environment, firms are continually required to renew and diversify their product and service portfolios and introduce innovations that promise something unique and distinctive within their market category. As firms adapt to the changing landscape, they must cope with the challenge of positioning their products optimally among their competitors (Zhao et al., 2017). Optimal positioning entails differentiation to secure a competitive advantage and at the same time, maintain a certain level of conformity and familiarity within the market category.

This dilemma of balancing differentiation and similarity has been explored through the concept of optimal distinctiveness, which has attracted scholarly interest in management studies in recent years (Zhao et al., 2017; McKnight & Zietsma, 2018). Optimal distinctiveness addresses one of the core managerial paradoxes of "how firms strategically manage competing pressures to be both 'like' and 'different from' their organizational peers" (Zhao et al., 2017, p. 93). Being distinctive enables firms to seize new business opportunities, while similarity ensures legitimacy among stakeholders, such as customers and investors.

While much research has focused on optimal distinctiveness between organizations, the concept can also be applied to a within-organization setting (Bu et al., 2022). Within an organization, being distinctive involves creating something that stands out from the firm's existing prototypes while remaining recognizable in terms of the firm's general design and brand. From the perspective of organizational capabilities, creating distinctive products, services, and business models necessitates the renewal and orchestration of existing resources and capabilities to develop new distinctive resources and capabilities. As companies develop their product portfolios, they have to renew their capability portfolios accordingly in order to be able to create new products: "For the firm, resources and products are two sides of the same coin" (Wernerfelt, 1984, p. 171). With "resources," Wernerfelt (1984) refers to the pool of intangible and tangible organizational assets needed to produce products. A firm's unique and non-replicable tangible and intangible resources can be seen as potential sources of competitive advantage (Barney, 1991).

In addition to possessing the resources needed for a business, firms need the ability to deploy these resources efficiently to produce desired outcomes (i.e., firms need capabilities). The concept of capability is "the ability to perform a particular task or activity" (Helfat et al., 2007, p. 1), and capabilities consist of a set of interconnected organizational elements, such as knowledge, intangible and tangible processes, and structures needed for using resources (Helfat & Peteraf, 2003; Leonard-Barton, 1992; Winter, 2000). Capabilities are a context-specific concept—what types of capabilities are needed and what are the essential building blocks of them depend on the type of company's business and other contextual factors. There is diversity of definitions in academic discussion and even wider diversity of capabilities in practice, but overall, there is a rather commonly shared

view about the nature of capabilities—they are organizational skills (Nelson & Winter, 1982) that involve necessary knowledge about how to conduct the task at hand in an efficient way.

When making significant changes to their product offerings, companies must build and further develop their capabilities to create new products and corresponding production processes. Due to the nature of capabilities as organizational skills, involving a lot of "how to" knowledge, in-house development activities play an essential role in capability development. While some ingredients of capabilities, such as technology, information systems, or special expertise, can be at least partly sourced from outside the organization, the integration and coordination of different elements—so that they function efficiently together—are fundamental activities that cannot be sourced from the markets. Procedures, routines, and processes—essential key elements of capabilities—develop especially with experience accumulation (Zollo & Winter, 2002) through learning-by-doing. Hence, in the capability development process, local learning typically plays a significant role (see Zollo and Winter [2002] for the potential roles of other types of learning processes).

Building on the evolutionary view of organizational learning (Nelson & Winter, 1982), capabilities evolve gradually through experiences of success and failure. This dynamic process is influenced by the organization's existing capabilities, which can both facilitate and impede the creation of new distinctive assets and capabilities. The learned capabilities, existing product design, and brand form a strong foundation and support for further change and learning. However, to create something genuinely new and distinctive, organizations must critically assess their existing capabilities and practices. Incumbent organizations can, on the other hand, utilize their existing capabilities in developing new ones (Cohen & Levinthal, 1990; Zahra & George, 2002), but the cumulated asset base may also be a source of organizational inertia (Gilbert, 2005; Leonard-Barton, 1992; Tripsas & Gavetti, 2000), hindering the development of capabilities that differ significantly from existing ones. Hence, when developing distinctive products and corresponding distinctive capabilities within an organization, incumbents meet the need to leverage their existing resources and capabilities while coping with the organizational rigidities and path dependencies involved in existing capabilities. From the organizational learning point of view, when developing new distinctive capabilities, incumbent companies have to support unlearning, in addition to being active in acquiring new knowledge by means of experimental learning or other learning processes (Sharma & Lenka, 2022).

When creating capabilities that are distinctive within an organization, but still based partly on existing assets and integrated as a part of the company's production system, incumbents meet the need to find ways to utilize existing assets without being too tightly bound by them. In this study, we explore how an incumbent organization builds its capabilities to create a distinctive sub-brand product. We examine how existing organizational structures, on the one hand, enable and, on the other hand, restrict and hamper the possibilities for capability development. We aim to show what issues incumbent companies meet when trying to achieve within-organization optimally distinctive positions with new products, and how tensions in capability development were managed. By doing this, we aim to open up the intertwined relationship between products and capabilities and their development.

3. Data and Methods

We adopted a single-case study design to provide an in-depth and contextual understanding of the social phenomena under inquiry (Yin, 2018). This study analyzes a Finnish media company that publishes a well-established daily newspaper (main brand). The case company's newspaper has managed to increase its subscriptions in recent years and has made significant investments in news and lifestyle content. In 2019, the newspaper initiated a development project to renew its economy and financial news. The project aimed to enhance the value of economic and financial news for the main brand and, ultimately, to create a sub-brand product to target a specific underserved customer segment, mainly young and ambitious men. The sub-brand was launched in 2021 and focuses on in-depth economic and financial content over short-term news, addressing the needs of an individualistic, goal-oriented, and even anarchistic audience. To meet their interests, the sub-brand has developed a digital multi-content product covering topics such as investing, technology and science, careers, and foreign and international politics. The sub-brand has a distinctive appearance, both in digital and print, and covers topics in a way that the main brand cannot as it reaches the entire nation. Consistent with digital transformation (Parviainen et al., 2017), the organization had to develop its capabilities and adopt novel ways of thinking and working to create this new sub-brand, including product elements and production processes.

Following the case study approach, we utilized multiple data sources (Yin, 2018) to gain an in-depth and comprehensive understanding of the case (Table 1). The primary data consisted of 27 qualitative in-depth interviews conducted in 2022 with the sub-brand's development team and editorial staff (Table 2), resulting in 268 pages of transcription. Interviewees were selected using purposive and snowball sampling methods to ensure a variety of perspectives from all key individuals involved in different stages of the process. The interview protocol covered the drivers and preconditions for the transformation, the development process, and the coexistence of the main brand and the sub-brand. The interview protocol focused on the resources and capabilities required to develop and produce the sub-brand and the different organizational roles and activities around the development. Finally, the interview protocol captured how the sub-brand was maintained and further developed after the launch and the lessons learned during the project. The protocol was supplemented with clarifying and supplementary questions, where necessary, to allow for in-depth exploration by the researcher. To broaden and corroborate the emerging findings, we used secondary data collected from 2021, 2022, and 2023. These data included researcher's notes from meetings with the case company, documents from the company's own sources and published by other media, and documents received from the case company.

Table 1: Data overview

	Primary data	**Secondary data**		
	Interviews	***Material published by case company***	***Material published by other parties***	***Researcher's or case company's internal documents***
No. of data items	27	20	5	5
Data collection period	April 2022 – August 2022	January 2022 – March 2023	January 2022	March 2022 – June 2022
Description of the data	Semi-structured interviews with 16 members of the top management and multidisciplinary development team responsible for developing and launching the new brand. Semi-structured interviews with 11 members of the editorial staff working with the new brand. In total, 11 interviews were conducted in person and 16 interviews using Teams.	News of case company's operations and podcasts published by the company itself, articles written by the company's editorial team, and product and target group information available on the company's websites.	News of the new product launch published by other media outlets.	Information about the profiles of open vacancies in the case company and notes from the meetings with the case company representatives prior to the interviews.
Role in analysis	Overview of creating a within-organization sub-brand, including the entire process across several organizational levels/silos.	Accounts of the company's actions related to digital transformation and creating the sub-brand, as well as demonstrations of the sub-brand's product elements and existing target groups.	Accounts of the company's actions related to digital transformation and creating the sub-brand.	Overview of the company's strategic and operational actions related to digital transformation and creating a sub-brand, as well as demonstrations of the company's actions to develop its resources and capabilities for such actions.

The analysis aimed to capture how capabilities were developed in the creation of a within-organization sub-brand and how the existing organizational elements influenced this development. The analysis sought to explain the relationship between product-related factors and capabilities and the issues arising from development. To develop a chronological understanding of the ongoing transformation, the analysis began with interviews with the development team. The perspectives of the multidisciplinary group of interviewees were constantly integrated. After the initial stages of open coding, different themes began to emerge regarding various aspects of capability development. At this stage, following abduction logic, we sought to find frameworks from the capabilities literature that would capture the conceptual structure of the emerging findings. We chose Leonard-Barton's (1992) model, as it fit well in describing the construction of different dimensions that form a core capability and the requirements for it. We aimed to abstract *open codes* by identifying congruent *themes* and then assigning them to the existing categories of *capability dimensions*. The analysis used secondary data to gain an initial understanding of the transformation and to validate the interview findings, specifically in identifying distinctive skills and knowledge that needed to be acquired outside the organization. To enhance the validity of the analytical process, this study employed data triangulation, utilizing insights from various data sources and cross-functional perspectives across the organization.

4. Findings

Following Leonard-Barton's (1992) definition, we approached the development of a core capability through four dimensions. The first dimension is skills and knowledge base, which refers to the skills, experience, and knowledge embodied in people. Second, managerial systems refer to organizational structures and processes used for creating and utilizing new knowledge and enabling employee engagement, continuous product management, and the organizational integration of different resources and other elements to work together. Third, technical systems include databases and technical systems themselves, as well as the specific technical knowledge and skills needed in production. Finally, values and norms are higher-level goals and objectives that are embedded in the organizational culture, create a shared understanding of what is considered professionally desirable, and shape the direction of the organization's development.

The findings indicate that the main brand performed two roles in the development of capabilities—facilitator and inhibitor—which can be disaggregated into different dimensions. The following sections provide a detailed description of the findings, supported by the coding structure (Figure 1).

4.1 Skills and Knowledge Base

Personal proficiency represents the central point of the skills and knowledge base and, therefore, emphasizes the importance of finding the right individuals whose expertise matches the sub-brand's content. Personal proficiency comprises an individual employee's specific expertise derived from prior experience or education, including existing networks. To maximize this, the final profiles of each editorial position in the sub-brand were matched to the research data of the target group and the recruited individuals.

Audience insight is critical to the development and production of a target group media, moving from a journalist-centric view to an audience-centric view. This required an advanced ability to interpret and integrate large amounts of detailed research and user data into daily routines. To better understand the audience and their perspectives, the editorial staff used a variety of methods to empathize with them. For example, they began content planning by creating a fictional person from the target audience.

Sub-brand fluency refers to adopting the style and tone of the sub-brand through written guidelines and experimentation. Building fluency requires creating a shared understanding of the brand among employees and, most importantly, translating this into content decisions to maintain differentiation and attract the right audience. Achieving sub-brand fluency requires an open-minded, brave, and innovative approach that reflects the desired sound and look of the sub-brand.

Journalistic development refers to maintaining and building the capacity to keep up with the sub-brand, as the product elements differ from those of the main brand. For traditional news media, this represented a new way of operating. Journalists have to question their old and personal journalistic preferences and renew their storytelling and content choices. Journalists must learn how to incorporate visually demanding outputs and include them in the planning of content while working with visualists.

Collective expertise builds on the synergies created by the co-existence of the new and main brands. For example, the sub-brand benefited from expanded in-house skills and knowledge resources. In such a large organization, there was always an expert in certain niches. Furthermore, the existing skills and resources of the main brand enabled the day-to-day operations of production, visual design, and information technology.

These aspects contributed to the development of the sub-brand's capabilities by aligning hard skills with the needs of the target group and enhancing the building of brand identity and differentiation. In terms of skills and knowledge base, the main brand was a *facilitator*. The financial investment in acquiring new staff came from the main brand, while its brand, reputation, and background helped attract, for example, candidates representing the top of the market. The main brand played an important role as an advocate, as it aimed to create a suitable environment for the sub-brand's editorial staff to learn about and maintain the sub-brand's distinctive style. Additionally, the main brand provided the established production processes on which the sub-brand was based. The culture of collegial assistance also grew out of the established roots of the organization and was directly transferred to the sub-brand. Although the main brand provided existing systems and data to support audience insight, it also hindered the adoption of the new unusual approach for traditional news media to implement a target group product due to the existing capabilities resisting the new ones.

4.2 Managerial Systems

Research, development & innovation represents the prevailing approach of the development project. A significant amount of resources was invested in finding the right focus for the sub-brand and ensuring that its implementation was separate from the main brand. The project was completed by a multidisciplinary team of people from different levels of the organization, and outsourced research activities were also used. To ensure that the right strategic direction was maintained, top management played an active role in decision-making. The case company also established long- and short-term steering groups to monitor the development of the sub-brand. As part of the innovation phase and the definition of the sub-brand manual, a printed dummy version of the new product was developed, including a lot of testing of different story types and elements.

Employee engagement supports the prevailing idea that the sub-brand equals its editorial staff and that through active engagement, it is possible to enhance the success of the brand. The editorial staff was given an active role in the final development of the sub-brand and its new final product. From that point on, the editorial staff created and developed the product mostly on the basis of their own experience, and after some trial and error, they were also involved in readjusting the goals to better suit the nature of the sub-brand. From a management perspective, unleashing the full potential of the editorial staff required the editor to act as a facilitator, which differed from one's usual role.

Organizational integration considers the issues that arise when the sub-brand's editorial team is brought under the umbrella of the main brand. Although both brands had their own journalists, many day-to-day production processes were shared, including visual design and development. Due to COVID-19 and maintaining the sub-brand's fluency, the editorial staff were initially physically isolated from the rest of the organization. This led to difficulties in learning, such as organization-specific communication habits. Eventually, the editorial staff moved to the same office space as other staff, and the editor joined the same desk as the other editors to facilitate a better exchange of information, knowledge, and ideas. Although there were benefits, management must continuously evaluate the extent to which integration and separation are necessary and how to manage two different journalistic cultures without sacrificing the focus of the sub-brand.

Adaptive product management is the driving force behind the creation of the sub-brand and supports other managerial systems. It aimed to ensure a focus on the target group. The organization employed adaptive product management, which involved actively revising the product based on trial and error and learning from the process. This approach enabled the organization to make ad hoc decisions and revise tasks among staff as necessary.

These issues emphasize the significance of ongoing learning and the use of accurate, data-based information for the development background. While seeking to achieve the appropriate level of organizational integration, the sub-brand invested in employee engagement and adaptive product management, which enhanced the development of skills and knowledge, as well as the adoption of values and norms that ensure the overall relevance and effectiveness of capability development and serving the target group.

These issues emphasize the significance of continuous learning and the use of accurate data-based information to inform development. While seeking to achieve the appropriate level of organizational integration, the sub-brand invested in employee engagement and adaptive product management, which enhanced the development of skills and knowledge, as well as the adoption of values and norms that ensure the overall relevance and effectiveness of capability development and serving the target group.

The main brand supported these actions by acting as a *facilitator*. It made all the resources and capabilities available for various development activities and was able to react quickly when the operations or the strategic direction needed to be revised. Furthermore, the main brand sought to create a conducive environment in which employee engagement could flourish. On the other hand, the main brand also acted as an *inhibitor*, as most of the processes and structures for the sub-brand were adapted from the main brand, but these often hindered the revision initiatives and hampered the implementation of the sub-brand elements. Although the prevailing atmosphere supported an adaptive and engaging approach, the existing systems hindered it. Therefore, in this case, the main brand also divided and consciously or unconsciously maintained a threshold between the brands.

4.3 Technical Systems

Clustered technical expertise originates from the main brand's existing systems. The technical skills and knowledge required by the sub-brand were clustered around specific individuals and/or departments that were separate from the sub-brand's editorial staff, such as the digital development team. Large technical development projects had to be undertaken in conjunction with the main brand, and smaller development needs tended to be prioritized based on the developers' personal views. Furthermore, creating and modifying digital layouts specific to the sub-brand's focus required coding expertise. In many ways, knowledge of the production systems was centralized, challenging the day-to-day operations of the sub-brand.

Platform specificity refers to the characteristics of the platform on which the main brand and, therefore, the sub-brand operate. In this case, the organizational culture was heavily focused on text, while the sub-brand's original goal was to provide content in a variety of formats. However, the platform was not designed for audio, both technically and in terms of branding, which presented challenges in terms of content production and reaching the target audience. The work was complicated by the fact that digital and print production were part of the same system. Therefore, it was necessary to consider the print version while maintaining a digital-oriented approach. To meet the initial objectives of the offering, the organization had invested in testing other third-party platforms and channels.

Customer-centric design and data relates to technical systems by emphasizing the user experience, particularly in comparison to competing international offerings. The sub-brand sought to be recognizable among other economic and financial news media, which required differentiation from the main brand, including, for example, the mobile app. The focus on the specific target group also revealed gaps between the operational domains and

the systems. The available data did not correspond with the defined target group, indicating that the data collected and analyzed were not completely equivalent to the defined target group and goals.

Developing the sub-brand's capabilities required leveraging technical expertise while balancing the main brand's organizational constraints, overcoming platform limitations, and prioritizing customer-centric design and data analysis. In this domain, the main brand's role as a *facilitator* and *inhibitor* created a contradiction. For example, the main brand offered significant resources and existing systems to realize the sub-brand's customer experience objectives. However, it did not bend to the sub-brand's needs and prevented the sub-brand from implementing the desired features of the sub-brand's product, such as mobile app features or audio content.

4.4 Values and Norms

Professionalism represents the established journalistic culture of the main brand, which the sub-brand has begun to follow both consciously and unconsciously. The journalistic work in the organization was driven by strong ambition and goal orientation, characterized by an artistic mindset and often leading to work being seen as a lifestyle. Interviewees even described how prevailing values encouraged the aspiration to be a heroic journalist.

Responsibility is the foundation of the main brand, which is widely recognized within the organization and in the market. The sub-brand was expected to adhere to the same ethical and quality standards as the main brand to avoid any harm. The main brand's reputation and market position gave it significant power to influence people's lives, particularly through content decisions, which needed to be taken seriously.

Specialization comes from the origin of the sub-brand, which shifts the focus from customer loyalty to loyalty for the target group. This meant keeping the promise of delivering the desired value to the specific target group and staying on the intended path of the sub-brand that best served the target group. Maintaining this required path independence and uniqueness from the main brand.

Freedom plays an essential role in ensuring sub-brand fluency. This appeared through the discussion atmosphere between the editorial team and management. This embraced the self-direction and ability of the sub-brand staff to be themselves, which finally equaled the sub-brand.

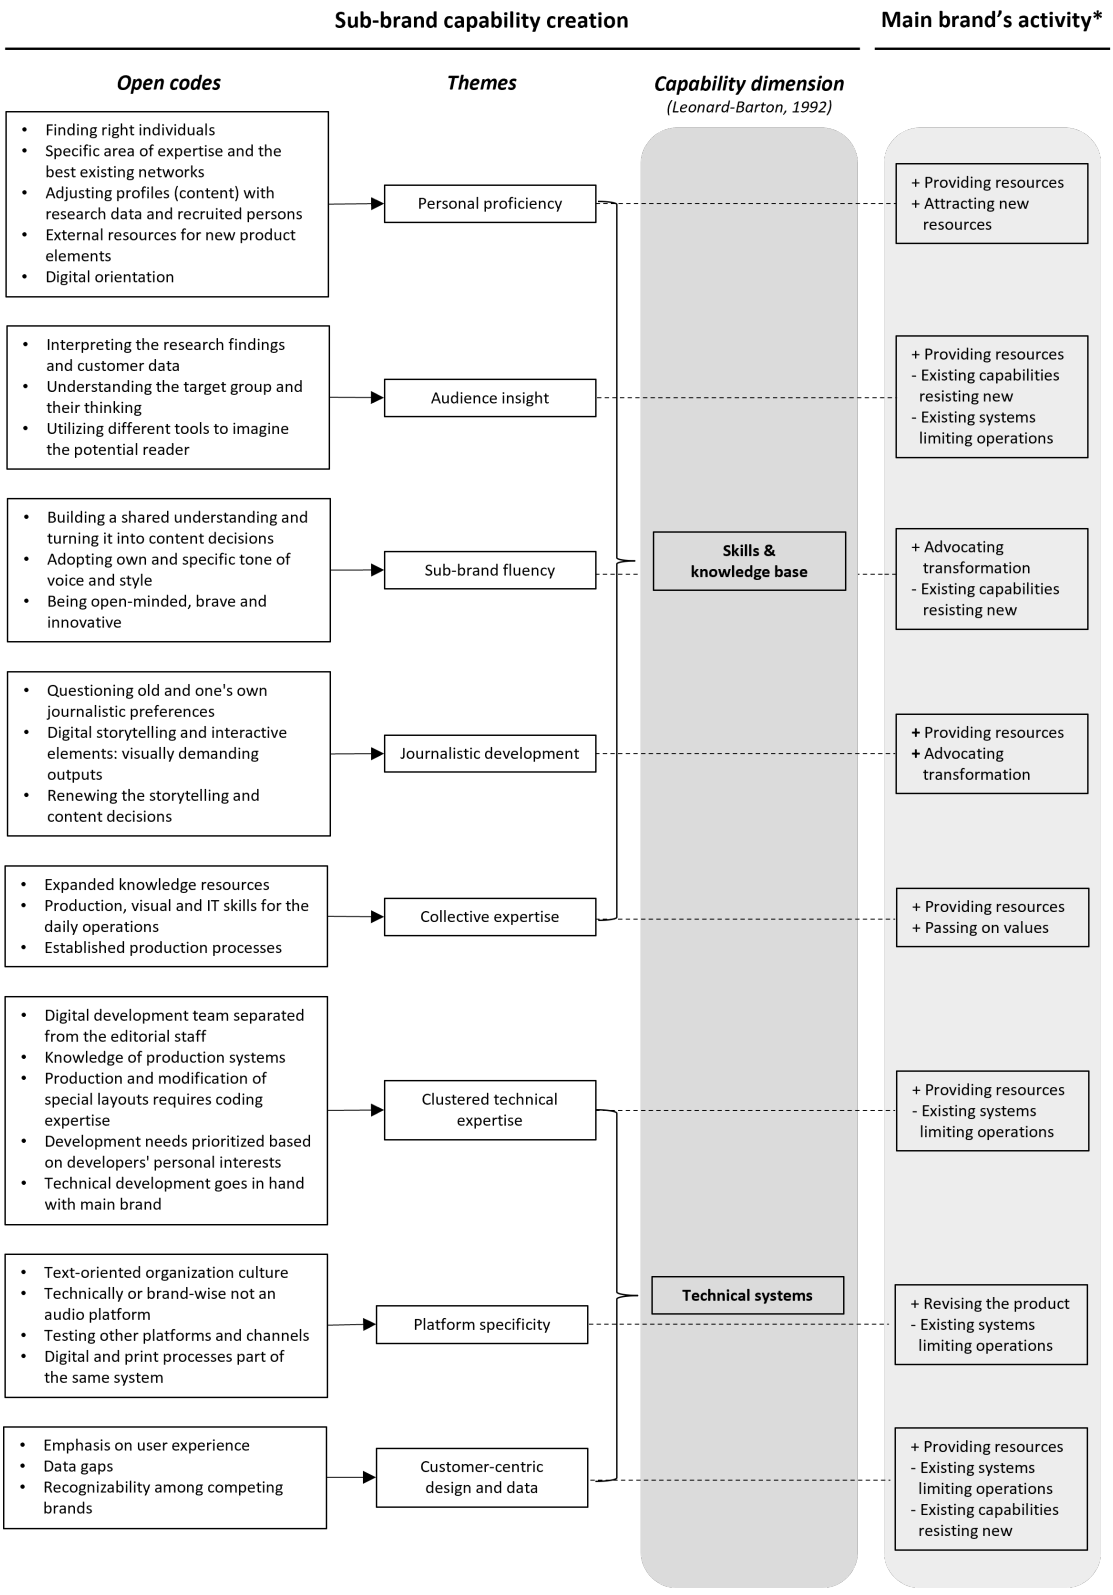
Values and norms played a critical role in ensuring the sub-brand's alignment and recognizability with the main brand. They also helped maintain favorable skills and knowledge originating from the main brand while enabling the sub-brand to differentiate itself by creating its own unique identity and ensuring the development of new capabilities.

The main brand delegated some of its values directly to the sub-brand, which, in this case, could be seen as acting as a *facilitator*. Being associated with such an established brand helped the sub-brand gain credibility and legitimacy in the market. On the other hand, the main brand acted as an *inhibitor*, as its capabilities dominated the organization and thus hampered specialization and freedom. These values relied heavily on the target group's focus and the role and expertise of individual employees, which challenged the prevailing manners of the main brand. To compensate for this, the main brand still sought to promote the right atmosphere for these values to flourish and be put into practice, paying particular attention, for example, to strengthening employees' self-confidence.

4.5 Key Events and Activities in the Capability Development Timeline

Based on our empirical analysis, the timeline in Figure 2 demonstrates capability development and the impact of the main brand on the capabilities of the sub-brand over time. The analysis shows that capability development is a dynamic and long-term process consisting of multiple overlapping events. The key events constituting the development of each capability dimension may occur at one point in a time (e.g., reorganization of tasks) or continue existing over time (e.g., balancing between legacy and freedom).

However, as illustrated in Figure 2, the relative emphasis on different capability dimensions may vary throughout the process. For example, management systems play an important role throughout the process, while the importance of skills and knowledge base increases as the focus shifts to embracing the new value proposition. In addition, as discussed earlier, the presence of the main brand in capability development can have an ambivalent and twofold impact, but the timeline indicates that this is likely to occur at different times rather than simultaneously; what is initially facilitative may later be inhibiting.



* Plus (+) refers to main brand's activities that facilitate sub-brand's capability development and minus (-) refers to main brand's activities that inhibit sub-brand's capability development.

5. Discussion and Implications

Our study has demonstrated how a company that developed a novel sub-brand sought optimal distinctiveness (Zhao et al., 2017) within an organization, not only toward external audiences (Bu et al., 2018). We approached the challenge from the capability development perspective and unveiled four particular dimensions related to a core capability: skills and knowledge base, managerial systems, technical systems, and values and norms (Leonard-Barton, 1992). In addition, our study reveals how new capability development is affected by the main brand and its existing structures and capabilities.

We contribute to the academic literature on organizational strategic renewal by illustrating how organizational capabilities are developed when an organization is seeking within-organization distinctiveness by updating its product portfolio. We explore how a company builds new capabilities when it aims to create a differentiated sub-brand product and corresponding capabilities. In this capability-building context, the company operates with balancing needs to be detached from and integrated into the main brand. We found that capability development in the context of internal distinctiveness is a complex organizationally embedded challenge that requires consideration of distinctive skills, professional norms and values, and how managerial and technical structures and systems are set up. It particularly highlights the power of organizational path dependencies (Gilbert, 2005; Leonard-Barton, 1992), which continuously challenge the development of new sub-brand-related capabilities. Our analysis clearly shows that existing structures and capabilities hinder renewal processes. On the other hand, the main brand also supports the development of new capabilities. In this study, the existing resource base, values, and norms created foundations for building the new sub-brand. In fact, development requires continuous ambidextrous balancing between integrating and separating existing and new elements (Maijanen & Virta, 2017). The challenge and question for management is how to leverage existing resources and capabilities, keeping in mind the goal of creating something divergent from the existing brand.

Our study relates to the topical issue of media research, namely how media organizations need to continuously innovate and expand to new markets and customer groups to sustain competitiveness in the highly competitive digital media business (Villi & Picard, 2019). As a study, this represents research on the micro-level foundations of capability development (Helfat & Winter, 2011; Teece, 2007). The study highlights the challenges, particularly for media managers, since the development process must be managed with a clear strategy to maintain the right balance in the interplay between old and new. Due to path dependencies, the old easily hampers new initiatives. However, our study also demonstrates that achieving balance is possible but requires a systematic and constant strategic approach when building operational capabilities.

For practitioners, our study demonstrates the interdependence between product elements and capabilities and emphasizes the significance of integrating capability development into product development. Additionally, the results indicate that achieving within-organization optimal distinctiveness cannot be accomplished solely by introducing new product elements and capabilities but also by recognizing and addressing organizational issues that hamper capability development. In particular, our findings provide insights into the benefits and drawbacks of developing a sub-brand product embedded in the main brand from a capability viewpoint. The main brand can accelerate capability development, for example, by providing knowledge, resources, and credibility. Furthermore, it can promote a favorable environment for development and transfer its values to the sub-brand, supporting the delivery of the intended distinctive value proposition. However, it is important to note that the established capabilities of the main brand may dominate the new capabilities of the sub-brand, and that the existing technical or managerial systems may not be equipped to serve the sub-brand's objectives. Therefore, managers must be aware of potential pitfalls that could derail the sub-brand's capability development from its intended path and, consequently, deteriorate the desired distinctiveness of the new product.

As for the limitations, although the study uses data triangulation, the findings should be interpreted with caution, as they are mainly based on qualitative interview data and are limited to a single company operating in the Finnish media industry. However, capability building is always a context-specific activity impacted by organizational conditions. Despite these context-specific limitations, this study increases our knowledge of the dynamics of capability development and opens avenues for further research, such as a multi-level study on capability development: how different organizational levels and units (e.g., top managers, middle managers, editorial team, marketing and sales, and data and analytics) perceive, experience, and also contribute to capability development. Furthermore, a more focused study on the interplay between the main brand and the sub-brand would be interesting to better understand how sub-brand-related capabilities affect the main brand.

Digital Technological Solutions in Knowledge Transfer in Higher Education

Luiza Piersiala
Częstochowa University of Technology, Faculty of Management, Częstochowa, Poland

luiza.piersiala@pcz.pl

Abstract: In a world of constant change and ongoing technological globalization, the challenges facing education are multidimensional. The modern generation of the academic community, especially technical universities, is increasingly demanding in terms of teaching materials: they expect dynamism, a digital approach and very good visual quality. The knowledge provided to them should be presented in an engaging way and using the latest technologies. The world in which society functions, especially young people, is described as a nanosecond culture, i.e. one in which everything is expected to be available immediately. Education has been digitized. Remote learning forced a change in the way knowledge was transferred. Classes and the method of transmitting knowledge should be adjusted to current requirements and the surrounding reality, which will be attractive, immersive and motivating for further learning for students. Traditional ways of education are no longer sufficient to meet society's complex expectations as people often change careers, seek new educational opportunities, and have difficulty coping with life, work, and competing for educational demands. The article is an attempt to answer the question: what digital methods and tools are used by students in the process of acquiring knowledge. Which of them are the most effective? The CAWI method was used for research. The respondents were full-time and part-time students of the first cycle (bachelor's/engineer's studies) and the second cycle (supplementary master's studies). The time scope of the analysis covers the period from November 2023 to December 2023. A survey was carried out with the participation of 245 student representatives.

Keywords: Education, Knowledge, Digital Approach, Digital Native, Learning Environment, Higher Education

1. Introduction

Digital learning provides greater control and autonomy over learning itself and enables learning in context, that is, in the place, time and conditions that the student finds most appropriate. The aim of the article is to examine what digital educational devices are needed and most frequently used in higher education.

In recent years, education has changed and been digitized. Remote and/or hybrid learning has been introduced. Which, in consequence, resulted in a change in the way of transmitting knowledge. Currently, it is important to remember to adapt it to the current situation and the requirements that students place on lecturers. The aim of this approach is to create attractive, interesting and motivating lectures and lessons for further learning. Technology and ongoing digitization have improved the effectiveness of learning and the process of acquiring knowledge. According to Mete, Riegel, Kozen, and Polka (2017), technology has not only transformed into a powerful tool in everyday life, but has also significantly influenced education. Currently, students are considered to be the first generation of the so-called “digital natives” They have grown up with technology all their lives, they know mobile phones, tablets, computers, playstaion and many other electronic devices from birth (Acquah & Katz, 2020).

The first part of the article presents the characteristics of the examined student. Then, the tool and the research sample were characterized. The results, conclusions of the research, their limitations, and recommendations for further research are presented.

2. Literature Review

In the 21st century, there has been an explosion in research and learning (Krawczyk, 2022). Both lecturers and students must adapt quickly to new technological developments. It is reasonable to assume that this pace of AI development will increase.

Analyzing "4 trends that will shape the future of higher education" it can be indicated that current students, are those who can learn anywhere, from wherever they want, is to do the so-called "learning from everywhere", for whom active lectures are important (placing lectures with active learning), are those for whom it is important to learn from examples of phenomena that are relevant to the environment. And finally, they are people for whom using formative assessment instead of high-stakes exams. Real learning relies on principles such as spaced learning, emotional learning, and the application of knowledge (World Economic Forum, 2022). Students are referred to as "digital natives" (Ivan, 2022) because they have grown up with digital communication technologies since birth. Digital natives born with advanced digital media technologies are acknowledged as the first

generation of the 21st century. Digital natives are different from previous generations because they are unique addicted to the Internet. They closely follow technological developments, interact and communicate regularly through various means of mobile communication, such as mobile phones and social networking sites, they can easily express their wishes and deliver them continuously and more

access to virtual environments (Azimi et al., 2021). Digital natives show a preference for using graphics to communicate and feel comfortable with multitasking, preferring to receive immediate feedback and seek gratification (Xie et.al, 2022). This is someone who is fluent in Twitter, Facebook, Instagram, WhatsApp, SnapChat, podcasts, YouTube, online news, text messaging, instant messaging (Yue et al., 2023). They are well versed in smartphones, iPads, smartwatches and more (Piersiala, 2023). The daily lives of digital natives are influenced and governed intensely by the advancements in new media technologies due to being born in the digital opportunities such as advanced technological tools like smartphones with fast and uninterrupted internet connection (Fortunati, 2022). Also referred to as the "iGeneration" or as having "digital DNA" from birth, this group is also people raised in a "nanosecond culture." They are multitaskers and switch quickly between tasks. They are capable of performing tasks at high speed. Native digital students prefer to learn visually rather than through text; they want an environment rich in images. They like information presented in the form of graphics, charts, tables and images rather than long reading tasks.

Currently, interactive boards, virtual learning environments, e.g. Moodle, videoconferencing, applications and software, games, tablets and smartphones have started to be used more often in lecture halls (Nikou and Aavakare, 2021). Lecturers started recording podcasts, tutorials, instructional videos, e-books. They began to conduct synchronous lectures and use videoconferencing. Future employees are those who, when looking for a job, will not be defined by the diploma obtained or the degree held, but by their competencies and skills (The Burning Glass Institute, 2022). It is important to remember that the next generation that will come to study at universities is the alpha generation. This is the touchscreen generation. What defines them is: immediacy, digital-first, haptic interaction, personalization, interaction (games), incidental learning.

Education has transformed over the past few decades. Since the onset of the recent pandemic, schools and universities have been forced to put a lot of their teaching online. Technology breaks up the limitation of time and improves students' learning autonomy (Liu & Li, 2020; Huang et al., 2020). The challenge posed by the Covid-19 pandemic was the transition from classroom learning to online and hybrid learning with the use of technological solutions. At the same time, universities had to develop ways to use modern learning methods while ensuring high-quality teaching (Reis et al., 2022). Currently, interactive boards, virtual learning environments, e.g. Moodle, videoconferencing, applications and software, games, tablets and smartphones have started to be used more often in lecture halls (Nikou and Aavakare, 2021). Lecturers started recording podcasts, tutorials, instructional videos, e-books. They began to conduct synchronous lectures and use videoconferencing. Such tools and such methods are certainly conducive to the positive transfer of knowledge. It can be said that students need such tools, and lecturers need to learn to use such tools. According to Riegel and Mete (2017), students and faculty should share knowledge. There is feedback. Students have a wealth of knowledge to impart to lecturers, and lecturers have a wealth of knowledge to offer to students. Mutual learning can have many positive effects. This idea of mutual learning applies to technology (Haytham, 2023, pp. 23-33). The experience of the past two years has shown that technology is conducive to bridging time and space barriers. It has turned out that it is possible to learn asynchronously and synchronously. The opportunities arising from the development of technology in learning should be exploited, adapting to the requirements of today's students. Teaching materials supported by photos, graphics, videos should be used. Given the current trend of nanoseconds, such solutions promote flexibility and mobility for both students and lecturers.

3. Research Methodology

The aim of this study, based on the above literature analysis, is to determine how students spend their time on the Internet, what devices they use and whether the use of e-books and audio recordings (podcasts) is useful for them. People were also asked about the use of educational e-learning platforms. The main research problem in this aspect was to answer the question: How do students use the Internet? What equipment do they use for this? Is it desirable for them to use educational platforms and e-books? And also determining where (in terms of equipment) they read and would they read if they could choose?

This is a pilot study conducted on a sample of 239 students. It is planned to conduct a study on a larger research sample, covering various faculties of technical universities in Poland. The questionnaire was developed by the Center for Modern Technologies of the Gdańsk University of Technology. The study used an online questionnaire

to investigate the digital birthing of Polish students. The basic research method was the CAPI method, based on a questionnaire. It consists of two parts. The first part contains basic information about students, such as gender, age, degree and field of study. The second part concerned students' answers to questions about their study habits. The participants were informed about the purpose and course of the study and their right to withdraw from the study at any time. Generally, participants completed the questionnaire for approximately 10 minutes.

4. Results

The research was carried out in the period November – December 2023 on a sample of 239 people. The characteristics of the survey participants in the research were analyzed based on the results from the metric part of the survey. The research group represented was: 126 women and 113 men. All the respondents were students of the Częstochowa University of Technology (Poland) from the Faculty of Management, full-time and part-time students of the first cycle (bachelor's/engineer's studies) and the second cycle (supplementary master's studies). This study adopted an online questionnaire to examine Polish learners' digital nativity and their intentions to acquiring knowledge. The most respondents (48%) are aged 22 to 24. Another 35% are respondents aged 19-21. The survey was also completed by 6 respondents under the age of 18, 9 respondents aged 30-40 and 2 person over 41 years of age.

After the metrics section, the student was asked if they use a computer, tablet or smartphone to access the Internet. According to Figure 1, the most responses were given to a smartphone (174 answers) and the least to a tablet (5 answers). 96% have a Windows PC/laptop. The rest use OSX (Apple). Analyzing the distribution of responses regarding the system used on a smartphone indicated Android (52%). The rest of the students use IOS.

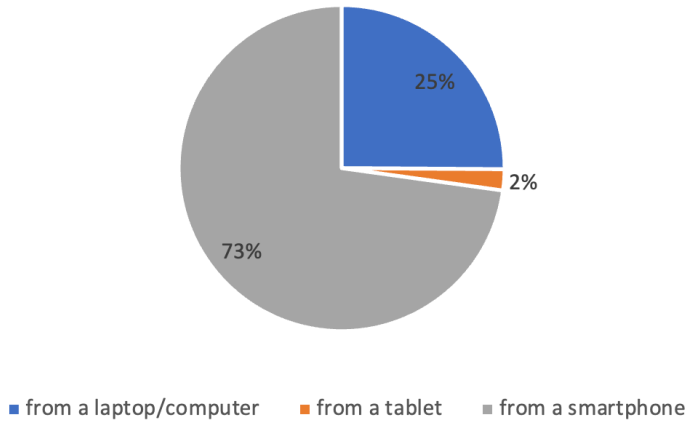

Figure 1: Preferences for spending time on the Internet

In the next question, students were asked: What is using a digital version of a textbook in the form of an ebook in the learning process for you? The distribution of responses is given in figure no.

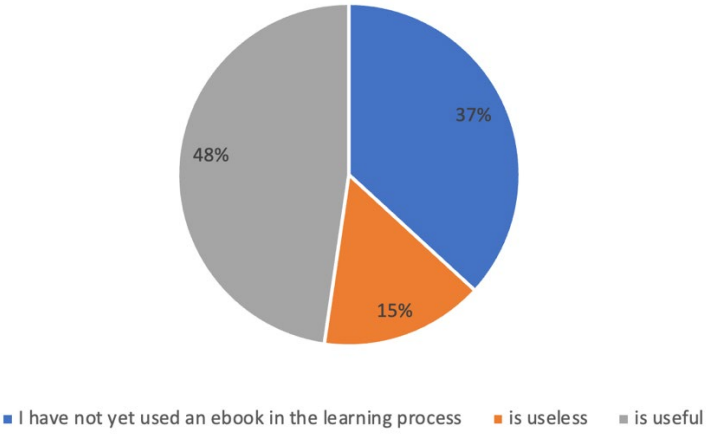

Figure 2: Preferences on using e-book in the learning process

114 respondents indicated that using an ebook (digital version of a textbook) in the learning process is useful to them. 88 respondents have not yet used ebooks in the learning process. In contrast, 37 indicated that it is a useless form of learning.

As many as 159 respondents indicated that they had not yet used an e-learning learning platform like Coursera, Doemstica, EdX or Udemy. 44 students indicated the answer "no, but I know how they work," and only 36 respondents answered in the affirmative "yes, I have used these learning platforms."

There was a similar distribution of responses to the question of what electronic equipment a student uses when watching video content, e.g. YouTube, as to the answer to the question of what device he uses when accessing Internet content. 66% then use a smartphone, 32% use a computer/laptop, the least 2% use a tablet.

In response to the question “The benefits of using audio/podcasts in learning for me are?” as many as 41% has not yet used this form of acquiring knowledge in the learning process. According to 22% of respondents, it is an unhelpful tool, while 15% more respondents indicated that it is a useful tool for them.

The next question was about reading various content, not only on the Internet, not only in the context of learning. The distribution of answers indicates that respondents are most likely to read using a smartphone (126 indications), followed by the answer: traditional books, printed press, other publications in paper form (67 indications), on a laptop/computer (28 responses) and the same number (9 indications) for the answers: on the tablet and on the e-book reader. The answers are shown in Figure 3.

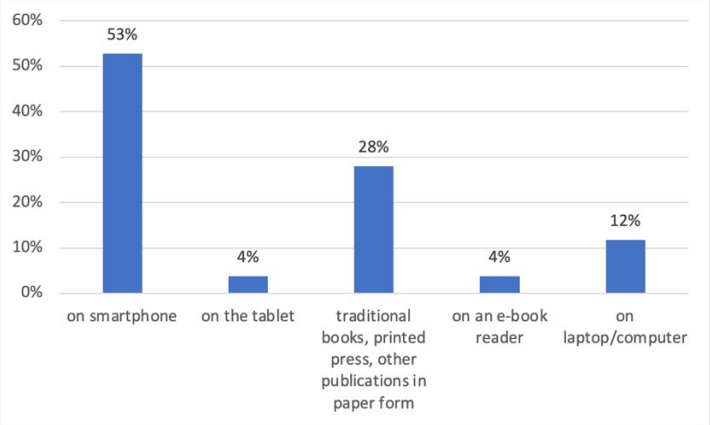

Figure 3: Answer the question “I read most often (not only in the context of learning)”.

The survey questionnaire also asked where the student would most like to read. Analyzing the distribution of answers, it can be indicated that respondents would most like to read using a smartphone (96 indications), followed by the answer: traditional books, printed press, other publications in paper form (83 indications), on a laptop/computer (43 indications). The fewest indications concerned the answers: on a tablet (9 indications) and on an e-book reader (8 indications).

The answers obtained are shown in the figure 4.

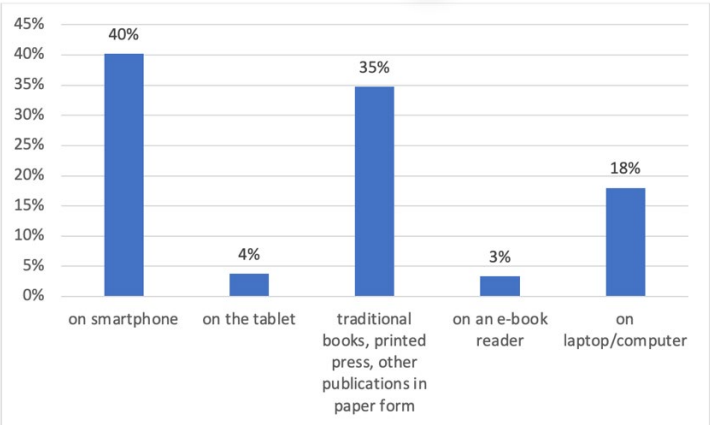

Figure 4: Answer the question "I would most like to read".

Summing up, it can be said that the person in our study is accustomed to using a smartphone on the Internet, both in terms of time spent on the Internet, as well as in terms of reading various content, not only related to science, and the willingness to read in general. The smartphone is also the most popular tool for watching video content on the Internet. The respondent does not use educational platforms used in e-learning, although he knows them. He assesses the use of the electronic version of the textbook as useful, but does not use audio recordings/podcasts in learning.

5. Summary

Analyzing the research results obtained, lecturers and students should focus on mutual learning, and lecturers should adapt their teaching methods to current challenges.

The author believe that education has been changing in recent years. Mutual teaching and learning is important. There are several opportunities to share knowledge between generations, one can learn from each other. Teachers or university lecturers need to undertake the creation of classes using a variety of technologies, adapt the topics presented to the current requirements of students. Universities need to move towards active learning and teaching skills that will survive in a changing world. Lecturers need to teach are skills that remain relevant in new, changing, and unknown contexts.

This study had some limitations. Firstly, considering the large population of Polish university students, the sample size was comparatively small, and the results of the study cannot represent all Polish university students. Further studies were suggested to enlarge the sample size. It is planned to conduct this study in other academic units in Poland and compare the results achieved between universities. It is also planned to increase the survey sample. Interestingly, when conducting the survey, many students were eager to discuss their expectations for teaching with modern technologies.

It is important to remember that the next generation that will come to study at universities is the alpha generation. Future employees are those who, when looking for a job, will not be defined by the diploma obtained or the degree held, but by their competencies and skills (The Burning Glass Institute, 2022).

PPP Projects Information and Methodical Support (CZ and SK Comparison)

Jan Pokorný and Marie Černá
University of West Bohemia, Plzeň, Czech Republic

pokorny@fek.zcu.cz
macerna@fek.zcu.cz

Abstract: Public goods and services administration represents an important tool supporting functioning of the state. Provision of public goods and services is closely related to the necessity to ensure relevant sources and setting the appropriate distribution channels, what in fact means, finding the suitable provider. Production of public goods can be provided by both sectors, private or public. If a public entity produces a public good, it is possible to talk about in-house production. In the opposite situation, when external private entity produces a public good, it is possible to talk about out-house production. This contribution is focused on the issue of Public Private Partnership (PPP) projects as one of the out-house production variants. The aim of the contribution is to compare the availability and complexity of information about the given projects for potential contractors in the Czech Republic and Slovak Republic (Slovakia). To be able to make this comparison, authors of the article conducted the qualitative research. Used method was document and text analysis. To identify the relevant literary sources, systematic literature review followed by the traditional literature review, were used. Authors expected that there will be solid database of information available to the potential conductors of PPP projects. Also the way of its presentation was expected to be thoughtful and complex. Provision of information and methodical support in specified area can influence the final willingness of both sides, contractors and contracting authorities, to enter this project focused on provision of public services, traditionally provided by the public sector, by the private sector. The contribution is finalized using the method of synthesis that enables the authors to describe the main differences in ways of PPP projects information presentation. It was found that currently provided information and methodical support in the area of PPP projects administered by the authorities on the central level in selected countries can be described as insufficient. This finding contradicts the original expectations of the authors.

Keywords: Information Support, Out-House Production, Public Affairs Administration, Public Sector, PPP Projects

1. Introduction

Public goods and services administration represents an important tool supporting functioning of the state, respectively of the public sector. Existence of public goods is further related to questions linked with the acquisition of resources for their provision or the production and distribution of these goods. Within the framework of the public sector system, resources are obtained by limiting the private sector (by taxation, or temporarily by a debt manner), as stated by Pavel (2013).

Production of public goods can be provided by both, the public and the private sector, or by their combination (Ferdman, 2018). In terms of production, it is possible to talk about in-house production, if a public entity produces a public good, or about the possibility of outsourcing (out-house production), which is provided by an external private entity. In the case of the use of external entities for the production of a public good, it is possible to divide it into public contracts or Public Private Partnership (PPP) projects (Ochrana et al, 2010). This contribution is focused on the second of the mentioned methods, PPP projects. In the case of combined form of production, there is cooperation between both entities, when individual advantages are used in the phases of the project (risk, know-how, financing, etc.).

Political and economic issues are closely related to the issue of production. The primary question is: "Is it possible to have selected public good or service provided by the private sector?" This seems to be a highly political issue. This option is more difficult to imagine, for example, in the area of justice or defence, however, in the case of infrastructure construction, the option of external production is almost certain. Economic questions are then asked in association with the convenience of the selected alternative. As part of this, it is possible to mention the 3E principle, where economy, efficiency and effectiveness are monitored (Jackson and Brown, 2003; Ochrana et al, 2010).

On the basis of an expert assessment of these facts, the optimal production variant should be selected, which may be related, but not necessarily, to the issue of distribution. In matters of distribution, it is also important to take into account how the public good is provided (basic education as a compulsory public good), or if there is any fee associated with the use (fee for issuing a passport).

This contribution is focused on the issue of PPP projects as one of the out-house production variants. The premise on which is the presented contribution based is the importance of information and methodical support prepared by central state administration bodies, primarily relevant ministries. The mentioned thesis has its justification in studies dealing with this issue, as political risk represents an important aspect in legislative support, but also in the possibilities of further support and its stability (Abd Karim, 2011; Hai et al, 2022).

The aim of the contribution is to compare the availability and complexity of information about the given projects for potential contractors in the Czech Republic and Slovak Republic (Slovakia).

2. Methods

In order to be able to reach the set aim, authors of the article conducted the qualitative research. Used method was document and text analysis. To identify the relevant literary sources, systematic literature review followed by the traditional literature review, were used.

Authors analysed the level of information and methodical support in the area of PPP projects provided by the authorities on the central level in selected countries, namely the Czech Republic and the Slovak Republic (Slovakia). The reason for selecting these two countries is their closeness to each other, which is caused by the fact that until 1992 they were a joint state entity. This significantly influenced the legislative environment despite the fact that they have been developing separately for almost three decades.

Authors expected that there will be solid database of information available to the potential conductors of PPP projects. Also the way of its presentation was expected to be thoughtful and complex. Provision of information and methodical support in specified area can influence the final willingness of both sides, contractors and contracting authorities, to enter this project focused on provision of public services, traditionally provided by the public sector, by the private sector.

Therefore, in the next part of this contribution, with respect to the defined aim, PPP projects are first presented, taking into account the production possibilities in a broader level. This overview is compiled on the basis of a literature research of professional publications. Similar approach is used also in the chapter, where the practice of PPP projects in the Czech Republic and Slovakia is historically defined.

The contribution further includes the analysis of information and methodical support compiled to this issue by the state authorities on the central level of both countries. Information base for contracting authorities and contractors (suppliers), websites of the ministries of finance in the Czech Republic and Slovakia, are used. This chapter is compiled based on the analysis of websites of Ministry of Finance of the Czech Republic and Ministry of Finance of the Slovak Republic where information about PPP projects is provided. To assess the outputs of both countries, the method of comparison is used.

At the end of the contribution, authors used the method of synthesis that enabled them to describe the main differences in ways of PPP projects information presentation.

2.1 PPP Projects

External production (out-house production) within the provision of public goods represents one of two possible production methods mentioned in the text above, internal and external production. Pavel (2013) names among the possibilities of internal production municipal office employees, budgetary organizations and funded organizations, as well as commercial companies within public sector entities. On the other hand, in addition to public contracts and PPP projects, external production includes commercial companies with majority or minority ownership of public sector entities. The authors do not fully agree with this division, because commercial companies, especially with minority ownership within the public sector, represent also the coordination of the second mentioned side (the private sector). Therefore, it would be better to classify it as a combined (mixed) form of production.

As part of external production, public contracts and PPP projects are significantly important. Public contracts represent a "classic" form of relationship between a public entity (contracting authority) and a private entity (supplier, contractor). The basic difference between PPP projects and public contracts is in their time layout and complexity. Even if also the PPP projects themselves can differ. PPP projects are usually announced as complex, in contrast to public contracts, where different parts (project, construction, operation, etc.) are competed. This is related to their mentioned time layout. Due to their complexity, PPP projects take longer time period (even in

the order of tens of years). This has implications for the form of financing and ownership (Sajko, 2008; Villani et al, 2017).

At the beginning, the implemented project is usually financed by a private entity and then after the start of the use of the given project (e.g. construction), payments are made by the contracting authority to suppliers (quasi-concessions), or fees are collected from users (concessions), which can replace payments from the public sector. If the fees flow to the contracting authority, then the contracting authority makes the payments to the supplier, and this is again a quasi-concession. During the concession or quasi-concession, the project is normally owned by the contractor, and after its end is ownership transferred to the contracting authority (Pavlík et al, 2007).

Related to this, it is possible to identify also other effects in the area of responsibility (supplier side) and control (contracting authority side). If the supplier does not meet the requirements with regard to the quality or quantity of the project, then payments may be suspended. All these matters are dependent on the contractual form of the project. The same applies to the sharing of PPP project risks. According to Abd Karim (2011), these include the following risks: political, economic, market, operational and other. In the case of a concession, the effects of business risk (non-use of project outputs) may occur on the supplier's side. In the case of a quasi-concession, this risk lies on the side of the contracting authority.

Among the significant risks on the side of the contracting authority is the long-term nature of the contract, when the supplier may go bankrupt. It also influences a burden on public budgets for the next several years, which can be decades, and therefore the possibility of handling public funds is affected and prevented by other elected officials (Willems et al, 2017). In this context, Delmon (2017) summarizes important principles related to this type of decision-making: prudent principle, good preparedness and selection, ability to be a partner and respond.

3. Comparison of Development of the use of PPP Projects

The use of PPP projects in the Czech Republic and Slovakia is illustrated in this chapter. This is further used as a starting point to analyse the results of a comparison of the practical form of information support for the given projects. It therefore serves to qualitatively assess the results of the analysis of the information and methodical support provided to the users of the given information by the ministries of finance in both countries.

3.1 The Czech Republic

The question of the use of PPP projects as part of external production began to appear in the Czech Republic in the 1990s. The issue of the use of PPP projects was primarily related to the lack of public resources to finance investments. The first attempts, however, were not successful. This was related, for example, with the bypass of the city of Pilsen in the framework of the completion of the “D5” highway (Pavel, 2007).

In the Czech Republic, more attention was given to PPP projects in the first decade of the 21st century. Pavel (2007) adds to this that: “...also the Czech Republic did not avoid the PPP fashion wave...” Among the projects that were created in this period are the “D3” highway, hospitals in “Pardubice” and “Na Homolce”, court premises and prisons, etc. (Pavel, 2007). The main subject of PPP projects was primarily material infrastructure such as roads, highways and buildings.

Popularization of PPP projects during this period was influenced by the approach of Mirek Topolánek's government, which tried to introduce the principles of the *New public management concept*. This ultimately did not happen in practice (Kroupa et al, 2015). This concept is closely related to the 3E principle and the aim is the efficient use of resources with high quality services for customers (citizens). To do so, the competitive environment between the public and private sectors is used, i.e. market principles, which also influence high level of responsibility in the public sector (Ostřížek, 2011).

As part of the support, in 2004, the Ministry of Finance established the PPP Centrum Inc. In 2013, the name was changed to CENTRUM-F, Inc. Two years later, the company was in liquidation, which was officially terminated, and therefore this centre was deleted from the commercial register, on January 21, 2016 (Justice CZ, 2024). The aim of this centre was to satisfy tasks associated with the coordination of the preparation of the legislative environment, to create information and methodical support, to share experiences within the framework of PPP projects, etc. The model for the establishment of this organization was practice from foreign countries (Šíp, 2005).

Currently, an important PPP project is the completion of the "D4" highway in the section between two cities, "Příbram" and "Písek". The government's intention for this project was approved in 2016. Two years later a tender was launched, and on February 15, 2021, a contract between the contracting authority and the concessionaire, who should complete the construction of the highway by the end of 2024, was signed (PPP D4, 2024). However, the idea of the "D4" completion project using a PPP project appeared before 2016, as in 2015 an *Analysis of the Feasibility and Advantage of Securing the R4 Project in the form of PPP compared to classic public contracts* was prepared (PwC, 2015).

The project thus represents a current example of a PPP project at the central level, which can subsequently influence the future direction in this area. As mentioned, PPP Centrum Inc., which was supposed to provide information and methodical support, went out of business. Within the framework of the contribution, attention is therefore paid to the Ministry of Finance of the Czech Republic, as also stated in the Introduction.

3.2 The Slovak Republic (Slovakia)

In 2005, in Slovakia was created a document called *Administration on the creation of conditions for the implementation of projects with private partnership*, which was created by the Ministry of Finance of the Slovak Republic (MF SK, 2005). Four years later, a document focusing on the analysis of the legal environment and its modification with regard to the possibility of using PPP projects was created (MF SK, 2009).

The effort to create an infrastructure construction project in the form of a PPP project in Slovakia dates back to 2007, although the debate had already started several years before during the era of Dzurinda's government. The infrastructure construction was divided into three packages, while the first package failed to be implemented. Although a concession agreement was signed in 2009, it lapsed in 2010. Originally, it was supposed to be a complex project with a duration of 30 years (Slovincová, 2021).

The second package was already more successful and in 2012 it was possible to open all its parts. The concession period was set to be 30 years (Via Pribina, 2024). The third package started to be implemented later. In 2015 the contract was signed and a year later the construction under this package started. The concession in this case should be terminated in 2048 (Slovincová, 2021).

Another three-decade-long project is a concession focused on the operation and maintenance of the "*Žilina Intermodal Transport Terminal*". The contract was signed in 2018 (Terminál Žilina, 2024).

From the above mentioned cases, it is clear that these projects had been considered in Slovakia in a similar period as in the Czech Republic. On a practical level, three more significant projects were implemented in Slovakia, which demonstrate the success of PPP projects in Slovakia.

4. Results and Discussion

As the first step leading to compilation of previous and following parts of this article was provided a systematic literary review. This review was focused on searching the literary sources dealing with PPP projects issue relevant for the Czech Republic and Slovakia in the Web of Science database. Authors tried to search for articles dealing with public private partnership projects or PPP projects. They search for the articles with this terms in their content and then in their titles. The results were limited by the years of publication (2004 – 2024) and by the countries/regions (Czech Republic and Slovakia). The results were 343 documents including 232 articles in journals. Results of this review are visible in the following figure 1.

Figure 1: Results of systematic literary review

Source: own processing, 2024

The results were further limited by the next requirement – articles should be focused also on methodical support of these projects. After adding this limitation, there were 273 relevant sources available. This was still quite wide range of articles. Therefore, the research was done focusing just on the articles with the terms public private partnership projects or PPP projects in the title. Further limits were used similarly as described above. This way 13 results were obtained, see figure 2. The results included 2 articles in journals, 9 articles in conference proceedings and 2 editorial materials.

Figure 2: Results of systematic literary review - shortlist

Source: own processing, 2024

Selected sources were then used as the background for compilation of introductory parts of this article. Then the authors decided to use also other sources (web pages) focused on this issue. Therefore, the traditional literature review was done.

From the previous chapter (compiled using the document and text analysis), it is evident that consideration of PPP projects occurred in the Czech Republic earlier than in Slovakia. However, important aspects in terms of practical implementation did not begin until about the mid of the first decade of the 21st century. Implementation of PPP projects was then unfortunately disrupted by the economic crisis at that time.

In terms of the practical implementation of PPP projects, the success of Slovakia is evident compared to the Czech Republic. Three important PPP projects were implemented in Slovakia, despite the failure of the first transport infrastructure package. In the case of the Czech Republic, there was a delay of almost ten years, which has not yet ended with success (with the commissioning of the affected infrastructure).

As part of a traditional literature review, the authors found that monitoring the availability of information about the given area is useful to monitor the websites of the Ministry of Finance of the Czech Republic (MF CR, 2024) and the Slovak Republic (MF SK, 2024). Table 1 points out the basic requirements of both websites with regard to what is traceable and graspable as information support within the framework of PPP projects. In the case of the Czech Republic, the term *public-private sector partnership* is used, in contrast, *PPP projects* are used in Slovakia. Within the sorting, it is clear that on the Czech website, you have to click on *public sector* and then *support from national sources*. On the Slovak website, it is possible to access *PPP projects* directly through the intermediate step of the *finance* item.

Table 1: Ministry of finance websites comparison in the area of PPP projects (CZ and SK)

Category	Czech Republic	Slovak Republic
Terminology	*public-private sector partnership*	*PPP projects*
Category (placement)	*public sector, support from national sources*	*finance*
Basic information	*yes*	*yes*
Phases (process)	*no*	*yes*
Methodical documents	*yes (the latest from 2013)*	*yes (the latest from 2020)*
Project examples	*no*	*yes (3 examples, the newest from 2018)*
Statistical information	*no*	*described*

Source: own processing according to MF CR (2024) and MF SK (2024), 2024

The main difference can be found in the content of the methodical support to PPP projects. Although both websites offer basic information, in the case of Slovakia, there is also a description of the process of the phases of PPP projects.

Another difference is the difference in the timeliness of the documents. In the case of the Czech Republic, there are documents from the period of 2007 to 2013. In the case of Slovakia, it is also possible to find older documents from 2008, but also more recent materials, or updated materials that relate to, for example, the preparation process, feasibility studies or the code for the preparation and implementation of PPP projects.

Another difference is visible in the presentation of project examples. Slovakia can offer and share information gathered during implementation of its three successful projects. Due to the current situation within the framework of PPP projects, no such information is listed on the relevant website of the Ministry of Finance of the Czech Republic.

The disadvantage of both websites can be seen in the fact that they do not provide statistical information of sufficient quality and quantity. In the case of Slovakia, there is at least a brief description of the development of the value of PPP projects. In both cases, the addition of such data would be beneficial, especially in the case of the Czech Republic. It can be stated that relevant information on the analysed area was also in the past provided on the websites of Czech institutions (Hejduková and Pokorný, 2020). It would be advisable to restore this state, because with sufficient support and economic efficiency, under certain circumstances, preference for the PPP project variant can be expected from the contracting authority, which can be a region or municipality in addition to central authorities. If such a support is not provided, then PPP projects are not preferred, as there are concerns on the side of the contracting authorities about insufficient use of this variant by the contractors.

5. In Conclusion

PPP projects represent specific alternative of provision of public goods and services by external private entities (out-house production alternative). Even if it seems that both analysed countries, the Czech Republic and the Slovak Republic, have currently more experience in the area of provision of public goods and services using the out-house production in the form of public contracts, PPP projects remain the realisable alternative which has its place in both mentioned economies.

It is necessary to write again that in both cases, the addition of more detailed and relevant data would be beneficial and may increase the public knowledge about this issue what may finally lead to greater acceptance of this type of public goods and services provision. This in fact means that with sufficient support (information and methodical) and economic efficiency, under certain circumstances, PPP project variant preference can be expected. Low level of information and methodical support, amongst other things, will lead to situation in which PPP projects will not belong to the preferred alternative for public goods and services provision.

During the conducted research was also found that currently provided information and methodical support in the area of PPP projects administered by the authorities on the central level in selected countries can be described as insufficient. This finding contradicts the original expectations of the authors.

Navigating Organizational Success: Knowledge Management Capabilities in Public Healthcare

Paula Pusenius and Harri Laihonen
University of Eastern Finland, Kuopio, Finland

paula.pusenius@uef.fi
harri.laihonen@uef.fi

Abstract: Knowledge Management (KM) has been studied in healthcare for over two decades and has an established role in healthcare management. By leveraging KM, healthcare organizations aim to enhance organizational performance, facilitate informed decision-making, and elevate service quality. However, KM faces specific challenges in healthcare, including siloed service provision and effective management of growing volumes of data and evidence. Public healthcare organizations encounter additional challenges due to the complex environment, conflicting values, wicked problems, and resource constraints. While research on KM in the public sector has increased recently, it remains relatively scarce. Notably, the capabilities of effective KM and its significance for organizations' survival have received limited attention. Finland has recently implemented a massive healthcare reform, which shifted the responsibility for organizing healthcare, social welfare and rescue services to new autonomous regional-level organizations, wellbeing services counties. This study explores how KM can support the success of public healthcare organizations after such a fundamental change. The central research question is: What are the critical KM capabilities when rebuilding KM function after a major public reform? To address this question, we employ a qualitative case study approach. Through the interviews of KM specialists from the newly established wellbeing services county, we gain valuable insights into the practical aspects of KM within an integrated public healthcare organization. Our key findings shed light on challenges related to diverse stakeholders and values, emphasize the importance of internal and external relationships, underscore the significance of specialist diversity, and highlight the value of KM to the healthcare organization.

Keywords: Knowledge Management, Healthcare Management, Public Sector, Reform, Capabilities

1. Introduction

The healthcare industry is characterized by its knowledge-intensive nature, as the economic activities within healthcare are intricately tied to the creation, accumulation, and dissemination of knowledge (cf. Miles, Kastrinos & Flanagan, 1995). In healthcare, knowledge in its different modes supports decision-making and is a source of value creation (cf. Grant, 1996). The value of health services emerges largely from the expertise and skills of healthcare professionals, knowledge shared through relationships, codified and tacit knowledge, and organizational culture (Evans, Brown & Baker, 2015; Grant, 1996). Digitalization, the fast-growing volume of healthcare data and national and international regulation of medical records have underlined the relevance of codified knowledge-related development. At the same time, in recent years, we have seen an increase in diversity within our societies, and the trade-offs between values (Bracci et al., 2021) also affect decision-making, especially in the public sector.

Knowledge Management (KM) has a long research history and a stable role in healthcare management (Lunden et al., 2017; Nicolini et al., 2008). However, the public sector is the least examined area (Massaro, Dumay & Garlatti, 2015) despite its significant societal role and the vital context the public sector serves for KM research. While research on KM in the public sector has increased recently, it remains relatively scarce. Moreover, KM has focused more on the context of information management (cf. Choo, 2002), and more attention needs to be paid to KM capabilities (Laihonen & Saranto, 2021).

The healthcare sector is under pressure worldwide due to economic recession, population ageing, workforce shortfall (e.g. Liu et al., 2017), digitalization and societal changes. These global trends drive, in particular, public sector healthcare for renewal to retain the ability to provide services and meet the users' growing expectations. To respond to these pressures, Finland has recently implemented a massive healthcare reform, which shifted the responsibility for organizing healthcare, social welfare, and rescue services from over 300 municipalities to 21 newly established wellbeing services counties. The reform aims to improve the availability and quality of basic public services and curb the continued cost growth (Ministry of Social Affairs and Health, 2023).

This article aims to elaborate on the role of KM as the critical component of organizational renewal and performance. It explores the practical aspects and role of KM in supporting the success of public healthcare organizations after a fundamental reform. The study aims to contribute to the knowledge gap regarding critical KM capabilities when rebuilding KM function. The central research question is:

What are the critical KM capabilities when rebuilding KM function after a major public reform?

Based on the literature and empirical data gathered through thematic interviews of KM specialists from one wellbeing services county in Finland, this article addresses the importance of KM in the public healthcare sector. Through the interviews, we gain valuable insights into the practical aspects of KM within an integrated public healthcare organization, especially for four key themes: (1) KM in practice, (2) the value of KM, (3) KM capabilities and (4) the future of KM.

The rest of the paper is organized as follows: The next section reviews the theoretical background of KM in public healthcare and briefly discusses the recent literature. Section three presents the study's context and methods, and section four presents the empirical results. Section five makes concluding remarks.

2. Theoretical Background – KM and KM Capabilities in Public Healthcare

The field of KM traces its origins to the knowledge-based view, which posits that knowledge plays a pivotal role as both a critical input in production processes and a primary source of organizational value (Grant, 1996). KM systematically identifies and strategically leverages an organization's knowledge resources (Von Krogh, 1998). KM encompasses various processes, including knowledge creation, storage, transfer, and application (Alavi & Leidner, 2001). Central to KM is enhancing an organization's overall performance (Kalling, 2003).

KM in healthcare has been studied for over 20 years (Lunden et al., 2017; Nicolini et al., 2008). By leveraging KM, healthcare organizations aim to enhance organizational performance, facilitate informed decision-making, and elevate service quality (Hujala & Laihonen, 2021). Studies examine KM in healthcare from different perspectives. For example, the processes and tools of KM (El-Jardali et al., 2023; Nicolini et al, 2008), barriers and enablers of knowledge sharing (Kim et al., 2011; Lin & Lo, 2015), KM´s impact on the effectiveness of healthcare (e.g. Laihonen & Sillanpää, 2014), and KM related to performance (for review, see Kosklin, Lammintakanen & Kivinen, 2023). However, the healthcare and public contexts should be considered when examining KM in *public sector* healthcare. In particular, the public sector presents a unique environment characterized by distinct organizational features, effectiveness concerns, and levels of representativeness, accountability, and responsiveness (Massaro, Dumay & Garlatti, 2015). KM in the public sector has a broad range of goals seeking to strengthen societal capabilities, cultivate a competitive workforce, and facilitate the participation of citizens in public decision-making (Wiig, 2002). A comprehensive literature review of KM in the public sector (Massaro, Dumay & Garlatti, 2015) underscores the need for tailored approaches recognizing the organizational idiosyncrasies inherent to the public sector.

Scholarly literature has acknowledged various impediments to implementing KM within the public sector. These challenges encompass both technological and cultural dimensions. For example, a strong emphasis on technology-driven approaches in KM initiatives (e.g. Tseng, 2007) may hinder the successful adoption and utilization of KM approaches. The public sector often grapples with incompatible information systems, leading to the lack of accessible managerial information (Behn, 2003), which poses hurdles to the effective utilization of KM practices. The hierarchical and bureaucratic nature typical for public sector organizations can impede knowledge sharing and even lead to knowledge hoarding (Evans, Hendron & Oldroyd, 2015; Amber et al., 2019). In addition to technological and cultural dimensions, the public sector must consider the convergence with political orientations. Public healthcare organizations encounter challenges due to the complex environment, conflicting values (Bracci et al., 2021), wicked societal problems (Jacobs & Cuganesan, 2014) and resource constraints. Recently, value-based healthcare (VBHC), aiming to optimize health system performance in population health, patient experience, and cost of care (e.g. Nuño-Solinís, 2019), has set new requirements for KM in public healthcare. Integration of care is one central principle of VBHC (Nuño-Solinís, 2019), directly impacting KM by calling for knowledge integration.

Previous research has demonstrated that organizational Knowledge Management Systems (KMS) play a pivotal role in an organization´s strategy and structure (e.g. Starns & Odom, 2006). A robust foundation in people, technology, and processes, beginning with strategic integration, is essential for successful KM implementation (Robu & Lazar, 2021). While technology facilitates KM, the organizational KM culture wields even more significant influence (Ghosh & Scott, 2006; Hujala & Laihonen, 2021). Within integrated healthcare organizations, a significant paradigm shift from isolated organizational and information structures to vertical and horizontal arrangements presents new challenges (cf. Laihonen & Huhtamäki, 2020). In public healthcare, KM also involves coordination of collaboration across multiple professions and sectors, bringing diverse objectives and regulatory mechanisms (Laihonen & Kokko, 2020).

KM capabilities are typically approached from the organizational perspective (Laihonen & Huhtamäki, 2020). Gold, Malhotra & Segars (2001) proposed an organizational capabilities perspective aiming to evaluate the essential capabilities of KM. These capabilities are classified into knowledge infrastructure capability, consisting of technology, structure and culture, and knowledge process capability, consisting of acquisition, conversion, application and protection of knowledge (Gold, Malhotra & Segars, 2001). This perspective, however, largely excludes individual experts' skills and competence. Alavi & Leidner (2001) view capability as one perspective on knowledge, which implies that KM is focused on developing core competencies, understanding the strategic advantage, and creating intellectual capital (Alavi & Leidner, 2001). Watson (1999) expands on capability, proposing that knowledge is not a specific ability for action but rather the capacity to utilize information. The capabilities of KM can also be interpreted through the lens of knowledge assets or Intellectual Capital (IC) traditionally categorized into structural, relational and human capital (Petty & Guthrie, 2000). Laihonen & Saranto (2021) concluded in their study that little attention has been paid to KM capabilities and competencies despite significant changes in the operating environment and technology after the above-mentioned seminal articles.

In the next sections, we look at the empirical results for the integrated public healthcare organizations' KM unit to understand better how KM helps an organization succeed. We focus on KM's practical work, the value it adds to the healthcare organization, the KM capabilities needed, and its future.

3. Context and Methods of the Empirical Study

3.1 Context of the Empirical Study

In Finland's recently implemented healthcare reform, the responsibility for organizing healthcare, social welfare and rescue services was shifted from 309 municipalities to 21 new autonomous regional-level organizations, wellbeing services counties in the beginning of 2023. Larger organizational structures aim to achieve more consistent and equal public services and savings, especially in administration. In addition, the Ministry of Social Affairs and Health is strongly advocating the shift towards value-based healthcare through various steering mechanisms. Therefore, the considerably increased size of the organizations, the integration of functions and the objective of moving towards VBHC bring new opportunities and challenges for KM. In addition, the wellbeing services counties have a dual leadership model with civil servant and political leadership. (Pirha 2024a)

The research was conducted within the Pirkanmaa Wellbeing Services County (Pirha), an administrative region encompassing 23 municipalities. Pirha boasts a population of approximately 500,000 inhabitants and serves as the largest wellbeing services county in Finland. Pirha assumes responsibility for social welfare, healthcare, and rescue services within this administrative framework. A workforce of approximately 19,000 employees manages these critical functions. (Pirha 2024a)

The case study was conducted in a newly established KM unit of Pirha. In Pirha's organization, the KM is organized as an independent unit, part of the strategic guidance and organization function with other vital divisions such as procurement, communication, finance, and human resources (Pirha, 2024b). The KM function was rebuilt on a previous organizational and technological basis. The KM unit members were recruited from previous organizations whose healthcare functions were merged during the reform. The KM unit consists of two teams, one focusing more on data quality and the other on reporting. In spring 2023, the unit employed 17 people.

3.2 Methods and Empirical Data

We chose a case study as a research method to gain an in-depth understanding of KM in public healthcare (cf. Yin, 2009). Thematic interviews were conducted remotely in April 2023, and 11 KM specialists from the Pirha KM unit participated. The interviews were recorded and transcribed, followed by a content analysis of the data (Drisko & Maschi, 2016). In addition, Pirha's Strategy and Strategy Implementation Programme, Pirha's Knowledge Management Programme and the KM unit's Data Quality Improvement Management Model were used as background material.

4. Results

The interview data provided a coherent picture of KM in Pirha. The interviewees answered many questions similarly, highlighting the importance of culture, diversity, networking and exemplary implementation. The

objectives of the KM unit are clear and shared. Also, interviewees stressed the role of systematic identity building. The main difference in tone emerged between the two teams – data quality and reporting. In October 2023, preliminary results were validated by presenting and discussing them at the monthly meeting of the KM unit. Based on feedback from specialists, the results provided a truthful picture of the unit's function.

4.1 KM in Practice – What is KM in Pirha?

Pirha's KM programme defines KM as *"a set of policies and technical solutions that make the right information available to the right people at the right time and in the right format"*. During the interviews, the experts were asked "*What is KM in Pirha*?". The specialists described the unit's key task as providing adequate and reliable information to support service delivery and other core activities of wellbeing services county. The support is provided by establishing relationships and networks and coordinating cooperation at different levels of the organization and with external actors (e.g. national steering of health information management). As one interviewee summarized:

"The key point is that enough information must be available for a wellbeing services county [of Pirha] to succeed."

Interviewees described that KM is currently being implemented in a situation where Pirha has several patient information systems in place after merging 23 municipalities and a hospital district to launch the wellbeing services county. There are also differences in patient record keeping practices. Thus, an essential and ongoing role of the KM unit is to ensure consistency and maintenance of data quality by supporting the development of service delivery competencies through record-keeping networks. In addition, the KM unit's tasks include combining data from different data sources, validating the data and producing visualized reporting coherently across a large and variable wellbeing services county, especially for the needs of senior management.

4.2 Value of KM – Why is the KM Unit Important?

Pirha's KM programme defines the value of KM to wellbeing services county as follows: "*KM enables high-quality and strategy-driven decision-making, management and operations*". The specialists were asked: "*Why is KM unit important to Pirha*?". KM unit was seen as an enabler; KM unit doesn't participate in management decision-making but enables it by providing a coherent and consistent view on the operations of the wellbeing services county for decision-makers, as interviewees put it:

"*If there was no central coordination [of KM], everyone would be doing their own thing and knowledge management would be fragmented*."

"*It's this size, which definitely requires it [the KM unit], but then there's also the role of national reporting obligations, which raises the importance of this information to even different levels because it's linked to funding*."

The KM specialists saw that the KM unit's robust reporting and advocacy role enables service providers to concentrate on their expertise. Meeting national reporting obligations was also seen as a critical benefit of the KM unit. As the funding of the wellbeing services counties is based on the operational information reported to national bodies, the role of the KM unit in ensuring the quality of data and implementing data collection and reporting is crucial in financial terms. The responsibility for harmonising data quality highlights the developmental function of the KM unit. In addition, interviewees saw the KM unit playing an essential role in translating KM's needs into the service delivery language to motivate health professionals to improve data quality. From a public service perspective, the interviewees identified the KM unit's activities as increasing openness and transparency and thus value for money for citizens.

4.3 KM Capabilities - What are the Key Capabilities of the KM Unit?

Pirha's KM programme defines that in Pirha "*KM is decentralised and centrally coordinated [...] competence and skills are needed both close to service operations and centralised in the KM unit*". This capability topic is broad, and we categorised the responses according to the Intellectual Capital tripartite framework to human capital (HC), relational capital (RC) and structural capital (SC). The lens of IC enables organizational and individual capabilities, competencies and skills to be considered equally.

In terms of human capital, respondents highlighted the role of broad substantive skills. The KM unit has expertise in primary healthcare, specialised healthcare, social care as well as in technical skills such as data modelling and

reporting. In addition to hard skills, soft skills such as change management skills, communication skills, and leadership skills were highlighted. Among the personality traits, motivation, curiosity, and willingness to develop were considered particularly important. A deep understanding of the operational environment is vital for the KM unit:

"It's extremely important that we understand the services, the issues involved, and how the organization works. What legalities exist in the public sector, what cultures exist in healthcare, and what cultures exist in social care in relation to record-keeping."

The role of relational capital emerged as particularly important in the interviews. The KM specialists identified the strategic role of KM in supporting the core activities of the organization. As one of the respondents pointed out:

"We are nothing alone."

KM specialists' diverse knowledge and work experience in previous organizations enable them to build relationships across the entire organization. This is essential for the "decentralized and centrally coordinated" concept; the KM unit is a small area of responsibility in a large and multifunctional ecosystem. The role of networks was highlighted, with the KM unit functioning at the hub of a wide range of networks horizontally, vertically, and at the regional and national levels.

Two key elements emerged from the structural capital describing an organization's intangibles: The systematic building of policies and processes and the role of culture. Building policies and processes was seen as exceptionally important due to the role of KM unit whose task is to form a coherent picture of all the data from the multifunctional and multi-professional organization. As interviewees stated:

"[KM's] job is to frame; the content comes from service operations."

"In Data Quality Improvement Management Model all these different roles are considered […] the aim is that every single professional understands the chain of reliable information formation."

When interviewees spoke about KM units' culture, they mentioned repeatedly openness, trust, and low hierarchy. Good culture was seen as a competitive advantage for KM unit to succeed and has been systematically developed:

"We are a brand-new unit and a very heterogenic team, so it is essential to have a good culture and be a unified team, and we have done much work for that."

4.4 The Future of KM

In the interviews, the specialists were asked, "*How do you see the future of KM?*" At the time of the interviews, the KM unit and the Pirha Wellbeing Services County had only been in operation for a few months, and many of the answers about the future were related to stabilisation and clarification of the role of the KM unit in the near future. This involved consolidating several patient information systems and expanding the data volume of the data pool to enable efficient knowledge processing. As one interviewee put it:

"Hopefully, in a year, we have clarified the situation regarding the data sources and the data pool. [...] the work will then be more about developing new reports than about trying to hunt down the different municipal systems and how to connect them to the data pool."

In addition, the expansion of networks and the growth of KM capabilities and competencies in Pirha were seen as areas of future development.

"We should focus on building [KM] capability and on the fact that if we build that capability, then we will have the resources in the future through it [...] As we need more [KM] resources for our lines [of operational activity]."

As regards external factors, respondents highlighted national KM development; at the time of the interviews, national information production and national requirements for reporting were partly unclear and cumbersome. This was seen to be linked to the reform and would be addressed in the future. Regarding general technological developments, several respondents identified the growing role of AI as an exciting opportunity to develop KM. In addition, respondents considered using various health technology data (including smart watches and intelligent rings) as possible future data sources for KM. Forecasting and prediction also emerged as a prominent

feature of the longer-term future. The answers were not limited to KM, but the role of KM in facing the wicked problems of social and healthcare was considered:

"[...] that we have found, with the support of knowledge, a solution to the fact that people want to work in this sector, as in the social and health sector, and that it makes sense to work and also to use these services [of Pirha]. But there are so many other things in it than this KM, but yes, it also has its role to play."

5. Discussion and Concluding Remarks

The study aimed to better understand the critical KM capabilities when rebuilding KM function after a major public reform. To answer this question, we highlight three areas of KM capabilities. Each of these three perspectives offers a wealth of opportunities for future research. The recognized capabilities are not KM capabilities per se (cf. Gold, Malhotra & Segars, 2001; Alavi & Leidner, 2001) but especially during the change, these upper-level capability areas seem to be stressed. It seems that the KM unit in Pirha can handle operational tasks well; thus, it can be concluded that operative capabilities are in place. However, without a legitimate organizational position, a certain kind of renewal capability, and an ability to recognize "the right things", KM will not be able to meet the growing expectations.

First, KM needs to have sufficient legitimacy to act. Positioning KM at a strategic level enables KM to support effective organizational renewal in change and thus act as a *dynamic capability of an organization*. The case organization Pirha explicitly positions KM as an independent organizational entity, which does not imply that the KM unit operates in isolation. On the contrary, KM is considered an integral part of the organization, aligned with its fundamental mission: promoting the well-being of the area's inhabitants by supporting the core functions of the organization. This alignment with organizational strategies has been stressed in KM literature previously (e.g. Starns, & Odom, 2006).

Second, major changes in the operational environment necessitate continuous renewal of KM capabilities. The previous literature provides various frameworks to study KM capabilities, but what our data adds to these existing models is the importance of resilience and inter-organizational and inter-sectoral collaboration – KM capability should not be considered only as an independent and static reporting function but maybe more as the capacity to utilize information as Watson (1999) phrased it. In terms of relational capital, there is a need for the active building of networks and connections both inside and outside an organization. From the human capital perspective, diversity and continuous learning are essential. Also, organizational structures and technological solutions must be flexible enough to enable basic activity and renewal. The role of culture in encouraging and supporting change cannot be overemphasised. Indeed, it seems that the IC framework may help to conceptualize and better understand KM as an organizational capability.

Third, KM must have a capability to raise the level of abstraction from efficient KM to effective KM (cf. Hujala & Laihonen, 2021). This means that KM must be able to exploit the existing data. However, on the other hand, it is essential to explore novel ways to acquire, use and process data for forecasting and prediction and to ask different kinds of questions (cf. Laihonen & Huhtamäki, 2020). This may help collaboration across multiple professions and sectors, bringing together diverse objectives, values and legislative and regulatory mechanisms (cf. Laihonen & Kokko, 2020), which further allows KM to focus more on wicked problems in the future (cf. Dumay, 2020).

Knowledge-Based Approach to Sustainable City Management: An Example of European Smart Cities

Aleksandra Radziszewska
Czestochowa University of Technology, Czestochowa, Poland

aleksandra.radziszewska@pcz.pl

Abstract: This study aims to examine the relationships between the use of knowledge-based approach in key areas of sustainable city management (urban planning, mobility and transportation management, and environment protection) and city's position in the global smart cities ranking (the IESE Cities in Motion Index). A case study methodology is adopted to examine and compare the possibilities of implementing knowledge-based approach in sustainable city management, in order to gain a better understanding of this new urban phenomenon. Data and information about knowledge-based smart city initiatives have been collected from secondary sources. The presented case studies were explored through desk research using online resources, such as the web pages of smart city initiatives. Smart Cities were selected based on their rankings in the IESE Cities in Motion Index. In addition, multiple regressions were used to identify the relationship between the independent variables (environment protection, mobility and transportation management, urban planning) and dependent variable-value of city's ranking in the IESE Cities in Motion Index . The results illustrate that the majority of cities use smart-city solutions in all categories to improve city management, efficiency and achieve sustainability goals. All research hypotheses have been accepted, therefore knowledge-based smart city solutions implemented in all key areas of sustainable city management (urban planning, mobility and transportation management, and environment protection) positively influence performance of achieving sustainability goals. The selection of a limited number of case studies is a limitation of this research. It is therefore important to explore the potential of knowledge-based approach in urban development and city management in more detail by considering more cases. Future research should explore the impacts of other variables related to sustainability, which can determinate performance of sustainable city management. A future study should try to validate the result by using a wider sample. The research combines quantitative and quantitative analysis in order to identify the determinants of effective achievement of sustainable development goals in city management. This study provides a form of grounding for further discussion to debate over of the operational functioning, planning, design, development, and governance of smart sustainable cities in the future.

Keywords: Sustainability, Sustainable Urban Development, Knowledge-Based Approach, Sustainable City Management, Sustainable Smart Cities, the IESE Cities in Motion Index

1. Introduction

Knowledge-based development is a vision of development that considers knowledge as the central structuring element of a development strategy. The smart city must be able to exploit knowledge that result from data management. This knowledge will result in better decisions in order for the modern city to address its main challenges. Smart cities are exposed to technological issues tied to the huge mass of data which pass within them. These data can carry knowledge and, by the way, the city authorities aware of the existence and of the potential of this knowledge, can exploit and use them.

The basis for efficient sustainable city management are effective information flows and ability of knowledge extraction from the fast growing data resources.

The most important challenge for cities authorities now and in the future, in the context of development of sustainable city management, is to integrate the data resources and to deliver valuable information flows for the efficient knowledge management processes for urban development.

The literature does not pay much attention to the organizational and managerial solutions during the transition from a classic city to a smart city, therefore the paper try to explore the potential of the knowledge-based managing of urban development.

The motivation for this study is to identify the main dimensions of the sustainable city management and their influence on a city's position in the global smart cities ranking.

This study aims to examine the relationships between the use of knowledge-based approach in key areas of sustainable city management (urban planning, mobility and transportation management, and environment protection) and city's position in the global smart cities ranking (the IESE Cities in Motion Index).

A case study methodology is adopted to examine and compare the possibilities of implementing knowledge-based approach in sustainable city management, in order to gain a better understanding of this new urban phenomenon. Data and information about knowledge-based smart city initiatives have been collected from

secondary sources. The presented case studies were explored through desk research using online resources, such as the web pages of smart city initiatives. Smart Cities were selected based on their rankings in the IESE Cities in Motion Index. In addition, multiple regressions were used to identify the relationship between the independent variables (environment protection, mobility and transportation management, urban planning) and dependent variable-value of city's ranking in the IESE Cities in Motion Index .

The paper will enable researchers and scholars to direct their future work to the emerging paradigm of knowledge-based smart sustainable urbanism, and practitioners and experts to identify common problems and potential ways to solve them, all as part of future research and practical endeavours. It give also an opportunity to identify areas for further improvement while leveraging areas of strength with regard to the future form of such urbanism.

The paper is structured as follows: After this introduction the next section presents the literature review with discussions of the research model and hypotheses development. Then research methodology is presented in detail. Finally, research findings are outlined and discussed, implications are explored, limitation and futures research are described.

2. Literature Review and Hypotheses Development

Concepts linked to environmental protection to characterise cities have given rise to initiatives and experiments such as green city, eco-city, low carbon city, smart city, evolving towards more integrated approaches to sustainability (Yigitcanlar and Kamruzzaman 2015; Trindade et al. 2017). Mori and Yamashita (2015) view a sustainable city as the one that can generate the maximum socioeconomic benefits for its population without losing the environmental and equity parameters, measured by appropriate indicators.

A smart city, for instance, will seek the goal of achieving its sustainability with the support of modern technologies. In fact, information and communication technologies (ICTs) can bring numerous benefits to cities, but its implementation as an end in itself is not enough to make it a sustainable city (Ahvenniemi et al. 2017).

Knowledge-based development (KBD) is a vision of development that considers knowledge as the central structuring element of a development strategy for cities and regions (Lönnqvist et al. 2014).

Knight (1995) envisioned knowledge-based development of cities as basis for sustainable development, emphasising the relevance of the process of transforming know ledge resources into local development. Following this view, cities should build their own unique knowledge stock by identifying their own particular strengths. This statement on knowledge-based urban development (KBUD) seems very adequate to describe actual challenges. The increasing importance and complexity of the city and the requirement that development is sustainable calls for a new integrative framework for thinking about the development of cities. Urban planners are facing new issues and need new approaches in order to facilitate new forms of development (Knight, 1995).

To construct a knowledge-based social structure, urban planning also needs to incorporate knowledge creation (May and Perry, 2011). Knowledge has become critical to social and economic development, while promoting economic growth and increasing competitiveness.

The integration of technology into urban infrastructure is a significant aspect of a Smart City. This involves the use of Information and Communication Technology (ICT) and other innovative technologies to manage the city's assets, including transportation systems, power plants, water supply networks, waste management, and other community services. The aim of technological integration is to improve the quality of services, reduce costs, optimize resource consumption, and enhance interaction between citizens and the government.

The concept of Smart City seeks to make maximum use of modern technologies, mainly information technologies with the aim of achieving sustainable development goals. Social and environmental sustainability is a major strategic component of smart cities (Lee et al., 2023).

The concept of a Smart City extends beyond mere technological integration. It also encompasses sustainable practices Sustainable practices involve the implementation of strategies aimed at improving environmental sustainability, including the promotion of renewable energy sources, waste management, water conservation, and sustainable urban planning. The goal is to create a city that is not only technologically advanced but also environmentally friendly (Rahmat et al. 2023).

Improving environmental sustainability through anti-pollution plans, support for green buildings and alternative energies, efficient water and waste management, and policies that help counteract the effects of climate change

are essential to ensure the sustainability of cities over time (Su, Hu and Yu, 2023). In light of the aforementioned evidence, the initial hypothesis of this study can be formulated as follows:

H1: Knowledge-based solutions in area of environmental protection positively influence sustainable city management

The application of data-driven solutions within the domain of transport and traffic management is a particularly prevalent phenomenon in the context of both smart cities and sustainable smart cities (Savastano et al., 2023).

The future of urban mobility and transportation is confronted with two significant challenges: facilitating travel over vast territories and ensuring access to public services. The quality of life of a city's inhabitants is affected by mobility and transportation, which encompasses road and route infrastructure, the vehicle fleet, public transit and air transport. These factors can be key to a city's sustainability over time (da Silva, Santos and Setti, 2022).

Artificial intelligence (AI) is now playing a pivotal role in the advancement of urban development. Furthermore, it is assisting local authorities in the collection of data regarding the inhabitants of a given city, thereby facilitating the efficient management of resources. To illustrate, a city that employs AI to mitigate traffic congestion is well-positioned to address its mobility challenges. The utilisation of AI tools facilitates the real-time collection of traffic data, enables the prediction of traffic congestion, enhances mobility and alleviates congestion in key areas (Singh et al., 2022; Cruz and Paulino, 2022). In light of the aforementioned evidence, the second hypothesis of this study is thus proposed:

H2: Knowledge-based solutions in area of mobility and transportation management positively influence sustainable city management

The field of urban planning has historically been regarded as a key driver of sustainable development in urban areas. Consequently, urban planning is inextricably linked to the concept of sustainability. In order to enhance the liveability of any given territory, it is essential to consider local master plans and the design of green areas and spaces intended for public use, while also prioritising smart growth strategies. The objective of new urban planning methods should be the creation of compact, well-connected cities with accessible public services (Son et al., 2023). The management of urban infrastructure represents a significant application of the Internet of Things (IoT) and big data analytics, facilitating monitoring, control, automation, and optimization. This encompasses the operation of roads, railway tracks, bridges, and tunnels (Sanchez et al., 2023). This is pertinent to the occurrences and alterations pertaining to the structural characteristics of urban infrastructure, which have the potential to elevate risk and expenditure, and ultimately compromise safety and service quality. In this regard, the Internet of Things (IoT) devices can be employed to enhance incident management, optimise emergency response coordination and service quality, and reduce operational costs across all infrastructure-related domains (Wang and Yin, 2023). In light of the above, the third hypothesis of this study is as follows:

H3: Knowledge-based solutions in area of urban planning positively influence sustainable city management

Knowledge-based, smart and sustainable city is a conceptual framework that displays a knowledge- based urban development strategy aimed to promote smart and sustainable cities through the operationalisation of a knowledge management integrated approach (Yigitcanlar and Lönnqvist, 2013).

3. Research Methodology

The presented study was conducted in June 2024. Its purpose was to determine the relationship between datafication and a city's position in the global smart cities ranking (IESE Cities in Motion Index 2024).

The IESE Cities in Motion Index is a study published annually by the business school of the University of Navarra (IESE) that aims to evaluate the development of the world's cities. It assesses several socioeconomic aspects of development, including human capital, social cohesion (which includes employment, female participation in the work force, etc.), governance, sustainable development, mobility and transportation, urban planning, international outreach, and technology. IESE Cities in Motion Index offers a platform for a comprehensive initial diagnosis of the cities and, through comparative analysis, aims to serve as the first point of reference. The index compares 183 cities globally, looking at 114 criteria grouped into nine dimensions: human capital, social cohesion, economy, governance, environment, mobility and transportation, urban planning, international profile, and technology (Lai and Cole, 2023).

IESE Cities in Motion Index defines smart city as a way of city governance to maintain future sustainability and the quality of life of inhabitants, which generate business opportunities for collaboration between public and private sectors. (Berrone & Ricart, 2020).

A case study methodology is adopted to examine and compare the possibilities of implementing knowledge-based approaches in sustainable city management, in order to gain a better understanding of this new urban phenomenon. Data and information about city initiatives have been collected from secondary sources. The presented case studies were explored through desk research using online resources, such as the web pages of smart city initiatives. Smart Cities were selected based on their rankings in the IESE Cities in Motion Index 2024.

In addition, multiple regressions were used to identify the relationship between the independent variables (environment protection, mobility and transportation management, urban planning) and dependent variable - value of city's ranking in the IESE Cities in Motion Index. The IESE Index were selected on the basis of temporal and thematic relevance, as it reflects the current results in several indicators, which are the priority indicators of city's technological development and sustainability.

The table below (Table 1) presents the values of dimensions related to sustainability according to IESE Cities in Motion Index 2024.

Table 1: The results from the IESE Cities in Motion Index 2024- the value of dependent and independent variables

City	Value of IESE Cities in Motion Index (dependent variable)	Value of independent variables according to IESE Cities in Motion Index indicators		
		Environment protection	Mobility and transportation management	Urban planning
Amsterdam-Netherlands	72.21	21	28	5
Barcelona - Spain	64.17	68	11	15
Berlin-Germany	75.66	10	9	4
Bilbao - Spain	47.66	61	55	93
Brussels-Belgium	56.04	72	23	33
Copenhagen-Denmark	70.68	3	19	39
London - United Kingdom	100.00	24	4	1
Paris- France	84.29	53	6	13
Stockholm - Sweden	66.64	6	14	60
Turin - Italy	48.49	81	36	40
Vienna - Austria	65.86	17	12	10

Source: The IESE Cities in Motion Index 2024

Environment protection refers directly to the notion of sustainable urban development. Green technologies, green buildings, renewable energy, efficient waste management, reliable water supply, and methods to counter climate change are essential. These measures determine the long-term sustainability of smart cities. It is also essential to consider elements such as the promotion of environmental sustainability through anti-pollution strategies, measures to support green buildings and alternative energy sources, adequate water and waste management, and the implementation of policies that mitigate the impacts of climate change to ensure the long-term resilience of cities.

Urban planning means the design process that determines the components required for the construction of a city. Planning enables the efficient construction of a city while ensuring a high standard of quality of life. Currently, urban planning is inextricably linked with sustainability. To enhance the quality of life in any urban area, it is crucial to consider local master plans and the design of green spaces and public areas, and to promote sustainable and intelligent urban development, with convenient access to essential public services.

Transportation management and smart mobility are core elements of sustainable city management. Smart mobility is also one of the main areas of the smart city concept. Mobility represents, in a narrower sense, the movement of inhabitants. In a broader sense, it refers to access to services, health, and social care, but also, for example, the ability to commute for education, work, family, recreation and so on. The difference between mobility and smart mobility lies in the public's access to different information in real time. In the short term, the goal of smart mobility is to manage and monitor the transport of the population in real time. As for the long-term goal, it is about developing innovative and sustainable transport systems and making the transport and logistics solution of a given smart city more efficient. Smart mobility priorities include, for example, reducing environmental pollution, reducing traffic congestion, making citizens' mobility more efficient or reducing noise in the city (Simonofski, A., et al. 2023).

4. Results and Discussion

This section presents data obtained through secondary analysis of best practice strategies from selected sustainable smart cities. A case-study approach was used to explore the role of knowledge-based solutions in sustainable city management.

A sample of 11 case studies that use knowledge- based solutions (in form of data-driven applications) deployed in real-world settings were identified from secondary sources. All analyzed cities are included in the IESE Cities in Motion Index 2024 and they have been also included in the regression analysis. The results are presented in the Table 2.

Table 2: Knowledge-based smart city solutions (in form of data-driven applications) related to sustainable city management – results of case study analysis

City	Examples of knowledge-based solutions (in the form of data-driven applications) related to sustainable city management
Amsterdam- Netherlands	• Smart lighting controls for energy efficiency and saving • Traffic reduction
Barcelona - Spain	• Communication and green technologies • Smart water efficiency • Smart public transportation • Smart noise control solutions
Berlin-Germany	• Smart metering • Smart transport systems
Bilbao - Spain	• Smart parking systems
Brussels-Belgium	• Energy efficiency through smart sensors • Smart mobility systems • Real-time transportation information • Waste management • Environmental monitoring
Copenhagen- Denmark	• Smart energy incubators and energy labs smart transport systems • Smart noise control solutions
London - United Kingdom	• Green and smart technology application in transport and parking -pollution and congestion control • Smart noise control solutions
Paris- France	• Smart applications for lighting, road circulation, waste management and environment monitoring • Online transportation control system
Stockholm - Sweden	• Fiber optic communication network • Smart noise control solutions
Turin - Italy	• Smart meters
Vienna - Austria	• Energy efficiency via smart sensors • Smart mobility systems

Source: own study

The results demonstrate that the majority of smart cities employ knowledge-based solutions in the form of data-driven applications across all categories with the objective of enhancing city management efficiency and achieving sustainability goals. The most prevalent data-driven solutions identified include transport and traffic, mobility, energy, power grid, environment, buildings, infrastructure and urban planning.

A variety of data-driven traffic control systems have been implemented with the objective of optimising the performance of city services. These include systems which provide interactive notifications of parking availability and distribution, as well as bike and car sharing, digital public transit payment, predictive maintenance of transportation infrastructure, real-time public transit information, and road navigation. These applications facilitate agent-based simulations of transport systems and the myriad of scenarios they may encounter. This enables the development of sophisticated systems capable of integrating and responding to a multitude of entities, including the shortest routes, minimal waiting times, and diversions that are aware of traffic congestion, thereby providing optimal traffic solutions.

Cities employ data-driven technology for the management of transport and traffic. This encompasses the administration of transport services based on the data received, as well as the automated control of traffic signals based on data collected on traffic congestion using sensors embedded in the traffic lights.

The utilisation of advanced technologies, facilitated by the city's Wi-Fi network, enables the real-time monitoring of air quality in terms of the presence of various substances. This allows for the implementation of timely preventive measures and the monitoring of the condition and composition of green space in urban areas. The real-time data collected about the air quality in the city are subjected to analysis in order to determine the impact of the solutions that have been adopted in terms of improving environmental conditions, as well as to identify the areas where further actions are needed. The deployment of low-cost sensors in urban areas enables the detection of noise levels and pollution, facilitating the identification and mitigation of violations pertaining to municipal policies on these matters. The implementation of smart noise control solutions in urban environments facilitates the optimisation and centralisation of data collection, integration, processing, analysis, and dissemination by unifying the information obtained from noise sensors produced by different suppliers and sound level meters distributed throughout the city.

The application of a knowledge-based approach to urban planning, coupled with an analysis of data pertaining to the population, enables the consideration of emerging demands for the development of various venues. In other words, the utilisation of data-driven technology in planning is associated with the planning of districts, streets, and urban infrastructure based on the collection of information on the movement of residents and their activities.

In addition, multiple regressions were used to identify the relationship between the independent variables (environment protection, mobility and transportation management, urban planning) and dependent variable - value of the IESE Cities in Motion Index 2024 .The results of regression analysis have been shown in the table 3.

Table 3: The results of regression analysis

Independent variables	Standardized coefficients	t	Significance level
	Beta		
Environment protection	0,386	4,367	0,000
Mobility and transportation management	0,369	3,841	0,000
Urban planning	0,391	4,673	0,000
Dependent variable: value of the IESE Cities in Motion Index 2024 . R^2 = 0,827, F = 28, 394, significance level = 0,01.			

Source: own study

The result shows that R-square was 0,827, which demonstrates that independent variables explain 82,7 % of the variance in value of the IESE Cities in Motion Index. The linear relationship between independent variables (environment protection, mobility and transport management and urban planning) with value of the IESE Cities in Motion Index is significant with an F-value of 28,394 at the 0,01 significance level. Therefore, the model fits this study.

The significance level of environment protection with value of IESE Cities in Motion Index was 0,000, which is less than 0,05. Therefore Hypothesis 1 is accepted. Environment protection was the second highest coefficient (beta = 0,386), hence, higher level of data-driven solutions related to sustainability positively influences the value of the IESE Cities in Motion Index and a city's position in the global smart cities ranking.

The significance level of mobility and transportation management with in value of IESE Cities in Motion Index was 0,000, hence, Hypothesis 2 is accepted. The beta value for this variable was 0,369. Therefore, higher level of level of data-driven solutions related to mobility and transportation management has a significant positive effect on the value of the IESE Cities in Motion Index and a city's position in the global smart cities ranking.

The significance level of urban planning with the value of the IESE Cities in Motion Index was 0,000, therefore, Hypothesis 3 is accepted. The test also showed that urban planning had the highest coefficient (beta = 0,391) compared to others independent variables. In other words, sustainable urban planning has the highest positive impact on city's position in IESE Cities in Motion Index.

This study demonstrates that the cities exhibit a high level of advancement in knowledge-based solutions, manifested in the form of applied data-driven technologies. However, there is a slight discrepancy in the implementation of such technologies across different city systems and domains with respect to sustainability areas. Furthermore, there is a moderate discrepancy in the level of preparedness with regard to the availability and advancement of the competencies and infrastructure required to generate, transmit, process, and analyse vast quantities of data in order to extract valuable insights for improved decision-making and a deeper understanding of urban operational functioning, management, and planning in relation to sustainability.

5. Conclusion

The potential of knowledge-based solutions lies in their capacity to facilitate the development of smart sustainable cities. By leveraging their informational landscape, these solutions can enable cities to understand, monitor, probe, and plan their systems and environments in ways that facilitate the achievement of optimal sustainability. Furthermore, they are providing novel avenues for more judicious decision-making with regard to the knowledge required to monitor, comprehend, and plan the development of cities in a more effective manner.
A considerable number of smart cities around the world have initiated investigations into the potential of knowledge-based solutions for addressing and overcoming the significant issues and complex challenges associated with sustainability and urbanisation.

In terms of the value of this work, the outcome will assist strategic city stakeholders in understanding the potential actions and investments that could be made to advance smart sustainable urbanism on the basis of knowledge-based solutions and approaches. Furthermore, it will provide an opportunity to identify areas for further improvement while leveraging areas of strength with regard to the future form of such urbanism. Furthermore, it will facilitate the direction of future research and practical endeavours by scholars and practitioners towards the emerging paradigm of knowledge-based sustainable urbanism.

Finally, this paper provides a foundation for further discussion and debate regarding the operational functioning, planning, design, development, and governance of smart sustainable cities in the future. Furthermore, it provides a foundation for further research, including both qualitative and quantitative studies, on the relevance of knowledge-based solutions and their role in accelerating sustainable development.

The research presented here combines quantitative and qualitative analysis in order to identify the factors that contribute to the effective achievement of sustainable development goals in city management.

It is evident that the choice of a restricted number of case studies represents a limitation of this research. It is therefore important to explore the potential of knowledge-based smart city solutions in urban development and city management in greater depth, with a view to considering a larger number of cases. Nevertheless, an analysis of the best practices identified in the selected case studies can provide valuable insights and practical guidelines for the development of a smart city model.

Further research is required to investigate the influence of additional variables associated with sustainability, which can be used to assess the efficacy of sustainable city management practices. A subsequent study should endeavour to corroborate the findings by utilising a more extensive sample.

Moreover, as this study has demonstrated that applied technological solutions already exist in many cities, it would be highly beneficial to conduct a more expansive and diverse comparison involving a greater number of cities with the aim of elucidating the most pervasive trends in knowledge-based sustainable city management.

Abstract: Knowledge-sharing between employees is a complex and dynamic interpersonal process that we investigate using a system thinking approach. Individuals make their knowledge-related decisions (seeking, sharing, hiding knowledge) based on various factors (their traits, experiences, perception of others and the context). Overall, organizational knowledge-sharing is a product of behavioural dependencies and changes in the behavioural patterns of individuals as well as the interactions between individuals and groups. In this paper, our goal is to investigate how employees' reactions to the behaviours of others in the organization, due to disruption or individual behavioural strategy, affect the extent of knowledge-sharing over time. To do this we identify several feedback loops in solicited knowledge-sharing interactions and build an agent-based simulation model of knowledge-sharing in 40-person organization. We perform two 'in silico' experiments. The first investigates the organizational consequences of a local disruption that immediately reduces the inclination to seek and share knowledge of a group of individuals. The second experiment compares the organizational consequences of four strategies for deselecting individuals who have previously declined to share knowledge. The results of the first experiment show that the local event causing higher likelihood of knowledge-rejection affects the overall organizational knowledge exchange due to disruptions in knowledge-seeking attempts. The second experiment indicates that knowledge source selecting strategy reduces not only rejection rates, protecting emotion resources of the seeker, but also reduces knowledge seeking attempts and knowledge-sharing. Empirical studies are needed to obtain more data to enhance the model's realism and to verify or refute the modelling assumptions.

Keywords: Knowledge-Sharing, Knowledge-Hiding, Knowledge-Seeking, Agent-Based Simulation

1. Introduction

Knowledge-sharing among employees enables knowledge possessed by one individual to be spread throughout an organization to other employees who can subsequently apply it, improve upon it or use it as a source in the creativity process (Anand, Muskat, et al., 2020). With that, knowledge-sharing encourages organizational knowledge flow and consequently improves performance (Sung and Choi, 2018). However, knowledge-sharing is based on discretional behaviours that need to be well-understood to be governed in alignment with organizational needs (Foss et al., 2010).

Numerous studies have reported lists of antecedents of asking and providing information and knowledge (cf. Lim et al., 2020; Witherspoon et al., 2013). However, comprehending intraorganizational knowledge-sharing is difficult because organizations are complex social systems comprising diverse interacting individuals who are themselves sub-systems, constantly adapting to changes in their environment, including the behaviours of other individuals (Wang et al., 2009). For example, Borgatti and Cross (2003), who analysed knowledge-seeking and Anand and Walsh (2022), who studied knowledge hiding, emphasised that previous knowledge exchange experiences affect individuals' later behaviours (asking for and providing knowledge), signalling the need to study knowledge-sharing dynamics. Also, disruptive events in one part of the organization affect individuals not only in that part but also in other areas.

The complexity of knowledge-based interactions in organizations makes their study challenging using standard methods, such as regressions, that apply a linear, open-loop approach (Wang et al., 2009). Very few studies investigate the dynamics and spatial contexts in knowledge-exchange interactions while considering individual attributes, their previous behaviours and changes in the organizational environment. One of the few examples is Pires et al. (2024), who used an agent-based simulation that included both spatial and temporal factors and behavioural rules that individuals followed. They found that knowledge-sharing in the simulated hospital depended on individuals' physical movement and changed over time.

In this paper, we adopt a system thinking approach and identify the feedback loops in solicited knowledge-sharing to investigate how employees' reactions to the behaviours of other employees affect the extent of knowledge-sharing in the organization. Specifically, we use an agent-based simulation model (Bonabeau, 2002)

to conduct 'in silico' experiments of knowledge-sharing in a 40-person organization over 20 working days. In the first experiment, we analyse how a disturbance within a group decreases the whole group's positive responses to knowledge requests and, hence, overall organizational knowledge-sharing. In the second experiment, we investigate the effect on overall knowledge-sharing of a range of rejection-response criteria, from never asking the rejector again to no limitations.

Our agent-based simulation model itself has a specific novelty, aiming to represent some of the day-to-day behaviours of office staff, for example, their locations in the office, the locations of people they work with, and their impromptu encounters while walking past or taking a break. This methodological approach enables us to investigate various knowledge-exchange behaviours, including knowledge-seeking, knowledge-sharing and knowledge-hiding between heterogeneous individuals interacting in an organization under different conditions (Macy and Willer, 2002). The results of each interaction influence the individuals involved in a knowledge exchange event and others in the organization. Among the primary simulation outputs are the time spent on knowledge-sharing and the count of individuals' attempts to request knowledge, receive it or be rejected.

2. Theoretical Background

2.1 Solicited Knowledge-Sharing

When knowledge-sharing between individuals occurs as a result of a knowledge request and knowledge response, it is termed *solicited* knowledge-sharing (Teng and Song, 2011). Solicited knowledge-sharing covers the behaviours of knowledge-seeking (Haas and Cummings, 2015), reactive knowledge-giving (Zhang and Jiang, 2015) and knowledge-hiding (Oliveira et al., 2021). The nature of these behaviours depends on the individual's traits, including attitudes, motives and abilities (e.g., Anand et al., 2022; Lim et al., 2020; Witherspoon et al., 2013), the characteristics of the context they are acting in (Cummings and Teng, 2006), and the interpersonal ties and social capital between knowledge-seeker and knowledge-giver/hider (Reinholt et al., 2011).

2.2 Feedback Loops in Solicited Knowledge-Sharing

We use a system theoretic (Senge, 1990) approach to analyse interpersonal knowledge-sharing because this approach offers a holistic perspective to the phenomena usually studied linearly. This approach enables understanding complex, dynamic processes over time and within a specific context (Rubenstein-Montano et al., 2001). In this approach, people are viewed as sub-systems of the organization system. On the individual level, the results (outputs) of individual behaviours (e.g., rejecting a request for knowledge) alter the attributes of all individuals involved in the interaction (e.g., those who asked for knowledge and those who decided to hide it). These changes in individuals' attributes are now inputs to their future behaviours, either reinforcing or reducing the inclination for such behaviours. These are feedback loops that "alter the state of the world, causing changes in nature and triggering others to act, thus giving rise to a new situation which then influences our next decisions" (Sterman, 2001, p. 12).

In the case of solicited knowledge-sharing, our analysis focuses on five key feedback loops (depicted in Figure 1). These loops illustrate how the outcomes of behaviours (such as knowledge-seeking, giving, or hiding) influence (feed back) an individuals' future willingness to engage in these behaviours and their preferences for selecting knowledge-exchange partners (Zhang and Jiang, 2015). For instance, Loop 1 represents the feedback loop for a knowledge seeker (A) when a suitable person to ask for knowledge was not found (nobody met A's selection criteria). This feedback loop could lead to a change in the knowledge seeker's search strategy (Lim et al., 2020), such as shifting from asking others to self-study, perhaps using an organizational repository or an internet source.

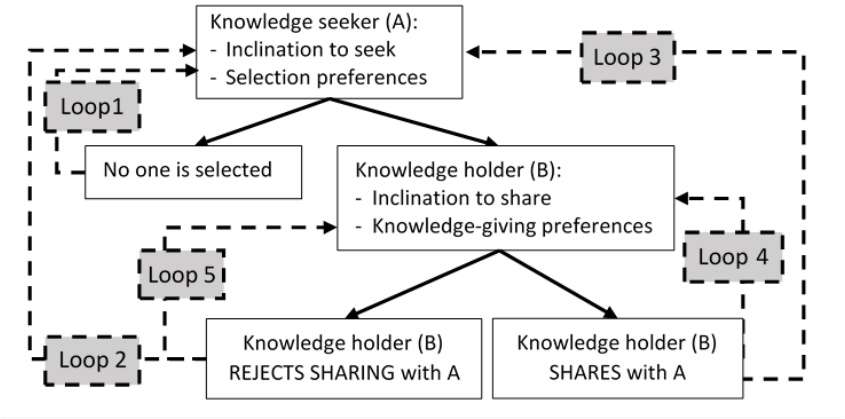

Figure 1: Dynamic model of solicited knowledge sharing

From the perspective of a knowledge seeker (A), the rejection of a knowledge request (Loop 2) initiates negative reciprocity feedback (Černe et al., 2014). The rejection can lead to negative emotions and distrust towards the person who hid knowledge and, to some extent, towards others in the organization. This can increase the likelihood of A hiding knowledge from others in the future (Anand, Centobelli, et al., 2020). Rejection can also increase the social cost of asking for knowledge, leading the rejected knowledge-seeker (A) to reduce their willingness to ask others in the future to conserve their emotional resources (Lim et al., 2020).

From the perspective of the knowledge-holder (B), rejecting sharing (Loop 5) could affect their future inclination to seek and share knowledge as it reduces their perception of psychological safety (Jiang et al., 2019), weakens workplace relationships, and decreases organizational citizenship behaviour (Kaur and Kang, 2023). It will also affect B's future selection preferences when requesting knowledge (decreased inclination to ask a person they previously rejected) - assuming negative reciprocity (Anand, Centobelli, et al., 2020).

When a knowledge request is accepted and knowledge shared, a knowledge-seeker (Loop 3) becomes more likely to ask for knowledge in the future (Leiß and Rausch, 2023). Furthermore, it increases the chances of knowledge providers being approached again, as their effective previous interaction would, among other things, increase the benevolence trust between the two (Mohammed and Kamalanabhan, 2019). Also, A's willingness to share knowledge with B or other organizational members would grow as a result of the need to reciprocate the receipt of knowledge (Lim et al., 2020). Loop 4, which represents feedback for the knowledge provider (B), represents the increase in their willingness to share knowledge due to positive feelings and satisfaction associated with helping. Providing knowledge also increases a person's inclination to ask for knowledge. It affects knowledge-holder selection preferences due to reciprocation expectations from the person to whom they gave knowledge (Lim et al., 2020).

2.3 An Agent-Based Model of Knowledge-Exchange in Organizations

The current agent-based simulation is capable of representing a wide variety of organization layouts and individuals. People are represented as autonomous, heterogeneous agents, each with their own attributes, which change during a simulation. They have a limited number of mutually-exclusive activity states available, with the main activities being solicited knowledge-exchange, simple working together (without a knowledge exchange incentive), and working alone. Agents have designated desks but can choose to walk to their designated break-place (e.g., kitchen/coffee station). They can choose to walk to another person's desk to interact or just communicate with them electronically. Taking breaks and going to others' desks provides individuals with opportunities for impromptu encounters, which increase tie-strengths between individuals. An example office layout is shown in Figure 3a. People are assigned to teams, and team members' desks are grouped together. We assume people work a 7.5-hour workday, but currently we make the simplification that the time of day does not affect people.

An individual agent's behaviour depends on the following main factors: their current attributes (e.g., knowledge level, organizational identification, psychological safety, familiarity with other people, location, current inclinations for each activity state option), their current activity state (e.g., taking a break), what others are doing, and what has happened in the past (e.g., knowledge exchange history, knowledge request rejection history). Agent attributes are initialised at the start of a simulation run and their values change dynamically

during the simulation. Everyone is initialized with one of three state preference profiles: an average person, a highly self-sufficient person who does not seek knowledge so often, or a frequent knowledge seeker. These profiles contain the agent's relative state choice 'probabilities', and they are altered dynamically in response to the agent's experiences. This means that an individual's inclinations, and hence decisions and behaviour, alter according to their experiences – which depend on the others in the organization. Records of past interactions are dynamic cumulative totals and could be considered 'memories' of past situations. The simulation output metrics include state frequency counts and durations for each agent (and hence for the organization) as well as overall interaction totals (such as total knowledge-sharing time), knowledge level, rejection counts, etc.

We took 1 second as our unit of simulation time because this enabled us to incorporate the impromptu encounters mentioned in the introduction. Hence, simulating one office day involved 27,000 simulation time steps (7.5 hours equals 27,000 seconds). At the start of each simulation time step, each person must decide what activity to do. They decide this by using their (dynamic) state preference profile. One of the simplifications we made is that when a person enters a state, the duration in that state is sampled from a plausible distribution of times and the agent stays in that state until that time has elapsed (there are no interruptions, no interactions within interactions).

The logic involved in a solicited knowledge-sharing interaction is shown in Figure 2.

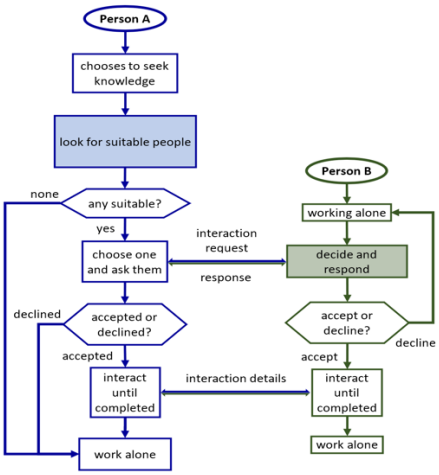

Figure 2: The procedure of arranging solicited knowledge-sharing

When a knowledge seeker (Person A) decides to ask around for some knowledge, they first need to look for suitable people who could be asked. This depends on what others are doing, A's characteristics, the others' characteristics, and what has happened in the past. Person A applies various (configurable) criteria that filter out unsuitable people and produce a set of potential candidates. For example, A would look for someone who:

- is not currently interacting with someone, and has not rejected A before, or has rejected A less than a certain number of times before (accessibility; e.g., Borgatti and Cross, 2003)
- is similar to A in various selectable ways (e.g., similar organizational identification, psychological safety) (similarity; cf. Lim et al., 2020)
- has a greater knowledge level than A (expertise; e.g., Borgatti and Cross, 2003)
- is someone A has some social relationships with (they have met before, preferably many times) (familiarity; e.g., van der Rijt et al., 2013)
- is someone A has exchanged knowledge with before (either direction), preferably many times (trustfulness; e.g., Mohammed and Kamalanabhan, 2019).

The second stage is that Person B has to decide whether to accept the request or reject it (a basic form of knowledge-hiding). This again depends on both agents' characteristics and the past. B also applies various (configurable) criteria, such as:

- B has organizational identification above a certain threshold (motivation; e.g., Phookan and Sharma, 2021)
- B perceives that the context is psychologically safe above a certain threshold (safety; e.g., Škerlavaj et al., 2023)

- B has some social relationships with A – they interacted before above a certain threshold (familiarity; e.g., Zhang and Jiang, 2015)
- B has exchanged knowledge with A before, above a certain threshold (trustfulness; e.g., Le and Lei, 2018).

If all the conditions are met, A's request is accepted otherwise it is rejected (a knowledge-hiding situation).

The simulation records counts of all the results of wanting to interact and all the reaction results. Each of the results of a solicited knowledge-exchange interaction (not finding a suitable person available, rejection of sharing, and sharing knowledge) has consequences for both the knowledge seeker and the knowledge holder. One of the results of interaction is the change in individual knowledge levels. Naturally, when Person A receives knowledge, A experiences an increase in knowledge level. In addition, we assumed that Person B, while explaining knowledge to A, also experiences a slight increase in their understanding. These rates of increase are set by model parameters. When Person A tries and fails in an attempt to seek knowledge from someone, then A's inclination to seek knowledge in the future is reduced (a model parameter sets the rate of reduction). On the other hand, when A's knowledge request is fulfilled, we assume that this would cause a slight increase in A's inclination to seek knowledge in the future (there is a model parameter for the rate of increase).

The model is controlled by twelve main parameters. At present, we do not have much relevant empirical data (e.g., distributions for the frequency of knowledge requesting or duration of knowledge-sharing sessions). For our initial experiments, we fixed some of these parameters at values that produced plausible results. We then conducted a coarse grid search of the resulting parameter space, using 'categorical calibration' (Thiele *et al.*, 2014) to filter out parameter sets that failed acceptability criteria. The most important parameter is the initial state preference profiles, which represent the individuals' activity preferences. Another parameter, *Minimum-Person-Match*, specifies a threshold for how close the match must be (0: 'anyone will do' to 1: 'must be identical') when an agent selects a person to interact with or decides how to respond to a request. When selecting a person based on an attribute value, a parameter *Positive-Response-Threshold* specifies a minimum threshold.

The number of replications was chosen such that the cumulative mean of the total knowledge-sharing time stabilized to within 5% (an arbitrary tolerance of typically less than 2 minutes) (Robinson, 2014). We found that 50 replications provided convergent cumulative outputs.

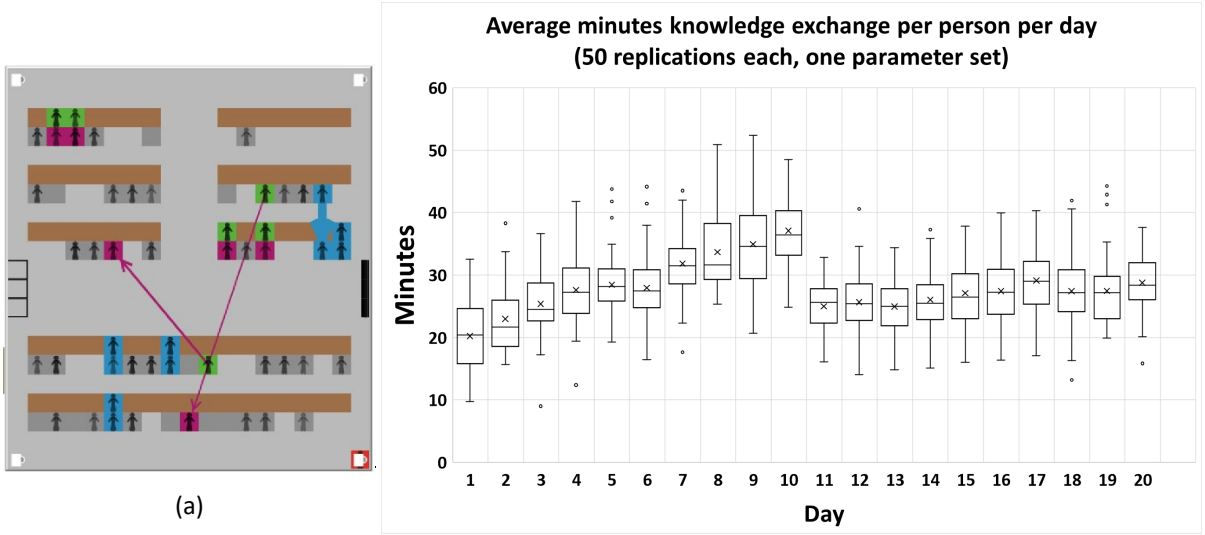
Regarding model verification, the simulation model was developed using conventional software engineering standards (such as error-trapping, meaningful variable names, unit testing). The model is implemented in NetLogo (Wilensky, 1999). Since there were no empirical data to validate the simulation model, all we could do was check that the model produced reasonable results, and sensitivity analyses were conducted to check that the simulation responded sensibly to changes in model parameters and agent characteristics.

3. Experiments and Results

We have conducted two preliminary experiments to investigate knowledge-sharing dynamics over 20 work days (i.e., four weeks). Both experiments were conducted with 40 staff members and used the same set of model parameters. Each scenario was replicated 50 times. The experiments' results cover the average time of knowledge-sharing and average counts of knowledge requests, rejection and acceptance attempts. Every result is reported per person per day.

3.1 Experiment 1 and Discussion

Our aim in Experiment 1 was to analyse the effect of a sudden increase in the likelihood of knowledge rejections in one group on knowledge-sharing in the whole organization. The scenario was that after ten days of normal working, an event occurred that drastically increased the likelihood of knowledge rejections in one of the four groups (Group 4, top-left corner Figure 3(a)). The disruptive event (perhaps some counterproductive, unethical behaviour of the team leader) caused a drastic drop (to 10%) in the group members' organizational identification and psychological safety. The simulation was run for ten more days after disruption.



(a)

(b)

Figure 3: (a) The office layout used in both experiments; (b) Average time spent on knowledge-sharing before and after the disruptive event in Experiment 1.

Figure 3(b) shows boxplots for the resulting distributions of minutes of knowledge sharing per person for each day. They show that the average time spent on knowledge sharing per person per day was increasing during the first ten days of ordinary work. The sudden negative event in Group 4 led to an observable drop in knowledge-sharing, from an average of around 37 minutes after the first ten days to approximately 25 minutes over the next ten days. The upward day-to-day trend from weeks one and two continued but at a lower rate. Analysis of agents' behaviour frequencies revealed that, as expected, average rejection attempts increased significantly in week 3 (11-15th day) and continued in week 4 (16-20th day), see Table 1. Also, in week 4, the variability of rejections between workdays increased. Moreover, while in week 3, the growth rate of knowledge request attempts revealed the same (around 20%), in week 4, the week average growth rate dropped (to 4%) but with higher day-to-day variability. After the disruption, the number of knowledge-seeking attempts when no one was available and suitable (failed search) started to increase (from 3% in week 2 to 11% in week 4).

Table 1: Differences between work weeks in individual behaviour frequencies (day average)

	#knowledge-seeking attempts	#failed searches	Failed searches per knowledge-seeking attempt	#rejected requests	Rejections per request
Week 1 (day 1-5)	1.30	0.13	10%	1.49	68%
Week 2 (day 6-10)	1.62	0.05	3%	1.77	64%
Week 3 (day 11-15)	1.98	0.17	9%	2.45	77%
Week 4 (day 16-20)	2.06	0.22	11%	2.68	76%

Note: All figures are averages per person per day

Experiment 1 examines the consequences of feedback Loops 2 and 5 depicted in Figure 1. The results show that the disruptive event immediately affected the decisions of a few organizational members, but the consequences affected overall knowledge-sharing shortly after, and this stayed at a lower level until the end of the experiment. This decreased overall knowledge-sharing was associated with a higher rejection rate. This increase in rejection attempts exacerbated the growth rate of knowledge-seeking attempts (Lim *et al.*, 2020). It can be explained by the increase in the social costs of requesting (Tidwell and Sias, 2005) and the individuals' intention to reduce them by generally decreasing their request attempts (Flynn and Lake, 2008). Knowledge hiding also deteriorated the relationships between individuals (Škerlavaj *et al.*, 2023), making it harder to find a trusted individual.

3.2 Experiment 2 and Discussion

In Experiment 2, we compared the consequences of four strategies to follow when experiencing a knowledge request rejection. This experiment refers mainly to feedback Loop 2 in Figure 1. Agents remember all rejections

(and acceptances) and can choose to never ask a rejector again. We compared the amount of overall knowledge-sharing during a 20-work-day period when an agent tolerates 1, 2, 3 or unlimited rejections before excluding the rejector completely. However, in all strategies, the inclination to ask others for knowledge declines after every rejection (at a rate set by a model parameter). To make the simulation more plausible, we catered for scenarios where rejection could be a result of factors not explicitly modelled, such as being busy on a deadline. For this, we introduced a random 1 in 5 chance of rejection due to other circumstances.

Table 2: Differences between strategies for responding to knowledge rejections

Maximum Rejections Allowed	Work Alone (mins)	Self-Study (mins)	Knowledge-sharing (mins)	#knowledge-seeking attempts	#accepted knowledge requests	#rejected knowledge requests	Failed searches per knowledge-seeking attempt
1	260	141	6	1.25	0.12	0.08	85%
2	220	116	19	1.44	0.45	0.28	55%
3	203	94	30	1.57	0.75	0.54	31%
unlimited	197	82	35	1.60	0.91	1.65	3%

Note: All figures are averages per person per day

The different strategies caused some differences in the 20-day behaviours and knowledge-sharing outcomes, as depicted in Table 2. It seems that continuing to consider a person suitable - irrespective of the number of times they have rejected you - results in increased knowledge-sharing overall. Although one might experience less rejections by never asking previous rejectors again (0.08 vs 1.65 times per person per day), because people have been excluded one is less likely to find some suitable (85% search failure compared to 3%).

These results suggest that severer strategies for selecting knowledge-holders protect the knowledge seeker from the social and emotional costs of rejections but at the expense of significantly lower knowledge exchange with others. It indicates the trade-offs an individual approaching other for knowledge needs to make based on cost-gain concept and conservation of resources theory (Lim *et al.*, 2020). Also, the experiment suggests a mechanism whereby knowledge hiding can hinder the flow of knowledge in an organization by decreasing knowledge inquiries and limiting the number of knowledge holders who can be approached for knowledge (Borgatti and Cross, 2003).

4. Conclusions

Our study emphasises the importance of investigating the behavioural and relational feedback loops in knowledge requesting, sharing and hiding. Identifying the consequences of knowledge-based behaviours affecting every actor involved in the exchange interaction is informative for theory and practice. We built an agent-based simulation model that performs as a platform for testing consequences of feedback loops in knowledge-exchange behaviours. We believe that our simulation model can usefully model the dynamic, spatial interactions between individuals engaged in knowledge exchange activities, and potentially provide a micro-level explanation of macro-level effects, such as the change in the extent of knowledge-exchange. Specifically, our “in silico” simulation-based experiments show that some consequences of rejecting to share knowledge have individual and organizational level consequences that manifest over time.

However, the simulation model currently has several limitations. For example, the model has not been thoroughly parameterized – only a limited grid search has been conducted. Empirical data are needed to increase confidence in the relative weights of the factors involved. There have been many simplifications that could be addressed, such as taking into account the type of knowledge exchanged, the time of day, the time taken to negotiate an exchange or a rejection (all of which currently take just one simulation time interval). Further models could include individual attributes such as employee tenure, hierarchical position in the organization, and age (Burmeister and Fasbender, 2018). There is a need for longitudinal empirical case studies to identify the feedback involved in knowledge exchange experiences, to find out the delayed effect of some decisions, and to identify the strategies that employees adopt.

Collaborative Policy Development for Effective, Flexible Working

Linzi Ryan
Maynooth University, Maynooth, Ireland

Linzi.ryan@mu.ie

Abstract: In the post-COVID environment, work flexibility is an increasingly important factor in employee attraction and retention. This new way of working is particularly challenging in the public sector as it is bound by high levels of rules, regulations and bureaucracy. Academic literature on the post-Covid ways of working is limited as the research takes time to catch up to current practices and does not fully capture or address the novel issues currently faced by public sector managers. With the increasing demand for flexible working, it is vital to explore how public sector organisations exploit opportunities and avoid potential risks in this new way of working. Through our empirical study with a public sector organisation, it is argued that the rapid shift to flexible working was possible as it leveraged off the pre-COVID organisational culture. High levels of organic tacit knowledge exchange were possible through staff's physical proximity in the workplace. Under new flexible work practices, this is often no longer the case. For sustainable, effective knowledge exchange, operational policies must capture, consider and support operant knowledge exchange in this new geographically dispersed work environment. Drawing on service design theory and public sector management literature, this study generates managerial and policy learnings, practices, and methodologies for collaborative work policy development. Firstly, we demonstrate that, as traditional operational policies focus on quantifiable, explicit knowledge and communication, a new user-centred approach to policy development is required. It demonstrates the managerial need for *collaborative* policy development, which engages staff in capturing both explicit and tacit knowledge for effective operations. Secondly, it identifies the implications of the loss of tacit knowledge exchange, particularly for staff new to the organisation. It highlights the implications of moving to online forms of engagement and collaboration and the impact on knowledge development and exchange. Thirdly, we show the importance of critical reflection within co-creative policy development. Critical reflection provides staff with opportunities and resources to question old practices, reflect on new practices and construct knowledge collaboratively.

Key words: Flexible Working, Policy Development, Use-Centred Design

1. Introduction

Although COVID initially forced remote working, for many organisations, it also revealed both a capacity to deliver services remotely and the need for a new user-centred approach (Williamson et al., 2022; Gavin, Poorhosseinzadeh, Mahan Arrowsmith., 2022; Palumbo et al., 2022). In the new post-COVID environment, it is becoming increasingly evident that the 9-5 office structure is no longer fit for purpose. Instead, hybrid ways of working - where employees divide their time between work and home - is increasingly becoming the norm in many sectors. While this empowers staff to do their best work and deliver better performance for employers, it presents some knowledge management challenges. Appropriate management practices with supporting workplace policies are required to fully exploit opportunities and avoid potential risks of this new way of working (AlMazrouei and Zacca, 2021; Hammer, 2021). This study focuses on the development of a workplace policy in an Irish public sector organisation, operating in a geographically dispersed hybrid work format. A qualitative research approach provides insight into the changes and challenges of knowledge management in this developing context, through the case study of the development of a workplace policy.

Hybrid working is a particularly difficult task for the public sector as it operates in a complex policy and political environment, with direct political oversight, and high levels of scrutiny and accountability (Hartley and Skelcher, 2008). More recently, the emergence of the 'New Public Governance' model puts emphasis on inter-organisational relationships, networks, collaborative partnerships, participatory governance and multi-actor relations (Krogh and Triantafillou, 2024; Bannink et al., 2024; Huxham and Vangen, 2013; Wu, Ramesh, and Howlett, 2017). This has placed greater emphasis on knowledge generation, sharing and management, within public sector organisations and the development of an organisational culture in which knowledge is valued, shared and utilised for public sector improvement (Karim and Majid, 2022). However, due to the complexity of public sector network, knowledge management has received limited attention (Haque and Turner, 2013; Chen and Hsieh, 2015; Puppim De Oliveira et al., 2015; Abdul et al., 2020).

This research presents an empirical project with an Irish national public sector organisation. Prior to Covid, the organisation operated a traditional 9am-5pm office format for the majority of staff. Due to its national remit, some roles required high levels of travel, but all staff had a base office as their primary base of operation. Covid restrictions – where all staff were required to work from home – demonstrated the organisations ability to work remotely and staff expressed their desire for more flexible work environments as restrictions were lifted. Having previously worked with the researcher on complex organisational issues, HR wanted to take a similar, human-

centred approach to a new workplace policy that was both innovative and flexible in its approach to work parameters. Due to industry-sensitive information, the case study organisation cannot be identified. To provide context, Ireland has eighteen State Agencies or public sector bodies that have a statutory obligation to perform specific tasks on behalf of the Government of Ireland. Each department employs a large number of public sector staff who remain in their positions regardless of changes in Government. State Agency activities include the implementation of national, regional, and local plans and policies, as well as EU plans and policies on the island of Ireland. Of the State Agencies, four - one of which is the focus on this study - are national economic development agencies. Their primary role is to support the long-term sustainable growth of the economic, social, cultural and environmental contributions of Ireland.

This paper details the qualitative methodology taken for the case study. The organisation was chosen for its innovative and flexible approach to work parameters. Data collection was through interviews with managers, and a series of interactive workshops which produced field notes and completed templates. The data was examined through thematic analysis to identify reoccurring patterns and themes related to knowledge management in collaborative policy development and used to generate recommendations for managerial practice.

2. Literature Review

The hybrid work model combines remote working from home and in-person working from an office-based location (Beno, 2021). While it existed before COVID, the pandemic expedited the use of remote work practices for both the private and public sector (Yang et al., 2021). This led many organisations to recognise that employees can work as productively at home as in the office (Lodovici et al., 2021). Hybrid work can be advantageous as it combines the benefits associated with remote work with those of the traditional office. For home-based work, it offers time flexibility, a better work-life balance and reduced commuting time. For office-based work, there is the ease of collaborating and coordinating, building of organisational culture, and greater innovation and creativity (Mortensen and Haas, 2021; Bloom, 2021). For these benefits to be reaped, adopting hybrid work practices requires substantial change across all levels of an organisation. Systems and structures must be adjusted or created entirely to support hybrid work, and policies must be created to ensure all necessary legal requirements are met while utilising the potential benefits of this new way of working (Shepherd, 2022).

To develop effective and appropriate hybrid workplace policies, organisations must understand the necessary changes in staff working behaviour (Harsch and Festing, 2020). Changes in communication - for example an increased reliance on Information Communication Technologies (ICT) - require clear processes and expected norms among team members (Kaiser et al., 2022). Interdependencies between virtual teams must be strengthened to enhance feelings of belongingness of members (Spitzmuller et al., 2023) and processes must be created to effectively manage knowledge across these new communication channels (Li et al., 2022). Organisational culture plays an important role in this change process. By collaborating with staff in the development of goals, organisations can develop holistic strategies and structures that support the changes needed for effective hybrid work (Silvestre, Marques, and Gomes, 2018). Fosterign collaboration is recommended as it can build trust between staff and management (Ansell and Gash, 2008; Chugh et al., 2015); promote resources sharing (Purdy, 2012); and reduce potential staff resistance to change (Abrell-Vogel and Rowold, 2014).

With its human-centred approach, governments have increasingly turned to DT as a way of reframing policy issues and generating and testing new solutions to organisational and public problems (Kimbell, 2016; Blomkamp, 2018). DT is suitable for *complex* problems as it offers a broad range of strategies to address open-ended challenges (Dorst, 2011). It enhances innovation, participation, and responsiveness (Parker and Heapy, 2006) by combining various sources of information, constructing it into readily understandable and usable formats, testing and refining solutions, collaborating with multiple actors, and integrating human factors and values into the development process (Olejniczak et al., 2020; Van Buuren et al., 2020). Accordingly, DT has been used as a human-centred approach to shape public policies and knowledge management.

“Knowledge” itself can be roughly divided into two categories, explicit and tacit (Nonaka, 1998). Explicit knowledge comprises numbers and words which can be readily shared. In contrast, tacit knowledge is highly personal and difficult to formalise and communicate (Gamble, 2020). As public sector organisations come under increasing pressure to continually learn and improve (Mc Evoy, Ragab and Mohamed, 2019), processes which utilise and maintain *all* accumulated knowledge within staff are becoming increasingly important (North and Kumta, 2018; Aladwan, Al-Yakoub and Adaileh, 2022). DT is an appropriate approach to this challenge as,

according to most policy scholars, through its collaborative process, it embodies the lessons learned from previous experiences in the development of new or reforming of old policies (Howlett 2019; Hermus et al., 2020; Lewis et al., 2020; Van Buuren et al., 2020). As a result, DT utilises *both* implicit and explicit knowledge to prevent the repetition of past errors and failures. It emphasises the value of understanding participant views and experiences to create a *holistic* approach to knowledge management.

3. Methodology

A qualitative research methodology was used to explore collaborative hybrid work policy development within a public sector organisation and, in particular, the impact of this new way of working on knowledge management. A case study approach was taken as it enabled the researcher to focus on the knowledge dynamics within a single setting and investigate contemporary real-life phenomena through contextual analysis of an environment (Creswell, 2007). This provided a rich context for investigating the knowledge transfer process(es) across multiple staff within a singular team, between teams and across departments working in a hybrid organisation. The limitations of a single case study are acknowledged, with multiple case studies creating more robust insights in a wider context (Yin, 2016). However, theoretical explanations of the data observed within this paper are applicable across similar organisations.

First, primary data was collected through managerial interviews with high-level management and the HR team. This was coupled with secondary data collected in the form of operational documentation. The initial data collection was to provide organisational and sectoral contextual information, and to capture managerial perspectives on current knowledge management practices. This was used to develop a collaborative workshop utilising a DT approach which has been shown to be effective in driving innovative operations, gathering key insights, and as a responsive framework to identify emerging challenges (Mutanen, 2008). The DT process is roughly categorised into two 'diamonds' consisting of two phases each (British Design Council, 2019): Diamond 1: Discover and define; Diamond 2: Develop and deliver. For this exploratory study, the developed framework focused on Diamond 1 to gain an understanding of current knowledge management practices and emerging barriers in a hybrid workplace. Though depicted as linear, the process integrates feedback loops as participants learn and evolve their knowledge.

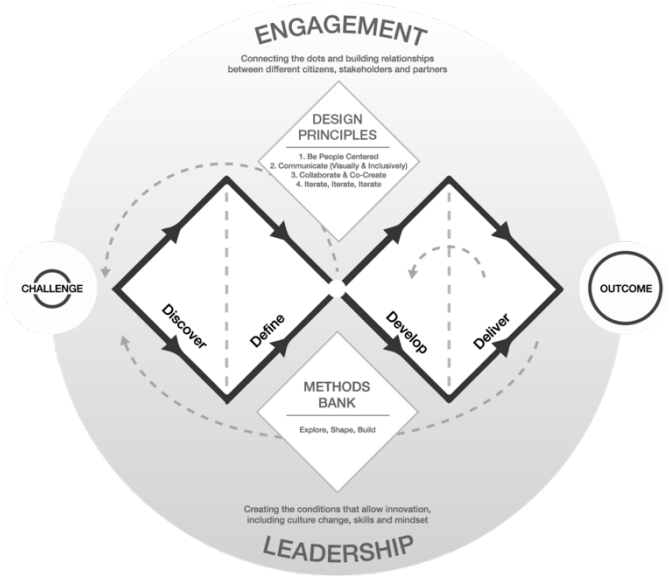

Figure 1: UK Design Council Double Diamond Framework

Secondly, nine workshops were then held with 142 staff, focussing on current knowledge processes (both formal and informal), knowledge transfer gaps and knowledge transfer awareness between new and established members of staff. Each workshop was 4 hours long and was held online to optimise attendance and collaboration in geographically dispersed teams. Participants were asked to complete a variety of tools (detailed in Results) and to provide additional insight/information through open discussion. Feedback loops were used to reflect on the information captured and the inclusion of additional information gained during discussion. Specific time was allocated at the end of each workshop to allow staff to provide feedback, highlight any key issues/considerations not captured in the tools, and ask additional questions. Detailed field notes of the

discussion between participants were taken, and supplementary notes were created immediately after the workshops in a 'debrief' to capture additional perspectives, observations, and thoughts.

Thirdly, the collected data underwent a rigorous analysis process to identify key themes and patterns related to knowledge transfer and management in the organisation. Following Creswell's methodology (2005), field notes and the completed workshop tools were systematically coded using qualitative data analysis software (Nvivo) (Creswell, 2015). Progressive data coding was used by first identifying broad-based codes to avoid premature interpretations. This was then progressively narrowed down to context-specific information, before organising information into themes. Themes were reviewed and refined to ensure their coherence and relevance to the research objective. Finally, themes were interpreted and synthesised to generate a comprehensive understanding of the organisation's knowledge transfer and management processes. This allowed connections, relationships and conversions of one form of knowledge to another to be mapped.

4. Results

This section examines the outcomes of the workshop in relation to knowledge management within the public sector organisation. It identifies key insights of knowledge transfer within this new hybrid way of working such as the impact of lost tacit knowledge transfer on operational flexibility; a link between activity objectives, communication platforms used and the knowledge generated and exchanged; and the impact of hybrid working on informal knowledge exchange within the wider organisational network.

The first phase of the DT framework required staff to document their primary activities. Several key themes emerged from the data analysis of this stage. Firstly, there was a strong relationship between tacit knowledge, conceptual knowledge and procedural flexibility which was overlooked in the transition to a hybrid model. Procedural knowledge – the knowledge of procedures, such as a series of steps or actions to accomplish a goal - and conceptual knowledge – knowledge of general principles, such as *why* each step is part of the process (Rittle-Johnson et al., 2015) - were easily captured by participants. Tacit knowledge - things that are "understood" without necessarily being said - allowed experienced members of staff to utilise procedural flexibility to circumvent barriers or address arising problems. Prior to hybrid working, the transfer of tacit knowledge occurred organically through informal discussion in a shared office space. If faced with a barrier, staff could simply ask colleagues for assistance and/or guidance. When geographically dispersed, informal discussions were significantly reduced. Contacting colleagues through an online platform such as Microsoft Teams had formal discussion connotations and staff were more reluctant to contact colleagues for help through these channels. This was particularly evident for new staff who were heedful of calls as they felt they were disrupting their colleague's work.

The second phase of the DT framework required participants to reflect on and capture the type of engagement most effective for each activity (e.g. face-to-face, online, blended or independent) and, most importantly, *why* this engagement was considered the most productive format. The emerging theme highlighted a link between the activity objective, communication platform and knowledge generation and exchange. Initially, staff believed most tasks could be completed in an online format. On reflection, activities could roughly be divided into three categories: Operational, strategic and independent. Staff believed planning activities that required knowledge generation, such as strategy development, ideation and insight development, required in-person collaboration. For these activities, the importance of ongoing tacit knowledge exchange during informal discussions such as during lunch or coffee breaks; and the impact of 'flowing discussion' for idea generation vs. the more stilted online discussion was recognised. This collaborative form of exchange facilitated analysis of the organisation's internal and external environment; identifying strategic issues based on these analyses; and formulating strategies, goals, and plans to address these issues. In contrast, operational activities focused on the exchange of explicit knowledge, such as project action updates, report generation etc. As information was easily captured and communicated, online delivery was considered appropriate. Similarly, activities completed independently, such as report generation/review and administration activities, could be effectively delivered from a remote location.

The third phase of the DT framework required participants to cross-share insights on their own work practices. This revealed the final theme: the importance of managing knowledge exchange across the full organisational network. The organisation consisted of nine geographically dispersed offices. Staff within a single team could be dispersed between locations, and multiple teams were frequently required to collaborate on projects. This resulted in a complex collaboration and communication network. As discussed in theme one, the increase in remote working impacted the informal knowledge exchange within this already complex organisational

network. During cross-share, the loss of tacit knowledge between teams became apparent. Collaboration between some teams was limited and frequently in a formal format for specific activities. As a result, staff were unaware of some interdependencies between teams outside the scope of their current projects. While this is a relatively new impact caused by hybrid working, in the long-term it has the potential to affect the wider organisational culture as informal exchanges between the employees can create trust, commitment and goodwill for the organisation as a whole (Gooderham *et al.*, 2011).

Overall, the thematic analysis revealed the importance of adapting knowledge management practices for this new way of working within the public sector. The findings emphasised the importance of capturing and facilitating both tacit and conceptual knowledge for organisational efficiency and culture management.

5. Discussion

This contribution provides valuable insights into the dynamics of knowledge management in the public sector hybrid way of working. As this is a relatively new change, there is a gap in the academic literature. These findings assist in addressing this gap by offering practical recommendations for knowledge management in a hybrid organisation for managers and policymakers.

Our first contribution is the identification of the need for human-centred, collaborative policy development. While organisational collaboration has proven difficult in the public sector (Kivleniece and Quelin, 2012), this project demonstrated that a comprehensive understanding of the organisational and staff needs can be established by engaging with the wider body of staff. The collaborative tools and open discussions created a shared organisational vision, and a holistic account of operational and knowledge requirements, both tacit and explicit. From a staff perspective, the process provided a structure for critical reflection on pre- and post-COVID operations, cross-sharing of experiences from different perspectives (e.g. new versus established staff), and a platform to voice their opinions to high-level management. From a managerial perspective, it provided a systemic and holistic understanding of the organisational operations, and how staff, knowledge and resources were integrated within the organisational system. In addition, it provided insight into the cultural impact of this new way of working, which is considered one of the most crucial factors in successful knowledge management (Robinson et al., 2005), highlighting the need for support structures to strengthen the relationship between teams and to instil a positive approach to knowledge sharing and recognition.

Our second contribution is the identification of reduced access to tacit knowledge and its impact on organisational conceptual knowledge and procedural flexibility. Procedures are clearly documented, conveying procedural information, e.g. facts and details. In practice, there were a diverse range of projects within the organisation requiring collaboration across multiple teams, resulting in a degree of variability within these procedures. Prior to hybrid working, tacit knowledge on how to utilise procedure flexibility for project variations was done organically through discussions in a shared workspace. The impact of hybrid working on this tacit knowledge exchange was underestimated and highlighted the potential for long-term impact on organisational output, e.g. a lack of understanding of procedural flexibility resulted in process delays. Put simply, it is not sufficient to assume that tacit knowledge is accessible and free-flowing in this new way of working. Organisations must proactively support tacit knowledge exchange to fully exploit this valuable asset for organisational efficiency, and innovative workplace solutions. *Tacit learning* must become a key organisational staff activity - consisting of dialogue and structured reflection (Bohm, 2012; Fahrenbach, 2023) – which is interwoven into staff activities, and is communicated and actively supported as a key organisational output.

Our third contribution highlights the impact of ICT on tacit knowledge transfer and knowledge generation. While research highlights the importance of adopting ICT technologies to develop adaptable, efficient and effective business operations (Chatterjee et al., 2022), ICT also impacts staff's collaborative actions and outputs. Within the organisation studied, staff initially believed that all activities could be completed online, as activities continued throughout the COVID lockdown when in-person meetings were not permitted. On reflection, staff recognised that this was facilitated by the knowledge and relationships established prior to COVID. Organisations must recognise the value of tacit knowledge exchange in collaborative activities and provide guidance and support for *adaptive* collaborative practices. Categorising activities based on their levels of discussion, tacit knowledge exchange and knowledge generation would provide guidance on appropriate collaborative formats and highlight the need to manage both explicit and tacit knowledge within the organisation.

Finally, the insights gained from the case study highlight the need for a new deliberate knowledge transfer strategy that accounts for the changing communication dynamics and channels across the wider organisational

network. Within the case study, the organisation had a complex communication network with projects crossing multiple teams and departments. This was further complicated by geographically dispersed departments and teams, typical of an Irish public sector organisation implementing and managing nationwide projects. Online communication platforms have the potential to effectively capture, organise, store, and share explicit knowledge across the service network (Igbinovia and Ikenwe, 2018). With the changing communication dynamic of the hybrid workplace, effective management of these platforms can streamline the transfer of explicit and operational knowledge across the service network, thereby freeing up time for in-person tacit knowledge exchange and generation.

Based on these findings, we recommend several practical managerial practices for hybrid organisations to optimise their knowledge management. The research highlights the importance of a culture of knowledge-sharing with multiple channels of knowledge exchange and generation. Knowledge transfer processes should be provided on the operational (explicit) and strategic (tacit) level. Operational guidelines based on the activity requirement can provide guidance on the appropriate communication format. In addition, as organisations frequently rely on their managers to ensure that a hybrid work model is successfully implemented, leadership competency training should be provided to support and reinforce the communication and collaboration channels in this new way of working.

6. Conclusion

By working with a public sector organisation on an empirical piece of research, this project provides valuable insights into the impact of hybrid work practices on knowledge management. The findings contribute to the literature by expanding the understanding of hybrid organisational communications, and provide practical recommendations for managers and policymakers in similar situations. Ultimately, knowledge is a key contributing factor in the development of effective, efficient and innovative operational solutions. The recommendations present a holistic approach for knowledge management in the post-COVID hybrid workplace.

There are some limitations to the case study. It adds to the limited body of empirical research within the public sector, but it is based on a single case study. Additional work is required to extrapolate the findings across multiple contexts. Regardless, the findings contribute to the existing literature on knowledge management in hybrid organisations and offer valuable, practical recommendations for public sector managers in this new environment. Similarly, public sector organisations are increasingly engaging with external stakeholders in collaborative governance. Similar research is required on the impact of hybrid work on the external communication and knowledge management with these third parties, and how best to operate in this new dynamic.

To conclude, knowledge management is a critical activity for hybrid public sector organisations for effective, and efficient operations. By understanding the nature of knowledge generation and transfer, both formal and informal, tailored strategies, processes and supports can be developed to ensure it is exploited to its full potential.

The Impact of Relationships on Knowledge and Leadership in Family Firms in the 21st Century

Agnieszka Rzepka and Magdalena Czerwińska
Department of Economics and Economic Management, Management Faculty, Lublin University of Technology, Lublin, Poland

a.rzepka@pollub.pl
m.czerwinska@pollub.pl

Abstract: Intellectual capital reflects the knowledge and thinking capacity that a particular company can use to achieve benefits (Muslih, 2021). It is often identified with organizational capital (Beltramino, 2020). At the same time, the significance of a human is to intellectual capital resources is often emphasized (Dessein & Pratt, 2022; Ozgun, 2022). Interactions between employees within an organization, as well as between employees and the environment, are of significant importance. Relations of this kind are even considered relational capital (Zhang, 2022). Family firms are pervasive organizations (Calabrò, et al.,2019) in all economies worldwide, and evidence shows that the presence of family in a business impacts the firm under wide range of circumstances. Innovation is a prominent one of them, and this study examines the way families affect innovation antecedents, activities, and outcomes. Research has shown that even though organizations expect leaders to have new skills, they still largely promote traditional models and mindsets. The authors draw on their study conducted over the last five years. The study is part of a larger research project. The research comprised four stages, with the number of enterprises surveyed in stage 1 being N=605. The results demonstrate the significant potential of this type of work and the numerous research gaps that remain for future exploration. Organizations should develop their leaders' skills and evaluate leadership in a way that allows them to successfully navigate ambiguity, take responsibility for handling rapid change, and engage with external and internal stakeholders. There is therefore an obvious gap between what organizations should do to support 21st-century leaders and what is currently happening. Today, 21st century leaders of the must adopt an agile approach to leadership and management, be proactive, and look for opportunities that will allow them and their teams to grow and develop.

Keywords: Leadership, Family Firm, Knowledge, Intellectual Capital, Inter-Organization Relations

1. Introduction

Inter-organizational relations between independent entities are now considered one of the key development trends in modern mechanisms for creating the competitiveness of enterprises (Arzubiaga, et al., 2018).

Management science and organizational theory contain a variety of concepts that underline the growing importance of inter-organizational cooperation (including, for instance, coopetition, network governance, and project management). There are also articles devoted to new organisational structures such as clusters, partnerships, networks, and alliances.

When examining the concept of interorganizational relations (Rzepka, 2023), it is imperative to emphasize the necessity of shaping connections between individual links according to the principles of trust and the division of risk and benefits. Relationships of this nature lead to additional synergistic effects and, as a result, a competitive advantage (Witkowski 2003).

At present, interorganizational relations are considered an increasingly important source of competitive advantages and profitable results (Grandor, 2012; Dyer et al., 1998). In this regard, interorganizational relations can be interpreted as a multi-subject action that is designed to achieve mutually consistent goals (Möller & Svahn, 2003).

1.1 The Role of Human Capital in Relationships Among Companies

Not only do properly shaped inter-organizational relationships provide access to valuable resources in the form of human capital, but they are also conducive to the creation, connection, and sharing of resources, as well as the acquisition of values for those involved in the arrangement. According to some managers, "as long as the value is being generated, everything in the relationship remains satisfactory" (Ritter, 2008).

Undoubtedly, the success of any modern enterprise depends largely on how its relationships with others are handled (Skalik, 2006). Hence, enormous importance is placed on the role and activity of the executive team, employees, and teams that are willing to collaborate with external entities. A significant role in the company's development is assigned to human capital that uses its own competence, intellectual ability, motivation, and

abilities to perform certain organizational roles, including the development of inter-organizational relationships (Vesperi, et al, 2023). Relationships (Bouazzaoui, et al., 2020) with customers, suppliers, competitors, and other stakeholders are built by the company's employees. It should be kept in mind that structural capital is formed through human capital, among other elements. It includes new products, patents, licenses, software, technologies, and relational capital (i.e., reputation, customer loyalty, and strong relationships with stakeholders) (Jackson & Dunn-Jensen, 2021).

Ability and competence, especially relational competencies associated with the use of knowledge, skills, abilities, and attitudes in the area of cooperation, are particularly important in the evolution of relationships (Rzepka, 2017). The creation of relational capital is supported by direct and personal contacts (links) of employees and executives with stakeholders, which are based on the ability to collaborate, on the capacity trust others, and on one's own credibility and one's core competencies. It is created on the basis of relational (Daghar et al., 2021) resources that are formed between the company and external stakeholders. It is a consequence of establishing appropriate relationships with customers, distributors, suppliers, and other entities that the company interacts with.

Relational capital could determine the efficacy of the company's affairs and its market success, both from a static perspective (seen as a resource associated with interpersonal relations) and from a dynamic perspective (seen as the ability to create and maintain close and lasting relationships based on trust and collaboration). Relational capital is created on the basis of inter-organizational relationships that involve employees as well as management (Versiani et al., 2021). It cannot function as a separate phenomenon, but it exists only in relation to human and structural capital, both of which create intellectual capital. In contrast to structural capital that remains the company’s property, relational capital is described as difficult to manage and control. This belief stems mostly from the particular characteristics of this kind of capital as ittakes an intangible form that is hard to describe, quantify, and measure.

The relationsships between the collaborating entities are unique and unrepeatable. This is attributable to the specific arrangements between the parties. Hence, a possible acquisition or replication of such relationships by other rival entities may lead to a number of hindrances.

As strong bonds between the entities involved in the relationship form and develop, they result in a flow of knowledge and information (Kellermanns et al. 2012). And this, in turn, results in the creation of a new range of products or innovations that foster the development of value.

The relations between the parties are fortified by dynamic changes in the environment as they lead to greater flexibility in the organization's activities in the area of problem-solving and decision-making byh involving the organization’s own competences and those of other entities’ . The transfer of knowledge is carried out through the means of human and relational capital, whereas the acquisition, maintenance, and renewal of resources necessary to create structural capital are carried out through the means of relationships.

Those involved in a relationship must identify variables prior to, during, and at the end of the relationship. These variables tend to be found in the areas associated with benefits and costs that arise as a result of the collaboration. Such values as trust and honesty, respect, openness, and clear rules of communication play an important role in the formation of inter-organizational relationships pertaining to human capital. Moreover, the evolution of the criteria for determining value indicates that the non-material criteria are becoming increasingly important, which stems from the growing complexity of economic interactions. Therefore, the determination of value is burdened with a constantly growing level of subjectivity and uncertainty.

1.2 Family Business

Family firms are the most predominant form of business organization and account for a large proportion of employment, business turnover, and gross domestic product (Bjuggren, Johansson, & Sjögren, 2011). The involvement of families in firms’ ownership, management, and governance is a key driver of organizational attitudes (Bennedsen & Foss, 2015), behaviors, and performances, especially those related to innovation. Since the beginning of the 21st century, academic interest in innovation within family companies has bloomed. This body of research has mostly emerged from family firm scholars, while mainstream innovation scholars have often overlooked family-related variables in their studies. Indeed, innovation is one of the main components of research on family firms that integrates family and business aspects and leads to a plethora of occasionally contradictory findings.

Family firms serve ast a unique setting for research because of the simultaneous existence of two fundamental sociological systems: the family and the business (Holt et al., 2018). Family ownership is the most prevalent type of business ownership worldwide (La Porta et al., 1999). Not only are the vast majority of small- and medium-sized firms family owned and managed, but large public firms are often controlled by families. Conceptually, what constitutes a family business is the subject of great debate in research on family businesses Daspit et al., 2021).

For the purpose of this study, a family firm is conceived according to the most comprehensive and reputable definition by Chua, Chrisman, and Sharma (1999), where the family business is a business governed and/or managed with the intention to shape and pursue the vision of the business held by a dominant coalition that is controlled by members of the same family or a small number of families in a manner that is potentially sustainable across generations of the family or familie.This definition helps distinguish family from nonfamily firms. Research on family businesses seeks to understand family firms in order to provide recommendations and/or frameworks to guide professionals to improve their performance, accelerate their development, and ensure their business' sustainability in the long run (Miller & Le Breton-Miller, 2005). Innovation is a means to stay relevant and competitive in the market. Thus, developing knowledge about family firm-generated innovation can help family firms thrive, thereby contributing to global economic prosperity.

2. Methods

The empirical aspect of this study is founded upon a structured investigation that forms part of an international project entitled *Teal Organizations in Economy 4.0*. The project was conducted across countries such as Poland, England, Hungary, Ukraine, the Czech Republic, Spain, Georgia, and the USA, focusing on the management personnel. The procedure for conducting research encompassed three stages: a pilot study in 2020, a foundational study in 2021, and subsequent follow-up studies in 2022 and 2023. The study included management personnel from a variety of small and medium-sized enterprises (SMEs) of varying size and spanning various geographical scopes. The selection of companies was based on the availability of SMEs, and the research was carried out by using a certified research platform.

This article focuses specifically on the 2022 study, which collected a total of 620 surveys (two rounds of 310 surveys) through a nationwide research platform. The primary data collection tool was a proprietary questionnaire, which was distributed in accordance with CAWI (Computer-Assisted Web Interviewing) technology standards. The survey was broken down into topics related to organizational leadership, innovation, and technologies implemented by the businesses participating in the study. These included existing relationships, agility and creativity, social capital, knowledge and information, trust, structure, and organizational culture. The research was and will continue to be conducted in accordance with the OECD-DAL (Organization for Economic Co-operation and Development: Definition and Selection of Competencies) recommendations.

A variety of methods, including data analysis, in-depth individual interviews, and a questionnaire, were used to gain a comprehensive understanding of the subject matter under investigation. This three-dimensional approach facilitated a comprehensive study of the phenomenon. The questionnaire was divided into five sections, each with 5 to 7 questions addressing a different topic.

The study's primary goal was to determine whether a family-owned organization is not only innovative but also capable of generating, implementing, and disseminating innovation. Furthermore, the study's hypothesis posited that the ability of a family-owned innovative organization to create an atmosphere that encourages learning and idea generation influences how well the organization functions. The study also aimed to show that a leader's role in creating and managing an organization is to cultivate a suitable organizational culture, with knowledge, transparency, and good communication between staff members and the outside world being essential components. Ultimately, the study aimed to ascertain the traits and elements—such as courage, honesty, and intuition—that impact the preservation of sustainability within companies.

The chosen method of statistical analysis was the use of the $\chi 2$ test, Pearson's Chi-square test for independence. The statistical analysis of the data obtained from the surveys was performed by means of SPSS STATISTICS 21 computer software.

The range of activities carried out by study participants is displayed in Table 1, along with information about the study's geographical reach, workforce size, and industry representation.

Table 1: Characteristics of enterprises

Dominant modus operandi of the company (%)		Geographic scope of activity (%)		Number of employees (%)		Industry (%)	
Commercial	16.6	Local	9.4	0-9	3.3	Aircraft	5.3
Production	28.0	Regional	27.3	10-49	55.1	Fuel market	4.0
Service	55.4	National	22.0	50-249	16.6	Car industry	3.8
		International	41.3	250-999	16.6	IT	11.4
				1000 -and over	8.4	Education	3.8
						Research and development	4.0
						Gastronomy	5.2
						Construction industry	5.3
						Trade	3.4
						Banking sector	10.0
						Other	43.8

Source: own study based on research by A. Rzepka

The table indicates that the majority of the study's participants were men who held managerial positions (57.9%) in service businesses (62.7 and 75.8%), with a workforce consisting of 50–249 workers (28.3%) and a global reach (42.5%). The respondents were predominantly from the banking, construction, and aviation industries (column 4, table 1). It can be demonstrated, based on the study's hypotheses, that the research's base model (Rzepka A.) includes variables influencing every dependency.

3. Results

The study's results shed light on the complex dynamics within family businesses as they endeavor to make well-informed and sustainable decisions while balancing the need for intuition in their strategic choices. It becomes obvious that family firms seeking to integrate sustainability into their strategies often confront various challenges that result from the interplay between tradition and innovation. These challenges encompass generational disparities in values and perspectives, resistance to change within the family, and the crucial necessity of establishing effective communication channels that span both personal and professional spheres.

Table 2: Statements regarding a company leader

	I strongly disagree	I disagree	Hard to say	I agree	I strongly agree
In relations with subordinates, a good leader should strive to shape their independent thinking and responsibility for their actions	1.0	2.1	18.0	44.2	34.7
Vision is a characteristic of a good leader that unites and inspires the team to act	0.6	3.4	19.1	38.9	37.9
Humility is a characteristic of a good leader, thanks to which they have the ability to acknowledge they have been wrong	0.3	3.2	18.6	42.9	34.9

Source: a study based on Agnieszka Rzepka's research

As shown in Table 1, over 70% of respondents agree with the qualities of a good leader, i.e., vision, inspiring teams to act (38.9% and 37.9%, respectively). Similarly, regarding humility (i.e., good leaders should admit when they are wrong), more than 76% of respondents agreed with the statement (columns 4 and 5). Good leaders know, appreciate, and respect their colleagues; they motivate them to do fruitful work, show support during times of difficulty, and have all the prerequisites needed to manage a team effectively. Leaders have specialist skills such as knowledge and professional qualifications, innovative skills, creativity, and analytical thinking (Rzepka 2023). However, the most important characteristics are interpersonal skills related to team building. A leader with all the qualifications to manage but who cannot communicate with the group will not succeed. According to my research, the effectiveness of a leader also depends on having skills that can be learned and constantly improved, regardless of one's predispositions. The leader should master social skills in effective team building and leading, i.e., the ability to communicate effectively, listen actively, provide feedback, motivate to achieve goals, have a positive self-presentation, solve problems, and exhibit assertive behavior. An effective leader should also be a visionary, an entrepreneur, an initiator, and a person open to spontaneous changes.

The research revealed that the integration of familial and commercial interests in these businesses can present complex difficulties. The management of personal biases and conflicts of interest, accountability and

transparency issues, and other factors were identified as potential obstacles to the effective integration of sustainability into strategic decision-making processes. This underscores the need for a holistic and forward-thinking approach by leaders in family businesses, that respects the past while harnessing the power of sustainability to ensure the enduring success of both the family and the business.

The research findings also align with the global trend of leadership in the 21st century, moving towards sustainability as a central imperative. Successful leaders understand that, although crucial, their responsibilities cannot be limited to generating profits. Sustainable leadership demands a deep commitment to environmental stewardship and ethical governance. Those advocating for sustainability concentrate on the long-term financial health of their companies as well as achieving a lasting and beneficial effect on the environment and society. They understand that environmentally responsible business practices are not only ethically justifiable but also a source of innovation, resilience, and competitive advantage. Consequently, sustainability emerges as a guiding principle to inform decision-making in family businesses and compels them to approach the matter from a forward-thinking and eco-conscious perspective.

4. Conclusion and Discussion

Today, organizational change refers to the transition of an organization from one state of affairs to another. Every company must embrace organizational change if it wants to remain competitive. If done correctly, organizational change can turn any company into a more competitive, efficient, and better place to work. However, organizational change is not easy.

The study points out the evolving nature of decision-making within family businesses in response to advancing technology and changing business landscapes. While data-driven decision-making remains essential, there is a growing acceptance of intuition-based decision-making approaches. These instinct-driven approaches correspond to the importance of agility and flexibility in today's fast-paced business world. The findings suggest that intuition, which is often based on experience and industry knowledge, should complement empirical data in decision-making processes. In their pursuit of sustainability, family businesses should adopt a hybrid approach, leveraging both intuition and data to respond to evolving consumer preferences for environmentally responsible products.

Understanding the fundamentals of relationships and capital, as well as how businesses use them (Rzepka, 2017), can help businesses manage their resources more effectively and control how appealing they are to investors. In particular, the obtained results make it necessary to construct a measurement model to assess the use of these relationships and capital, for example, by companies of various sizes, various sectors, managers, and rank-and-file employees. When making this kind of research model, it is important to make sure that it can be changed to fit a smaller group of indicators that show how these interorganizational relationships and intellectual capital work in order to give a true picture of how much of each is present in businesses.

The collaboration of enterprises in creating interorganizational relationships and their impact on their ability to innovate is a phenomenon that is becoming more and more apparent in the area of shaping intellectual capital in changing environments.

As technology continues to advance and the business environment continues to undergo transformation, there is a growing willingness within family businesses to make decisions based on instinct. As observed in contemporary management practices, instinct-driven approaches to decision-making have been gaining scientific ground for some time now. This change is a turn toward more agility and flexibility, which fits better with the needs of today's fast-paced business world. While data-driven decisions undeniably offer advantages, the intrinsic value of intuition and experience should not be underestimated. Conversely, it is important to recognize that instinct should not supplant data and analytics entirely. Instead, family businesses should take a complementary approach when seeking to be sustainable, using both intuition and empirical data to answer changing consumer preferences for environmentally responsible products.

Family firms are pervasive organizations in all economies worldwide, and evidence shows that the presence of the family in the business affects the firm in a wide range of circumstances. Innovation is a prominent one, and this study has examined how the family influences innovation antecedents, activities, and outcomes. The purpose of the framework is to synthesize the current understanding of family firm innovation and leadership and identify future directions that require further academic attention to deepen and extend knowledge about this crucial phenomenon.

The Role of the Freight Exchange in Knowledge Management of A Logistics Company

Robert Sałek and Anna Wiśniewska-Sałek
Czestochowa University of Technology, Poland

robert.salek@pcz.pl
a.wisniewska-salek@pcz.pl

Abstract: The growing importance of digitization of economic processes forces logistics companies to use modern technologies. This is a trend visible throughout the economy which has a significant impact on the logistics industry. The amount of processed information is constantly increasing and managing it is becoming a growing challenge. Freight exchanges are an integral component of the functioning of transport companies dealing with transportation of goods. This primarily applies to road transport, which constitutes the largest share in European transport. The use and role of freight exchanges are constantly growing. These are tools that enable obtaining information about cargo and transport services which is used in planning transport processes of logistics companies. The activities of logistics companies involve constantly acquiring information about potential customers. Transport processes require careful preparation and detailed planning of all activities performed during the transport of cargo. The dynamics of the logistics market do not always allow the full use of cargo space in vehicles, which is associated with a decrease in transport efficiency and thus a reduction in companies' profits. Therefore, the knowledge about additional loads, due to which companies will be able to fill empty cargo spaces or entire empty runs, is necessary. This is of great importance for companies from the SME sector, which often must compete on the market with large entities. Transport exchanges are, by definition, a valuable source of information on the basis of which the internal knowledge base is created, which also requires appropriate management. The authors conducted the research among small and medium-sized transport companies both nationwide and with international reach in Poland. This research was aimed at identifying the features and demonstrating the role of freight exchanges as a source of knowledge for enterprises. The process of planning the transport process was analyzed for the variant with and without the use of the freight exchange. A decision-making algorithm was defined, the task of which is to structure and organize knowledge in the field of the transport process preparation. The importance of digital tools in knowledge management was also emphasized.

Keywords: Transport, Management, Electronic Freight Exchanges, Road Transport, Knowledge Management

1. Introduction

Road transport plays a key role in ensuring the smooth running of logistics processes and the movement of goods and people in the economy. Due to continuous improvements and adaptations to the increasingly demanding market needs, it constitutes a strategic service sector with high popularity. Its significance for enterprises in satisfying transport needs is irreplaceable, which makes it one of the most important branches of transport in the economy (Miller and Nie, 2018). Due to the availability and the most developed infrastructure, it enables direct deliveries. Moreover, it can be used in combination with other branches of transport, which allows for comprehensive and effective supply chain management. Therefore, diverse logistics needs can be satisfied, and better operational results can be achieved (Pyza, 2010). Versatility and flexibility in transport are crucial for the effectiveness of many enterprises. Due to the possibility of delivering goods directly to customers, the company may offer a fast and effective service, which translates into increased competitiveness on the market (Nowakowska-Grunt and Strzelczyk, 2019). The use of freight exchanges is becoming more and more popular among companies since they help effectively manage logistics processes in today's digital world. They enable companies to optimize their transport operations, improve performance and costs, and increase visibility and control over their shipments (Palczewska, Barwiński and Borowiecki, 2015).

2. Literature Overview

2.1 Electronic Freight Exchanges

Information technology-based solutions in the transport industry, such as freight exchanges, have existed for years, but there are still challenges to automate and optimize processes. Electronic platforms provide an opportunity to transmit information about loads and obtain orders, but the process of adaptation of loads to vehicles and transaction finalization still requires the intervention of managers or brokers. There is still potential for further development and improvement in these solutions to ensure more efficient and automated functioning (Miller, Nie and Liu, 2020). Electronic transport platforms allow transport companies to flexibly adapt to changes in demand and provide quick access to offers from all over Europe (Wu, Huang and Chen, 2024).

Cabotage is becoming more and more popular among Polish transport companies, which allows them to generate profits without having to incur costs related to road infrastructure in Poland (Kisielewski and Leśniakiewicz, 2016). It is therefore crucial to use effective and developed transport platforms to maximize benefits for the country's economy (Ajith *et al.*, 2023). Electronic transport platforms, despite their great development in the last decade, remain relatively unknown to many employees of companies in the TSL industry (Grabowska, 2018). However, freight exchanges are gaining popularity among people who want to develop their careers in this industry, which may contribute to increasing the awareness of the possibilities and operating procedures of these platforms (Jenkins, 2024). The implementation of modern information technologies in the transport industry is crucial for the operational efficiency and competitiveness of companies (Norman-López *et al.*, 2023). The possibility of fast and efficient transaction and exchange of transport services contributes to the optimization of logistics processes, cost reduction and an increase in competitiveness on the market. Therefore, enterprises can dynamically respond to changing market conditions and take advantage of new development opportunities (Leończuk, 2013). Freight exchanges are an important component for the effective functioning of the logistics industry, enabling companies to access a variety of carriers and loads and streamlining the exchange of information between transport market participants (Choudary, Van Alstyne and Parker, 2019). Thanks to them, companies can quickly find the best transport solutions, which contributes to the optimization of logistics processes and reduction in transport costs (Witkowski, 2019).

2.2 Knowledge Management in the Transport Company.

Knowledge has become a key component for the organization, enabling it to develop and gain a competitive advantage on the market. Due to proper knowledge management, organizations can quickly respond to changes, innovation, and new challenges, which translates into their success and leadership in the industry. This is especially important in the era of globalization and dynamic changes, where the ability to effectively use knowledge may be decisive for the survival and development of the organization (Asrar-ul-Haq and Anwar, 2016). Modern enterprises increasingly recognize logistics as a key component of creating the company’s value, primarily through flexibility, integration, comprehensiveness, and coordination of processes (Budzik and Cichoń, 2023). Knowledge management (KM) is a key component for organizations due to the possibility of using their knowledge resources to improve strategy, decisions, and effectiveness. Through effective knowledge management, organizations may achieve sustainable commercial benefits, as evidenced by numerous studies and authors in the field of knowledge management. This is important for improving knowledge practices, organizational behavior and achieving better performance (Ngah and Bontis, 2016).

The development of the Transport-Shipping-Logistics (TSL) sector covers a wide range of assets, including knowledge, skills, and organizational processes. The key role in gaining a competitive advantage is played by the appropriate and effective management and use of these resources, such as employee competences, infrastructure, training, knowledge, brand, technologies, and customer service skills. The market success of transport companies depends on a comprehensive approach to the management of available resources and accumulated knowledge, as well as on the improvement in operational processes (Kowalska, 2021).

The use of appropriate IT tools such as telematics systems, logistics project management and knowledge management software is crucial for the efficiency and competitiveness of the company. Thanks to them, it is possible to improve business processes, optimize activities and use resources better, which translates into the company's success and development on the market (Pisz and Łapuńka, 2014). The implementation of modern IT systems, especially integrated logistics systems, plays a key role in the long-term development of enterprises. These tools enable the optimization of both internal and external communication through effective data exchange between various departments of the organization and with contractors. The development of these technologies is a consequence of changes in the approach to economic processes and increased significance of information and knowledge, which allows enterprises to improve their strategies and business models (Misztal and Fajczak-Kowalska, 2020). The approach to practical origins of knowledge indicates that knowledge in organizations has its roots in practices and is closely related to them. Since this knowledge cannot stand alone, there is a need to transfer it through sharing practices. Where practices are shared, knowledge flows, and where they are not, knowledge sticks to the context. Such a model confirms the integral relationship between knowledge and practices in organizations (Chen, 2022). Nowadays, in order to operate effectively, companies from the TSL industry should include the aspect of knowledge management in their business model. A complex knowledge management system (KMS) includes the processes of acquiring, selecting, processing, codifying, transferring, and creating knowledge, as well as sharing it and updating the knowledge base. The concept of knowledge management as a key company resource is based on the resource approach, which treats knowledge

as an important component of the organization's success. This requires the cooperation of five key components, such as importing knowledge from the environment, implementing new tools and technologies, experimenting, joint problem solving and developing key skills of employees. This is a key component that should be considered in the development strategy of companies from the TSL industry (Janczewska, 2018).

3. Research Methodology

The methodology developed for the purposes of this study concerns activities the research objective of which is to determine the share and importance of electronic freight exchanges in enterprise knowledge management. The subsequent stages of the research work are presented in Figure 1.

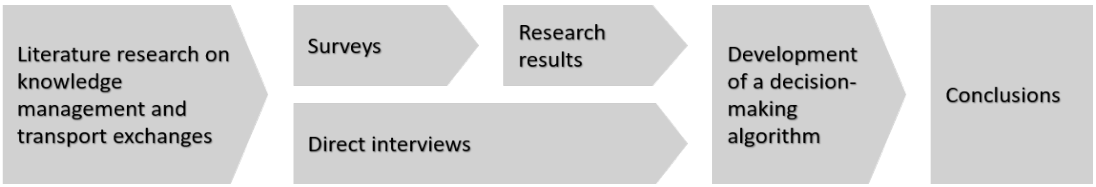

Figure 1: Research methodology diagram

Source: Own study

In order to determine the role of electronic freight exchanges in the activities of enterprises, the survey research method was applied (Nowak, 2024). The research addressed to logistics companies was conducted using a survey questionnaire. The survey form was constructed based on the knowledge of the selected topic and observations of individual practices in this area. The first part of the survey concerned determining the type of the enterprise participating in the study. The aspects considered included the duration of the company's operations on the market, the company's size in terms of employment and the scope of the company's operations. This allowed for specifying what types of enterprises use (or do not use) freight exchanges. The second part of the survey related to only freight exchanges. This part of the survey was completed only by the companies that support their activities using this tool. The issues raised in this part were to specify whether the freight exchange in the company is a relatively new tool and when they started to gain popularity among the respondents. The study was also to determine which freight exchange is the most popular, what purpose they are used for and how high, within the percentage range, companies rate their utility. When considering the results obtained using the survey, an attempt was made to determine the significance of freight exchanges and the following questions were answered:

- What types of companies are most likely to use freight exchanges and which ones prefer other methods of supporting transport?
- When did the freight exchange gain popularity among the respondents?
- Which freight exchange is the most popular among the surveyed enterprises?
- What role do freight exchanges play in individual enterprises?
- To what extent do they support transport processes?
- Is the freight exchange a basic or auxiliary tool?
- Will the activities of freight exchanges be expanded in the future?

Additionally, a decision-making algorithm was developed to structure the transport process. The objective of the actions taken was to isolate individual activities in the process of planning and organizing transport using the freight exchange to support the process. The algorithm was used to isolate the activities carried out, decision-making problems arising in the process and the expected consequences of the activities. The information resources of a medium-sized transport company providing domestic and international transport of goods in the form of full-truck loads and general cargo was used as the research subject.

The examined company is a family company carrying out transport orders in Poland and abroad. It obtains transport orders primarily through constant cooperation with regular customers and those acquired through participation in fairs and trade meetings. Based on the company's transport orders, the research was undertaken in the form of a direct interview, which was aimed at obtaining information for creating a decision-making algorithm for planning and organizing transport using the freight exchange. The following questions were answered:

- What activities does the process of planning and organizing transport consist of?

- What decisions are made during the process?
- What are the consequences of the decisions and actions taken?
- What is the course of the process of acquiring a customer in the execution of a standard order?
- At what stage does the company use the freight exchange in the transport process?
- What is the course of the process of acquiring a customer in the execution of an order using the freight exchange?
- What activities and decisions are made in the transport process using the freight exchange?
- What role does the freight exchange play?

The results of the first part of the research are presented in the form of charts illustrating the structure of the responses along with descriptions. The second part concerns the development of the decision-making algorithm in graphical terms and the characteristics of the role played by freight exchanges in the context of management of planning and organizing transport processes.

4. Research Results

4.1 The Survey

The survey consisted of ten questions, all of which were closed-ended questions. In the set of closed-ended questions, two of them were conjunctive questions in which the respondents could select several options. Completing the survey took approximately 3 minutes. The questionnaire was delivered to the respondents in 100% in an electronic form. The research was conducted for approximately 30 days, and as a result, 108 responses were received. The survey results and the distribution of responses are presented at Figure 2.

The analysis of the data for the first question indicates that most of the surveyed companies have been operating on the market for a relatively short time, from 1 to 5 years, constituting exactly half of the respondents. Only 26.9% of the enterprises have been operating on the market for over 10 years, and the group of companies with operation from 6 to 10 years amounts to 15.7%. The companies operating for less than a year constitute a small group, amounting to only 7.4%. The operations of companies in various scopes of time on the market are diverse and may affect their strategies and experience.

In terms of the analysis of the number of employees in the surveyed enterprises, the largest group was large enterprises hiring 250 or more employees (33.3%), followed by medium-sized logistics companies employing from 50 to 249 people (27.8%), small companies employing from 10 to 49 people (22.2%), and micro-enterprises hiring less than 10 employees (16.7%). Such distributions indicate the diversity of the employment structure in the surveyed companies.

The results of the survey indicate that most companies, since as much as 66.7%, operate internationally, while the remaining ones only domestically. It can be noticed that there is a significant difference between the companies operating locally and those with global presence, which may be related to various business strategies and the scope of activities of these companies.

The next question was to determine what percentage of the respondents use electronic freight exchanges. The confirmatory result was 77.8%, which leads to the conclusion that these tools are commonly used in logistics companies. This is the evidence that demonstrates their significant share in the logistics market and confirms that they are an important solution for the effective management of transportation of goods.

Another issue was to determine how long enterprises have been using electronic freight exchanges.
The dominant group turned out to be the companies that have been using freight exchanges for 1 to 5 years, accounting for 60.2% of all the respondents. 20.4% of the surveyed logistics companies have been using freight exchanges for less than 1 year. The companies that have been using freight exchanges for 6-10 years constitute a slightly smaller group, their percentage share is 13%. Only 6.5% of the respondents declared the use of freight exchanges for more than 10 years. This proves the increasing significance of freight exchanges in the logistics of enterprises and their growing popularity.

In terms of the question regarding the use of specific electronic freight exchanges, the respondents indicated that they most often use the Trans (60.2%) and TimoCom (46.3%) exchanges, which suggests their great popularity among users resulting from the reach and access to contractors. Less popular platforms are CargoGlob (20.4%) and Teleroute (13%). Only 6.5% of the respondents use the Wtransnet exchange and other

unnamed exchanges. When analyzing the answers to the above question, it can be noticed that the Trans and TimoCom exchanges are very popular.

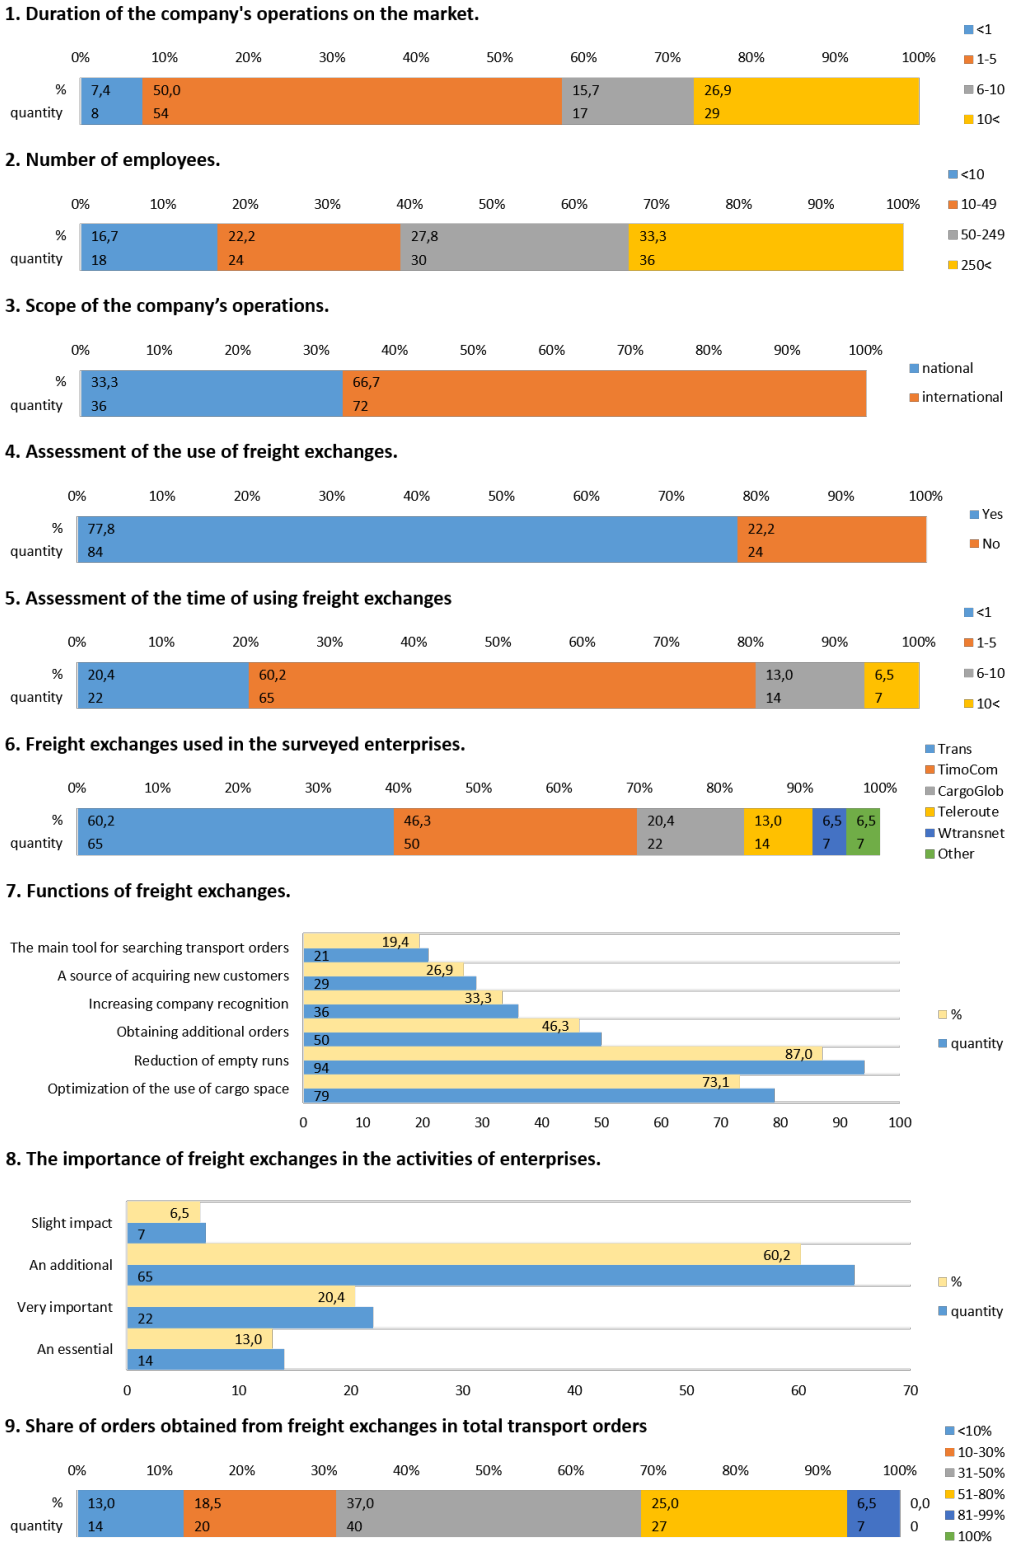

Figure 2: Distribution of responses from a survey conducted in transport companies

Source: Own study

Another important issue concerned the role of the freight exchange in the surveyed logistics companies. In this case, the respondents also had an opportunity to select several possible options. The vast majority of those

questioned (87%) described the role of the freight exchange as a way to reduce empty runs. For 73.1% of the respondents, freight exchanges are used to optimize the use of vehicle cargo space.

Additionally, about half of the respondents (46.3%) obtain additional orders during their runs thanks to freight exchanges. Increasing the company's recognition was declared by 33.3% of those questioned. 26.9% of the respondents describe the role of electronic freight exchanges as a source of acquiring new customers. The smallest group is the companies for which the freight exchange is the main tool for searching for orders - 19.4%.

Another issue was to determine the percentage share of orders obtained from freight exchanges in the total transport performed. Most respondents (37%) declared a percentage share in the range of 31-50% of orders. A quarter of the respondents indicated the range of 51-80%. For 18.5% of those questioned, the percentage of orders obtained from freight exchanges is 10-30%. On the other hand, 13% of the surveyed enterprises marked the range below 10%. Only 6.5% of the companies stated that the percentage of orders was 81-99%, while none of the respondents answered that they obtained 100% of orders from freight exchanges. The use of freight exchanges in searching for orders can be described as effective.

The last question was to determine whether the surveyed companies plan to expand their activities by using freight exchanges in the future. Among the respondents, no one declared this type of activities in the future, which is puzzling due to the increasing digitization of economies.

4.2 Decision-Making Algorithm and Knowledge Management System

The presented decision-making algorithm (Fig.3) illustrates the process of planning and organizing transport in the company specializing in road transport. It also shows the position of the company's knowledge management system in terms of the resources needed to implement the process.

The first stage of the process is to acquire customers. The following methods of acquiring customers in the surveyed company were considered: permanent cooperation; the customer present in the company's database, but not cooperating with the company on a permanent basis; customers acquired by participating in fairs and sales meetings. These are the three main ways of acquiring customers by the surveyed company. In the case of regular customers, the activities aimed at determining their credibility and possibilities of providing transport are omitted during the planning process, since they were inspected when establishing the cooperation. The following activities are not omitted in the case of customers acquired through sales meetings and customers appearing in the company's database. The surveyed company controls the credibility of contractors present in the databases using interviews and previous experience related to the fulfillment of transport orders. The company inspects the following aspects:

- did the customer pay for transportation?
- were they behind on payment?
- did the cooperation go smoothly?

If the answers to the above questions are positive, the company determines the potential contractor as suitable for cooperation. The credibility of customers acquired through sales meetings is determined by examining whether the company actually exists, through searching for customer opinions and conducting an initial interview. Based on the type and weight of the load, the loading location and the target unloading location, it is assessed whether the transport order can be completed for the company. If the customer is assessed as unreliable and/or it is impossible to fulfill the transport order, the offer is rejected. If the potential customer meets the above conditions, the details of the offer are discussed in more detail during the interview. It specifies potential means of transport, the exact route by the carrier, the method of securing goods and the formalities related to the contract and transport documentation. The initial quote for the order, methods and payment date are also determined. If the customer agrees to the transport conditions specified in the contract, the order is accepted and then generated in the system. In the absence of full agreement, the parties will attempt to negotiate a valuation. If, during negotiations the parties fail to find a solution, cooperation is not undertaken. The next stage is the analysis of the exact route by the examined company. It is determined whether the route will require supplementation. If there are no empty runs, the transport documentation is completed. If it is necessary to supplement the route, the company looks for customers using the Trans.eu freight exchange.

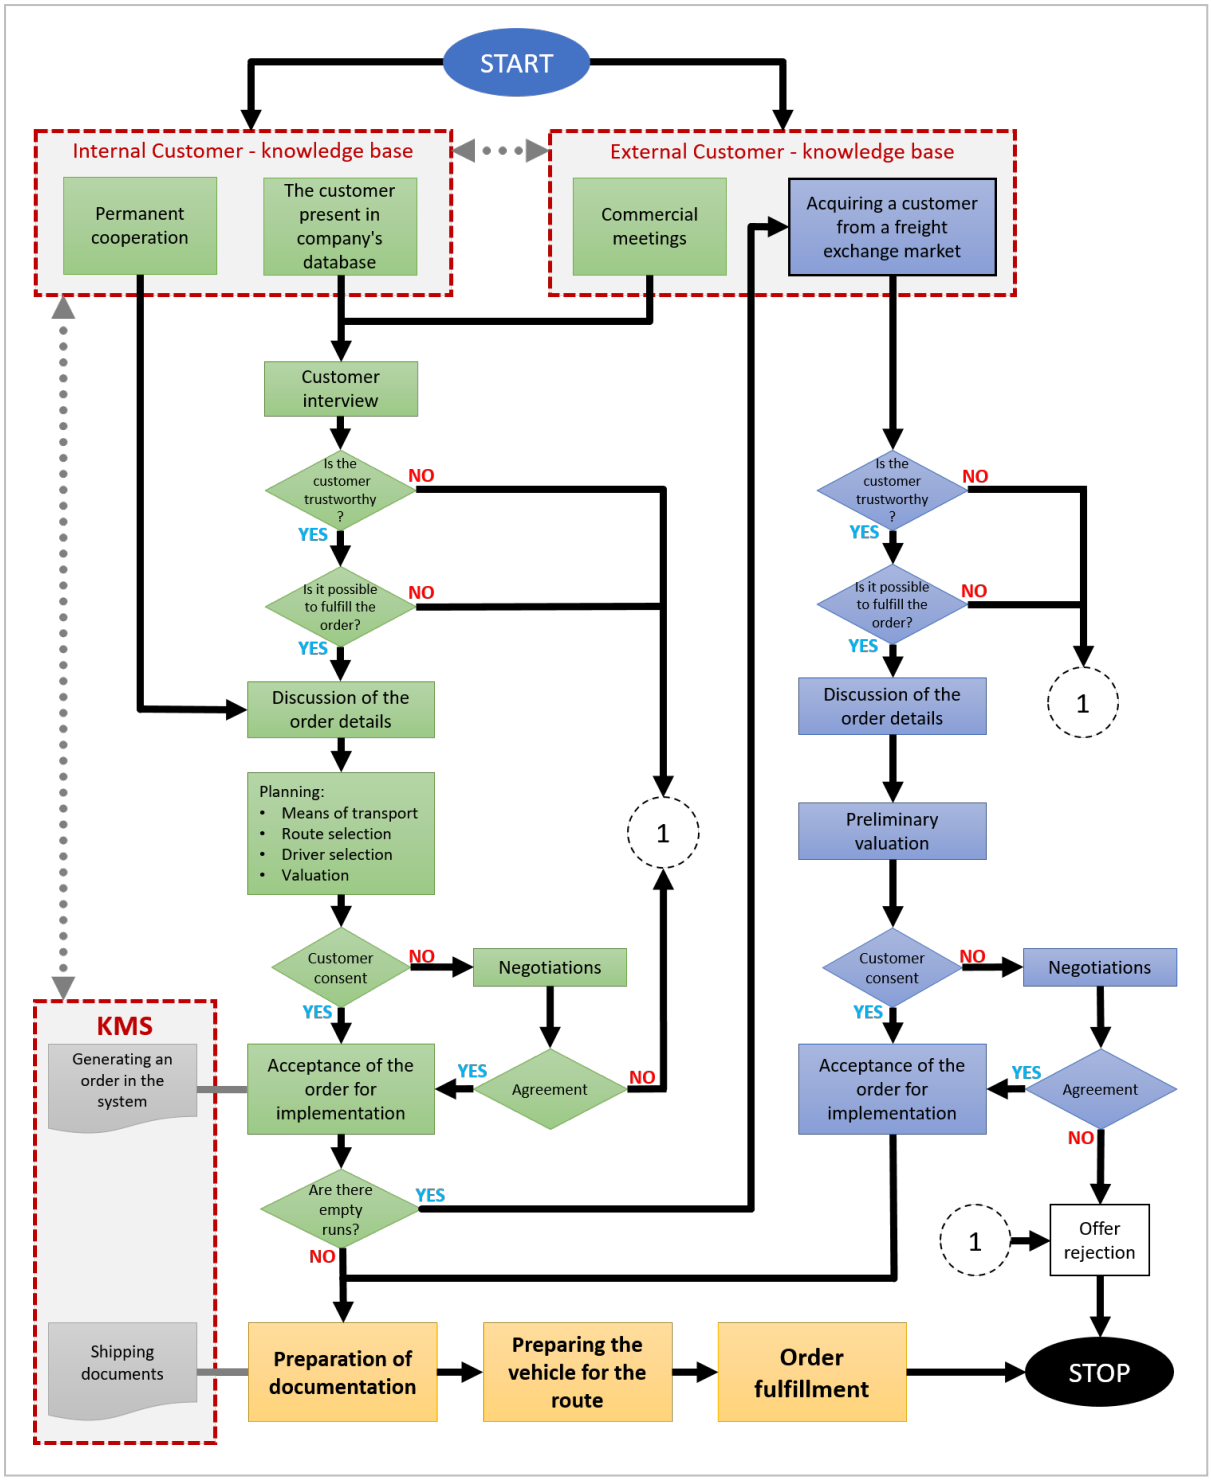

Figure 3:Algorithm for planning and organizing transport and KMS approach.

Source: Own study

The company searches for available goods and publishes its own advertisements. The credibility of the customer acquired by the company through the freight exchange is assessed based on the opinions provided by the freight exchange users who have cooperated with the potential contractor. Through the Trans.eu chat, the parties determine the type and quantity of goods and the date of transport. After obtaining the necessary information, the company determines whether the transport order is feasible. If it is not possible to fulfill the order, the company rejects the offer. If transport is undertaken, its details are discussed, and the rate is proposed. Like in other cases, the order is accepted if the customer agrees to the price, if not - the companies negotiate with each

other. If the negotiations are successful and the companies reach an agreement, transport documentation is prepared. The final stage of the planning and organization process is preparing the vehicle to set off on the road. This activity takes place in a workshop belonging to the company. At this stage, the transport process begins. The role of the freight exchange in the surveyed enterprise is primarily to reduce empty runs. With its help, the company minimizes the costs of providing services and obtains additional earnings resulting from obtaining a new order. The freight exchange improves the transport of goods, both domestically and abroad, and completes the transport process of the surveyed enterprise.

5. Conclusions

The development of the transport industry may not only increase the level of employment and stimulate economic growth, but also correct the economic and industrial structure and contribute to the constant acceleration of the process of integration of the city with the regions. Knowledge management in transport companies is a key component on the way to increasing competitiveness. The research indicated that the use of freight exchanges is a very important part of the company's knowledge management system. The key aspect is the proper placement of electronic exchange systems in the overall knowledge management system to make its use as effective as possible. The study showed that the freight exchange is a tool that plays an important role in planning and organizing transport. They are used to a greater extent by experienced and large enterprises, but they also play an important role in smaller entities. The study indicated that a small group treats them as basic tools. Electronic freight exchanges are primarily an additional tool supporting management and organizational processes. They act as an auxiliary tool that allows companies to minimize their costs by reducing empty runs and optimal use of vehicle cargo space. It also allows for increasing the availability of new orders during transport, which increases their profitability. It is less often used for marketing purposes. Enterprises rely more on direct contracts, which is why freight exchanges will be used on a smaller scale, but their importance in streamlining the company's operations is visible.

Using T2-Capability Profile Modelling to Anticipate Change and Development: Bridging the Industry and Higher Education Views

Juha Saukkonen and Sanna Nieminen
JAMK University of Applied Sciences, Finland

juha.saukkonen@jamk.fi
sanna.nieminen@jamk.fi

Abstract: Organizations depend on the capabilities their members possess to survive and succeed in the highly competitive operating environment. Typically, capability or competence profiles have been created cross-sectionally, serving the current needs of the organization, whilst the Knowledge (KM) and Human Resource Management (HRM) also need to be future-oriented, addressing the emerging needs for new capabilities in an anticipatory manner. The development of capability profiles has moved from I-shaped models stressing the need for deep professional special knowledge to T-shaped models where the emphasis is adding horizontal knowledge capabilities (about business processes and additional knowledge areas) to balance the deep vertical specialization to specific occupational areas. In an ECKM (European Conference on Knowledge Management) conference paper in 2022, a new model called T^2-model was introduced on a conceptual level (Saukkonen & Kreus, 2022). The development step to earlier T-shaped capability models was the addition of a second horizontal layer on top of combinatory capabilities – thus the name of T^2. The lower horizontal layer contains business-specific items (like supply chain management, quality, or project management) where advanced knowledge is needed. The higher horizontal layer contains items of phenomena where a basic level of knowledge is needed (e.g., financial literacy, AI principles, sustainability). In the experimental research design, capability profiles were created for selected professional positions. The capability profiles were created by both business professionals (individuals currently having or managing the profession in question) and higher education professionals (who educate undergraduates and graduates to the industry and function studied). The respondents filled into the visualized T^2-model the skills preselected from earlier literature to relevant and were also able to add the skills they felt were missing in the original list of skills for the profession in question. The results give early proof-of-concept of the viability of T^2-model as a method of bridging both HRM and KM within organizations as well as University-Industry views on the knowledge items and levels needed for the future. Furthermore, the results give a basis for the knowledge anticipation process. The paper elaborates on a new model for anticipation of knowledge and offers a process that organizations can use in designing their HRM and Knowledge Management. Using T^2-model may offer an improved integration to other areas of planning such as technology development and strategic change.

Keywords: Knowledge, Capability, Skills, Career, Competence

1. Introduction

1.1 The Scope and Aim of the Study

The research project aimed at pilot implementation of the T^2-profiling, which had been earlier presented in academia only on the conceptual level. The primary aim was to test and assess the profiling framework in itself but also to shed light on the capabilities demanded for professional success in what comes to areas of Purchasing Management and Digital Marketing Management. The results and conclusions were planned to be usable both for the guidance of lifelong learning and professional development in business as well as for the development of educational approaches in the fields leading students to the two professions under study.

1.2 Research Approach, Method and Sampling

The approach was exploratory and experimental. Via convenience sampling, the following respondent pools were created to do the categorizing of the capabilities.

Professional Title 1: Purchasing Manager

- 2 respondents from HEI (Higher Education Institution) – educators teaching and researching purchasing management
- 3 respondents from industry (2 from the manufacturing industry, 1 from wholesale)

Professional title 2: Digital Marketing Manager

- 2 respondents from HEI – educators teaching and researching digital marketing management
- 3 respondents from industry (2 from the manufacturing industry, 1 from retail)

The three categories of capability ”ranking” were:

EXPERT LEVEL = VERTICAL (DEPTH) LAYER capabilities are rather unique in the organization, crucial for success in the job, and present all the time when performing in the job

ADVANCED LEVEL = FIRST HORIZONTAL LAYER capabilities where someone else in the organization has expert level knowledge, capabilities needed continuously in the job and cooperate with others

BASIC LEVEL = SECOND HORIZONTAL LAYER capabilities not directly included in the job but knowledge of which support the work done in the job and acting in the work community.

The respondents to the study were chosen via purposeful convenience sampling, The respondents contacted were alumni from the HEI (Higher Education Institution) were the researchers work. When constructing the respondent pool, the researchers sought heterogeneity of company types and sizes in what comes to representatives from industry. The respondent pool consisted of professionals from industrial, wholesale and retail organizations. The company sizes varied from 100 people to 2000+ people organizations. The educators invited to the study were educators/researchers responsible for digital marketing and purchasing management courses and research .

The respondents were introduced (via LinkedIn message or e-mail) the aim of the study and expected workload for them. Once they reacted positively to the invitation to join, they were sent a slide with the T^2- structure and the preselected set of skills. The respondents' task (independently of each other) was to place the preselected capability areas to the T^2-model layers of expert/advanced/base level of capabilities demanded – *currently* -in the job in question. The sources of capability areas were:

- The future of jobs – report by Word Economic Forum (WEF, 2023)
- The final report of FUDIX (Future Digi Expert)-project (JAMK, 2022)
- Purchasing and supply management (PSM) competencies: Current and future requirements. (Bals et al., 2019)
- In addition, the respondents could add the capabilities needed in the profession but not listed by the researchers

The respondents worked by rearranging the capability text boxes on a MS PowerPoint slide that was coded by the sphere (purchasing or marketing & industry or education + the name initials) so that the researchers could have contacted the respondents and asked individualized further questions if needed. Also, the opportunity to act on the responses was kept alive with the informant coding – e.g. the next stage of further research could be the capability needs *for the future,* and looking at that, the ability to backtrack the responses to the person answering was maintained.

In the data analysis of the individual T^2-profiles depicted by the informants, the researchers aimed at pattern recognition (repetition of lines of thought by informants) but also in the issues where no pattern emerged, thus proposing a discrepancy of views that may, in turn, motivate further study and discussion. In the analysis, the researcher triangulation method was used i.e. two researchers performed their analysis independently, and then their findings were merged into a joint view. The approach was a quantitative one the researchers made their conclusions on pattern emergence based on the frequency of capabilities based on specific layers. The areas of interest were: 1) Within one profession: Which skills are typically based on certain layers i.e. what is the agreed core of a capability profile for that profession 2) Which capabilities are lacking a pattern i.e. in which issues the professional community agrees on a capability importance, and 3) Which capabilities form a pattern between the two distinct professions studied: What are the generic, interdisciplinary capabilities.

1.3 Research Gap, Objectives and Questions

The research gap identified links to the lack of practical instantiations of the capability profiles. Multiple studies have addressed the evolution of capability profiles and discussed the alternative models on a conceptual level. Empirical research on the feasibility of the capability profiles has been scarce. The role of business practitioners has been minor in testing the models and developing them further. In addition, higher education's role has been weak in impacting the contents of capability profiles and designing their processes.

The research objectives were:

- to test the practical feasibility of T^2- capability profiling with business and education professionals
- to find if the small samples of the professionals can agree on the capabilities and levels of expertise needed for the 2 professions in focus.

- to see how the educators' view corresponds to those of business professionals.
- to see if there are overlapping/shared capability areas and levels between the two professions (generic capabilities)

From the research objectives, the following research questions (RQs) could be created:

RQ1: What and on what level are the demanded current capabilities for the Purchasing Manager?

RQ2: What and on what level are the demanded capabilities for Digital Marketing Manager?

RQ3: Can some overlapping (=generic) capability areas be identified between the two professions?

RQ4: How well does the T^2-capability profile suit the quest to act as a framework for the improvement of professional capabilities in industries and education?

2. Literature Review

2.1 Skills, Competencies, Abilities, and Capabilities

The literature on capability-related research uses terminology and a range of conceptualizations that overlap. The related terms are often used interchangeably. For example, skill can be defined as the method for outcome connected with knowledge. And knowledge includes creativity, power of practice, communication skills, and technical skills (Takeda, 1999). Skills and competencies are used as the same concept but have distinct differences. Skills are learned abilities while competencies are inherent qualities that combine skills, knowledge, and abilities. Competencies are a set of integrated knowledge, abilities, and attributes that define what is needed to successfully perform a job. Competencies can be specific to a job or vary based on job content, performance situations, and performance criteria. Lee (2022) discusses the definitions and conceptual relationships of ability, competence, and skill. It concludes that "ability" is an individual and independent concept, while "competency" is a set or bundle of factors that includes both ability and non-ability factors.

The paper by Ruitenberg (2019) highlights that skills are specific and transferable capacities that can be perfected through practice, while competencies are broader attributes that involve one or more skills. Ruitenberg emphasizes that many human attributes exceed the concept of skill.

Lastly, capabilities, the focus of study in this paper, can be coined as a combination of knowledge, skills, experience, and competencies that enable individuals or organizations to perform certain activities or achieve desired outcomes (Whitfield et al., 2022). Capability involves the integration of prior knowledge, skills, resources, judgment, and experience to solve problems (Zvradkovic et al., 2014). Capability is seen as a complex, organizationally embedded, and firm-specific knowledge resource that supports competitive advantage (Keeley, 2014). The concept of capability can be used as a baseline for business planning, service specification, and design. It allows organizations to deliver their services in various business contexts with sustainable quality.

2.2 Capability Profiling

Capability profiling is a term used both for human and technology-driven performance evaluations. Capability profiling refers to the process of evaluating the capabilities or qualities of a system, process, or person on specific criteria or variables. The goal of capability profiling is to determine the extent to which a system or process meets customer expectations or specifications. It can be used to identify soft skills requirements in job descriptions, evaluate the process capability of IoT devices within self-organized ecosystems, or assess the process capability of a product or process in quality control applications. (Ajayi et al., 2019; Liu et al. 2018; Charki et al., 2016).

In the sphere of human capability assessments and enhancement, capability profiles are depictions of capability requirements/targets for a successful action in a professional role. Capability profiling contributes to organizational development and performance improvement by identifying and leveraging the various competencies and capabilities of a company. Through capability profiling, organizations can identify the skills and resources needed to implement their business strategies effectively (Liu, 2022). The shape, size, and contents of capability profiles are used in HRM processes from recruitment to training as well as to performance and compensation management. Originally, a wide range of archetypal profiles were established, namely those of specialist, generalist, and Phi-shaped (Macaulay et al. 2010, pp. 728–729). A specialist or in other terms an I-shaped (from the shape of the letter i in the uppercase font) professional profile describes a person who has a very deep understanding of his/her area of expertise but a limited width in other areas of expertise. The

generalist profiles can be described with the symbol "-" or as a hyphen-shaped profile, where there is width in various expertise areas but a limited depth in all of them. This profile might work for the general management or development manager positions within an organization. Phi- (π) shaped profile suggests that two distinctive areas of knowledge go deep, and the width is provided by the capacity to understand their interplay.

2.3 The Models of T- And T2 -Shaped Capability Profiles

The knowledge era in which companies currently operate, calls for new capabilities in both technological and behavioral dimensions and in combining these (Haapasalo and Kess, 2001). Yet, at the same time technological development requires people to gain a deeper and deeper understanding of their own field to provide their employers a true competitive advantage. So, there is the vertical depth required as in the original I-shaped capability profiling. However, combinatory capabilities are needed as the tendency is towards holistic, non-siloed, and interdisciplinary approaches, so also horizontal capabilities are of need. To accommodate these demands, capacity profiling moved towards talk and research on T-shaped capability profiles. As the symbolic letter T proposes, there is a need for a domain- and/or function-specific expertise (the vertical line in the letter) but in addition to that, individuals should possess width in their knowledge. This horizontal width offers the individual and organization flexibility via "empathy, breadth of knowledge, skills, experience, and complex communication abilities" (Demirkan and Spohrer, 2018). T-shaped models have been described to be fundamental for corporate knowledge management (Barile et al., 2012), innovation (Oskam, 2009), project management (Martinez et al., 2016) and service design and delivery (Saviano and Simone, 2015).

Some papers published in 2010s proposed that both vertical and horizontal dimensions should multiply in content. So there would potentially be more than one area of deep expertise but also various layers in the horizontal dimension (e.g. Heikkinen, 2018). To comply with the notions made on the multitude of contents for both the vertical and horizontal dimensions of capability profiles, Saukkonen and Kreus (2022) introduced a T2-model for capabilities based on the analytical assessment of the prior-art models and discussions with and observations of modern organizations (2022). In the T2-model there are altogether 3 layers, 2 of which are horizontal (width) and one vertical (depth).

The T^{2-}capability profile (the basic form of it shown in Figure 1) is built on the following pre-assumptions:

- despite the expressed needs for interchangeability of information and flexibility of the workforce, deep expertise skills possessed by an individual are still a valid demand for competitiveness 10
- the number of skills and competencies with deep expert-level knowledge cannot be many since the time and other resources of an individual and organization are constrained
- the interdependent nature of business functions in a modern organization set demands for the experts to understand the context-dependent (on the industry- and company-level) processes beyond one´s expertise
- in addition to deep expertise and context-dependent capabilities, there is a layer of context-independent competencies, which are needed across domains and industries

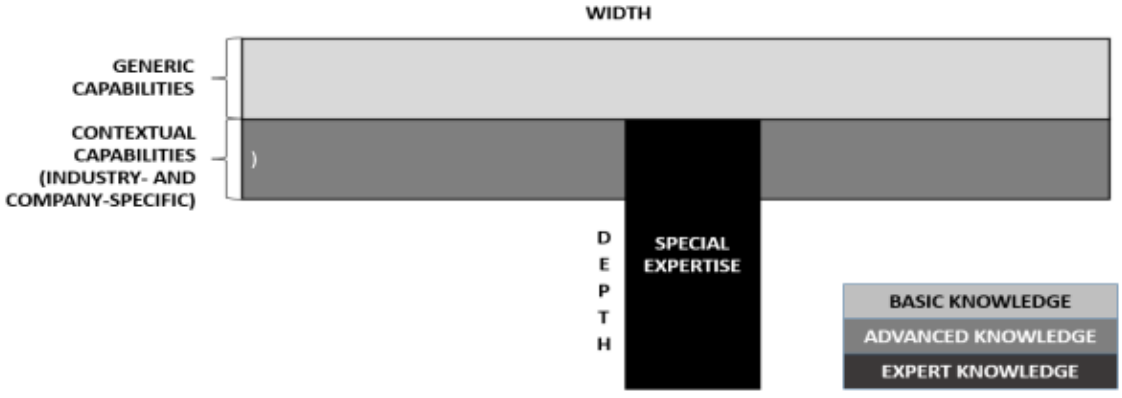

Figure 1: The format of the T^2-capability profile (Saukkonen, 2022)

3. Results

Altogether 10 different capability profiles were obtained from the respondents, to be analyzed based on the frequency of capabilities placed to specific layers, i.e.the data analysis was quantitative in nature. The overall

view was thus created by superimposing the 10 different profiles and looking for patterns that emerge from the data. In Figure 2 an exemplary T^2-profile depiction by a Purchasing Manager practitioner and in Figure 3 the depiction by a Purchasing Management educator is shown.

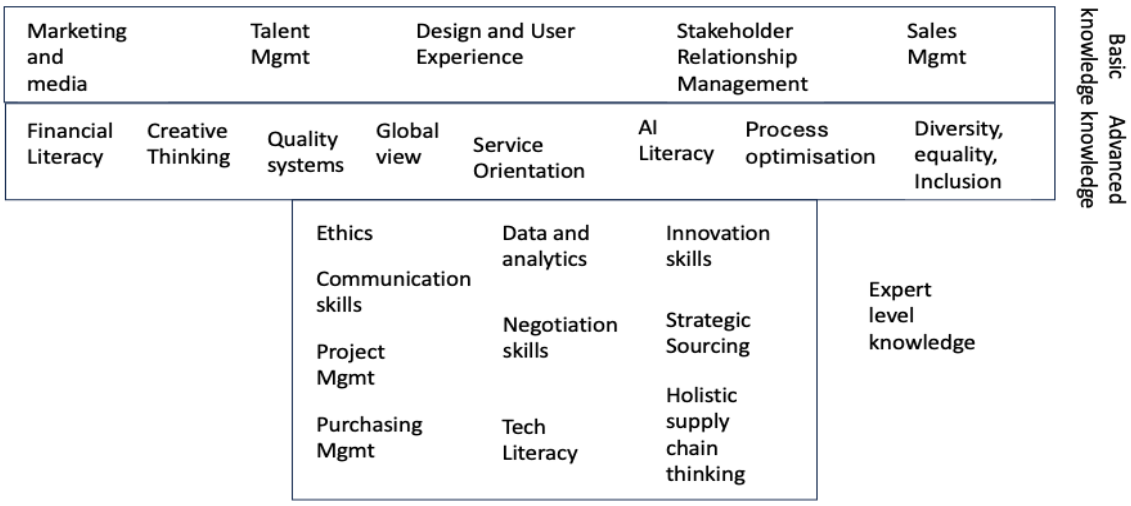

Figure 2: An example of the capability profiling by a Purchasing Management practitioner

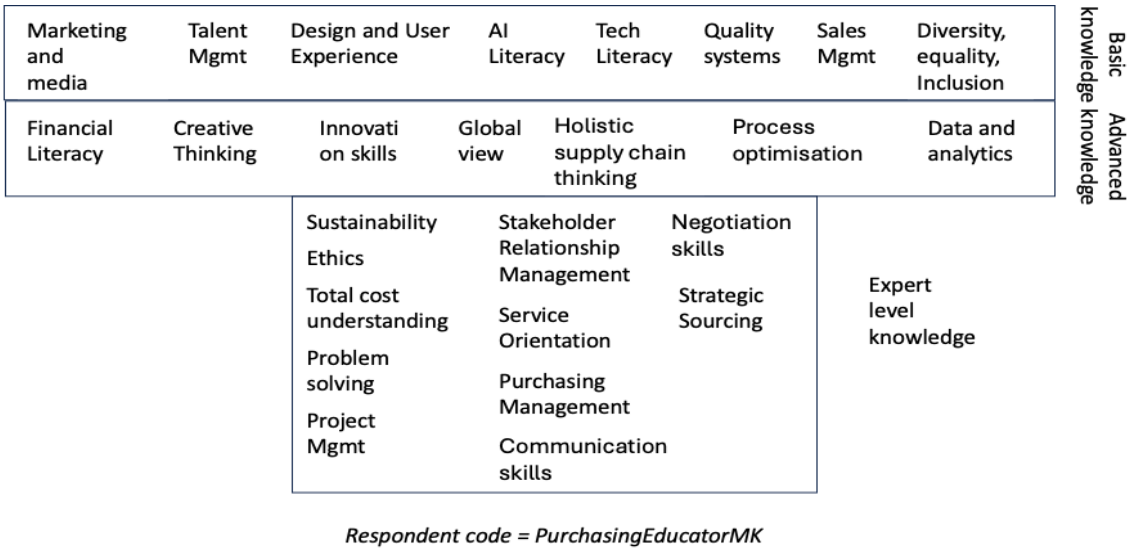

Figure 3: An example of the capability profiling by a Purchasing Management educator

When superimposing (placing on top of each other) the T^2-profiles depicted by the informants, the following patterns were identified.

- In the T2 model for a purchasing manager (PM) a greater agreement was reached than in what comes to the Digital Marketing Manager DMM case– especially on the depth dimension (Expert-level skills) may be partly due to some skills/competencies offered were taken from a sector-specific source=> conclusion: a sector-specific tailoring of competence listings needed when applying T2
- In the Digital Marketing Manager -case the informants added various and very specific skills to the expert level => conclusions: 1) the lack of sector-specific "vocabulary" (see above) may be the reason to that, and 2) the question of the difference between competence/capability and skills that prevails in academic literature is present also on the practitioner level. Educators used more broad concepts both when selecting from the given list and in adding new competencies.

- Soft skills of communication and negotiation were most often placed to expert level in PM sphere, whereas in DMM the opinion on that differed. Is DMM action currently more tech-laden than PM so transactions and communications happen online thus leading to a lower level of skill needs?
- Data and analytics are crucial for success in both professions – whereas the wider concepts of Tech and AI literacies were placed in the layers with a lot of variation.
- Financial literacy was placed clearly on the layer of advanced capabilities as well as project management was either expert or advanced competence required – across both cases.
- Ethical considerations are more present and capability-demanding in PM than DMM case
- Overall, the advanced level (first horizontal layer of combinatory capabilities) was very "crowded," giving a hint that modern business requires capabilities across organizational silos and functions.
- in the DMM -case the informants mentioned "customer journey"(expert level) and "customer relationship management"(basic level) in the category "other. The customer-related competencies were not in the pre-selected capability list and should be included in future work on the issue.

4. Conclusions

Based on the results displayed in Chapter 3, the following answers to the RQs can be presented.

RQ1: What and on what level are the current capabilities demanded of a Purchasing Manager?

The core capabilities of strategic sourcing, purchasing management, communication, and negotiation skills as well as stakeholder relationship management were commonly agreed upon by the informants and were placed on the expert level. Data and Analytics were also highly ranked among purchasing management informants - either expert or advanced knowledge level. The remaining capability areas based on the literature were placed on advanced or basic levels. Creative thinking and sales-related capabilities were ignored by some purchasing management informants.

RQ2: What and on what level are the capabilities demanded of a Digital Marketing Manager?

The core capabilities that most informants agreed upon to be demanded at the expert or advanced level were Marketing and Media, Data & Analytics, Financial Literacy, Negotiation skills, Creative Thinking, and Project Management. In what comes to the remaining 22 capability areas surged from the literature the opinions on the level of capability demanded varied between basic/advanced level skills. For example, the role of Ethics, the understanding of Purchasing management, and AI literacy varied a lot between informants. Interestingly, Data and Analytics were on average ranked higher than Creative thinking in what comes to managing digital marketing.

RQ3: Can some overlapping (=generic) capability areas be identified between the two professions?

Capability areas that were shared between the two professional communities were Data&Analytics, Negotiation skills, and Financial literacy. These areas can be seen to reflect the development tendencies of technological and organizational development across industries. Of the capability areas not shortlisted by the researchers, the additions by the informants were mostly related to Sustainability (PM case) and Search engine optimization (SEO) capabilities (DMM case).

RQ4: How well does the T^2-capability profile suit the quest to function as a framework for the improvement of professional capabilities in industries and in education?

The informants described the approach and "exercise" built on it as interesting and no negative reports were made on the usability of the T^2-tool. On average, informants placed 7 capabilities in the category of deep expertise level (8 in the PM case and 6 in the DMM case), 8 capabilities in the layer of advanced skills (9 in the PM case and 7 in the DMM case) and 6 capabilities to the level of basic skills (in both PM and DMM case). This finding highlights the complexity of the current world of work and the need for cross-disciplinary learning and practice. One informant commented that the size of the organization - how many people share the responsibilities in e.g. purchasing department – affects individual capability profiles.

For future purposes, a mode context/sector-specific "capability library" would add to the specificity of the findings and better guide the usage of the model in educational and learning purposes in both academic as well as in professional environments. The dilemma of whether the capabilities offered are too generic vs. too specific was prevalent. In addition, in a large corporation, the studies could be done on a company level with their specific structure and more focused set of organizational capabilities in mind.

As the study results propose, there are contrasting views on the importance (level required) of competencies within the professional (practitioners and educators together) communities in purchasing and digital marketing spheres. Those discrepancies may result from 1) the destructive features of emerging technologies reshaping professions, or 2) the contextual differences (like company size, the field of business, and geographical/cultural operating environment.) The study by Liu et al. (2018) shows that the capabilities requirements change as employees transition from one position to the other. Also, the capability requirements change as organizations transform from one focus area to another. The idea of dynamic capabilities, i.e., proactivity and reactivity to changes in the operating environment by the transformation of capabilities (Helfat et al., 2007) is likely to prevail as a core tool for competitive advantage, survival, and success of organizations.

5. Discussion

The results and the study's process highlighted the potential opportunities but also challenges in applying capability profile models into practice. The small sample of the respondents does not suffice for statistical proof of which capabilities belong to which layer of skills. However, the results indicate that the method chosen was actionable and understood by the respondents who represented experts on the areas studied. The sourcing of the skills from just three previous publications can cause bias. Even though respondents were encouraged to leave out of their T^{2-}model the proposed skills that they did not find relevant and /or add skills that were missing from the proposed list, the pre-selection of skills strongly directed the choices made by the informants. Furthermore, the skills were not described to respondents beyond the name of the skill, and that may have led to differing understandings of the content/meaning of the skills. Multiple roads ahead for academic advancement, as well as practical development of the T^2-model, can be identified: Firstly, via quantitative study the claims of the contents for the more tightly connected to a particular context a joint view can be reached for professions with statistical proofs. A quantitative study would also shed light on the effect of context to the views. SME (Small and Midsize Enterprise) companies were missing from the sample, and there the perceived capability demands might be different as delegation of tasks to a wider purchasing or marketing team is not a viable option. Secondly, via qualitative study the true meaning and contents of somewhat vague names of capabilities like “Tech literacy” (sourced from the World Economic Forum –publication “Future of jobs”) can be studied. Thirdly, by shifting the focus to capability profiling into *future* demands for professions, the tension between the current vs. future view (“as is” vs. “to be”) can be identified. That tension can then act as a guideline to educational institutions in designing and delivering learning paths for future professionals as well as upskilling the current employees in the profession. Finally, the intrusion of Artificial Intelligence and Machine Learning into human capital management will enable the creation of capability profiles with the means of technology (Weichselbraun et al., 2024), using job advertisements, job descriptions and performance assessments as datasets needed.

Anticipating Change and Development With Systematic Build-up of Critical Knowledge Assets: Blueprint for a Knowledge Roadmapping Framework

Juha Saukkonen, Anastasiia Mikhlina and Sanna Nieminen
JAMK University of Applied Sciences, Finland

juha.saukkonen@jamk.fi
anastasiia.mikhlina@jamk.fi
sanna.nieminen@jamk.fi

Abstract: Organizations of today act in a volatile operating environment that 1) implies challenges for firms in adapting to the new conditions but also 2) creates opportunities that new areas of knowledge and technology offer. To succeed, companies need to embark on the journey of visionary and strategic management also concerning knowledge management (KM). They also need to simultaneously link the change and development to make a continuum with the current offerings and operations. Technology Roadmapping (TRM) by e.g., Robert Phaal et al. (2004) has been introduced as a solution to describe the process of understanding and combining what is needed (external and internal business drivers) and what is possible (technologies available). In their meta-analysis of the knowledge roadmapping literature Letaba et al. (2015) conclude that technology roadmaps have supported the process of operationalizing strategies by mapping details of future R&D programs, technology and manufacturing capability development . However, technologies *per se* do not offer a competitive advantage if they are not paired with knowledge of how (and when and where) to use the technology and how to resource the build-up of the knowledge that will be relevant for the future. Competence mapping is a common tool that links jobs and skill needs to succeed in them. Competence maps act as inventories that sum up the knowledge possessions of departments and individuals in the organization. These mappings are however cross-sectional – focusing on current needs vs. current knowledge possessions – and do not link seamlessly to the overall vision and strategy of the organization. This conceptual paper introduces aims at creation of a blueprint for a new framework and process for Knowledge Roadmapping by integrating the findings of earlier research across the fields of technology, competence and knowledge mapping. The framework is built on Technology Roadmapping structure by Phaal et al. (ibid)., adding to it the layers of Critical Knowledge Assets (CKA) and Business Process Excellence (BPEx). E.g., new CKAs such as “data-drivenness” and “resource wisdom” directly affect the Product and Service offerings (PSOs) of a firm but also the effectiveness of the firm´s business processes and technologies that an organization can deploy. The framework is built by synthesizing the findings of extant literature on technology, competence, and knowledge roadmapping The theoretical contributions of the paper add to the knowledge pool of the nascent area of knowledge roadmapping and practical contributions serve organizations by offering a planning tool that ties KM to their overall strategic foresight.

Keywords: Knowledge, Capability, Anticipation, Career, HRM Strategy

1. Introduction

1.1 The Objectives and Research Question

The operational environment of organizations is knowledge-intensive, up to the point where the current tide across industries and societies can be called the knowledge economy (Powell and Snellman, 2004). To succeed, companies must be capable of creating, acquiring, protecting, and sharing knowledge.

Recently, advancements in technologies such as the Internet of Things (IoT), machine learning, and predictive and generative artificial intelligence have presented new opportunities for companies to to gather, analyze, and convert data into useful information. This information can help businesses make informed decisions that can lead to short- and long-term success. *Knowledge* is an essential resource that companies need to succeed in the foreseeable future. An environment that values knowledge as an asset also means that new knowledge brings with it destructive capacity since adjusting to the new “settings” of the operational environment can cause organizational crises (Freeman and Perez, 1988). Knowledge intensity—if well mastered—has the potential to help avoid the worst impacts of those crises and create new entrepreneurial opportunities via knowledge creation and resulting differentiated offer advantage (Moore, 2000). As a result, it can be claimed that modern KM needs to be dynamic in two senses of the word: It needs to contain the (future) time element as well as depict the dynamism of KM between an organization and its business partners (Saukkonen, 2020).

Organizations have applied many ways to keep up to date with the knowledge that they possess. The need for this type of inventory or deposit –approach of knowledge is well reflected in an often-quoted expression of the

need and difficulty of mastering knowledge by then-CEO of Hewlett-Packard Lewis E. Platt: "If only HP knew what HP knows we would be three times more productive" (Atwood, 2009). On top of mapping the current competencies, educational institutions and companies have engaged in efforts to anticipate the capabilities likely needed in the changing operational landscape. Anticipation as action and mindset is close to the foresight process, a joint effort of stakeholders to explore futures and interpret them to justify the present actions (Dufva and Ahlqvist, 2014) - e.g., in knowledge management. As Poli (2014) stated, anticipation brings in both calculable risks and incalculable uncertainties. Organizations vary in their capability to utilize futures in their decision-making (ibid.).

Companies aim to cope with and anticipate the change with their long-term plans for corporate strategy and their technology and product roadmaps. From the outputs of those efforts, different corporate functions - such as Human Resource Management (HRM) and Knowledge Management (KM) - get inputs in their function-specific visions and strategic plans. As Mintzberg (1987) coins the term, strategies are made purposefully and consciously before the action they will apply.

This paper aims to synthesize the existing models of roadmapping and the aims and scope of strategic knowledge management into a new framework to facilitate change management and strategic alignment of KM efforts. The research question i.e. the quest for new knowledge set at the start of the research journey is: *"How can the current tools of science, technology, competency and product roadmapping be further improved to better facilitate strategic and dynamic knowledge management?"*

This research aligns with the practical needs of the industry, echoing the remark of (technology) roadmapping by Letaba et al. (2015): "Practitioners and scholars alike are seeking new ways on integration of this technology market planning tool with other business processes while on the other hand, there are efforts for their customisation according to the needs of managers or policy makers."

1.2 The Approach and Method of the Study

The research approach and method of this paper is conceptual. The authors aim to understand and structurize the phenomena under study, combine the related concepts, and derive and propose a new framework for further study. Young (1995) proposed that an essential parameter of conceptual research is an attempt to give clarity to concepts systematically. Conceptual research can be used to develop new concepts and reinterpret existing ones (Leuzinger-Bohleber & Fischmann, 2006). Conceptual researchers investigate, e.g., the meanings and usage of concepts. The outcome of this study is built on existing concepts that have been combined into a proposal for a new integrative framework, "Knowledge roadmap", and a proposal for a roadmapping process that organizations can apply. In this research, the authors reviewed selected papers using Semantic Scholar, SciSpace and Google Scholar tools. The findings of the most relevant prior art studies are displayed in the literature review (Chapter 2), and elements identified in those papers as well as the elements found to be missing from current frameworks get integrated into the new framework. As is typical for conceptual research, the study also fulfils many criteria of exploratory research. Exploratory research is typically an initial investigation to clarify a problem and provide understanding and background information. It has the role of preparing for more conclusive future studies with limited prior knowledge. (Manerikar and Manerikar, 2014).

2. Literature Review

2.1 Competency and Knowledge Mapping

Competency mapping identifies and evaluates the skills and competencies required for different organizational job roles (Jaskiran et al., 2023). It may be used as a tool that supports understanding the strengths and weaknesses of individuals and directing their career development. It can also be used in talent acquisition, induction, training and development, and assessment processes in HR. Competency mapping can be visualized using knowledge or competence maps, which provide an overview of prevailing competencies in an organization. *Skill mapping* is a related concept that involves analyzing the skills and competencies required for a job position. Creating skill mapping involves analyzing the skills and competencies required for the job position, evaluating the employee's current skills and competencies, and creating skill mapping and learning activity plans based on their level (Komkrit, 2023). Competency and skill maps are cross-sectional; they are created for the current needs of competencies for job roles and map the skills (what, who, where) possessed at the time of analysis.. As Carvalho et al. (2013) commented, roadmaps that depict one or more possible routes to reach the destination have found their way into the planning in business and non-profit organizations over the recent decades.

According to Dönitz (2023), roadmapping is a flexible and practice-oriented tool for assisted strategic planning and can be used in various fields of expertise. Roadmapping has been claimed to have many affordances and claimed benefits for strategy development and innovation (Phaal & Muller, 2009). Roadmapping is a process that involves many stakeholders and is constantly evolving (Tang et al., 2011). Knowledge and competency roadmapping is a strategic approach that yields structured plans to guide organizations and individuals in assessing the needs and means of acquiring knowledge to achieve relevant competencies in a particular field of activity. The output of the process – roadmaps – serves as pathways that outline steps and milestones in time needed to reach the contents and levels of knowledge portfolio to reach a desired level of proficiency.

Numerous studies have shown the importance of knowledge roadmapping. Siebelink et al. (2021) reported that firms worldwide face challenges and need help with strategic and long-term development plans. Creating coherent plans and efficiently communicating them with employees is difficult, leading to the search for strategic development tools such as roadmapping (ibid.).

On a pragmatic level, knowledge roadmapping is a workshop-based tool that utilizes diverse knowledge from individuals to create shared knowledge in the form of a roadmap for navigating a strategic landscape (Pan, Liao & Zhang, 2023). It involves drawing on individual knowledge and transforming it into collective outcomes through shared meanings and commitment to act (Krull, Smith, & Husted, 2022). The aim is to improve knowledge sharing and ultimately achieve better strategic outcomes. Roadmapping facilitates face-to-face interactions between individuals in a neutral space, fostering knowledge sharing. Additionally, a positive disposition of individuals to share knowledge and imperatives to trigger knowledge contributions are essential factors in knowledge sharing during roadmapping. The role of the facilitator is also highlighted as crucial in promoting knowledge sharing. This multilevel approach to knowledge sharing in roadmapping provides insights into the relationship between individual knowledge and organizational-level outcomes.

2.2 Science, Technology, and Product Roadmapping

The process of roadmapping serves various purposes and helps in strategic planning, competence mapping, and knowledge asset planning. The study conducted by Siebelink et al. (2021) reviewed the roadmap as a strategic tool that helps companies surpass critical strategic challenges. Previous studies have shown that significant corporations such as Motorola and Philips have used roadmapping for decades to navigate product direction, anticipate potential risks, and make long-term plans. Adopting roadmapping has allowed firms to gain a competitive edge and improve their long-term planning capabilities.

Effective knowledge management is a challenge that most companies face, regardless of their industry or size. Qualitative research conducted by Sareminia et al. in 2018 shows that roadmapping for knowledge management can be a powerful solution to this challenge. The study developed a framework that offers a structural approach for organizations to efficiently manage their knowledge through visual roadmaps, opening new possibilities for effective knowledge management.

In 2015, Yee and Teoh conducted structured action research to create a unified roadmapping system that any organization could adopt. The system was designed to enhance a company's strategic capability. Unlike other studies focusing solely on technology roadmapping (TRM), this research explored knowledge management's "soft" aspects. Meanwhile, Phaal et al.'s 2009 study looked at technology roadmapping and their T-plan framework as a tool for navigating disruptive markets. Similarly, Moehrle et al. (2013) argued that technology roadmapping is an approach that can help companies address future challenges. These studies show that technology roadmapping is a valuable method for navigating change. Companies of different sizes and industries have widely used technology roadmapping to ensure their technologies align with their strategic objectives.

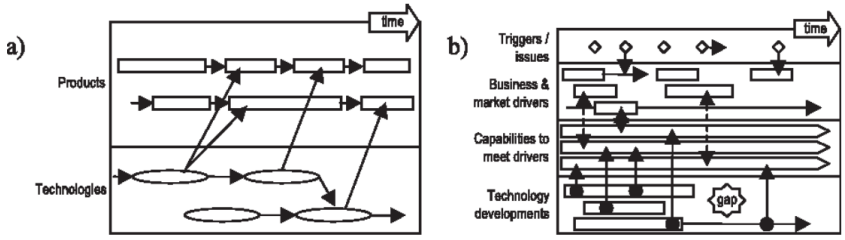

Figure 1: Examples of technology roadmapping process interim outputs in the T-plan model (Phaal et al., 2004)

Product-technology roadmapping is an effective method to ensure that current plans align with long-term objectives and specific steps. This approach creates a visual framework that consolidates knowledge across different structures within a company. According to Raymond et al. (2007), several crucial factors must be considered when creating a roadmap. These include the scope of the roadmap, the level of detail required, and the importance of data privacy throughout the process. Involving stakeholders from different company functions as well as technology and data analysis tools can enhance roadmapping.

2.3 Strategic Alignment of Knowledge Management

"Competitive strategy is about being different" (Porter, 1996). It means, for example, choosing a different set of activities to deliver a unique mix of values. Today, it more and more also includes the choices of knowledge and technology. The organization can be conceptualized as an institution for integrating knowledge (Grant, 1996). The simplified production task in an organization is transforming inputs into outputs. In this organizational context, the fundamental activities include creating, acquiring, storing, and deploying knowledge. Grant (1996) studied the coordination mechanisms through which organizations integrate the specialist knowledge of their members. The emphasis was primarily on the application of knowledge and the role of the individual.

Strategic thinking can and should lead to new options in the evolution of the business. Bolisani and Bratianu (2018) emphasize the importance of aligning knowledge when creating organizational value. The scarcity of tangible assets can be balanced with the availability of intangible resources. They see "knowledge strategy planning as a continuous effort of learning and adaptation to needs and opportunities that dynamically emerge from daily practices."

Aligning strategy with a knowledge management system improves innovation and business performance (Lai et al., 2022). Strategic knowledge management system alignment (SKMSA) has a significant positive impact on knowledge management (KM) and knowledge management system (KMS) performance (Figure 2.). SKMSA was defined in this study as the degree to which a firm's business objectives are supported by crucial KM entities such as processes (e.g. knowledge codification), skills, tools (e.g. knowledge map), and motivation (e.g. trust, rewards). It was concluded that "firms achieve their performance goals through SKMSA instead of developing a standalone KMS or business strategy." The study by Yoshikuni and Albertin (2020) demonstrated findings that knowledge management strategy (KMS) has significant, positive effects on IT strategic alignment, benefits of IT use, business process performance, and firm performance (Figure 2).

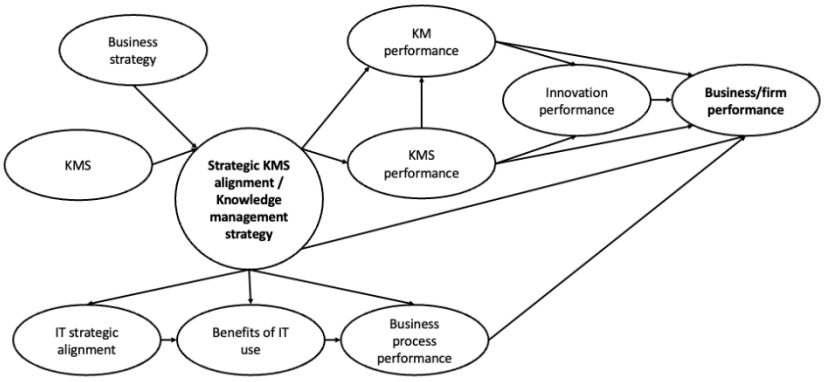

Figure 2: The strategic knowledge management system (KMS) alignment / knowledge management strategy has a positive effect on business/firm performance (Lai et al., 2022; Yoshikuni & Albertin, 2020)

Jami Pour et al. (2018) have suggested implementing KM strategic planning in practice. The main phases of KM strategic planning are review, orientation, implementation, and evaluation. The KM strategic review includes external environment analysis and internal environment. KM's strategic orientation consists of setting KM's vision, identifying the strategic knowledge gap, and prioritizing knowledge-oriented processes. KM strategy implementation includes allocating the KM resources, identifying appropriate KM mechanisms, identifying KM processes, and developing a detailed action plan. KM Strategic evaluation involves identifying key performance indicators (KPIs) and reviewing strategic priorities regarding emerging changes.

All in all, strategic alignment of knowledge management is essential, and as Prahald (1990) put it: "Unlike physical assets, competencies do not deteriorate as they are applied and shared. They grow."

2.4 Research and Tool Gap for Strategic and Dynamic Knowledge Management

The study got its motivation from the identified gaps of knowledge. Firstly, strategic knowledge alignment with other areas of planning (technologies, product, and service offerings, and resourcing both tangible and intangible resources). Secondly, the commonly deployed process of knowledge roadmapping does not specify the knowledge areas and their acquisition that need to be paired with technologies and business processes for the organization to reach its aims. Thirdly, the current knowledge mapping process is not dynamic but cross-sectional; it creates a knowledge inventory of the firm and its stakeholder network but not the evolution needed for future knowledge inventory. Finally, doing the roadmpapping by tying it into the firm´s strategies and visions (Internal drivers) and changes in operative environment (external drivers) would make the choices made in knowledge roadmapping easier to justify.

The prior-art literature in the topic area is not vast: In a Google Scholar Boolean search for academic papers about the roadmapping philosophy, close to 1000 papers had "technology roadmapping", “technology roadmapping” or “technology roadmaps” in the research title. In the case of “knowledge roadmapping”/” knowledge roadmapping”/” knowledge roadmaps” in the paper title only 3 papers were identified. Thus, knowledge roadmapping is an emerging but understudied area that requires increased interest, as well as the tools and frameworks that the technology roadmapping approach already has. Combining the vast prior-art knowledge of technology roadmapping and findings of the nascent area of knowledge of roadmapping, a new framework with theoretical and practical contributions would advance roadmapping research and practice. As proposed, knowledge roadmapping -approach can enlarge the current technology-focused roadmapping approach with “soft” issues and information systems. Despite the recognized need, effort in framework development has been scarce.

3. Results - A Blueprint for a Knowledge Roadmapping Framework and Process

3.1 The Structure of a Knowledge Roadmap

This paper's evolutionary step is the proposal to expand the product and technology roadmapping process. The new model below (Figure 3) would cover the knowledge needed to meet the operating environment and strategy changes more widely and deeply, emphasizing the crucial role of knowledge and knowledge planning in achieving organizations' goals.

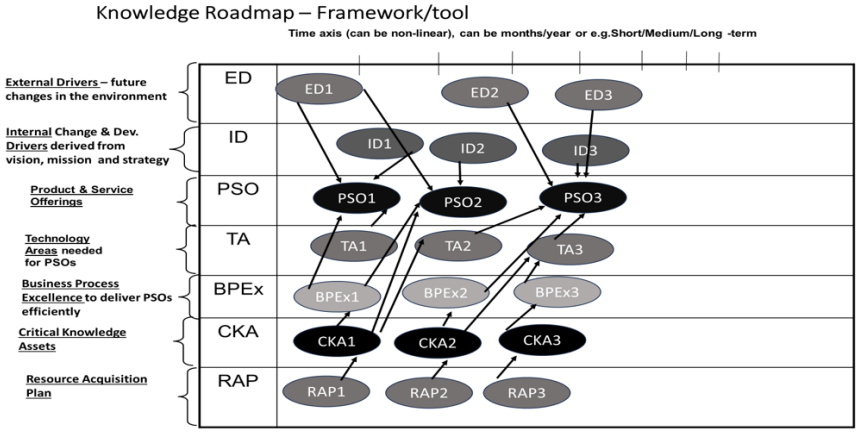

Figure 3: The elements and some hypothetical interconnections of the Knowledge Roadmapping framework.

External Drivers (ED): Changes in the operating environment that are foreseen, independent of the existence and action of the company doing the roadmapping. These drivers can be sourced from, e.g. Megatrend reports by institutes of futures research (e.g. SITRA in Finland, Fraunhofer Institute in Germany) and top-tier consultancy companies (Deloitte, Nielsen, etc.). The drivers can be sourced and arranged using e.g. the PESTEL framework: Political, Economic, Social, Technological, Ecological, and Legal drivers.

Internal Drivers (ID): The firm's strategic choices and development in the long run towards new business opportunities. The firm's vision, mission, and strategy are the main sources for the drivers. These may include targets for e.g. new marketentries, growth, market shares, profitability etc.

Product and Service Offerings (PSO): Resembling the layer of Product Feature Concepts (PFCs) in the T-plan approach by Phaal et al. (2004) , this layer depicts future offerings to chosen target market segments. The PSOs can be entirely new or development versions of existing offerings. They can be related to physical products or services offered—or a combination of the two.

Technology Areas (TA): On this layer, the organization maps the technology areas that have potential or are needed to bring about the PSOs mapped in the layer above. Mapping can also be done on a robust level ("location technology") or on a specific level, naming the technology like "Global Positioning System GPS."

Business Process Excellence (BPEx): The areas of operational excellence where the organization must be genuinely competitive to deliver PSOs efficiently and take the identified TAs into use. The business processes can be named according to the organizational divisions (marketing, purchasing, customer service, R&D, etc.) or on a more conceptual level (customer care, co-creation).

Critical Knowledge Assets (CKA): The areas of capability that the company must possess or have access to (if CKAs held, e.g. by a business network partners) to be able to excel in TAs and BPExs. Knowledge assets refer to the valuable resources and capabilities that an organization possesses in the form of knowledge. These assets can include internal knowledge developed within the organization and external knowledge acquired from outside sources. Knowledge assets can be categorized into different types, such as structural capital, relational capital, and human capital, each of which can contribute to firm performance. In today´s technology-laden operating environment, Improvement methods for knowledge acquisition include using advanced technologies like artificial intelligence and machine learning to automate knowledge extraction and analysis via "intelligent agents".

Resource Acquisition Plan (RAP): This layer focuses on how and when knowledge assets are acquired or created. Ways to secure knowledge availability range from own R&D projects and strategic hiring to license acquisitions and partnerships with other organizations.

3.2 Blueprint for a Process that Yields the Roadmap

The framework for knowledge roadmapping, proposed in section 3.1, can be developed through a series of workshops. The workshops will produce content for the different layers of the framework, connect the items across different layers, and put them into a timeline. The table presented below organizes the steps of the process into the order and themes of the workshops, desired outcome layers, and the stakeholders involved in each step. Overall, it provides a structured overview of the roadmap development process.

Table 2: Workshop-based process of creating a knowledge roadmap

Workshop order and theme	Desired Outcome Layers	Stakeholders in charge
1. Driver recognition	External Drivers (ED), Internal Drivers (ID)	R&D, Business Intelligence, all functions' representatives
2. Offering and techs	Product and Service Offerings (PSO), Technology Areas (TA)	R&D, Technology/ Product Development team, Sales&Marketing
3. Business processes and knowledge assets	Business Process Excellence (BPEx), Critical Knowledge Assets (CKA)	R&D, Functional Managers (= business process owners)
4. Resourcing and charting	Resource Acquisition Plan (RAP)	R&D, Business Intelligence; HRM

During workshops, charts and diagrams can be created using whiteboards, flipcharts, or specific ICT tools for roadmapping, such as Fibery, Productboard, Miro, and more. These exercises help better understand both internal and external markets, business drivers, and knowledge management. To ensure transparency and avoid frustration, guiding all participants throughout the workshop process is essential. The first driver recognition workshop may involve outside stakeholders like business consultants or strategic advisors. The structured approach presented in the table helps companies to navigate the complexities of strategic planning systematically. This approach allows them to create a roadmap that aligns with their objectives and goals while fostering agility and adaptability in response to internal and external dynamics that may change over time. This approach enables companies to plan strategically and respond to changes effectively.

4. Conclusions

The research question set in the beginning of the study was: *"How can the current tools of science, technology, competency and product roadmapping be further improved to better facilitate strategic and dynamic knowledge management?"*

With the exploratory research approach that aimed at creating a new framework to be tested and implemented later, this paper offers an enlargement of the pre-existing frameworks of technology roadmapping, competence and knowledge mapping. The framework is the theoretical contribution of the study. Certain elements and principles of the earlier frameworks, such as the time-boundness of the framework elements, layered structure, and the role of technologies (enablers) and internal/external drivers (change agents) and resourcing layer, were kept intact. In addition to these, the model introduced layers of Business Process Excellence and Critical Knowledge Assets. On top of the framework, the paper introduces a proposal for a process consisting of a series of workshops that will yield the framework content and a full-scale knowledge roadmap to fit the company strategy and changing operation environment. The process consisting of workshops that will yield company-level understanding of the "big picture" of knowledge management needs connected with other areas of planning is the practical contribution of the paper.

5. Discussion

Operational excellence and strategy are essential for the firm's long-term success. The Knowledge roadmapping framework helps to consider all the essential diverse elements systematically. Systematic and dynamic knowledge management can be spread across a firm's business functions and stakeholders via roadmapping. Operational excellence can be supported and developed via a systematic knowledge roadmapping process and parallel the strategic alignment of knowledge management can be established. The proposed Knowledge roadmapping framework and the process can be reflected against Zack's (1999) framework which discusses the areas of knowledge presented in Table n. With the Knowledge roadmapping framework, we can better consider the questions "knowing why, what, when, where, how, and who?".

Table 3: Knowledge roadmapping framework in reflection to Zack's knowledge framework

Knowing is made of…	Layers involved in the Knowledge Roadmap framework
Knowing WHY	External Drivers (ED), Internal Drivers (ID)
Knowing WHAT	Product and Service Offerings (PSO), Critical Knowledge Assets (CKA)
Knowing WHEN	External Drivers (ED), Internal Drivers (ID), (Resource Acquisition Plan (RAP))
Knowing WHERE	External Drivers (ED), Internal Drivers (ID), Product and Service Offerings (PSO)
Knowing HOW	Technology Areas (TA), Business Process Excellence (BPE), Critical Knowledge Assets (CKA)
Knowing WHO	Critical Knowledge Assets (CKA) and Resource Acquisition Plan (RAP)

Our conceptual paper introduces a blueprint for a new framework and process for Knowledge Roadmapping. Future research could study the implementation of the Knowledge roadmapping framework in different business contexts. A longitudinal, in-depth analysis of the outcomes of a knowledge roadmapping process would illuminate the actual outcomes.

Interplay Between Knowledge Management and Digital Transformation: Designing Solutions

Šarūnas Savickas and Lina Užienė
Kaunas University of Technology, Kaunas, Lithuania

sarunas.savickas@ktu.edu
lina.uziene@ktu.lt

Abstract: This paper explores the overlap between Knowledge Management and Digital Transformation, emphasizing their complementary nature and the necessity of integrated frameworks to maximize their synergistic potential. By reviewing various models and frameworks of the Knowledge Management and Digital Transformation interplay, it highlights gaps in current research, particularly in addressing the complex nature of the interplay, and proposes a comprehensive and novel conceptual framework to fill these gaps. The proposed framework includes core foundations of technology, people, culture and organization, a comprehensive list of risks and challenges, as well as actionable collection of synergistic solutions, offering both theoretical contributions and practical guidelines for organizations. The goal of the framework is to create a comprehensive approach to fully integrate Knowledge Management and Digital Transformation, aiming to maximize their synergistic impact. By bridging the gaps identified in current literature, levering overlap of both concepts and their unique dimensions, the novelty of the developed conceptual framework derives from the solution-focused approach, and it acts both as a foundation for future academic research and provides practical guidelines for organizations, which would enable a more strategic and holistic Digital Transformation and Knowledge Management integration and transformational journey towards Industry 5.0.

Keywords: Knowledge Management, Digital Transformation, Interplay, Framework

1. Introduction

As industries begin shifting from Industry 4.0 to Industry 5.0, Artificial Intelligence and other digital technologies are becoming more accessible and rapidly evolving, the synergy between Knowledge Management and Digital Transformation becomes a critical capability, that can drive synergistic value creation, innovation, and competitive advantage. Therefore, it is critical to review and understand areas of overlap and how these two concepts support each other, so that maximum synergy and value can be achieved.

Digital Transformation (DT) is a radical, continuous change, on all levels of an organization, which is triggered and supported by digital technologies, with the goal of creating new efficiencies, customer, and stakeholder value, across the whole value chain (Vial, 2019; Ahlskog et al 2022). The organizational change covers more than just the processes of the organization, according to Vial (2019), it can also be broken down into four main categories, and specific focus areas in each of them:

- Organizational structure – enable cross-functional collaboration, organizational agility, and ambidexterity.
- Organizational culture – embrace agile practices, innovation, entrepreneurship, to increase the value generation of DT.
- Leadership – cultivate a DT mindset and respond effectively to disruptions.
- Employee roles and skills – adapt to new roles and responsibilities brought by DT, focus on upskilling or reskilling to succeed in the evolving environment.

DT, creates a highly dynamic environment for organizations, making knowledge creation and efficient processing crucial (Nonaka, 1994), which necessitates efficient management of all knowledge processes within the organization.

Knowledge Management (KM), similarly to DT, is a continuous process, involving all organizational activities and dimensions, used to capture, store, manage and apply knowledge assets of the organization, with the goal of creating new organizational value and reach the objectives of an organization (Quintas, Lefrere, & Jones, 1997; Hilger & Wahl, 2022). In academic literature, there are usually four main KM processes identified (Alavi & Leidner, 2001; Ode & Ayavoo, 2020):

- Knowledge Creation – Involves identifying, creating, and acquiring internal and external knowledge.
- Knowledge Storage – Encompasses effective categorization, enhancement, storage, and continuous maintenance of knowledge.
- Knowledge Transfer or Sharing – Disseminates collected knowledge internally and externally.

- Knowledge Application – using knowledge to gain a competitive advantage, solve challenges, boost innovation, and create business value.

One of the main interaction points between KM and DT, are Knowledge Management Systems (KMS), which are systems and technologies, that support KM processes through coding and sharing of knowledge, creation of organizational knowledge directory and creation of both internal and external knowledge networks (Alavi & Leidner, 2001). Implementation of these systems, according to Purwadi & Sardjono (2024), requires organizations to focus on more than just the technology itself, but also on other key elements:

- Organizational agility – engage and motivate employees, enable decentralized decision-making, ensure leadership support, and foster a collaborative culture.
- Knowledge infrastructure – develop a flexible and reliable IT infrastructure that will support KMS.
- Knowledge empowerment – Align KMS strategy with business goals, onboard or empower talent, provide incentives for KMS use, offer upskilling and training, and create a trust-based environment.

These focus areas are closely connected to the organizational shifts occurring in DT, as summarized by Vial (2019), therefore KMS acts as a mediator between KM and DT, strengthening the relationship and improving the innovation capabilities of the organization (Sánchez Ramírez et al, 2022). DT provides tools and platforms, while KM ensures that the right information is effectively utilized to drive innovation, collaboration, and overall organizational success. More specifically, the changes that I4.0, and by extension DT, adoption brings, enhances the potential of KM, promoting both process and product innovation through knowledge acquisition from internal and external partners (Tortorella et al., 2022). Moreover, successful DT cannot be achieved without proper KM, as it is essential for identifying the needs, basis, and priorities of DT (Erceg & Zoranović, 2022). Synergy between DT and KM directly and indirectly enhances organizational performance, leading to sustainable competitive advantage and increased innovation. The competitive advantage of an organization is directly influenced by the usage of digital technology, as well as the overall commitment to DT and KM (Cardoso et al., 2023). Committing to KM, also facilitates Organizational Learning (OL), which further boosts long-term, sustainable, people-focused, competitive advantage (Anshari & Hamdan, 2022). This integration of digital technology, KM and OL practices, not only boosts competitiveness, but also helps drive DT by improving the innovation performance of an organization and enabling the creation of new products and services (Cheng et al., 2023).

Therefore, researching and understanding the interactions between the processes of KM and DT is highly valuable, offering both practical and academic benefits. Advancing research in this field prepares it for the inevitable and continuous impact of modern technologies, such as Generative AI, and the overall shift towards Industry 5.0, while also provides practical applicability – developing integrated synergetic implementation frameworks can aid leaders in making better decisions when driving DT and KM initiatives.

2. Theoretical Background

The following chapter examines various selected studies that attempt to either build new KM and DT frameworks, or compare already existing ones, the research type, findings, and limitations identified by the authors are summarized in Table 1.

A comparative analysis of different KM models, in the context of DT was done by Tinz, Tinz, & Zander (2019), who found that new challenges introduced by I4.0, are not widely addressed by the current models. Conceptual framework by Seng Cheong & Cheng Ling (2020), only focused on external knowledge, knowledge protection and mobility, and innovation capability and manufacturing performance as the outcomes, missing other potential interactions and solutions. Evans & Price (2020), based on their interviews with 72 C level executives, about information and knowledge asset management supported by DT, created a conceptual Holistic Information Asset Management model, that also supports DT, but it solely focuses on knowledge asset management, and validation of the model in practice is needed. Another conceptual, not empirically evaluated, model was developed by Dovleac, Ionica, & Leba (2021), that integrates Agile processes, together with the concept of Quality 4.0, enabled by I4.0 and in synergy with KM processes. Silvia, Santos & Souza (2021), integrated the knowledge conversion model of Nonaka (1994), together with I4.0 principles, to develop both a theoretical relationship and diagnostic model, though it also needs to be evaluated in practice and expanded with more KM and I4.0 practices and dimensions. Framework by Anshari & Hamdan (2022) focused on the skills and competencies required in the context of KM, Organizational Learning (OL) and I4.0, but is also missing empirical validation, and requires more thorough analysis.

Table 1: Research papers conceptualizing or analysing KM and DT integration frameworks.

Authors, Year	Research type, context	Findings	Limitations, future research
Tinz, Tinz, & Zander, 2019	Comparative analysis of KM models in the context of DT and I4.0.	I4.0 introduces new challenges such as human-machine, machine-machine interactions, and data protection. Current KM models do not widely address these challenges.	Future KM models need to include the new challenges and interactions in I4.0.
Seng Cheong & Cheng Ling, 2020	Conceptual paper that builds a conceptual framework of interplay between KM, innovation capability and manufacturing performance in the context of I4.0.	Conceptual framework, which connects external knowledge sourcing, knowledge mobility, knowledge protection, innovation capability and manufacturing performance.	Requires empirical validation.
Evans & Price, 2020	Longitudinal qualitative research - interviews with 72 C level executives and board members on information asset management and how it supports DT.	A conceptual Holistic Information Asset Management model, which supports DT by focusing on benefits, environment, leadership, information systems, behaviour, attributes, quality, performance, and justification.	Validation of the model is needed in practice.
Dovleac, Ionica, & Leba, 2021	Conceptual paper that integrates I4.0, KM, Agile and Quality management practices into a single framework.	Developed an Agile based framework, to implement Quality 4.0, an I4.0 based approach to quality management, in synergy with KM processes.	Models needs to be empirically tested, using knowledge graphs.
Silvia, Santos & Souza, 2021	Systematic literature review to identify how SECI model applies to DT and principles of I4.0.	Developed a theoretical relationship and diagnostic model between I4.0 principles, tacit and explicit knowledge, as well as the SECI modes of knowledge conversion.	Needs deeper understanding of other I4.0 principles, KM dimensions and its impact on management practices during DT. Model lacks empirical testing.
Anshari & Hamdan, 2022	Literature review and focus group to identify critical new skills and capabilities that KM can build for success in I4.0.	KM can improve organizations learning strategy, allow to build a sustainable competitive advantage quicker, upskill and re-skill employees, and in the context of I4.0, focuses on three dimensions – people, process, and technology.	Larger scope for literature analysis, test proposed models to develop KM strategies, use a case study approach

The selected papers reveal that, despite active research in the field of KM and DT interplay, there is a lack of in-depth frameworks that fully explore the interplay between these processes, including the foundations, risks, and possible synergistic solutions. KM should be studied as an overarching organizational concept, but such studies, especially those focusing on practical applications, are currently scarce (Wolf & Erfurth, 2019). Tinz, Tinz, & Zander (2019) reviewed five different knowledge management frameworks, in the context of KM challenges that can be found in smart factories – knowledge identification, development, exchange, use, preservation, evaluation, data protection and human-machine and machine-machine interactions. They found that existing models only partially address these challenges, particularly human-machine interactions, and data privacy, while future models should incorporate OL culture and address the challenges of I4.0. OL is critical in the KM and DT research field, as evident from studies on upskilling and reskilling, ignoring this integral aspect creates significant research gaps. Model developed by Anshari & Hamdan (2022) includes the human-machine and machine-machine interactions and OL, though focuses strictly on employee upskilling, missing other KM and DT interplay aspects, such as organizational strategy, culture, and specific technology dimensions. The SECI-based model by

Silvia, Santos & Souza (2021) specifically addresses tacit knowledge integration but lacks a deeper understanding of other I4.0 principles and the application of technology or KMS dimensions.

The selected research papers, highlight significant gaps in the current research on the interplay between KM and DT, emphasizing the need for comprehensive frameworks that address foundational aspects, risks, and synergistic solutions. Available models are only partially addressing challenges and interactions between KM and DT, miss critical elements such as OL (Tinz, Tinz, & Zander, 2019) or application of technology (Silvia, Santos & Souza, 2021) are highly focused on a specific element of the interaction (Anshari & Hamdan, 2022). This creates a need to develop a conceptual framework, which would fully explore the interplay between KM and DT, incorporate broad aspects of the interaction, including organizational, cultural, technological, and people-related aspects, and provide a comprehensive list of actionable solutions stemming from the interplay.

3. Conceptual Model

The conceptual model presented in the following chapter is founded on the premise that KM and DT are complementary processes – both are continuous and encompass all organizational levels, activities, and dimensions, with a common objective to generate new organizational value in accordance with the specific goals of the organization. This cyclical and complimentary relationship is the first element of the conceptual model. Due to the identified research gaps, the model also incorporates the common core foundations, shared challenges, and risks, as well as the possible synergistic solutions. The risks and synergistic solutions are not depicted having a one-to-one relationship, due to the processes being closely interconnected, and one solution can potentially affect multiple risks or dimensions of the KM and DT synergy. This creates an integrated, cyclical, conceptual model, which reviews multiple dimensions of interaction between KM and DT, their impact on an organization, and suggests a concrete list of possible synergistic solutions that would drive the interplay of KM and DT forward.

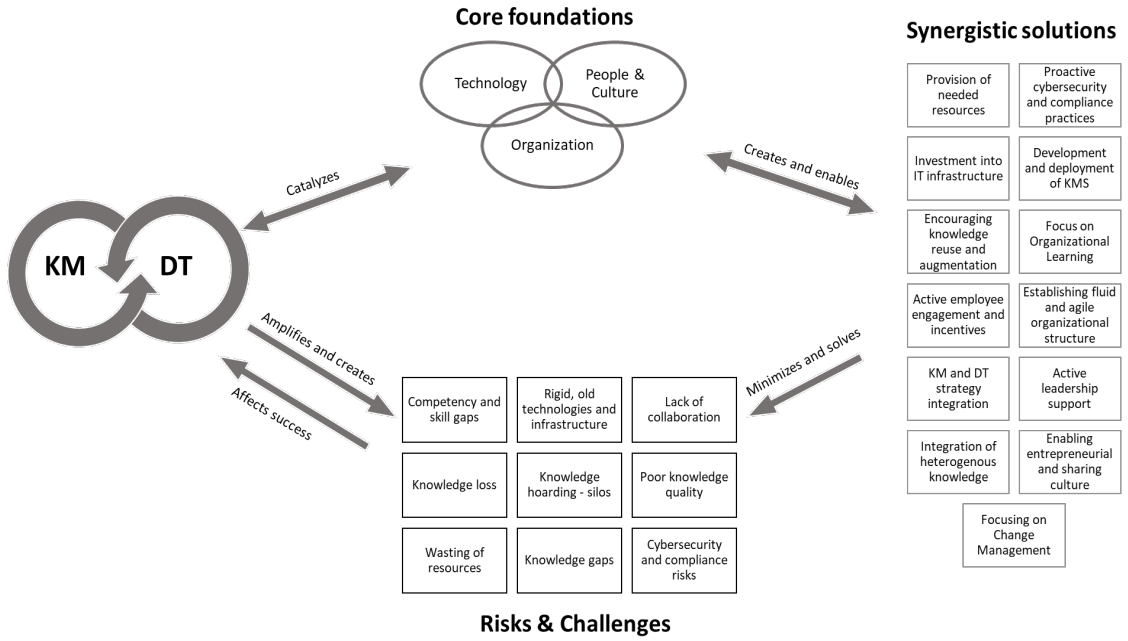

Figure 1: Conceptual model of KM and DT interplay

3.1 Core Foundations

Second group of elements in the conceptual model, are the core foundations that are common between KM and DT processes, and in their intersection become even more critical – Technology, People & Culture and Organization.

Technology is a key element of DT as evident from the various definitions presented in the literature – it can be both a trigger for DT, and its enabler (Vial, 2019; Warner & Wäger, 2019). In the context of KM, the key technological enablers can be summarized under the term KMS, which can be viewed as an extension of other various technologies used in DT, it can also help transform gathered information into knowledge. Implementing

a KMS, similarly, to implementing any other digital technology, becomes a DT project and requires focus on the key areas of implementation of the actual technology, leadership and strategy alignment, cultural and process changes, as well as organizational context, needs and available resources (Maramba & Smuts, 2020). Therefore, Technology becomes a core concept in both DT and KM fields, which can be a trigger and an enabler at the same time.

Second required core foundation are the People and Culture, namely – the culture of knowledge sharing, entrepreneurship, and human centricity. DT requires a culture, which embraces change, takes on risks, allows learning through failures and pilot projects (Abdallah, Shehab, & Al-Ashaab, 2021; Vogelsang et al, 2018). This constant innovation and experimentation, creates a knowledge-rich environment, in order to reap all its benefits and use the generated knowledge effectively, a knowledge friendly culture of sharing and trust is also required, which will in turn empower more learning, pilot projects and technology adoption (Gupta et al, 2022). People, their skills and knowledge, are the critical resource in the success of DT initiatives, and organizations should start their transformation from the changes of the people, culture, and organization, instead of technology (Kane, 2019). This creates a human-centric approach, and companies that can combine human resource management with KM, through diversity, inclusion and people empowerment policies can improve their organizational performance as well (Cillo et al, 2021).

The third overarching foundation is the Organization, which includes its strategy, processes, leadership, structure, and the environment it operates in. DT must be recognized as an integral part of the overall business strategy, closely integrating DT strategy with the business's broader strategy (Ubiparipović et al., 2020), which requires alignment with the organization's unique situation, environment, and capabilities. A similar approach is needed for KM, where its strategy should also align with business goals and fit the unique internal and external environment (Gupta et al., 2022). Due to the complexity of technologies and the new dependencies and relationships DT creates, organizations need a common KM and DT strategy to maintain control over these processes (Wolf & Erfurth, 2019). It is primarily the role of senior management or leadership to develop these strategies, provide resources, engage and empower employees to use them, and enhance the flexibility of organizational structures (Gupta et al., 2022). Another crucial element of the Organization foundation is how well it adapts to the changes of the environment. Organizations that integrate KM strategically, can leverage dynamic capabilities to anticipate and adapt to market shifts, build effective relationships with suppliers and customers, and efficiently allocate resources (Wessam & Nermin, 2023). In summary, the Organization foundation encompasses strategy, structure, leadership, processes, and adaptability to the internal and external environment, serving as a critical enabler in both KM and DT, and it becomes critically important in its intersection.

3.2 Risk & Challenges

Third group of elements are the various risks and challenges, which are either common to KM and DT, or is more pronounced in one of the processes, but their interplay amplifies and highlights these issues.

These risks affect the success of the interplay between KM and DT, as well as the implementation of the required capabilities and their efficiency. Most of the risks have a stronger or lesser impact on all the core foundations, yet certain risks are more pronounced than the others. Challenges were identified in the conceptual model are summarized in Table 2:

Table 2: Risks and challenges of KM and DT interplay.

Risks & Challenges	Description
Competency and skill gaps	Covers the risks of not having required training, competencies, or skills to effectively participate in KM and DT activities. Having employees who have the required skills and competencies is a critical success factor for DT (Ubiparipović et al, 2020) and for KM.
Rigid, outdated technology and IT infrastructure	One of the critical barriers of modern technology integration and DT, which can also stop development of effective KMS (Gupta et al, 2022; Ubiparipović et al, 2020). Heterogenous systems are also found to be a major barrier for Industry 5.0 implementation (Leng et al., 2022).
Lack of collaboration	DT is a knowledge-intensive process requiring collaboration among employees with diverse expertise across complex projects (Vogelsang et al., 2018). Extending collaboration

Risks & Challenges	Description
	beyond organizational boundaries allows partners to work as experts, focusing more effectively on specific areas of innovation and DT (Ubiparipović et al., 2020).
Knowledge loss	Retention of critical knowledge is a focus area in KM research – loss of such, mostly tacit, knowledge, can lead to business continuity risks (Nakash & Bouhnik, 2020). Knowledge loss happens due to multiple distinct reasons – employee attrition, intentional and unintentional forgetting, or unlearning.
Knowledge hoarding or silos	Closely related to the risk of knowledge loss is the creation of knowledge silos, as attempts to prevent loss can lead to dependency on a few employees who hoard knowledge (Nakash & Bouhnik, 2020). Additionally, the lack of collaboration and cross-functional cooperation can foster a competitive and mistrustful culture, posing significant challenges to DT efforts (Brink, Packmohr, & Paul, 2022).
Poor data, information, and knowledge quality	For a successful DT, correct data needs to be provided to the right user, available real-time and cover many different aspects and alternatives (Vogelsang et al, 2018), knowledge that comes from a variety of sources, is structured, mapped, and high quality, are some of the KM Critical Success Factors (CSF) (Onofre & Teixeira, 2022).
Wasting of resources	Inefficient usage of knowledge, technology, or knowledge gaps, can lead to duplication of work, and thus – wastage of resources, such as labour, machine, time, or monetary resources (Gupta et al, 2022).
Knowledge gaps	Because DT transforms the entire organization, it demands extensive organizational knowledge. If the IT department understands digitization but lacks insight into other functions' processes and needs, it creates a knowledge gap that hinders effective DT implementation (Brink, Packmohr, & Paul, 2022). Additionally, Industry 5.0 requires diverse technological knowledge to reorganize the manufacturing value chain (Leng et al., 2022).
Poor cybersecurity and compliance	Due to the integration of modern technologies, external partnerships, intentional and unintentional knowledge loss risks, cybersecurity and overall compliance to standards and policies becomes a critical organizational risk (Hammoda & Durst, 2022; Schnasse, Menzefricke, & Dumitrescu, 2021). Additionally, human-centric approach of Industry 5.0, generates vast amounts of sensitive, human-related information, security of which, becomes even more critical (Leng et al., 2022).

3.3 Synergistic Solutions

The main goal of this article is to provide a comprehensive list of synergistic solutions that arise from the interplay of KM and DT and helps minimize or completely remove the identified challenges. These are the more specific solutions and focus areas, which can also be a part of or enable the needed capabilities, and in the interplay of KM and DT, these solutions can gain even more importance, thereby simplifying the decisions to implement them. The identified synergistic solutions are summarized in Table 3:

Table 3: Synergistic solutions of KM and DT interplay.

Synergistic solutions	Description
Provision of needed resources	Identify and provide necessary time, material, and human resources for KM and DT, ensuring employee engagement through rewards and appropriate allocations.
Proactive cybersecurity and compliance requirements	Implement concrete cybersecurity policies and address emerging risks to control and minimize knowledge loss and leaks (Ubiparipović, et al 2020)
Investment into IT infrastructure	Invest in IT infrastructure and update outdated systems to create a solid technological foundation for DT and KM (Gupta et al, 2022).

Synergistic solutions	Description
Development and deployment of KMS	KMS enhance KM processes with advanced digital technologies like AI and automation, improving knowledge creation, sharing, application, and reuse (Gupta et al, 2022). While KMS can support every KM process, its success in knowledge application, reuse, and augmentation depends on employee engagement (Shrestha & Saratchandra, 2023). Specifically, AI-enabled KMS can simplify knowledge delivery, improve personalization and reach, and make knowledge available in real-time for quicker decision-making (Taherdoost & Madanchian, 2023).
Encouraging knowledge reuse and augmentation	Prevent duplication by improving knowledge quality and encouraging reuse and active augmentation (Nakash & Bouhnik, 2020).
Facilitating OL	Promote a culture of learning and knowledge sharing to address skill gaps and enhance organizational effectiveness, particularly with I4.0 technologies (Tortorella et al., 2022). Life-long learning of employees, is also a critical requirement to achieve the human-centric and sustainable goals of Industry 5.0 transition (Leng et al., 2022).
Fluid and agile organizational structure	Organizations cannot successfully manage DT with the old, static hierarchical structures, and should become more flexible, open, and quickly adapt to changes by adapting their organizational model as well (Smith & Beretta, 2020).
Active leadership promotion	Leaders should inspire, support, and promote KM and DT initiatives, fostering a culture of trust and learning, create more robust, integrated strategies and lay the required foundations for organizational and cultural changes required (Inkinen, 2016; Mazorodze & Buckley, 2019).
KM and DT strategy integration	Concrete steps must be taken to integrate the KM and DT together and into the organizational strategy, then cascade it down to functional leaders and strategies, to make sure there is a common vison in the organization (Mathew & Rodrigues, 2019; Mielli & Bulanda, 2019).
Active employee engagement and incentives	A properly motivated employee, through incentives or gamification of KMS, can help ensure a high quality of knowledge within the KMS, and help build the knowledge sharing culture (Friedrich et al, 2020).
Enabling entrepreneurial and sharing culture	Foster collaboration, trust, and experimentation to support an entrepreneurial and knowledge-sharing culture (Vogelsang et al, 2018; Gupta et al, 2022)
Integration of heterogeneous knowledge	DT increases the heterogeneity of knowledge that is required for a successful transformation, and at the same time, it creates a highly heterogenous knowledge (Yoo et al, 2012). Develop methods and strategies to manage diverse knowledge assets, addressing collaboration, knowledge loss, and hoarding challenges.
Focusing on Change Management	Lack of change management can lead to DT project failures (Brink, Packmohr, & Paul, 2022). KM strategies like personalization, codification, and organizational learning (OL) can boost readiness for change and reduce organizational cynicism, aiding project implementation (Imran et al, 2016).

4. Discussion

The proposed conceptual framework of KM and DT interplay addresses multiple limitations and future research directions identified by other models, frameworks, and research of KM and DT interplay. First, as suggested by Wolf & Erfurth (2019), it addresses both KM and DT as overarching organizational concepts with a focus on practical solutions of the interplay. The suggested framework also incorporates OL, knowledge sharing, upskilling and reskilling challenges raising from the human-machine interactions, data security and privacy risks, all of which were suggested by Tinz, Tinz, & Zander (2019) as critical missing elements of the current frameworks. The technological and strategy dimensions not considered in the frameworks developed by Anshari & Hamdan (2022) and Silvia, Santos & Souza (2021), are included as the core foundations, and their specific elements are identified as both the risks and synergistic solutions.

Every organization has a unique set of variables – internal and external environment, set of strategies, weaknesses and opportunities, which also creates a unique environment for both KM and DT (Gupta et al 2022; Ubiparipović et al 2020), the size of the company, maturity, industry and organization type, all have an impact on the technology adoption and KM activities of the company as well (Wessam & Nermin, 2023). This complexity and uniqueness of every organization, suggests that the KM and DT integration frameworks, also need to be flexible and address the complexities of different industries and organizations, by addressing the specific solutions and risks in the context of organizations of different sizes, maturity levels, industries, and geographical locations.

To advance the integration of KM and DT, it is essential to link these findings with broader academic research and practical implications. The proposed framework highlights the synergy between KM and DT, focusing on specific solutions from this interplay and acknowledging the challenges in diverse organizational settings. This is crucial as it reflects the difficulties highlighted in the literature concerning DT efforts, especially in aligning technological advancements with human-centric approaches (Kane, 2019; Vial, 2019). As KM and DT are dynamic and continually evolving, the framework must also adapt to ongoing technological changes and align with dynamic capabilities theory (Warner & Wäger, 2019). It should ensure efficient use of technologies in KM processes, remain relevant in guiding organizations to Industry 5.0, and address the associated technological and socio-economic challenges (Leng et al., 2022).

Filling in the theoretical gaps of academic research is a strong foundation for the proposed conceptual model, but to gain more in-depth, nuanced knowledge, and for the model to stay both academically and practically relevant, it needs to be empirically validated, remain flexible and change together with the KM and DT concepts.

5. Conclusion

This paper explores the relationship between Knowledge Management (KM) and Digital Transformation (DT), emphasizing how their integration can drive innovation and competitive advantage from Industry 4.0 to Industry 5.0. By examining various frameworks, the study highlights gaps in the current literature and models, particularly in fully integrating KM and DT. These gaps underscore the fragmented approach to tackling the challenges and opportunities of KM and DT interaction.

Theoretically, this paper contributes to the literature by proposing a novel, conceptual, framework that connects the risks, challenges, foundations, and synergistic solutions stemming from the interplay between KM and DT. Because there is a lack of similar frameworks, it can serve as a foundation for future academic research and help build more integrated, cross-functional, and solution-oriented frameworks.

In practice, the developed framework serves as a guide to help practitioners understand the risks and potential synergistic solutions created by the interplay of KM and DT. The framework's foundational elements offer general guidance, while the risks and challenges section provides a detailed list of obstacles that could prevent organizations from realizing the full value of KM and DT, necessitating leadership attention. The synergistic solutions section offers a comprehensive set of focus areas and actionable strategies that, with sufficient resources and support, can help mitigate risks and guide organizations more effectively through their transformational journeys.

Despite its contributions, this study has limitations, primarily because it designs and examines a conceptual framework. Future research should empirically validate and adapt this framework across various industries, organizational and DT maturity levels, and cultural contexts. Such research could tailor the framework to unique environments and deepen understanding of specific parameters that organizations need to address. This would enhance the framework's practical applicability and its ability to create synergistic value from the interplay between KM and DT.

In conclusion, as businesses continue to evolve in a digitally interconnected environment of constant change, understanding the nuanced relationship between KM and DT becomes critical. This paper sets the stage for further research and practical implementations that could potentially reshape how organizations leverage knowledge to achieve sustained innovation and competitive advantage.

Balancing Trust and Surveillance in Hybrid Work: Insights from a Pilot Study on Workplace Monitoring

Veronica Sbalzer, Gayatri Sudarshan Shetty and Kathrin Kirchner
Technical University of Denmark, Ballerup, Denmark

gayatrishetty99@gmail.com
kakir@dtu.dk

Abstract: Many knowledge workers have shifted to work hybrid by being partly in the office and partly at remote locations. This brings freedom for knowledge workers, but managers are concerned about the performance of their workforce when they are not working from the office. One means to check performance constantly is by collecting and analyzing performance and behavior data to monitor employees, which is a form of algorithmic control. On the one hand, this can lead to conflicts between employees and managers as employees feel that managers mistrust them. On the other hand, employees might trust transparent monitoring that helps them focus on core tasks. To learn more about balancing trust and surveillance, this pilot study surveyed 45 knowledge workers in an engineering company in Denmark, a country with high levels of trust in society. We developed an online survey to investigate managers' and employees' opinions about workplace monitoring. We found that all participants had a negative to neutral attitude toward monitoring, although managers were slightly more favorable. Furthermore, data collection for work-related purposes to improve the work situation might be appropriate, although a trustful relationship between managers and employees is the most important. Thus, if a form of monitoring is going to be introduced at the workplace, it is essential that all stakeholders – managers, employees, HR, and union representatives – are involved and that complete transparency is achieved in terms of which data is collected and for which purposes. Only then can a balance between trust and surveillance be achieved, including maintaining a positive working climate.

Keywords: Hybrid Knowledge Work; Workplace Monitoring, Algorithmic Control, Trust

1. Introduction

In recent years, a transformation of work practices has been underway, where knowledge workers work partly from the office and partly from anywhere, allowing greater flexibility but continuing the collaboration with fellow knowledge workers at the office. As organizations transition towards a more structured system of hybrid work arrangements, there is a concern about workers' performance when they are not visible in the office. On the one hand, working from home can help workers solve their work-life conflicts, which leads to higher job satisfaction and, thus, higher performance (Naqshbandi et al., 2023). On the other hand, working from home can cross the line between work and family life and thus lead to lower performance (Wöhrmann & Ebner, 2021) or does not improve performance as the family might disrupt the work or people feel isolated (De Valdenebro Campo et al., 2021).

From a managerial perspective, working from home or anywhere has consistently raised concerns surrounding the potential loss of managerial control (Eurofound, 2020). Implementing worker monitoring practices seems like a cost-effective solution to address these concerns (Ball, 2021). Monitoring is observing and tracking employees' activities, primarily during remote work (Ball, 2010). Such monitoring technologies encompass a wide range of tools and methodologies, including but not limited to keystroke logging, tracking online search histories, and the use of digital surveillance systems (Eurofound, 2020). In 2020, the global demand for employee monitoring software was growing, with a 108% increase in April and a 70% rise in May compared to figures from 2019 (Brown, 2020). Research suggests that a significant proportion of employers have already integrated such monitoring tools into their companies: A US study found that almost 80% of employers reported using employee monitoring software to track performance and online activity among remote employees. Similarly, Gartner research indicates that the global adoption of tracking tools will increase from 60% registered at the beginning of the pandemic to 70% within the next three years (Hickok & Maslej, 2023). This is also confirmed by a Danish survey, which indicates that 63% of employees experience workplace monitoring with data collection (The Danish Society of Engineers, IDA, 2024). The case of Denmark is especially interesting, as the country scores high in trust in society and at the workplace (OECD, 2020), which might also relate to the hybrid work situation. Although Danish managers might be interested in learning more about their workers' performance when working outside the office, monitoring them would raise mistrust. Furthermore, following the European GDPR, options for workplace monitoring are limited and should not break into workers' privacy at home.

Managers seek ways to monitor their workforce effectively, which can lead to tensions between employees and management. Understanding the different attitudes of employees and managers towards workplace monitoring is therefore essential before extensive monitoring is introduced. Based on a survey among knowledge workers and their managers in a Danish Engineering company, this study aims to answer the following two research questions:

1. Do employees and their managers perceive workplace monitoring differently?
2. What data types do remote employees consider acceptable for sharing within the context of monitoring?

2. Literature Background

2.1 Monitoring as Algorithmic Control at the Workplace

Artificial intelligence increasingly influences people's work and thus also influences human resource management by relying on data and algorithms for managerial decisions (Parent-Rocheleau & Parker, 2022). This algorithmic management is the "large-scale collection and use of data to develop and improve learning algorithms that carry out coordination and control functions traditionally performed by managers" (Möhlmann et al., 2021, p. 2005). Algorithmic management, as a part of Artificial Intelligence techniques, has been conceptualized in algorithmic control and algorithmic matching (Möhlmann et al., 2021). Kellog et al. (2020) discuss six different forms of algorithmic control, one of which is algorithmic recording (or monitoring), where any data on employees is collected and analyzed during their work. Algorithmic management is often discussed in a gig work context but also exists in traditional work settings (Lippert et al., 2023).

Worker monitoring in companies is not a new idea, as it can be traced back to U.S. history from the early to mid-19th century. The introduction of structured shifts, production quotas, and strict timekeeping created a more regulated work environment than prior labor practices. This necessitated increased supervision to ensure productivity and efficiency, which prompted the beginning of worker monitoring (Hickok & Maslej, 2023). While tools like time clocks or cameras were historically used for monitoring performance, digitalization of many knowledge workers' tasks, electronic data collection, and analytics allow for measuring performance and the workers' behavior. Through systematic digital behavior analysis, these tools provide insights into individual and collective behaviors, unravel work patterns, and identify key contributors to overall productivity. Several tools are already available on the market, e.g., Prodoscore, which collects metrics about the utilization of tools, internal collaboration, and workload for activity analysis and performance measurement (Prodoscore, n.d.). Another tool is Teramind, which tracks keystrokes, website, and application usage and assesses files to detect threads and monitor productivity and compliance (Teramind, n.d.).

Policies and guidelines governing employee monitoring, when primarily aligned with the interests of the employer rather than the employees, can trigger privacy concerns (Chang et al., 2015). In general, employers do not need employees' consent for various forms of monitoring if it is based on the legitimate legal interest of the employer. Employers must follow GDPR principles when handling personal data during monitoring, ensuring lawful and transparent data processing, accuracy, limited data retention, security, and being accountable for compliance.

Jeske (2022) identified two purposes for monitoring workers: (1) Employees can only be trusted to work in the company's best interest when visible in the office. This can lead to resistance from employees toward monitoring, and thus, poorer performance and conflicts between employers and employees. (2) Monitoring allows employees to get an overview of the current performance and helps them to focus better on core tasks. This higher transparency can lead to trust among employees, especially if they are involved in the design of the monitoring systems.

Vitak and Zimmer (2023) found from a survey among U.S. adults that the acceptability of workplace surveillance practices is context-dependent and that reductions in privacy and autonomy at work could amplify power imbalances, particularly among vulnerable employees. The authors conclude that some forms of workplace monitoring are justified, such as tracking work-related communication and ensuring security. Nevertheless, they express concerns about the extent of data collection and the proliferation of predictive algorithms that claim to predict hiring, firing, and promotions.

2.2 Workplace Monitoring in Denmark

Understanding how individuals react to the implementation of workplace monitoring is crucial for organizations aiming to foster a positive work environment while embracing technological advancements. Denmark is known for fostering a strong sense of trust in workplaces, and this characteristic plays a crucial role in the country's work culture. The Danish work environment traditionally thrives on mutual trust between employers and employees. This trust is deeply embedded in the social fabric. It is reflected in various aspects of the workplace, such as open communication, collaborative decision-making processes, and a generally flat organizational structure.

A Danish representative questionnaire among managers in Danish workplaces found that digital tools for collecting employee data are widespread in the Danish labor market and that most people have experienced them already (Hald et al., 2024). It reveals a divided landscape, with nearly half of the managers expressing support for data collection while a substantial minority remains skeptical. A key finding of the report underscores the significance of communication and guidelines in fostering trust and a healthy working environment in the context of data ethics. The survey found that managers who openly communicate about collecting employee data with their employees are less likely to damage their relationship with their workforce.

3. Methodology

Data was collected through an online survey in a Danish Engineering company in November/December 2023. The company has a general policy allowing people to work 2-3 days from home, but it is up to the manager to decide based on the specific task they need to perform. They keep track of their tasks via MS TEAMS to ensure transparency and project work if a worker needs to take over another colleague's tasks. The company does not use any digital monitoring tools on the individual level. However, the task performance is measured so that it becomes transparent how much time was spent on a task for project management reasons. This can be used to compare task performance, e.g., between departments, which could lead to additional training or providing better tools to solve tasks.

The survey collected demographic information and answers to 12 questions inspired by the Theory of Planned Behavior regarding attitudes toward surveillance, subjective norms, and perceived behavioral control (see Table 2). The questions used a Likert scale ranging from 1 to 7, where 1='Strongly Disagree' and 7='Strongly Agree.' The questions were analyzed with a T-Test to answer our research question 1 about the different perceptions of managers and employees toward monitoring.

Furthermore, a factorial vignette design was used to answer our second research question, inspired by (Vitak & Zimmer, 2023). This experimental and survey design mix helps investigate judgments in a particular context and under certain conditions (Wallander, 2009). Following this approach, the survey participants had to evaluate different vignettes around workplace monitoring, using the question:

Your company will begin collecting and monitoring employee data through a new company software. [Data collected] may be collected to [purpose of data collection].

Table 1 overviews the two factors and items combined to build the vignettes. The items ranged from reasonable regarding work practices to issues that might be considered highly private. Combining the two factors in Table 1, 64 scenarios would be possible. To keep the answering time for the survey low, every participant got only a randomly assigned set of 32 scenarios for evaluation.

To back up our results and get deeper insights into the participants' perceptions toward monitoring, open questions were included at the end of the survey regarding how workplace monitoring would influence the workplace positively and negatively.

Table 1: Factors and Items for the vignettes, inspired by (Vitak & Zimmer, 2023)

Factor	Nr. of levels	Items
Data collected	8	The average length of your work sessions and the length of the breaks you take during the workday
		Internet usage and website history
		The task completion time and amounts
		Communication logs (emails, chats)

Factor	Nr. of levels	Items
		File and document access history
		The record of all keys typed on your computer and your mouse activity
		Webcam and audio recordings
		Work phone activities
Purpose of data collection	8	Evaluate performance and give individual feedback
		Identify individual training and development needs
		Determine eligibility for promotions and higher compensation
		Ensure compliance with company policies
		Enhance team collaboration and communication
		Ensure healthy working environments
		Improve worker productivity
		Monitor the effectiveness of remote work tools

The participants were asked to rate the appropriateness of each vignette on a 7-point Likert scale, with 1 indicating 'Highly Inappropriate' and 7 representing 'Highly Appropriate'. Every survey participant got 32 scenarios to evaluate. The data is hierarchical, as the participants responded individually, and the responses for multiple scenarios by the same individual are not independent. Given this, Linear Mixed Effects Models (LMMs, (Hox et al., 1991)), especially restricted maximum likelihood (REML), are well-suited for analyzing hierarchical data structures, as they allow for the modeling of both fixed effects (population-level effects) and random effects (individual-level effects). This approach accounted for the correlation among responses from the same individual while treating responses from different individuals as independent.

Forty-five complete answers were collected in the company. From them, 82.2% were male and 17.8% female, with an age range between 24 and 69 (average age 42). 98% were full-time workers, and they came from various departments, but most of them worked in the engineering or the sales and marketing departments, which are classic knowledge workers' areas. Most survey participants have worked for several years in the company, with an average of 18 hours per week from home. One-third (N=15) were managers; the other 30 answers came from employees.

4. Findings

4.1 Different Perceptions of Managers and Employees

As can be seen in Table 2, both managers and employees expressed relatively low scores in the "Attitude toward monitoring" questions, indicating a general skepticism or negative outlook towards the benefits of monitoring for productivity, data confidentiality, and communication with managers (all mean values show negative opinions below the neutral point 4). As for the questions within the "Social norms" category, there is a perceptible shift toward a more positive stance, with scores closer to the neutral point 4 on the scale. In the "Perceived behavioral control" questions, managers and employees exhibit balanced scores, reflecting a more confident perception of their ability to adapt to monitoring tools and maintain effective work-life balance. Significant differences between managers and employees can be only seen in two social norm questions, where managers score significantly higher than employees regarding following the higher-level management's monitoring opinions.

4.2 Vignette Analysis

The first model used LMM on all eight values in the collected data attributes (Table 1). The dependent variable was the "perceived appropriateness". Similar to (Vitak & Zimmer, 2023), the item "communication logs (emails, chats)" was used as constant as it was the attribute with the least privacy concerns. According to the results in Table 3, "Work phone activities" and "task completion time and amounts" have the highest Z-Score and are thus perceived as highly appropriate with a significant p-value (see Table 3). This may be attributed to privacy concerns, a desire for autonomy in online activities, perceived intrusiveness, or potential cultural and organizational factors.

Table 2: Results from the T-Test for managers and employees

Category	Item	Manager Mean (SD)	Employee Mean (SD)	T-value	p-value
Attitude toward monitoring	I believe that remote monitoring of my work enhances my productivity.	2.73 (1.870)	2.33 (1.605)	0.708	0.485 n.s.
	I think remote monitoring is beneficial for maintaining data confidentiality and preventing unauthorized access.	3.00 (1.648)	3.00 (1.597)	0.000	1.0 n.s.
	I feel that remote monitoring respects my privacy and is not intrusive	3.20 (2.042)	2.47 (1.795)	1.181	0.249 n.s.
	I believe that remote work monitoring would contribute to a better performance evaluation.	2.93 (1.792)	2.40 (1.499)	0.992	0.331 n.s.
Subjective norms	I think remote monitoring is a necessary tool for improving communication with my manager.	2.60 (1.805)	2.27 (1.760)	0.589	0.561 n.s.
	I think that my friends, family, and colleagues have influence on my opinions	3.27 (1.831)	3.73 (1.999)	-0.781	0.441 n.s.
	I feel like my decision to support remote monitoring aligns with the expectations of my immediate supervisor.	4.07 (1.668)	2.77 (1.612)	2.493	0.019 *
	I perceive strong social pressure to comply with management's decisions in regard to remote monitoring practices.	3.73 (1.580)	2.63 (1.520)	2.230	0.034 *
Perceived behavioral control	I feel confident in my ability to adapt to remote monitoring tools and processes.	3.93 (1.710)	3.80 (1.864)	0.239	0.813 n.s.
	I feel in control over the way remote monitoring is implemented in my workplace.	4.07 (1.792)	3.70 (1.765)	0.650	0.521 n.s.
	I feel capable of managing my work effectively while being monitored remotely	4.00 (1.890)	3.57 (2.046)	0.705	0.486 n.s.
	I feel confident in my ability to maintain a work-life balance while being remotely monitored.	3.80 (2.077)	3.50 (1.978)	0.464	0.646 n.s.

Table 3: Results for LLM – data collected

Item	Coefficient	Mean (SD)	Z-score	p-value
The average length of your work sessions and the length of the breaks you take during the workday	0.281	0.291 (1.283)	1.283	0.200
Internet usage and website history	0.158	0.171 (0.922)	0.922	0.356
The task completion time and amounts	0.607	0.120 (5.049)	5.049	0.000***
File and document access history	0.249	0.199 (1.251)	1.251	0.211
The record of all keys typed on your computer and your mouse activity	0.562	0.210 (2.678)	2.678	0.007***
Webcam and audio recordings	0.213	0.165 (1.290)	1.290	0.197
Work phone activities	0.913	0.034 (26.570)	26.570	0.000***

In the second model (Table 4), regarding the purpose of data collection, "ensuring compliance with company policies" is used as a constant, following (Vitak & Zimmer, 2023). "Determining eligibility for promotions and higher compensation and "improving worker productivity" gained the highest and significant Z-Scores and are thus considered highly appropriate (Table 4). On the other hand, purposes such as "Monitoring the effectiveness of remote work tools" and "Ensuring healthy working environments" showed lower Z-Scores that were not significant.

Table 4: LLM results for data collection

Item	Coefficient	Mean (SD)	Z-score	p-value
Evaluate performance and give individual feedback	0.627	0.314 (1.999)	1.999	0.046**
Identify individual training and development needs	0.507	0.258 (1.969)	1.969	0.049**
Determine eligibility for promotions and higher compensation	0.701	0.091 (8.054)	8.054	0.000***
Enhance team collaboration and communication	0.617	0.269 (2.297)	2.297	0.022**
Ensure healthy working environments	0.479	0.301 (1.592)	1.592	0.111
Improve worker productivity	0.859	0.113 (7.627)	7.627	0.000***
Monitor the effectiveness of remote work tools	0.309	0.278 (1.113)	1.112	0.266

These differences may stem from the nature of the purposes themselves. Objectives directly related to individual growth and career advancement, like promotions and productivity improvement, may be perceived as inherently aligned with personal and organizational success. In contrast, monitoring tools associated with broader organizational effectiveness or health considerations might introduce more complex perceptions, potentially triggering privacy concerns or uncertainties.
Furthermore, we looked at age, gender, and role (manager, employee). Age (coefficient 6.915, p=0.006***) positively affects the perceived appropriateness. Gender is not significant. Role (coefficient 5.927, p=0.000***) also positively affects perceived appropriateness. The interaction terms are not statistically significant.

4.3 Open Questions for Monitoring and Data Collection

Negative to neutral opinions toward monitoring and data collection were also expressed in the answers to the open questions. Managers expressed that monitoring "*is the same as micromanagement*" and "*…a sign of serious mistrust in employees*" – trust and a good relationship with their employees are vital for the surveyed managers. If monitoring was implemented, it would require "*a lot of transparency and agreed start*." One manager expressed that "*…time and time efforts are not a good monitoring tool*", especially when discussing knowledge work.
Also, the employees mentioned trust as very important, e.g., "*it feels that they do not trust that I do my work." Moreover, "it will damage the trust in the company and management."* and "*this is an invasion of privacy*." Several participants would consider working less from home when monitoring would be introduced or even changing the company. Nevertheless, one employee mentioned that he trusts the company *"…will keep my data safe, that is what we do here*." Another issue is the unique nature of work that the employees do, "*so-called brain work – you can't put a timer on this."* The survey participants mentioned that ideas might be developed in front of the coffee machine, during lunch breaks, or on the way home, and not in front of the computer. Hence, monitoring knowledge work is generally different.

5. Discussion and Conclusion

Our results show that monitoring work was considered negative to neutral among the survey participants. For the first research question regarding the different perspectives toward workplace monitoring, we found that managers always scored higher than employees. However, significant differences could only be found in the subjective norms, as managers agree more that they need to be aligned with their supervisors regarding monitoring. The reason might be that managers consider the benefits this implementation could bring the company. Some advantages are optimization in resource allocation, streamlining workflows, and identifying areas for improvement, ultimately leading to cost savings and improved productivity. From the employees' side, monitoring might negatively affect their performance and job satisfaction and lead to enhanced stress, as discussed in (Siegel et al., 2022). In a high-trust country like Denmark, the concerns toward monitoring may also be rooted in the perceived lack of trust (as employees cannot be trusted when not visible in the office) (Chang et al., 2015), concerns related to privacy (The Danish Society of Engineers, IDA, n.d.), and potential negative consequences associated with the implementation of monitoring tools.

The vignette scenarios addressed the second research question, discovering the acceptability of various data types and purposes for monitoring remote employees' work. "Work phone activities" and "task completion time and amounts" were universally perceived as the most appropriate for monitoring. The latter attribute aligns with the research by (Vitak & Zimmer, 2023). Furthermore, monitoring "task completion" is already regularly

done in our case company as it is crucial for project management. Regarding the purposes of data collection, ”Determining eligibility for promotions or higher compensation” and ”improving worker productivity” were seen as the most appropriate data collection purposes for monitoring, aligning with organizational goals related to career advancement and overall efficiency, as also seen in the Danish survey conducted by (Hald et al., 2024).

The biggest issue with introducing workplace monitoring among managers and employees was the concern about the decrease in trust, which is especially an issue in Denmark as a country of high trust (Sønderskov & Dinesen, 2014). If workplace monitoring should be introduced, it is necessary to balance trust and surveillance and thus include all stakeholders from the beginning – employees, managers, HR, and union representatives. The reason for the monitoring needs to be clear to all, and only acceptable data (e.g., task completions) for acceptable purposes (e.g., ensuring compliance or promotion) should be collected so that it becomes clear who is using data for what. Furthermore, feedback sessions should be introduced to discuss the monitoring and its effects and hear about the employees' concerns. However, as the survey participants expressed, a good relationship between managers and employees is very important, and trust is much better than micromanagement. If monitoring is used to support employees instead of suppressing them, it can even help to increase trust (Jeske, 2022).

This pilot study has limitations, as it included only 45 managers and employees in one Danish Engineering company. This introduces the possibility that those who chose not to participate in the survey might hold different perspectives or experiences than those who responded. This potential bias affected the generalizability of our findings. Furthermore, as the company does not use extensive workplace monitoring, this study could only ask for perceptions toward the influence of monitoring at the workplace. Furthermore, we could not investigate the effect of an already-used tool. In the future, data collection needs to be extended to gain deeper insights into workplace monitoring perceptions.

Knowledge Sharing Techniques in Academic Libraries in Africa: A Perspective from the University of Namibia

Andjengo Anna Shiimi and Madeleine C Fombad
University of South of Africa, South Africa

46726160@mylife.unisa.ac.za
fombamc@unisa.ac.za

Abstract: Knowledge sharing practices in academic libraries is increasingly recognised as a tool for competitive advantage and has become a buzz word for enhancing service delivery in academic libraries in Africa. African scholars are increasing conducting research to establish knowledge sharing strategies in libraries. The International Federation of Library Associations and Institutions reiterates the value of knowledge sharing techniques in academic libraries. Notwithstanding, knowledge sharing practices are still ad hoc and informal. and academic librarians are still grappling with integrating the different knowledge sharing techniques. This article investigates the perceptions of knowledge sharing among university of Namibia library staff to establish the techniques of knowledge sharing. The overall findings reveal that library staff are aware of the various knowledge sharing techniques in academic libraries but are yet to adopt and integrate these techniques. The findings further revealed a preference to technological-based knowledge sharing techniques over human-based or interpersonal knowledge sharing techniques. This article resonates with the findings of most academic libraries in Africa and therefore adds to the body of knowledge on knowledge sharing in academic libraries from an African perspective. Unlike most studies on knowledge sharing that seeks to establish strategies, this article focuses on establishing perceptions of librarians and the different ways by which techniques for knowledge sharing may be enhanced.

Keywords: Knowledge Sharing, Academic Libraries, Namibia, Knowledge Perceptions, Knowledge Sharing Techniques, Africa

1. Introduction

Academic libraries, like most organisations are striving to foster knowledge sharing to stimulate productivity, encourage innovation, and remain competitive in the higher education landscape. The organisational growth and the job performance of academic librarians is contingent upon the extent of their knowledge sharing activities (Ajegbomogun and Diyaolu, 2018:6; Olatokun and Njideaka, 2020:297). The International Federation of Library Associations and Institutions (IFLA 2015) reiterates the value of knowledge sharing techniques in academic libraries. Researchers have perceived knowledge sharing as a cornerstone to the success of academic libraries as it enables library staff to exchange knowledge, skills, and experience. The plethora of studies on knowledge sharing practices in academic libraries in Africa reveals that academic libraries are conscious of the value of knowledge sharing in enhancing the services of libraries although knowledge sharing is still practiced at an ad hoc basis (Izu and Fombad 2024; Bumbie-Chi 2020; Muchaonyerwa and Mutula 2017; Tahleho 2016; Lekay2012; Abdur- Rafiu and Opesade 2015:14; Kabiru 2016:31; Antwi, Ankrah and Frimpong 2020:34; Olatokun and Njideaka 2020:306; Bumbie-Chi 2020:316; Iilonga 2019:171; Muchaonyerwa and Mutula, 2017:11). Notwithstanding there remains a dearth of research on integrating tools and techniques for knowledge sharing in academic libraries in Africa. Also, studies have revealed that library staff are fully cognizant of the concept of knowledge sharing and its benefits and its potentials in increasing productivity and service delivery notwithstanding the lack of a holistic approach to organising knowledge within these libraries (Izu and Fombad 2024; Bumbie-Chi 2020; Muchaonyerwa and Mutula 2017).

Academic library staff perceive knowledge sharing as happening in an uncoordinated, and informal manner, primarily through one-to-one conversation among library staff (Bumbie-Chi 2020). Henttonen et al (2016) noted that Individual -level knowledge sharing affects individual work performance. A knowledge-friendly organisational culture will enhance the organisational performance of an organisation (Liu e t al 2021).

Namibia which is the focus of this study is one of the countries in sub-Sharen Africa. The University of Namibia is one of the four universities in the county with twelve campuses. Each of these campuses has its own library that serves a diverse community. The university of Namibia sixth strategic plan seeks at building and exchanging knowledge through collaboration. Studies on knowledge sharing in Namibia have primarily focused on corporate, public, and ministerial libraries and there has been little focus on academic libraries. Knowledge sharing occurs at the University in at an ad hoc manner. Against this backdrop, this article investigates knowledge sharing perceptions among library staff at the University of Namibia, with a view of suggesting techniques enhance knowledge sharing.

2. Literature Review

2.1 Perceptions of Knowledge Sharing In Academic Libraries

Knowledge sharing is the exchange of articulated or consensual facts, opinions, viewpoints, and scientific knowledge among individuals and groups that encourages knowledge flow, which, in the end, enables the dissemination of knowledge, enhance growth, productivity and success of any organisation. Successful knowledge sharing depends on the eagerness of staff members to share their experience with one another, which results in existing knowledge within the individual, division, or team of an organisation made available to others (Ram and Gupta, 2014:780; Ajegbomogun and Diyaolu, 2018:3). Researchers have established a relationship between knowledge management technologies on the culture and organisational performance. (Liu et.al 2023) Perceptions are opinions or points of view that shape how people act or react in specific situations (Bumbi-Chi, 2018:151). There is a general perception that although library staff at certain levels understand the concept of knowledge sharing, academic libraries have yet to implement policies and strategies to harness library staff expertise as well as formalise knowledge sharing in their library operations (Bumbie-Chi 2018:151; Muchaonyerwa and Mutula 2017; Tahleho 2016; Mayekiso 2013; Lekay 2012). There is also a perception that knowledge sharing in academic libraries is uncoordinated, with the main channel of knowledge sharing being informal communication. among co-workers during regular conversations. Also, there is a perception of a general lack of well-defined policies to achieve knowledge sharing activities (Bumbie-Chi 2018; Muchaonyerwa and Mutula 2017; Maponya 2004) Despite their optimism about knowledge sharing, library staff still prefer to share knowledge on a one-on-one approach (Bumbie-Chi 2018:173; Onifade, 2015:91).

2.2 Techniques of Knowledge Sharing in Academic Libraries

The techniques for knowledge sharing may be classified as human and technological centered. Human cantered techniques facilitate the transfer of tacit-to-tacit knowledge. Examples of human centered techniques are meetings face-to-face sharing, mentoring, Community of Practice, storytelling conversations by water coolers and peer assist. Meetings occur when employees who share common ground and experiences gather in a loosely structured setting to discuss ideas and challenges across organizational levels and to present functional actions. Meetings foster collaborative knowledge sharing through informal and formal networks and provide opportunities for staff to validate their practical knowledge and enhance certain skills like verbal communication and logical reasoning (Aljuwaiber, 2019:235; Khoro; 2019:17). Face-to-face knowledge sharing allows for more extensive discussion whereby individuals offer and receive comments until, they arrive at a consensus. Even though there are other platforms that can be used to share knowledge, Face-to-face exchanges is desired because it facilitates knowledge transfer (Kommey and Fombad 2023). Mentorship happens when a skilled and superior employee with extensive knowledge and experience is required to share their knowledge and experience with less skilled co-workers to provide advice and moral support. A mentoring relationship focuses on guidance and learning between two people (Lefika and Mearns 2015:27). Mentors can help their mentees get more job opportunities and reciprocal networks, learn new skills and knowledge, advance in their careers, and do better work (Khoro, 2019:15). Community of Practice are group of individuals who share mutual goals and collaborate on a regular basis to advance their knowledge in a particular subject (Bratianu, 2018). It can also be viewed as a social interaction group formed to promote learning and innovation within an organisation through knowledge sharing.

On the other hand, the technological centered techniques focus on information communication technologies (ICTS), knowledge management systems and data bases to facilitate explicit to explicit and tacit to explicit knowledge sharing. Technologies such as the internet, intranet, electronic mail, social media, Facebook, Twitter, WhatsApp, Flickr, Instant messaging, Blog or Weblog, instant messaging, blogs, video conferencing, knowledge sharing systems, databases, data mining, portals and artificial intelligence technologies are widely acknowledged as a means of sharing or disseminating knowledge within an organsation.The electronic mail may be used to convey knowledge and promote awareness through reference services in academic library (Valumani, 2016). Social media sites such may be used to share knowledge and improve service delivery in libraries (Umaru and Omame, 2020:5-6). For example, blogs may be used to raise awareness about library news, the acquisition of new consignments, solicit user feedback about library services, provide virtual outreach programs through information (Boateng and Liu, 2014:125; Hilsop 2018:217). Instant messaging may also be employed to enhance the delivery of reference services because it allows library staff to respond to user inquiries immediately. Videoconferencing technologies are face-to-face interplay, which allows participants to vividly see and hear each other, and in turn engage in simultaneous discussions where questions and points are clarified using

demonstrations (Alkhaldi, Yusof and Aziz, 2013:410). Amongst the systems and databases that could be used to share knowledge are expert-locater systems, electronic document management systems, incident report databases, data mining, lesson-learned databases, and best practice databases. Expert-locater systems are knowledge repositories that aim to organize knowledge by identifying and finding professionals who are knowledgeable about a particular topic within an organization and makes such information available to other employees (Janus 2016:35). Expertise location activities encompasses mentoring program facilitation, knowledge gap identification, operational support, and continuing professional development designed to disseminate knowledge among library staff (Hameed Basheer). Electronic document management system is robust software that advocates the process of creating, searching, storing, and retrieving documents electronically. Data mining technology is used in academic libraries to obtain statistical evidence pertaining to user circulation, library collection statistics and other search patterns. Lessons-learned systems collect knowledge gleaned from previous experiences, with the goal of capturing and providing lessons that can benefit other employees (Wang and Wang, 2020:8). It also provides others with insights into how they dealt with similar events, as well as advice on how library staff should provide services. According to Taskin and Van Bunnen (2015:164). Best practices databases describe successful efforts, which are usually the outcome of reshaping business operations and may be relevant to organisational processes (Taskin and Van Bunnen, 2015:164). Artificial intelligent technologies such as Optical Character Recognition, Categorization and Discovery: algorithms offer opportunities in enhancing knowledge sharing and fostering collaboration. Challenges and opportunities abound in leveraging personal knowledge managed through Chat GPT (Nazeer et. al 2023)

3. Research Methodology

The study adopted a mixed-methods approach and a case study design. A census of the entire university of Namibia library staff consisting of 104 respondents was utilised to gather data using questionnaire and a total of seven library management were purposefully sampled to gather data through interviews. Seventy five out of 104 target respondents completed the survey. The survey data was analysed using the Statistical Package for Social Sciences (SPSS) software (Version 26) and Microsoft Excel 2019. The interview data was organised thematically in accordance with the set objectives.

4. Social Exchange Theory (SET)

The Social Exchange Theory (SET) of Homans (1958) is a theory that suggests that social relations can be better defined by the exchange of rewards and costs between both partners (Romani-Dias and Carneiro, 2019). Apart from material or content rewards, exchange awards include intangible benefits such as peer group support, trust, confidence, and recognition (Romani-Dias and Carneiro 2019:464). Knowledge sharing is a type of social exchange that allows people to share their knowledge with their co-workers and to expect a reciprocal exchange of knowledge (Wang, Xiang, Yang and Ma 2019:871). Trust is an important basis for measuring the relationship between benefits and costs. (Jinyang 2015:175). When applied to this article the social exchange theory (SET) provides insight into the motivation for sharing knowledge amongst library staff by using the four basic concepts that influence interpersonal exchange processes which are cost-benefit analysis, reciprocity, social penetration, and equity and inequity (Arsawan et al., 2020). This indicates that the cost-benefit analysis of knowledge sharing in university libraries is determined by the level of trustworthiness shared by library staff.

5. Findings

The article seeks to accomplish the following objectives:

To establish library staff perception on knowledge sharing at the university of Namibia library

To establish the knowledge sharing techniques among library staff at the University of Namibia

6. Perceptions of Library Staff on Knowledge Sharing

The findings on table 1 below revealed that respondents fully understood the importance of sharing among co-workers at the university of Namibia library in enhancing library services and in becoming more innovative and creative, and appreciated the need to share knowledge. The findings were further corroborated by the following qualitative responses.

Interviewee 1*: "In my view, knowledge sharing is crucial and should be practiced openly."*

Interviewee 2 *"Sharing knowledge and expertise, in my opinion, would enable staff members to gain skills through participation in knowledge sharing activities, which could contribute to the better provision of innovative and creative library services to improve performance".*

Interviewee 3*: "In my perception, knowledge sharing is the process by which knowledgeable individuals share their expertise with others, thereby bringing innovation and creativity to library operations*".

It is clear from the qualitative and quantitative findings that library staff understood and valued knowledge sharing, whether tacit or explicit knowledge, as part of their dairy library operations in order to provide efficient services. They believe that sharing knowledge among co-workers has a beneficial effect on enhancing library services and making them more innovative and creative. This is consistent with much of the literature by Africa researchers that describes library staff positive perceptions of the value of knowledge sharing in among co-workers for improving knowledge flow and library service delivery (Izu and Fombad 2024; Akporabore, 2015:32; Muchaonyerwa 2015:125, Bumbi-Chi, 2018:151; Chipeta, 2018:119; Onifade, 2015:96).

Table 1: Perceptions of library staff on knowledge sharing

	Strongly agree	Agree	Neutral	Disagree	Strongly disagree
I believe knowledge sharing is a process in which knowledgeable individuals share their knowledge with their co-workers.	74 (98.7%)	1(1.3%)	0(0%)	0(0%)	0(0%)
Sharing knowledge can help library services to be more innovative and creative.	51(68%)	20(26.7%)	4(5.3%)	0(0%)	0(0%)
I am cognizant of the benefits derived from sharing knowledge with myco-workers.	65(86.7%)	9(12%)	1(1.3%)	0(0%)	0(0%)
I can use the experience of others to solve a problem at work if I share my knowledge.	60(80%)	10(13.3%)	2(2.7%)	3(4%)	0(0%)
I feel that sharing knowledge will enhance my library skills.	(46.7%)	33(44%)	7(9.3%)	0(0%)	0(0%)
I believe that 'knowledge is power,' I refuse to share it with others.	0(0%)	0(0%)	1(1.3%)	21(28%)	53(70.7%)
I believe it is important for co- workers to share. their knowledge?	58(77.3%)	14(18.7%)	3(4%)	0(0%)	0(0%)

7. Knowledge Sharing Techniques Among Library Staff at the University of Namibia

The second objective examined the various techniques utilized by the university library staff to impart knowledge. The findings in table 2 below reveal meetings and face-to-face techniques as the two human centred techniques of knowledge sharing. It is worth noting that library staff were aware of various knowledge sharing techniques such as discussion forums, monitoring and brainstorming, organisational culture, coaching, and job shadowing, monitoring, brainstorming, organisational culture, and job shadowing. The open-ended question identified "presentations" "Informal discussions amongst colleagues" "Departmental WhatsApp groups" "Emails and Zoom "as techniques.

Table 2: Knowledge sharing techniques

Techniques for knowledge sharing	YES	NO
Meetings	75 (100%)	0(0%)
Face-to-face knowledge sharing	70(93.3%)	5(6.7%)
Job rotation	47(62.7%)	28(37.3%)
Discussion forum	27(36%)	48(64%)
Monitoring	22(29.3%)	53(70.7%)

Techniques for knowledge sharing	YES	NO
Brainstorming	22(29.3%)	53(70.7%)
Organisational culture	19 (25.3)	56(74.7)
Coaching system	16(21.3%)	59(78.7%)
Job shadowing	15(20%)	60(80%)
Community of Practices	7(9.3%)	68(90.7%)
Storytelling	6(8%)	69(92%)

The qualitative findings revealed an inclination towards the use of technology techniques as noted the following responses.

Interviewee 1*: "staff meetings, in-house training this hosting Zoom meetings and having a departmental WhatsApp group.*

Interviewee 2*: "The use of generic email or email list to all staff, meetings, phone communication, and presentations staff. Face-to-face knowledge sharing, departmental WhatsApp groups "*

Interviewee 3*: "Staff training, email lists, mentorship programs, job shadowing programs, ongoing planning, and job rotation programs, seminars, e-mail, library website,"*

Interviewee 4: "discussion over the telephone, giving a presentation after attending a workshop, having informal discussions among colleagues, creating departmental or campus library WhatsApp groups, using an email list, and holding group meetings via Zoom".

Interviewee 1*: "I primarily use knowledge sharing platforms such as computers, electronic email facilities, websites, portals, forum, the internet, and the telephone, as well as departmental WhatsApp group, Twitter, Facebook, and Instagram, and Wiki to communicate with other colleagues and share information and knowledge".*

Interviewee 2*: "Well, I personally use email, Zoom, University of Namibia forum Imo, YouTube, and online newsletter, as well as social media platforms such as Facebook, ResearchGate, Twitter, and WhatsApp."*

Interviewee 3: *"I mostly use computer-based technology such as work electronic mail, Facebook, Twitter, the internet, and WhatsApp for the campus library or department".*

Interviewee 4: "I am personally aware of knowledge sharing technologies such as Facebook, WhatsApp, emails, Twitter, Skype, Instagram, Wiki, internet, blogs, telephones, and LinkedIn. However, I have had exposure to technologies such as the internet, email, WhatsApp, Twitter, and Facebook. Additionally, departmental or campus WhatsApp groups are used to share insights and experiences among co-workers".

The qualitative findings further revealed the awareness of knowledge sharing systems by academic librarians although usage is still at its infancy.

Interviewee 1: "I *am personally conscious of systems such as Google cloud, Moodle content sharing/Learning Management System, expert-locator systems, LibGuide, electronic resource and institutional knowledge repository incident reports, library news portal, electronic document management systems, incident reports, just to mention a few. However, I have only used a few of these technological systems, including the institutional repository, LibGuide, electronic resources, and library news portal".*

Interviewee 2: ". *We are not incredibly good at it, and some management teams have requested, for example, a shared folder to house all library institutional documents such as annual reports and statistical documents so that they can be easily found, but it is still in its infancy*.

Interviewee 3: "*There are numerous knowledge sharing systems available for use in any library or organisation, including expert-locator systems, electronic document management systems, incident reports, data mining, lesson-learned databases, and best practice databases, electronic resources, and the LibGuide system, However, we lack the majority of the ICT systems that we would like to have for the flow of knowledge, but I am aware of the basics for the time being: the institutional repository, the UNAM portal, library news, electronic resources, and the LibGuide system".*

Knowledge sharing systems has been used in academic libraries, to support and facilitate the distribution of both explicit and tacit knowledge. This helps library staff be more effective at their jobs and improves the efficiency of the library operations (Akporabore, 2015:34; Bozzato, Eiter & Serafini, 2018:77). Technologies such as expert-locator systems, incident reports, and instant messaging, expertise locator system provide a platform for accumulating enormous amounts of technical expertise by harnessing existing knowledge, skills, and experience to enhance productivity and service delivery (Wang & Wang, 2020:7). Janus (2016:35) noted that expertise locator system assists in connecting library staff with knowledgeable professionals at the appropriate time. This implies that the library staff has systems in place that identify, locate, and connect library staff with right expertise on a certain subject and make such knowledge available to other co-workers in a reasonable amount of time.

The findings revealed that academic librarians were aware of social media platforms:

Interviewee 1: ". *Twitter, Facebook, Instagram, Wiki, and WhatsApp are some of the social media platforms that I am familiar with. Other platforms, such as LinkedIn and ResearchGate, I specifically use them on a personal level to distribute research knowledge".*

Interviewee 2: "I *am aware of common networking sites and platforms such as Twitter, Facebook, and LinkedIn. From the qualitative and quantitative findings, it is apparent that most of the techniques used but the library staff for sharing knowledge was technology based. Apparently, mobile phones, WhatsApp, email Zoom, Facebook and Twitter Video conferencing meetings, email, and phone conversations online training, presentations, where the most used technologies for knowledges sharing among co-workers*

Social media technologies such as Facebook and Twitter were the most frequently used techniques for reciprocating knowledge among library staff and across campus libraries. The Google cloud, portals, electronic resources, and the LibGuide system were also used Technologies such as IMO, Skype, Instagram, LinkedIn, Snapchat, ResearchGate, YouTube, Imo, Tik-Tok, Wiki, and other interactive digital tools were the least used.

These findings are consistent that of researchers in academic libraries in Africa (Bumbi-Chi, 2020; Izu and Fombad 2024; Chipeta, 2018; Bumbi-Chi, 2018; Tahleho, 2016; and Onifade, 2015). It is apparent from the findings that the internet, Facebook, electronic email, WhatsApp, telephone video conferencing, Twitter, Instagram, Instant Messages, portal, Snapchat, university of Namibia forum, ResearchGate, YouTube, and Imo as methods used to share knowledge among the university of Namibia.

Notwithstanding the inclination towards ICT based techniques, and the importance perception about its usage, the findings revealed an underutilization of these tools for knowledge sharing. The underutilization stems from difficulties encountered when using these systems, poor network, and internet connection, lack of appropriate ICT infrastructures that support knowledge sharing, insufficient funding for university library operations to acquire modern technological systems, thus impeding knowledge sharing and service delivery. These challenges are consistent with studies on knowledge sharing in academic libraries in Africa whereby academic libraries are inundated with poor networks internet connectivity, a lack of modern infrastructure, and the absence of technological systems that support knowledge sharing across campus libraries. making it difficult for library employees to share knowledge and improve performance and service delivery.

8. Conclusion

The article investigated the perceptions on knowledge sharing among University of Namibia library staff and identified the different techniques used for knowledge sharing and suggest ways by which these techniques may be enhanced. Drawing from the findings, the study recommends library management to implement a policy that formalizes knowledge sharing techniques and creates awareness of the importance and value of knowledge sharing. The policy should incorporate the integration of modern technological infrastructure and artificial intelligence technologies that facilitates the flow of knowledge among library staff and across campus libraries. Both technological-based and human-based knowledge sharing techniques should be prioritized in the library operations. Systems, and technologies such as a best practices database, blogs, electronic document management, and lessons learned systems should be explored. The acquisition of artificial intelligence technologies for knowledge sharing is crucial because it has the potential of revolutionizing knowledge sharing in academic libraries. Progressively, library staff should be continuously trained on ICT-related topics to remain current in their field of expertise and to adapt to the changing world of technologies when reshaping and redesigning library operations. The library management should set aside adequate funds for the acquisition of appropriate technological infrastructure, the maintenance of adequate internet connectivity, and the frequent updating of the library website. Consequently, without proper and substantial technological infrastructure and tools, the success of knowledge sharing is bound to be unsuccessful.

Human cantered approaches to knowledge sharing such as Community of Practice, Storytelling, rewards, and incentives, encouraging a leaning organization discussion forums, mentoring, brainstorming, organisational culture, coaching, and job shadowing should be encouraged. To this end, the elements of trust and reward as noted in social exchange theory are crucial in realizing the human centred approach to knowledge sharing. Successful knowledge sharing will not only enhance service delivery and trust among academic librarians but it will enhance quality education thus realizing the sustainable development goal that will actively contribute to inclusive, equitable, and quality education. These findings contribute to the growing body of knowledge sharing tools and techniques implemented in academic libraries in Africa and promotes a positive perception of knowledge sharing in academic libraries.

Research Trends in Knowledge Management and Innovation: a Bibliometric Review

Monika Sipa and Marcin Sitek
Czestochowa University of Technology (CUT), Częstochowa, Poland

monika.sipa@pcz.pl
marcin.sitek@pcz.pl

Abstract: Due to the important role of knowledge and innovation in the development of organisations or economies, these issues continue to receive considerable attention from practitioners and researchers. Knowledge and innovation are closely related concepts. Without proper knowledge management (KM), it is difficult to design and implement changes, while, on the other hand, innovation creates a demand for new areas of knowledge and continuously develops it. The main objective of this paper is to identify the leading challenges in knowledge management and innovation, by exploring the key themes, their connections and the latest research trends in this area. Using the SCOPUS citation database, publications were reviewed to answer the following questions: (RQ1) How has the perspective of academic research addressing both knowledge management and innovation evolved over the last twenty years? and (RQ2) What are the leading research areas and new trends in research simultaneously addressing knowledge management and innovation? The analysis covered the years 2003-2023. The collected data was pre-selected and then, based on the frequency of co-occurrence of key terms, mapping was performed and keywords were extracted using VOSviewer software. In the years under review, there has been an increase in the number of publications dealing with the topic of knowledge management, including those linked to innovation. Publications in this field are mainly concentrated in three research areas: Business, Management and Accounting, Computer Science and Engineering. Most studies come from China. The dominant research unit in this research area, according to the affiliation of the researchers, is LUT University. Issues such as knowledge sharing and transfer of knowledge, learning organisations, competition or information management among others, continue to be of interest to researchers. Among the most recent trends, research is dominated by: green innovations, mediating roles, big data and covid-19. The study helps to understand the challenges that have arisen for research in the analyzed area in the last two decades. It can provide a valuable study and a guide for identifying available and future research directions on knowledge management and innovation.

Keywords: Knowledge Management, Innovation, Vosviewer, Bibliometrics

1. Introduction

Researchers have eagerly explored knowledge management (KM) and innovation for many years. Both concepts are recognised as key determinants of sustainable growth for economies and businesses. The concept of KM has gained importance with the emergence of the knowledge economy and technological advances. Knowledge management is the systematic process or practice of capturing, storing, sharing and productively using knowledge to improve learning and enhance organisational performance.(Mateu, 2014) It is an essential element in the development of tangible and intangible production that determines the effectiveness of an organisation (Tavasieva et al, 2019, Mustafa and Rexhepi, 2024). As noted by Jain (2016), with the increasing importance of knowledge for economic and business development, ethical and legal issues such as privacy, confidentiality and intellectual property are becoming increasingly relevant.

Innovation is the introduction of new or significantly improved products, operational processes, marketing methods and organisational or management methods in business practices (Ayandibu et al., 2020). They allow organisations to progress in terms of turnover and profits, as well as in terms of knowledge, experience, productivity and quality (Baporikar, 2014, Baporikar, 2015, ul Hassan, 2014). They influence productivity, consumer benefits (Young, 2015), global competitiveness (Krishnamoorthy and Damle, 2017) and economic progress in both developed and developing economies (Mehdi, 2022). In times of rapid technological development, shortened product life cycles, globalised markets and increased competitiveness, innovation is indispensable (Godin, 2017).

Due to the complex and multi-faceted relationship between knowledge management and innovation, these issues are often considered together by researchers. Many authors point to the positive relationship between knowledge management and innovation (Guetat and Dakhli, 2013, Ologbo and Nor 2015, Dow et al., 2019), which are connected through continuous and complex interactions (Guetat and Dakhli, 2013). As highlighted by Barbaroux et al (2016), the evolution of knowledge management processes is linked to the implementation of interactive, collaborative and open innovation models. They cover different types of knowledge and processes at various stages of innovation.Effective knowledge and innovation management is crucial for an organisation's competitive advantage and long-term survival (Guetat and Dakhli, 2013, García, 2020). The rapid development

of information and communication technologies (ICT) strongly influences the processes of knowledge creation, dissemination and exploitation (Nurulin et al., 2019, Martins et al., 2022). Achieving organisational success requires attention to people, processes and technology (Omotayo and Akintibubo, 2024). Employees who engage in knowledge management processes enable the company to push the boundaries of its innovation capabilities (Ologbo and Nor, 2015). To increase innovative thinking among employees, it is necessary to regularly implement knowledge management practices (Luturlean et al, 2021) and, in particular, to encourage creativity and openness in information management (Al-Zagheer et al, 2024).The issues of knowledge management and innovation are hardly new, but the dynamically changing environment allows them to be explored on different, and indeed all-new, levels. Therefore, the main objective of this study was to identify the leading challenges in knowledge management and innovation by exploring the key themes, their connections and the latest research trends in this area.Using the SCOPUS database, publications were reviewed to answer the following questions: (RQ1) How has the perspective of academic research addressing both knowledge management and innovation evolved over the last twenty years? (RQ2) What are the leading research areas and new research trends simultaneously addressing knowledge management and innovation? The focus was on articles published between 2003 and 2023. The results are presented in tabular form and as visual representations showing the resulting research clusters, generated by the VOSviewer software.

2. Data and Methodology

This paper used a bibliometric analysis to identify current research trends among leading scientific publications related to knowledge management (KM) and innovation issues, as used by many researchers (e.g. Carlsson and Noyons, 2009, Zhang et al, 2019, Ruas et al, 2017, Gudanowska, 2017; Gorzeń-Mitka,2020, Lobonţ et al, 2021). As emphasised by Klincewicz et al (2012), this method makes it possible, among other things, to determine the current state of knowledge in a given area, indicate knowledge gaps, predict future research developments in a given area and identify areas characterised by a relatively high saturation of conducted research and links between research areas.

The data for the study was obtained from Web of Science (WoS) and SCOPUS databases. Using the search mechanism of these databases, scientific publications containing the terms "knowledge management" and "innovation" in the "Article title, Abstract, Keywords" box were extracted. The analysis covered publications from the last two decades, i.e. from 2003 to 2023. Further analysis focused on the SCOPUS database due to a slightly larger number of publications indexed there. The results obtained were organised and partially aggregated. The study comprised several stages:

1. Extracting the number of publications on the analysed research area in the WoS and SCOPUS databases and assessing changes in their number in the longer term.
2. Identifying the dominant subject areas into which publications were classified based on the SCOPUS database.
3. Identifying countries/regions, scientific centres and universities of key importance for the analysed research area based on the SCOPUS database.
4. Identifying publications of key importance for the analysed research area based on the SCOPUS database citation index.
5. Identifying research sub-areas based on co-occurrence relationships of the keywords "innovation and knowledge management" in the SCOPUS database using the VOSviewer programme.

The analysis used software like Excel and VOSviewer (Visualizing scientific landscapes, version 1.6.18), as well as data analysis tools available in Web of Science and SCOPUS databases. The analysis covered bibliographic data extracted on 5 April 2024.

3. Analysis Results

At the outset of the analysis, the Web of Science and SCOPUS databases were filtered, and a time series analysis was performed, reflecting the number of included publications addressing innovation and knowledge management. Over the years, there has been a dynamic increase in the number of indexed studies dealing with these issues. The first such studies appeared in the SCOPUS database in 1994, and in Web of Science in 1996.

In the case of WoS, this was the publication by D.W. Straub, The effect of culture on IT diffusion: E-mail and FAX in Japan and the U.S., Information Systems Research, 5(1). There were two entries in the SCOPUS database: J.C. Spender, Making knowledge the basis of a dynamic theory of the firm, Strategic Management Journal 17, pp.

45-62; and R. Sanchez and J.T. Mahoney, Modularity, flexibility, and knowledge management in product and organization design, Strategic Management Journal 17.

This paper analyses publications from 2003 to 2023. By 2003, the total number of relevant papers was 7,648 in the WoS database and 8,672 in SCOPUS. (Fig. 1) Further, it should be noted that in 2007 the number of publications indexed in both databases exceeded 200 papers per year, and in the last decade it was at least 300 and 400 papers annually. The figures were slightly higher in the case of the SCOPUS database, with 600 items on the analysed issues indexed in 2003. The dynamically increasing number of publications in both databases indicates a constantly growing interest in knowledge management and innovation.

Figure 1: Publications devoted to knowledge management and innovation in the WoS and SCOPUS databases (1996-2023)

Source: own elaboration based on WoS and SCOPUS data

SCOPUS data was analysed in greater detail due to the slightly higher number of publications. Taking into account data aggregation, the publication output was analysed according to the thematic areas to which the publications were classified; the country of origin of the authors with the most publications (geographical arrangement) and the scientific centres represented by the researchers with the most frequently published and most frequently cited publications.

In the SCOPUS database, publications dealing with knowledge management and innovation are dominated by conference papers (48.65%) and scientific articles (44.55%). Together, they account for 93.20% of all papers. The other types of publications represent a small percentage of the analysed dataset. (Tab. 1)

Table 1: Main publication types

Document Type	Number of publications	Structure	Document Type	Number of publications	Structure
Conference Paper	4,152	48.647%	Editorial	23	0.269%
Article	3,802	44,546%	Note	15	0.176%
Review	256	2.999%	Short Survey	7	0.082%
Book Chapter	196	2.296%	Conference Review	3	0.035%
Retracted	48	0.562%	Data Paper	3	0.035%
Book	28	0.328%	Erratum	2	0.023%

Source: own elaboration based on SCOPUS data

An analysis of the thematic areas into which the SCOPUS publications were classified leads to the conclusion that the identified papers mainly represented two areas: business, management and accounting (22.12% of publications), as well as Computer Science (21.87% of publications). The other areas with more than 1,000 papers published in the last two decades were Engineering, Decision Sciences and Social Sciences. The distribution across all SCOPUS subject areas is shown in Figure 2.

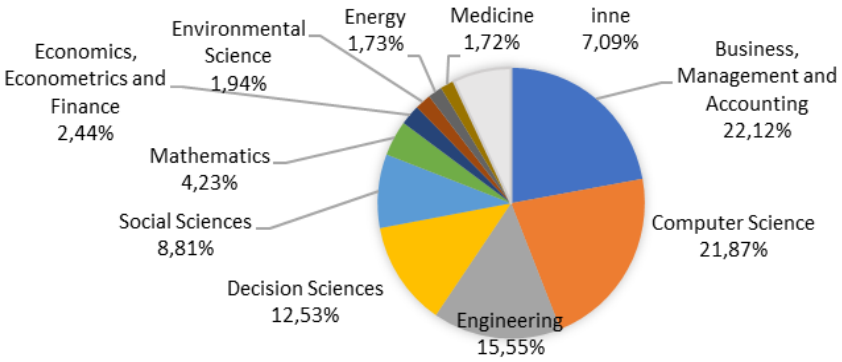

Figure 2: Main subject areas

Source: own elaboration based on SCOPUS data

The authors of publications dealing with knowledge management and innovation were mostly researchers from LUT University in Finland; Zhejiang University and Harbin Institute of Technology from China; Universidade de São Paulo in Brazil and Politecnico di Milano in Italy. (Tab. 2)

Table 2: List of research centres of origin of researchers addressing KM and innovation — Top 5

No	Affiliation	Number
1	LUT University	72
2	Zhejiang University	59
3	Harbin Institute of Technology	54
4	Universidade de São Paulo	46
5	Politecnico di Milano	42
5	Bucharest University of Economic Studies	42

Source: own elaboration based on SCOPUS data

When analysing the country/region of origin of the authors with the highest number of studies on the issue at hand, the dominant position of China is evident. Authors from the United States come second and those from the United Kingdom third. Further countries in the ranking are Germany, Spain and Italy. A list of the top ten countries and research centres of researchers addressing KM and innovation is presented in Table 3.

Table 3: List of countries of origin of researchers addressing KM and innovation — Top 10

No	Country/Territory	Number of Publications	Structure	No	Country/Territory	Number of Publications	Structure
1	China	1,437	13.26%	6	Italy	417	3.85%
2	United States	959	8.85%	7	Australia	324	2.99%
3	United Kingdom	691	6.38%	8	France	296	2.73%
4	Germany	490	4.52%	9	Taiwan	282	2.60%
5	Spain	450	4.15%	10	Brazil	275	2.54%

Source: own elaboration based on SCOPUS data

Considering the source of publications, the leader in the number of publications on knowledge management and innovation is the Journal of Knowledge Management, with 174 such publications. More than 100 research papers in this area were published in "Lecture Notes in Computer Science Including Subseries Lecture Notes in Artificial Intelligence and Lecture Notes in Bioinformatics" (133 items), "ACM International Conference Proceeding Series" (112 items) and "Communications in Computer and Information Science" (111 items). Figure 3 shows the ranking of sources with the largest number of publications dealing with the issue in question.

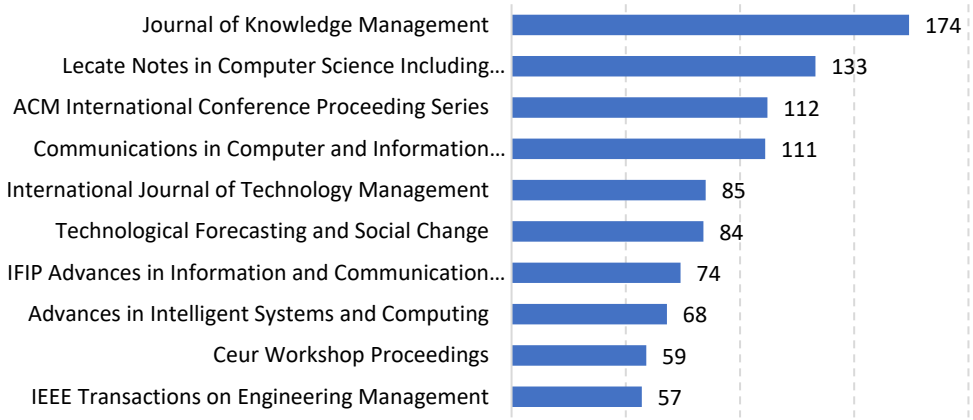

Figure 3: List of sources with the largest number of publications on KM and innovation

Source: own elaboration based on SCOPUS data

According to the SCOPUS database, the most published researchers included Gardoni, M. (20 papers), Kianto, A. and Matos, F. with 19 publications each, and Schmitt U. with 13 papers. (Fig. 4)

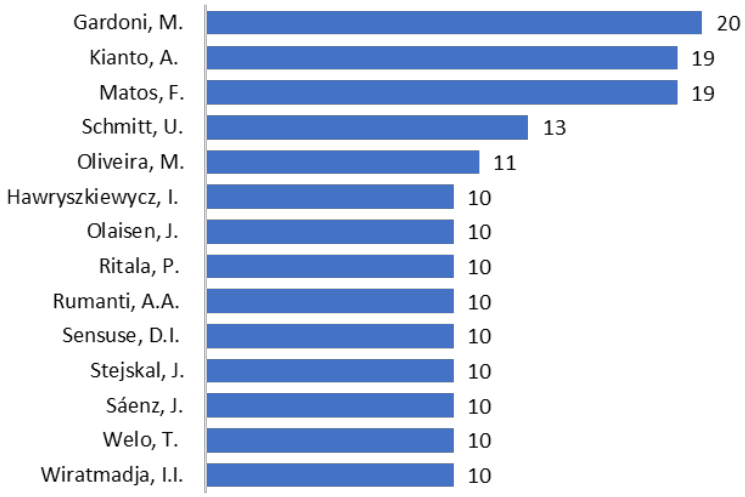

Figure 4: Authors with the highest number of publications on KM and innovation — TOP 5

Source: own elaboration based on SCOPUS data

Notably, the publications of the above researchers are not among the most cited. Of the ten most cited publications addressing both knowledge management and innovation, the article by Argote, L., McEvily, B. and Reagans, R. titled Managing knowledge in organizations: An integrative framework and review of emerging themes, published in 2003 in Management Science, ranked first with 1,494 citations. Table 4 shows a ranking of the ten most cited publications addressing knowledge management and innovation.

The next step in examining bibliometric data was word co-occurrence analysis which, as noted by Liu et al (2015), is used to identify key research topics in a research field or knowledge domain. The analysis involved preparing a map of knowledge and research trends related to knowledge management and innovation in the context of SCOPUS publications indexed between 2003 and 2023. VOSviewer — visualisation software that is particularly helpful when working with large amounts of data — was used for building and visualising bibliometric networks, as well as for scientific mapping. It was used to group and evaluate research sub-areas. The data file generated in the SCOPUS database was further analysed using the VOSviewer visualisation software. Due to the large size of the initial database (8,535 items), only articles published in the years analysed were considered for further analysis. Ultimately, 3,730 items were analysed.

It was decided that "indexed keywords" should be used in the correlation analysis because they reduce duplicate or similar terms (Zhang et al, 2016). To make the visualisation clearer, a term extraction was also performed

with an indication of words with a minimum of 15 repetitions in bibliographic descriptions. In addition, such terms as China, Australia, article, data mining, India and issue were eliminated from the set.

Table 4: Most cited publications on KM and innovation (TOP-5)

Author	Title	Journal	Year	Number of citations
Argote, L., McEvily, B., Reagans, R.	Managing knowledge in organizations: An integrative framework and review of emerging themes	*Management Science*	2003	1,494
Gertler, M.S.	Tacit knowledge and the economic geography of context, or the undefinable tacitness of being (there)	*Journal of Economic Geography*	2003	1,394
Jensen, M.B., Johnson, B., Lorenz, E., Lundvall, B.A.	Forms of knowledge and modes of innovation	*Research Policy*	2007	1,144
Schilling, M.A., Phelps, C.C.	Interfirm collaboration networks: The impact of large-scale network structure on firm innovation	*Management Science*	2007	1,090

Source: own elaboration based on SCOPUS data

Based on these assumptions, a database of 184 keywords was obtained and presented in the form of a map. (Fig. 5) The map illustrates current trends in research addressing knowledge management and innovation and shows the links detected over time. The major keywords "knowledge management" and "innovation" were removed because they appeared in all articles (Liao et al, 2023). The terms analysed were grouped by occurrence and strength of interconnection, resulting in seven clusters of terms. Each cluster is marked by a different colour: blue, green, red, purple, blue, yellow and orange.

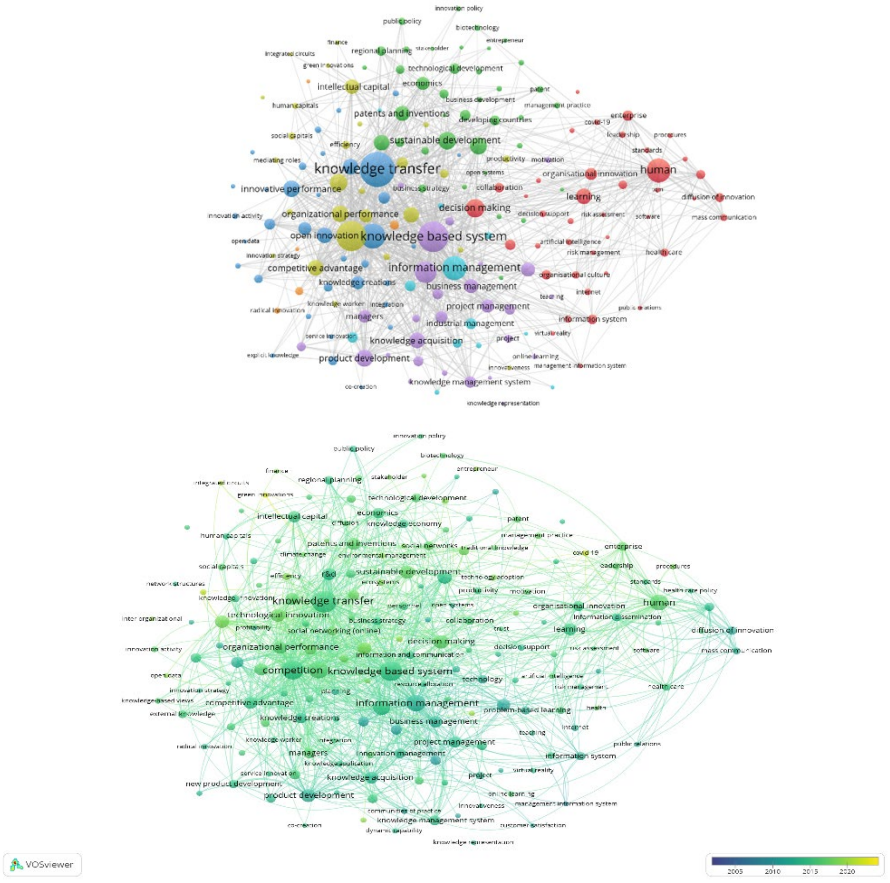

Figure 5: Maps of the intensity of link co-occurrence between keywords and links detected over time

Source: own elaboration using VOSviewer and SCOPUS.

The size of the items (nodes and font) in the maps indicates the frequency of co-occurrence of a given term and the links between network nodes represent their co-occurrence in the analysed group of publications. The larger the item, the greater its importance and popularity relative to others (Perianes-Rodriguez et al., 2016). The distance between the visualisation items roughly indicates their relatedness in the co-occurrence network, so the closer two items are to each other, the stronger their links (van Eck and Waltman, 2019). The stronger the link, the more frequently both terms appear in publications. The map created using VOSviewer features numerous links, making the network quite dense, especially in its central part. It comprises 184 items and 6,836 links, with its central part containing the most frequent keywords. The topics most strongly linked to others within the network were: "human resource management", "employee" and "information management".

The first cluster categorised in VOSviewer is the most numerous, with 40 keywords.(Tab. 6) It is marked in red. The term with the highest link strength (Tls) is "human" (Tls= 655), followed by "decision making" (Tls=512). These terms also have the highest co-occurrence rates (O) in the group, at 182 and 129, respectively.

The red cluster includes publications addressing issues related to artificial intelligence, decision-making, learning, communication and health care. This group also includes terms relating to information, information dissemination and retrieval, the information system and the "management information system". Further, it includes research relating to organisational innovation and the diffusion of innovation, as well as risk management and risk assessment. Publications in this group examine innovation and knowledge management in terms of leadership, organisational culture, trust, creativity and collaboration. There are also references to standards, procedures and TQM. The most frequent and most linked keywords in this cluster are "human" and "diffusion of innovation". Their minimum link strength is 42. References to COVID-19 and "digital storage" are relatively new. For these, the average publication years (AvgPY) are 2021 and 2018, respectively. The average publication year for all issues in the cluster is 2014.79.

The next cluster comprises 38 items and is marked in green. This cluster focuses on issues related to business development, productivity, entrepreneurship, investments, performance assessment, employment and "business strategy". The strongest and most linked relationship in this cluster relates to such keywords as "technology transfer" (Tls =441; O=111) "research and development" (Tls =413; O=101) "sustainable development" (Tls =371; O=118) and "patents and inventions" (Tls =359; O=96).

The dominant term with the highest number of links and the highest link strength (Tls =441; O=111) is "technology transfer". Other related topics are "technological development", "technological forecasting" and "technology adoption". The articles in this cluster focus on issues related to the knowledge economy, knowledge exchange, economic development, economics, research and development, patents and inventions, intellectual property, the innovation system and innovation policy. They also refer to social networks, big data, software design and sustainable development. This cluster includes knowledge management and innovation in the context of economic and enterprise development, i.e. entrepreneurs and other stakeholders. The issues at hand also relate to technological development and forecasting, as well as technology adoption and transfer.

The average year of publication for the entire cluster is 2015.8. Looking at the links detected over time, one can see that the most recent publications in the cluster refer to "big data" and "entrepreneur" (average year of publication: 2019).

The third cluster, marked blue, is related to knowledge, innovation, networks and collaboration. It comprises 35 terms. The highest link strength within the blue cluster occurs in the case of "knowledge transfer" (Tls=954; O=316). This is also the third-highest score for the entire link map. Other blue cluster keywords with high link strength include "knowledge sharing" (Tls=677; O=197) "commerce" (Tls=463; O=97) "innovative performance" (Tls=430; O=108) and "open innovation" (Tls=378; O=98). Notably, much of the research categorised into this cluster relates to networks — innovation, knowledge and social ones, as well as network structure and complexity. A significant number of keywords refer in various ways to innovation and knowledge. In the case of innovation, these include collaborative innovation, innovation activity, innovation process, service innovation and knowledge innovation. In terms of references to knowledge, the blue cluster included research referring to such things as explicit and external knowledge, as well as the creation, application, diffusion, integration and flow of knowledge, and tacit knowledge management. Co-creation, integration, absorptive capacity and crowdsourcing were also among the keywords. Looking at the average time of publication, this group's most recent studies on knowledge management and innovation refer to "open data" (AvgPY=2018.69) and "inter-organisational" (AvgPY=2018.53) issues. The average year of publication for the entire cluster is 2015.32.

The fourth cluster ranked in VOSviewer covers slightly fewer keywords — 27. It is marked in yellow. The most frequent and strongly linked cluster components are "competition" and "competitive advantage" — the strength of the link between them is 95. These terms are the most frequent and linked items not only in the cluster but also in the entire network. The main keywords characterising this cluster are "competition", "competitive advantage", "organisational performance", "technological innovation" and "human resource management". In this cluster, the term "competition" has the highest link and co-occurrence strength (Tls=1073; O=253). This group of publications primarily focuses on issues related to competition, organisational knowledge management, human capital, innovation and environmental management — "climate change" and "green innovation". Analysing the links detected over time, it is noticeable that the yellow cluster is a collection of issues that have begun appearing in publications relatively recently. The average year of publication for the entire cluster is 2016.24, with the lowest AvgPY value being 2013 for "planning" and the highest being 2014.9091 for "competition". New issues covered in innovation and knowledge management publications include green innovation, for which the average publication year is 2021.61, and "mediating roles", with an average publication year of 2020.46.

The fifth cluster ranked in VOSviewer comprises 27 keywords and is marked in purple. This research area concerns knowledge-based systems, learning organisations and product development. The most frequently used keyword in our sample of documents is "knowledge-based system (KBS)". Being the most prominent issue in the group, it is in the central part of the map. The purple cluster covers publications relating to business and project management, knowledge acquisition and information technology. These are the strongest and most linked relationships within this group. Considering the time of publication, the keywords in the purple cluster are not new issues in the context of research considering knowledge management and innovation. The average year of publication for the entire cluster is 2014.06. The keywords in this cluster also include some with an AvgPY of 2010. These are "knowledge engineering", "communities of practice" and "enterprise resource planning".

A further, sixth, cluster comprises 12 keywords. It is marked in light blue. The three main keywords characterising this cluster are "information management", "strategic planning" and "industrial management". "Information management" (Tls=796; O=183) is characterised by the greatest link and co-occurrence strength and is located close to the central part of the map. This cluster also includes publications relating to product innovation, dynamic capability, marketing and customer satisfaction. Looking at the average publication time, one can see that this cluster contains keywords that have not been heavily used in recent years. In this cluster, the most recent studies on knowledge management and innovation are related to "entrepreneurship" (AvgPY=2018.78). The average year of publication for the entire cluster is 2013.75.

The last cluster (orange) includes only 5 keywords. This cluster is the least numerous and the weakest in terms of total link strength and occurrences. The cluster covers the following keywords: "incremental innovation", "innovation capability", "knowledge management strategy", "mergers and acquisitions" and "radical innovation". In this cluster, the term "innovation capability" has the highest link and co-occurrence strength (Tls=168; O=45). The orange cluster contains publications on innovation and knowledge management in the context of innovation capability, including incremental and radical innovation, knowledge management strategy and the changes brought about by mergers and acquisitions. The correlations detected over time show that all the keywords in this cluster, although seemingly familiar, are still readily used in publications addressing innovation and knowledge management. The average year of publication for the entire group is 2015,425, and for individual keywords, it does not extend beyond the last decade. In this case, the lowest AvgPY value is 2013.75.

Looking at the map as a whole, it is also worth highlighting the keywords with the highest link strength regardless of cluster affiliation. The most frequent and most interlinked items among the selected map clusters were "technology transfer" (green cluster) and "knowledge transfer" (blue cluster) — 37 lines. Numerous links also exist between "knowledge transfer" and "competition" (yellow cluster), for which the link strength is 36.

4. Summary

This study presents the evolution of research addressing knowledge management and innovation, which are key factors in developing and building the competitive position of actors and economies. They contribute to solving the challenges of change in organisations and their environment. A co-occurrence network analysis using VOSviewer software was employed to identify new trends in this area. The analysis covered publication data from two decades. The main findings of the study are as follows:

- The number of publications indexed in the analysed databases is systematically increasing, which indicates a growing researcher interest in knowledge management and innovation.
- The issues analysed in this study are typically considered in business, management and accounting, computer science and engineering.
- By forming a keyword co-occurrence network map and simultaneously analysing research activities addressing knowledge management and innovation, it was found that the boundary themes in this research consist of seven representative areas, focused on such main keywords as competition, knowledge-based system, information management, knowledge and technology transfer, innovation capacity and sustainability.
- Recent trends in research addressing innovation and KM refer to green innovation, COVID-19, mediating roles, integrated circuits, big data and entrepreneurship.

This study aimed to identify selected challenges in an exploratory manner and may form the basis for continued work in this area. Nonetheless, it also has certain limitations that open up possibilities for further consideration. The issues of innovation and knowledge management are multidimensional, and this study analysed only the leading trends in these areas. The focus was only on major trends, limiting the analysis to data from the SCOPUS database. Further in-depth research using multiple databases would be advisable. From the point of view of research methodology, a more in-depth analysis of citations, the number of article downloads from the database or the co-existence of author or research centre relationships could be devised. Summarising the trends identified in the study, it can be concluded that knowledge management and innovation continue to pose a challenge for modern actors and economies and are areas of exploration for academic researchers.

Innovation in Development Projects in Poland in the Context of Company

Marcin Sitek and Monika Sipa
Czestochowa University of Technology, Faculty of Management, Department of Economics, Investment and Real Estate, Czestochowa, Poland

marcin.sitek@pcz.pl
monika.sipa@pcz.pl

Abstract: This article aims to identify the introduction of innovations in the activities of residential developers in relation to company size. In order to achieve the objective, the results of a survey conducted in Poland in the form of a questionnaire among developers of the primary residential market, implementing investments in the field of multi-storey multi-family construction, were used. The research conducted allowed the identification of the percentage of residential developers introducing innovations in their real estate projects. Moreover, the structure of the innovations introduced was presented, taking into account the role they play in the market. A correlation of the innovations introduced in their activities with the size of the company and the market range in which the company operates was revealed. The information presented is of key importance today due to the need for innovation in renewable energy sources, which allow for diversification and security of supply in the context of the armed conflict in Ukraine. Introducing innovations in the real estate market is becoming necessary in EU countries due to regulations aimed not only at increasing the competitiveness of EU economies through increased innovation but above all at achieving sustainable development goals — including net-zero carbon emissions. EU regulations introduce strict requirements concerning, among other things, the energy performance of buildings, which will result in the need for innovative projects not only in the primary market but also for projects aimed at modernizing the existing stock (secondary market), which, according to research, is often carried out by smaller companies that have not yet applied innovative solutions in their operations.

Keywords: Innovation, Renewable Energy Sources, Sustainable Construction, Climate Neutrality.

1. Introduction

Socio-economic development is linked to the development of science and technology, where innovation became the catalyst for social and economic change (Fundacja Innowacji i Nowoczesnych Technologii, 2021), thus contributing to the competitive position of regions.

The further dynamic development of the world economies was made possible by the introduction of innovation (Hult et al,2004; Jin et al, 2004). Article 173 (2016) of the Treaty on the Functioning of the European Union (TFEU) within the framework of the Lisbon Strategy (2000), Europe 2020 strategy (European Commission 2010), and now within the framework of Sustainable Europe until 2030 and initiatives such as the “Green Deal” (Green Deal 2022) and Fit for 55 (2023), explicitly emphasis sustainable development, ecological transformation and achieving climate neutrality, which is possible through the implementation of innovation (Innovation Policy, 2023). This implies that green transformation developments will largely affect the real estate sector, as this sector is highly energy-consuming and accounts for a large proportion of greenhouse gas emissions.
The geopolitical situation, namely the armed conflict in Ukraine, is also a driver for innovation in the real estate market. As a direct consequence of Russia’s invasion of Ukraine, the price of raw materials, particularly energy commodities such as oil, natural gas and coal, of which Russia is a strategic exporter, rose dynamically and by leaps and bounds. The situation was all the more serious as Russia was the EU’s main supplier of energy resources, which, combined with successive restrictions, such as the embargo on imports of individual raw materials from Russia, resulted in a cascade increase in their price and also in energy security risks. (Karlinski, 2022; Polish Economic Institute, 2023).

The motivation for addressing the problem was (until the COVID-19 pandemic and the Russian intervention in Ukraine) the highly accelerated economic development associated, among other things, with innovative activities. In Poland, over the last thirty years, the centrally planned state economy was replaced by market economy mechanisms. This creates the necessity to intensify the implementation of innovations to increase the competitiveness of the Polish economy.

Innovation is the basis of knowledge-based leadership, enabling the use of advanced integration methods and practices to achieve organizational goals (Hallinger and Suriyankietkaew, 2018; Faouri 2023, SAhouwen et al. 2022). In light of the above, it can be concluded that green knowledge management is a particularly important concept meaning the management of capabilities and knowledge related to sustainable technologies and

environmental practices. This means that knowledge management is one of the elements of effective implementation of innovations.

Taking into account the current geopolitical risks and the EU regulations being introduced, especially the consequences of real threats resulting from climate change and environmental degradation, an attempt was made to analyze the problem presented above. The paper aims to identify the role of innovation in the activities of residential developers in Poland in the context of changes triggered by the geopolitical crisis and EU legislative initiatives.

The paper reviews the literature on innovation in the real estate market, legislative initiatives undertaken by the EU, particularly in the area of innovation, climate and energy policies, and the consequences in the state's economy and policy caused by the conflict in Ukraine. The author's own survey was used, which was conducted among residential developers in Poland in the second half of 2020 and in the second half of 2022. The results of the study are then presented and discussed in the context of the literature review provided in the preceding section. Synthetic conclusions from the conducted research were used to formulate general recommendations for the development of the Polish housing sector.

2. Literature Review

The dynamic development of world economies is made possible by the introduction of innovation. The most comprehensive market definition is cited by the Oslo Manual (OECD/European Union, 2018):

A new or improved product or process (or a combination thereof) that differs significantly from an entity's previous products or processes and that has been made available to potential users (product) or put into use by the entity (process). However, for the real estate sector, the market definition of innovation was defined according to Bac (2014) and Pryston (2012) as: innovations in the real estate market particularly concern production methods and new goods, i.e. new construction methods and techniques ensuring the creation of a new product (building or structure) meet with energy, ecological and utility standards. They concern production factors (goods, services, production methods, sources of raw materials, or organization of production processes) and new economic activities or new services. Therefore, innovation in the real estate market stimulates pro-ecology, issues of energy efficiency, ergonomics and renewable energy sources. Innovations in the real estate market will stimulate sustainable development.

The development trends of innovation are: (Kamiński 2022):

- the increase in the share of new technologies — web and mobile solutions — is one of the most significant developments in the real estate market,
- the development trend of innovations concerning big data, databases, machine learning, neural networks or artificial intelligence — is widely used in real estate valuation and decision-making support in the investment process,
- the development trend of geolocalization is an extraordinary tool, highly useful, used in marketing, navigation or local services,
- the development trend in construction innovations points to the important influence of electronics and building automation on the functioning of buildings.

As can be seen from the literature analysis (COM 2019; European Climate Law 2021; Green Deal 2022; Fit for 55 2023; Just Transition Fund 2021; Fit for 55, 2023; Fit for 55, 2023; COM 2021). EU countries have committed to achieving climate neutrality by 2050 and thereby fulfilling their obligations under the Paris Agreement (The Paris Agreement, 2015). The EU's green transformation comprises a package of initiaties among which those applicable to the real estate sector should be particularly highlighted:

- Green Deal (2022), (European Climate Law (2021) as the heart of the Green Deal, 2019). The European Green Deal is a package of policy initiatives that aims to put the EU on the path to a green transition and ultimately to achieve climate neutrality by 2050. In this regard, the UN's "Our Common Future" Report (United Nations, 1987, pp.18–19, 119) as well as Vademecum Bezpieczeństwa (2018) emphasise that the importance of energy for the world's developing economies will be increasing.
- the Fit for 55 package (Fit for 55, 2023) as a set of proposals to revise climate, energy and transport legislation and introduce new legislation to bring Union law in line with its climate goals.

- European Climate Pact (2021). - The EU and its Member States have committed to reduce net EU greenhouse gas emissions by at least 55% by 2030, compared to their 1990 levels (European Commission, 2016; COM 2020);
- European industrial strategy, including circular economy. The EU is counting on European industry to steer the transition towards climate neutrality (COM 2020; European Parliament Regulation, 2021);
- In March 2020, the European Commission presented a new roadmap for a circular economy, highlighting the need to ensure green recovery from the Covid-19 pandemic.
- The EU has introduced the Just Transition or Sustainable Finance Mechanism (Parliament Regulation..., 2021; Just Transition Fund JTF, 2021) to financially and technically support regions as a result of the transition to a low-carbon economy. From the perspective of the topic under discussion, the most important consequence of the war in Ukraine seems to have been the increase in the price of energy raw materials, as well as of the supply of such raw materials. This has resulted in an even stronger pressure to develop innovations within the framework of renewable energy sources, driven by the increased importance of energy self-sufficiency (Kolany 2022).

Rapid changes in the perception of technology and knowledge management have led to an increase in interest in ecological knowledge management as a source of competitive advantage (Abbas and Sağsan 2019; Santoro et al., 2019). Managing ecological knowledge is a fundamental factor for a company's survival, leading to great results, such as increasing competitive capabilities in the market (Hottenrott et al., 2016). Optimizing the knowledge process prompts companies to further focus on sharing and organizing green knowledge to replace traditional business perceptions for sustainability (Buter & Van Raan, 2013; Tajpour et al., 2022). The current level of developers' knowledge regarding ecology and green knowledge management requires the development of knowledge, support and transfer of know-how of the innovation project management process. Therefore, the presented EU requirements forcing the implementation of innovations, especially in the field of energy efficiency, should result in the implementation of innovations combined with appropriate knowledge management in this area. To be effective, the process of introducing innovations should be associated with appropriate knowledge management in this area.

Developers, including residential developers, are pursuing a variety of projects - for example lofts. Brown (2018) distinguishes several elements of a successful model for modernization and its management. He points to value as the guiding principle for managing innovation, assuming that value must be based on comfort, well-being, health and aesthetics. He also notes the very topical issue of guaranteeing energy savings and the savings-related integrated supply chains that can provide “a whole-home approach”.

In Poland, price, comfort, well-being, health and aesthetics are also factors driving innovation in the real estate, especially the housing, market. Zhang (2020), on the other hand, shows that risk is one of the driving factors for implementing innovation by investors in the Chinese real estate market. He demonstrates that risk has a positive impact on firms’ innovation performance, including R&D investment, innovation level and other innovation outcomes.

This should be understood in the context of risk appetite, as the taking of risks allows for above-average returns. Therefore, taking into account the risk of non-innovation, one can conclude that it is a driver for increased innovation in business, also for developers.

Killip and Owen (2020) argue that in order to study the real estate investment process, usually in the secondary market, two markets need to be analyzed: the first is the market of repair, maintenance and improvement (RMI) of houses, where energy efficiency, and thus the implementation of innovations, is not the most important; and the second is the market of deep modernization, where the main goal is energy efficiency and thus precisely the implementation of innovations such as energy efficiency. The first market — the RMI market — is dominated by small and medium-sized enterprises, especially micro-enterprises, operating in local markets. Those companies do not maximize profits or focus on the energy efficiency of buildings. In the second market, companies are focused on energy efficiency and are usually large companies working together in regional and national markets. The same situation exists in the primary residential market.

Taking this into account, it is important to emphasize that EU regulations (especially energy regulations) and the need to innovate within the framework of energy decarbonization have also introduced smaller companies to the real estate market (European Court of Auditors, 2017). They presuppose the necessity to reduce the energy consumption of buildings, of the entire stock not only newly built but also the already existing one, in order to meet the standards of having appropriate energy certificates for buildings. If these conditions are not met by

2050, it will not be possible to rent or sell a flat without meeting these conditions. (Central Office for Construction Supervision, 2024).

The introduction of innovations in the housing market refers not only to the use of housing but also, importantly, to resource efficiency in the housing production industry and operational energy efficiency. Industrialized Housing Construction (IHC) is a strategy for implementing emerging innovations in resource-efficient housing (Rohn et al. 2014). Under this strategy, innovations, including RES, are important drivers of value creation in the housing Modular technologies can compete with traditional technologies in the context of sustainability and, at the same time, serve as a cost-optimal solution in the decarbonization of building resources (Kaczorek et al., 2023).

The analysis of the literature has made it possible to identify a research gap in the implementation of innovations by residential developers in the real estate market, which is most relevant to real estate development activities in Poland. To answer the research questions presented below, a survey was conducted and the results analyzed. The research questions were set as follows:

1. What is the percentage of residential developers implementing innovations in Poland?
2. Does the market range of operations of a development company and its size influence decisions to implement innovations in residential projects?
3. What type of innovation is most frequently implemented by residential developers in Poland?

3. Material and Methods

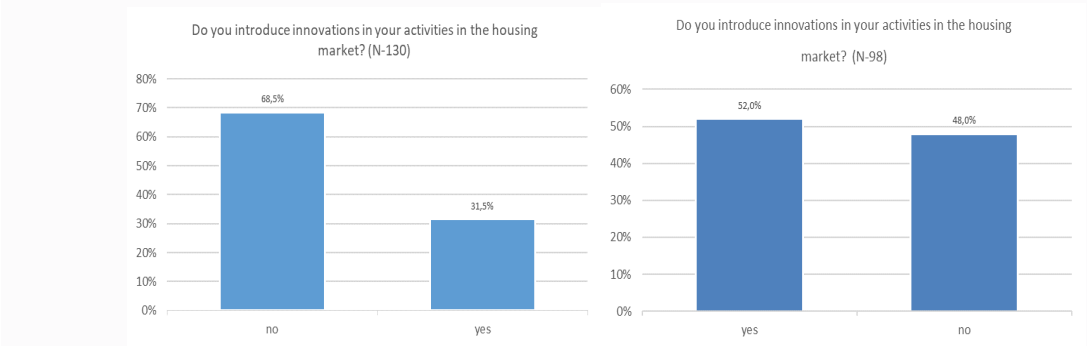
The survey of innovations among primary market residential developers in Poland in the context of company size and market range of the company's operations, motives for their implementation and changes that have taken place in this field in recent years was carried out based on surveys conducted using the CATI (computer-assisted telephone interviewing) method. The survey was not narrowed down to one group of developers, e.g. medium-sized companies, but small, medium-sized and large companies were surveyed, as the selection criterion was the capital strength of the companies, i.e. the implementation of large residential projects. It was decided to carry out such a survey because even developers classified as small enterprises carry out investment large projects in Poland, involving subcontractors in their projects. The survey was conducted twice at a 2-year interval.

Innovation surveys among residential construction companies in the primary market were conducted in August 2020 and in November 2022. The study was conducted on a nationwide sample. The first survey was conducted in August 2020 on a sample of 130 respondents with a then-identified total population of (±5%) 324 entities. This was followed by a further survey in October/November 2022 carried out using the same method on a sample of 98 respondents selected from a total population of (±5%) 230 entities. The research conducted allowed for the identification and analysis of developers' perceptions of innovation in the period before and after the outbreak of the war in Ukraine.

4. Results and Discussion

Preliminary analysis of survey data in the period 2020–2022 (Sitek 2020-2022; Sitek 2023a; Sitek 2023b) clearly indicated the influence of developers' market range on decisions to innovate.

This paper, based on the analysis of the 2020 and 2022 surveys, compared the actual readiness of developers to innovate in the residential property sector in Poland (figure 1)



a) survey 2020 b) survey 2022

Figure 1: Do you introduce innovations in your activities in the housing market?

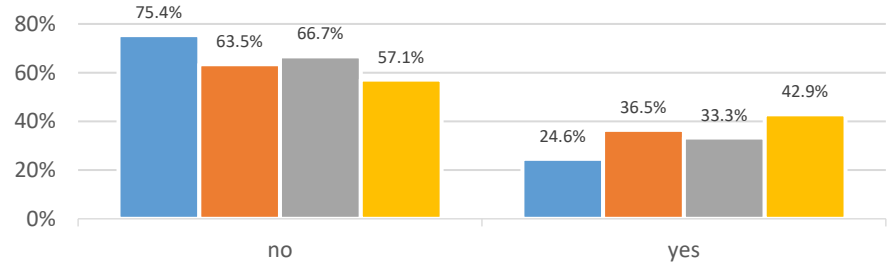
Source: author`s elaboration

The presented surveys showed that the low percentage of companies declaring to introduce innovations in 2020 resulted from three main factors as: the customers choose standard construction, translating into a lack of demand – 23.6%, preference for proven solutions – 22.5% and high costs of innovation – 15.7%.

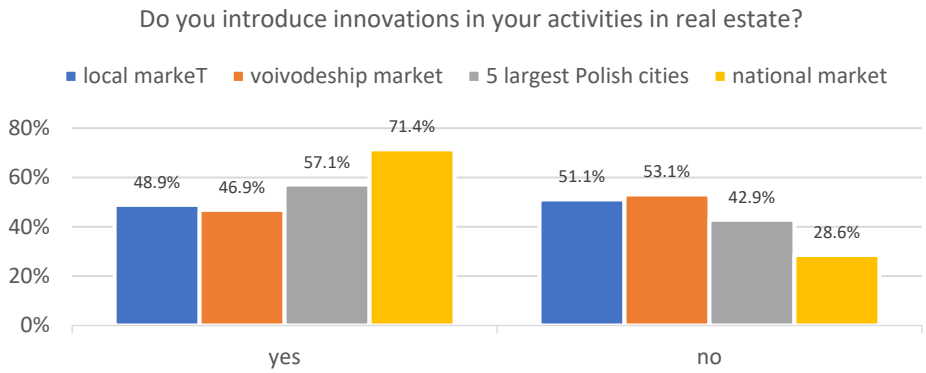
In 2022, on the other hand, developers identified, as the three main determinants of not implementing innovation in their business, the lack of need for it — 23.4%, the difficult market situation — 23.4% and the lack of innovative projects. This shows, first, that the awareness of the need to innovate on the part of residential developers is high, which increases the number of companies declaring innovation . Secondly, that despite the continued importance of the lack of demand/need and the preference for proven solutions in 2022, high investment costs are not shown to be one of the main determinants of the lack of innovation implementation. Whereas the drop in demand was caused by high inflation and consequently high interest rates and limited access to mortgage loans. The increase in costs, on the other hand, was caused by the high price of raw materials, which translated into higher prices for construction materials. On the one hand, there was a major increase in the price of coking coal and, consequently, steel, but also, on the other hand, the price of wood, which in Poland was imported in large quantities from Ukraine, among other countries.

It is impossible not to mention that the most important factor indicated by respondents in both surveys, i.e. the lack of need/demand, changed dramatically in July 2023 in connection with the enactment of the Energy Efficiency Directive. This directive imposes such a need, i.e. it determines the demand for sustainable construction, where buildings should be energy self-sufficient and even generate a surplus of energy obtained, obviously, from renewable sources.

When considering the introduction of innovations from the point of view of the range of activities of the analyzed entities, one can see a clear relationship presented in figure 2.



a) 2020 r.



b) 2022 r.

Figure 2: Do you introduce innovations in your activities in the housing market?

Source: author`s elaboration

It can be observed that both enterprises operating in a wide (nationwide) range and those operating in the five largest Polish cities are much more likely to introduce innovations than enterprises with a small (local) market range of activity. This confirms the general trend also presented in studies by Kilip and Owen (2020) who emphasize that companies operating locally usually do not use innovation, unlike companies with a larger market range. Moreover, firms with a local market range tend to be small companies operating more often in the market for retrofitting and refurbishment of existing space, while firms with a larger market range are larger and more often involved in projects in the primary market (COM 2019; European Climate Law 2021). In addition, the smallest companies, employing a few people, clearly indicate that they do not innovate in their activities, while those with larger employment are more likely to declare the implementation of innovations in their projects (figure 3).

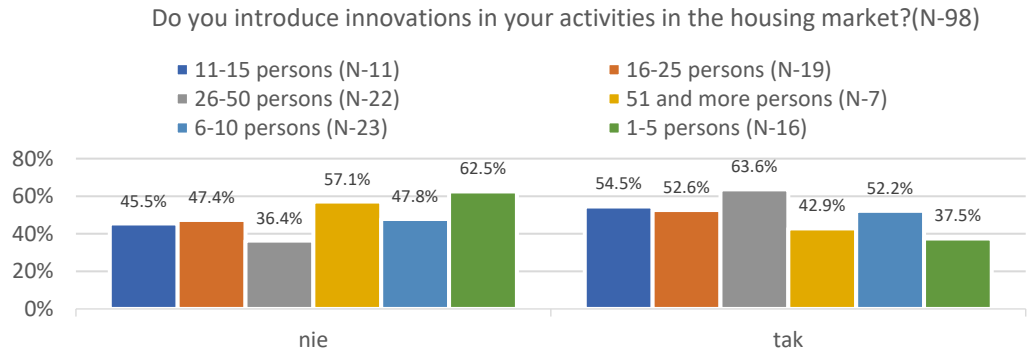


Figure 3: Do you introduce innovations in your activities in the housing market?

Source: author`s elaboration

They unanimously stated that the most frequently introduced innovations belonged to the category of technical and technological (product) innovations (36.52%), marketing innovations (32.17%), financial innovations (20%) and process and organizational innovations (11.3%). In 2020, the types of innovations used were as follows: technical and technological — 39%, marketing — 25%, and financial — 9%, with a surprising percentage of answers indicating process and organizational innovations — 27%. Invariably, the most important and also the most frequently applied innovations are those from the technical and technological category. This seems understandable given the fact that this group includes renewable energy sources or specific materials. It is this category of innovations that allows a real reduction in subsequent operating costs of the property, which is why customers pay attention to it. It can be concluded that in the situation of the implementation of EU regulations related to “Fit for 55”, the role of innovations from the technical and technological category will increase even further. Comparing the results received from respondents in the two surveys, it can still be seen that invariably the marketing innovation category is fairly often chosen by developers, which may be related to advances in showing the offered product using drones or virtual presentations to better showcase their property. The implementation of marketing innovations is relatively low-cost and produces tangible results. A clear difference can be seen in the implementation of financial innovations and process and organizational innovations presented in both surveys. In 2020, process and organizational innovations accounted for a large group with 27% of responses, while financial innovations accounted for 9%, which may have resulted from the fact that interest rates on loans were low at the time and thus access to conventional financing was good. In 2022, as already mentioned, respondents highlighted the difficult market situation, attributable to, among other things, weak demand associated with expensive loans. This situation could have been a reason to look for alternative ways of financing real estate, starting with offering long-term rentals and ultimately offering the option to buy the flat later.

In reference to the above, the importance of knowledge management in the process of implementing innovations should be emphasized. According to respondents' indications, technical and technological (product) innovations are the most frequently chosen and important innovations. However, introducing this type of innovation is a complex process that requires unique knowledge not only related to the innovation itself but also to its appropriate placement in the entire project. Errors in this area result in high costs. Therefore, developers need support not only in the process of acquiring and developing innovations but also in their proper management as part of green knowledge management.

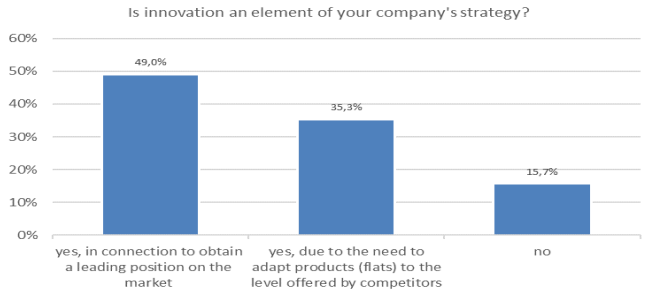

Figure 4: Is innovation an element of your company's strategy?

Source: author`s elaboration

The largest proportion of respondents (49%) stated that they incorporate innovation into their strategy in order to achieve market leadership, followed by (35.3%) indicating that they incorporate innovation in order to catch up with their competitors, while the smallest group (15.7%) does not incorporate any innovation into their strategies (figure 4).

Residential developers in Poland see the advantages of implementing innovations, and they see the risks of not implementing them, especially in the long term, and this is reflected in their strategies. Why, therefore, about half admitted that they do not implement innovations? It seems likely that the wider market has not exerted sufficient pressure on developers to use innovation to gain a more competitive advantage. Despite the rapid development of the real estate market, there is still a shortage of flats in Poland, which may be the reason for this situation. In addition, the process of implementing innovations is not easy and often unfamiliar to developers, which is why they do not reach for new solutions. This clearly indicates the need of knowledge transfer of appropriate innovation management and thus knowledge management. It can be concluded that developers want to introduce innovations, therefore obtaining appropriate competences in the field of knowledge management can facilitate and accelerate this process. In both surveys, the respondents clearly confirmed that the implementation of innovations causes difficulties in managing such projects (Figure 5).

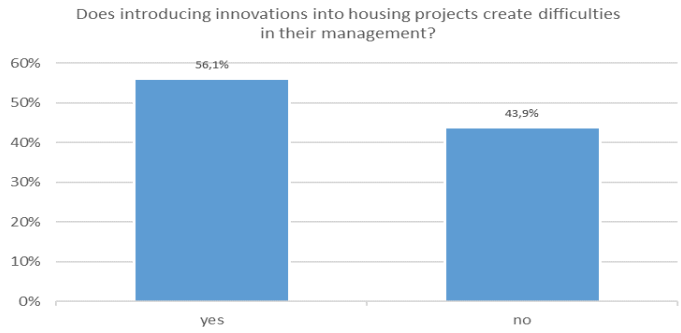

Figure 5: Does introducing innovations into housing projects create difficulties in their management?

Source: author`s elaboration

In conclusion, developers in Poland point to clear problems in managing innovative projects. Over the two years separating the two surveys, this state of affairs hardly changed. On the other hand, the EU-initiated legal changes described in the literature review will confront developers with the requirement of implementing innovation in their projects. This will not happen immediately, but over the next few years, which is not a long period in the real estate market. Therefore, developers should adapt as quickly as possible to future changes, not only in the area of innovation project management, but also in the area of innovation creation, knowledge and implementation. Here, a significant role can be played by support from the state and the EU, which is developing tools, for example, to finance such activities. Developers themselves have indicated that in order to develop innovative activities on the market in Poland, they need help from other external entities, especially public ones.

This leads to the conclusion that assistance, especially in the creation and development of innovations, should be directed to research centers and universities, which in cooperation with companies would create innovations addressed to business.

5. Conclusion

The conducted survey showed that:

- Findings about the number of residential developers with the appropriate capital strength to carry out projects for the construction of multifamily multi-storey residential properties in Poland have shown that there were fewer such enterprises in 2022 than in 2020 (by 44 entities), which may have been caused by difficult market conditions following the outbreak of war in Ukraine.
- Despite a decrease in the number of selected entities, in the general population an increase was observed in the number of developers declaring that they were introducing innovations. This shows the positive direction of the Polish residential market and the awareness of the importance of innovation among developers.
- A higher number of developers introducing innovation was observed in the group of companies operating in a broad market in geographical terms than those operating locally. This may reflect the greater importance of innovation in a situation where there is a need to compete on a broad market, or the market of the largest Polish cities.
- The persistently high percentage of developers not innovating in their business is primarily determined by a lack of demand/need for innovation. In 2022, respondents also pointed to difficult market conditions as a reason for not innovating. In the context of the described changes related to the "Fit for 55" package and the directives being enacted, it can be concluded that the primary determinant, i.e. the lack of need to innovate, has changed by 180 degrees.
- Invariably, the most important and also the most frequently applied innovations are those from the technical and technological category. This is understandable given that this group includes renewable energy sources, specific materials or construction techniques.
- Respondents indicate that a lack of innovation increases the risk of bankruptcy, which is why they include elements of innovation in their strategies. Gaining a competitive advantage and thus a leading position in the market was identified as the main factor for including innovation in strategies.
- Respondents declare that innovation creates problems in the management of development projects. Therefore, the development of knowledge and support, and the transfer of know-how of the management process in innovative projects seems to be important. In this case, the development of knowledge about green knowledge management seems crucial.
- Respondents clearly indicate the need for adequate support in the process of innovation implementation, from external, and especially public, entities. Although the EU is trying to create tools to support innovativeness, it is evident that a systemic change is needed at the level of the state, i.e. Poland.
- It should be emphasized that the most important action to be taken in this situation is identifying the needs of developers in the innovation implementation process in the context of providing them with adequate support and preparing them for the implementation of innovative projects that can meet current and future requirements of sustainable development.

In conclusion, it should be stated that the introduction of innovation into the real estate market is becoming a necessity in European Union countries due to regulations aimed not only at increasing the competitiveness of EU economies through increased innovation but, above all, at achieving sustainable development goals — including net-zero carbon emissions — introduced under the Green Deal, and "Fit for 55". These regulations introduce strict requirements concerning, among other things, the energy performance of buildings, which will result in the need for innovative projects not only in the primary market but also for projects aimed at modernizing the existing stock (secondary market), which, according to research, is often carried out by smaller companies that have not yet applied innovative solutions in their operations. In this context, it can be concluded that it is important to investigate the needs of the smallest enterprises in introducing innovations, and the role of green knowledge management in this process which sets the direction for future research.

Variation in Strategies for Deleting Unusable Content Across the Major Wikimedia Projects

Sebastian Skolik[1] and Piotr Konieczny[2]

Abstract: One of the negative effects of the rapid development of the information society is the problem of the reliability of content created by millions of users on the Internet. Socially created Wikimedia projects, the largest of which is Wikipedia, quickly developed procedures for identifying and eliminating problematic content. The article presents an analysis of the procedures for removing articles and the discourse on deleting content conducted among active users of the ten largest language versions of Wikipedia. Previous research focused primarily on the lack of neutrality in making decisions about content to be deleted and the resulting social inequalities, and was usually limited to the English-language Wikipedia. Based on previous participant observation, we noticed that individual language versions have different solutions in the context of ensuring project quality, which results in the emergence of different types of problems. We therefore looked into how much the approaches to deleting articles differ in different language versions. At the same time, we attempt to identify the common characteristics of the users who most often initiate discussions about deleting articles. To do this, we analyzed Wikipedia pages used to debate articles submitted for deletion (AfD) in 10 of the largest language versions of this project. The guidelines for submitting articles, the content of automatically generated messages helpful in conducting discussions, and the specific design of the websites where the debates took place were taken into account. Moreover, for three language versions (French, Swedish, and Polish), a statistical analysis of the activity of users of these websites was performed. It was noticed that the procedures for running AfD websites were similar in the analyzed language versions, but they differed significantly in terms of design and automatically generated messages addressed to debate participants.

Keywords: Quality of the Content, Wikimedia Projects, Online Communities, Socially Constructed Strategies, Knowledge Selection

1. Introduction

The emergence of technologies facilitating knowledge sharing among internet users has contributed to the rise of egalitarianism. At the same time, this has led to increased uncertainty regarding the quality of information found in cyberspace. Consequently, various methods have been developed to cope with acquiring useful knowledge. It can be observed that a significant portion of publications regarding behavioral strategies in the virtual space focused on information search strategies (West & Leskovec, 2012; Rodi, Loreto, & Tria, 2017). In the case of Wikimedia, the largest online community of volunteers dedicated to knowledge sharing, research on behavioral patterns often focused on technical and substantive issues related to editing Wikipedia articles (Iba et al., 2010; Hachey et al., 2013). Some studies examined differences in Wikipedia co-authors' approaches to the quality of content created within this service. Among them were cross-sectional papers that addressed the quality of Wikipedia and related projects, to a lesser extent touching upon the complex individual behaviors of users (Mayfield & Black, 2019; Lewoniewski, Węcel, & Abramowicz, 2023), as well as addressing the issues of egalitarianism and the difficulties novices face in mastering the intricate rules of the project (McDowell & Vetter, 2022, pp. 55–65).

In these studies, the focus was primarily on ways of reacting to information being continuously added to the project. Hence, there was a strong emphasis on the difficulties faced by new users. As the project develops, both standards and requirements are becoming increasingly higher. This means that new content posted on Wikipedia is generally much better than what was created in the early stages of the service. Although the rules in all language versions are similar, individual solutions and interpretations of rules for specific cases may vary. Previous studies have also pointed to certain relationships between patterns of behavior and membership in different national cultures (see: Konieczny 2020, 2023).

However, the issue of the community's evolving efforts to remove knowledge resources that were becoming increasingly unacceptable has not been subject to significant scholarly attention until now. Due to this fact, we have set ourselves the exploratory goal of researching and determining this variability. Following the principles of grounded theory (Konecki, 2018), we do not initially assume hypotheses that could be statistically tested. Instead, we pose research questions regarding the diversity of approaches to dealing with the removal of content that does not meet the standards set by Wikipedia communities.

In the next chapter, we review subject-related literature, primarily in the areas of behavioral strategies in virtual environments and concerning practices of detecting and removing articles on Wikipedia. In the methodological section, we present our approach to qualitative research and the method of collecting empirical material.

2. Literature Review

In the theory of mind and the evolution of language developed by Robin Dunbar, it is assumed that the primary function of language was to strengthen group bonds rather than to transmit precise information. Furthermore, the development of human cognitive abilities was not so much related to solving problems associated with functioning in the natural world, but rather to resolving dilemmas in the social environment. This concept is known as the social brain hypothesis and is also referred to as the Machiavellian intelligence hypothesis (Gamble, Gowlett, & Dunbar, 2014). Building social relationships thus involved employing various strategies that led to the formation of specific cultural patterns. These established patterns can be described as evolutionarily stable strategies in evolutionary theory (Dawkins, 2016). Since this is an ancient evolutionary mechanism, it is visible in various cultural environments, including cyberspace, where individuals and communities make decisions about building shared knowledge resources.

Strategies of action adopted by Wikipedians have been described in relation to both conscious choices and unconscious patterns. Wikipedia is often depicted as a place where strategic decision-making processes are co-created by a global community. It is emphasized, however, that certain factors may limit engagement in creating open strategies and thus may lead to frustration among some users (Dobusch & Mueller-Seitz, 2012; Nketia, 2016).

In large social projects, including the volunteer-created Wikipedia, there is considerable diversity among actors, including collective actors. Collective actors can include groups involved in thematic WikiProjects, welcoming committees, administrator groups or arbitration committees. Additionally, some actors do not contribute to shaping shared knowledge resources. As the Wikimedia projects have many language versions, users' actions in each of them may differ due to cultural differences. This diversity has been observed in previous studies (Konieczny 2020, 2023). In cultures with high power distance, a hierarchical structure grows, leading to a longer path to "promotion" from a novice to a user with, for example, administrator privileges (Skolik & Karczewska, 2021). Conversely, cultures with stronger individualism tend to have a smaller number of rules relative to the number of users and a higher number of edits per article (Kukowska & Skolik, 2021). It can be assumed that in "shame cultures," which have a lower Individualism Index, Wikipedians may be less inclined to make corrections to others' articles or may try to create their own articles in a way that avoids the need for corrections.

Individual behaviors may stem from the cultural background of the individuals, but this diversity is mitigated by the strong organizational culture of Wikipedia. For Wikipedians' actions to be acceptable, they must not violate a set of norms — rules, guidelines, and procedures — the number of which rapidly increased in the early years of Wikipedia's development (Kittur et al., 2007; Butler, Joyce, & Pike, 2008). Some users (often called vandals or trolls) intentionally break the established rules, attempt to destroy content, or incite "edit wars." This, in turn, leads to an ongoing "arms race." Special filters are created to quickly detect destructive behaviors, leading to modifications in behaviors among such disruptive users. The greater the awareness of such threats, the more the community may mobilize to cooperate in eliminating them. Although vandalism-detecting scripts are constantly modified, continuous human monitoring is needed to interpret unique behaviors (see: Jankowski-Lorek et al., 2016). This, in turn, requires a stronger internalization of rules. Over time, the number of rules becomes so large that newcomers have significant difficulties in mastering them, even if they are academics (Konieczny, 2021). Standardization also leads to greater technical complexity. Therefore, initiatives aimed at facilitating entry for new users periodically emerge.

An important modifier of behaviors can be the attitude of Wikipedians towards the content contained in the encyclopedia they co-create. In this context, two opposing attitudes are described: inclusionism and deletionism. The supporters of inclusionism lean towards including articles on niche topics, and even all content for which the appropriate sources of information can be found. On the other hand, the proponents of deletionism argue that the priority should be maintaining and raising high standards and removing content that, due to its insignificance, should not be included in Wikipedia (Mayfield & Black, 2019; Worku, Bipat, McDonald, & Zachry, 2020).

The main arena where the supporters of inclusionism and deletionism compete is the discussion pages for articles up for deletion (referred to by the acronym AfD). Administrators, users with privileges allowing, among other things, the deletion of a page, consider the opinions of those in favor of keeping the entry and those in

favor of its deletion. It is worth noting that only 20% of article authors participate in such discussions (Mayfield & Black, 2019). AfD pages contain both nominations for articles identified for deletion shortly after their creation and those whose flaws were not previously noticed. This also contributes to less involvement from their authors, who may have stopped contributing to Wikipedia earlier (sometimes, years earlier).

The decision-making process by administrators in AfD discussions may depend on the number of participants in the debate. In the English-language version, it has been observed that administrators' decisions are influenced by the number of votes for deletion or retention of the entry, despite nominally considering only the quality of arguments (Taraborelli & Ciampaglia, 2010). In the Polish-language version, however, a very large number of participants in the discussion may result in closing the debate as not leading to a consensus. In such a situation, the entry under discussion is not deleted (Skolik, 2013). The participants in the discussion may vary in their flexibility towards the arguments put forward, and their goals for participating in the discussion may differ. Some may strive, regardless of the arguments, for the deletion of the entry, while others may aim to retain it, and some may change their decisions depending on subsequent arguments or improvements made to the articles. Viewing AfD as a playing field involving many players, the stakes in the game could include, for example, the general aim to improve quality (by either deleting or improving the entry) or mobilizing a greater number of Wikipedians to address the problem on a broader scale (articles in a specific field where quality has not been previously addressed).

So far, the focus has been on narrow aspects of such discussions, primarily considering the effectiveness of actions or the inequality of opportunities in arguing between new and experienced Wikipedians. However, there has been a lack of research that would capture the diversity of behaviors leading to the complexity of decision-making processes on pages where deletion discussions take place.

3. Materials and Methods

To classify strategies related to making decisions about article deletion, we conducted qualitative research using a netnographic approach (Kozinets, 2015). Content analysis was employed, with a focus on pages outlining deletion rules as well as randomly selected discussions about article deletion. We did not formulate statistical hypotheses but instead formulated two research questions as follows:

1. What strategies do users adopt in the process of deleting articles that are identified as unacceptable?
2. What strategies do communities of individual language versions develop for articles targeted for deletion?

For the research, 10 of the largest language versions of Wikipedia were selected (the largest as in weighting both the number of created articles and the size of active user communities). These versions included English, Swedish, German, French, Dutch, Russian, Spanish, Italian, Polish, and Japanese. It was assumed that large communities have greater capabilities to identify low-quality content and can create their own tools and decision-making standards for its elimination. The research was conducted from January to April 2024. During this time, a comparison of deletion and archiving systems was conducted, enabling decisions on content selection for analysis. The analyzed AfD pages were created between 2005 and 2013.

The content analysis consisted of several stages (Fig 1.). Initially, attempts were made to identify the differences between language versions, which could result from the development of different action strategies by communities. To achieve this, we compared how different Wikipedias differ with regard to the following:

- Discussion flows in individual AfDs.
- Procedures for submitting articles for deletion (starting an AfD).
- Tools aiding in creating AfDs, such as template messages manually or automatically added by users.
- Methods of archiving submissions.

In the second stage, user comments posted in individual AfDs were analyzed. Twenty such discussions were randomly selected from each language version. If individual pages were archived and categorized, the PetScan tool was used to select these pages. In some language versions, individual AfDs were not categorized, but sets of discussions were archived with daily dates provided. In such cases, two discussions from each year in the last decade were randomly selected. This approach allowed for the selection of discussions where AfD procedures had already been institutionalized, and users might be more engaged in interpreting the rules. For translating comments (the authors only use Polish, English, and Russian), Google Translator was used for this purpose. In doubtful cases (users often make linguistic errors), consultation with individuals proficient in the respective

language proved most often necessary with regards to Japanese as the quality of machine translation between European and Asian languages lags behind that of European to European, which approaches near-perfect quality - at least for tasks such as understanding AfDs.

The coding of comments was conducted in several steps. Firstly, unique comments that did not repeat verbatim were selected in each language version. Subsequently, they were coded as follows: the type of comment was determined, and each comment was assigned categories - detailed and more general. This approach allowed for obtaining a general overview of users' action strategies in the studied language versions. Coding was done by one author and spot-checked by another to improve reliability.

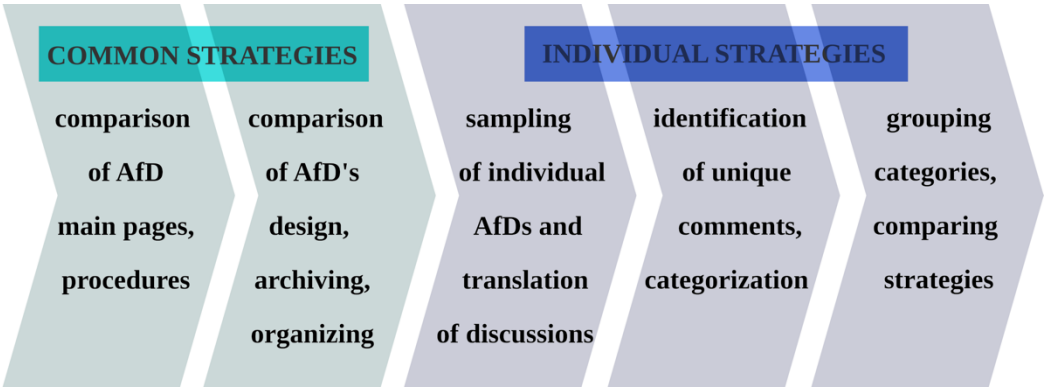

Figure 1: Stages of the analysis of common and individual strategies related to making decisions about article deletion in Wikipedia

4. Results

Among the wide variety of strategies implemented in AfD, we distinguished two primary types: strategies undertaken by individual users and strategies adopted by the language community of Wikipedia versions.

4.1 Common Strategies

The frameworks for the handling of AfDs are established by community procedures. They primarily include the timeframe for action, the manner of conducting the debate, and how it is concluded. In this regard, the studied language versions did not differ significantly. In each of them, emphasis was placed on participants presenting their arguments rather than just expressing support or opposition to the deletion of the entry. Some AfD regulations explicitly state that the deletion procedure is not a vote. In the English version, such non-substantive comments are often ignored or criticized, while in the Polish version, they are struck out. The timeframe for reaching a consensus on the deletion of an article is almost universally set at seven days. Shortening or lengthening was applied if situationally permissible. In the Russian and Japanese versions, some nominations are not closed even for many months.

Certain differences in procedures are visible regarding the opening and closing of AfDs. In the English, Spanish, and French versions, special help pages with tips on how to nominate articles for deletion have been created. In some versions, actions to be taken before nomination are required (e.g. searching for sources in English Wikipedia), while in others, recommended (e.g. in Polish, to inform the author and relevant WikiProjects). On the other hand, when closing the discussion, besides the duration of the discussion, required actions are common. Closers are generally asked to summarize the discussion and based on that, decide the fate of the nominated article.

The greatest differences among the examined language versions were observed in the design of AfDs and related user interfaces and tools. Specific solutions were found in each of the studied language versions in this regard. In the Italian version, the "temperature of discussion" is measured by placing a message about the length of the discussion next to the links to individual AfD discussions. The longer the discussion, the warmer the color of the indicator. In the Polish version, a tool aimed at "cooling down" the discussion is a message encouraging users to express their opinions in a civilized manner, which appears above the AfD page when it is being edited. The Spanish version of the AfD category page contains tables with information about ongoing discussions: the number of users, the number of days since the last edit, and the number of days until the discussion is closed. Additionally, it includes a dictionary of acronyms most commonly used within AfD. A similar glossary is present

in the Dutch version, but it distinguishes itself by explicitly recommending the use of acronyms when submitting articles for deletion.

In some language versions, special subpages are created for submissions of pages that are not articles, and in some cases, subpages are created for individual thematic areas. The greatest diversity in this regard is visible in the English version, where discussions are separately held on topics such as Media, Organizations, Biography, Society, Web, Games, Science, Arts, and Places. These topics are further divided into subtopics, totaling several dozen (e.g. for individual countries, or branches of science). In these discussions, templates with icons are sometimes used, which immediately indicate the commenter's position. The Japanese version has as many as 20 icons for preferred AfDs outcomes. In the Russian version, templates (messages) with declarations of improving the article are used, specifying the time needed for improvement.

Significant differences were also observed in the structure of pages. The German version contains separate sections for submitting articles, lists, categories, user pages, meta pages, and templates. The division of the subpage into sections is also visible in the Swedish version, but in this case, separate positions on what to do with the article are presented in different parts of the page: delete, keep, neutral, merge, redirect. In the French version, each AfD page discussion is preceded by several elaborate messages about the AfD procedure and the possibility of participating in it. In other versions, such messages are either not used or placed so as not to overshadow the main part of the discussion.

The diversity of solutions in the design of AfD pages reflects different approaches to addressing issues related to understanding messages, persuading appropriate actions, or organizing arguments. Each of these aspects pertains to controlling the process of article removal. Some of the solutions developed are not compatible with other language versions. For example, synthesizing solutions from the French, Swedish, and German versions would lead to excessive expansion of AfD pages and could consequently result in cognitive overload.

4.2 Individual Strategies

Analyzing 200 AfD discussions from 10 language versions, some consisting of a few sentences and others spanning several pages, 767 unique comments were identified. Uniqueness meant that comments repeated within the same language version (comments copied by subsequent participants in discussions) were not considered. This allowed for determining the scale of qualitative diversity. Out of all the identified comments, 760 were categorized, and the categories were divided into three types: comments relating to Wikipedia's core principles, comments concerning the quality of the discussed articles, and comments related to the course of discussions at AfDs.

The most frequently posted comments (399 cases) fell into the first category (Table 1). These included comments where those advocating for deletion cited specific provisions in established policies, comments expressing doubts about the application of these provisions in individual cases, and opinions questioning specific principles of the policies themselves. Discussions at AfDs can thus be seen as an arena through which interpretations of Wikipedia's core principles are created and modified. Some rules have been developed after recurring discussions in AfDs within a particular thematic scope (this is particularly common with regards to clarifications of notability criteria; notability means importance and is an important consideration in deletion, i.e. it concerns the question of whether a topic is important enough to merit a Wikipedia article). These discussions often revolve around establishing entry thresholds for articles in a specific area of knowledge, as evidenced by the results of this study. A total of 240 comments (over 30%) were related to the recognition or non-recognition of notability. On the other hand, the submission of multiple articles within a certain scope is a strategy employed by individual users to initiate debate among the community and establish specific notability criteria. A significant part of comments also addressed reliability and verifiability issues, most commonly the lack of sources or the presence of low-quality sources.

Table 1: Comments relating to Wikipedia's main principles

General categories	Specific categories
Notability / What Wikipedia is not (240)	lack of demonstrated notability: topic is local, niche, unknown, the entry is too detailed, or a directory/catalog entry arguments for notability: popularity, media coverage, reach, influence, uniqueness, award-winning; arguments about the lack of references to the article (also in other language versions); and failure to meet specific notability criteria.
Verifiability / No original research (93)	Issues related to lack of citations (sources of information), including the problem of no sourcing for an extended period; searching for and obtaining sources of information; verifying content in sources; determining the credibility of sources, including rejecting and accepting primary sources. Criticism of speculation or original research (forbidden on Wikipedia).
Neutral point of view (36)	Issues related to self-promotion, censorship, advertising, subjective views
Copyrights (18)	Detecting and removing copyright violations
”Ignore all rules” (12)	Arguments about the usefulness or harmlessness of weak articles; denial of specific rules; the need to describe all topics within a certain scope regardless of their individual significance.

It was somewhat surprising to see AfDs being used for discussions on the removal of copyright-infringing content. Out of 18 such comments, 15 originated from the Japanese version, which, incidentally, less frequently employs AfDs for other purposes. In other language versions, procedures related to the removal of copyright-infringing content are usually conducted on separate pages. Transferring discussions on this matter to AfDs may be a good strategy if other pages are not as popular among Wikipedia users in a given project.

Among the comments of the second type, there were more opinions from inclusionists, pointing out the possibilities of improving the content or arguing about the existence of similar articles that have been accepted. Deletionists, on the other hand, pointed out issues such as articles not being improved for a long time, the inappropriate form and style, including faulty translations from other language versions, the presence of false information, and the problem of posting many low-quality articles. Conciliatory-minded Wikipedians, in turn, suggested taking actions that facilitated preserving someone's work, including improvement, integration with other articles, or temporarily moving content to the authors' drafts (Table 2). Understanding the arguments of the participating sides in the debate often led to finding solutions that could be acceptable to adversaries.

Comments of the third type most commonly focused on the behaviors of other users. This included both detecting inappropriate behaviors and expressing positive emotions towards the actions of others. Their appearance in the discussion often led to the development of side threads about the AfD procedure itself and contributed to involving a greater number of users in the discussion. Emotionality can therefore promote greater engagement and the development of more favorable decisions; however, it often leads to a situation where consensus is not reached due to the length of the discussion (see: Skolik, 2013). This type also included ethical evaluations of actions related to the subject of the article, such as writing biographies for payment and assessing the protagonists of the biographies (Table 3).

Table 2: Comments relating to the quality of existing articles

General categories	Specific categories
Comparisons (53)	Pointing out analogies to other articles or other language versions, mainly in the context of the need for the existence or removal of an article.
Correcting or not correcting articles (47)	Pointing out the lack of necessary changes in content for a long time and suggesting the need for more time for improvement; Declaring improvement, making corrections during AfD, and creating articles from scratch; Indicating one's own involvement in improvement; Suggestions for improving the article, including suggestions to move them to user sandboxes.
The form of the article (42)	Pointing out inappropriate form, style, failure to meet standards for old articles, insufficient length of articles; issues arising from incorrect translation of articles and discrepancies between titles and content.
Integration/redirection (33)	Pointing out the need to include the issue in a more general article; integrating content; converting articles into redirects to other articles; moving content to another wiki; and changing articles into disambiguation pages.
Currentness (23)	The problem of lack of updates; pointing out that Wikipedia is not intended for describing current and future (uncertain) events.
Detecting of false content (16)	Describing content as nonsense, garbage, hoaxes, pseudoscience; Detecting falsification of information.

General categories	Specific categories
Series of problematic articles (10)	Detecting authors of many weak articles; arguments about the need for mass deletion of articles within a certain scope.

Table 3: Comments relating to the course of the AfD

General categories	Specific categories
Etiquette/expressing emotions (56)	Assessing the behavior and competence of commentators, including accusations of vandalism and trolling; critically evaluating the course of AfD; expressing thanks (including for content improvement), apologies; joking; expressing discouragement from further action.
AfD internal issues (28)	Canceling AfD; duration of AfD; meta evaluation of AfD; monitoring changes in AfD; opting out of AfD; closing AfD; the issue of "clogging AfD" by too frequent submissions.
Decision making (27)	Questioning and circumventing AfD decisions; reminding that AfD is not a vote; informing about previous discussions on the same topic; suggesting discussions outside of AfD; the issue of repeated deletion and speedy deletion.
Approval/disapproval (11)	Expressing approval of actions, including integration, deletion, or retention of the article; discrediting other participants.
Conflict of interest (8)	Pointing out the independence of the content of the article from the subject it covers; the issue of paid editing; recognizing the primacy of principles over personal judgments.
Subject of the article (7)	Assessing the subject of the article; the issue of posting private data about the subject.

5. Discussion and Conclusions

The research revealed a significant diversity in the behaviors of participants in article deletion discussions. It captured the specificity of technical and organizational solutions, which would not have been possible by analyzing only predefined cultural dimensions (Konieczny 2020, 2023). At the same time, the similarity of procedures in the analyzed versions of Wikipedia may indicate a strong organizational culture. Individual users' comments mostly referred to Wikipedia's main principles. Additionally, arguments, argumentative styles, and counterarguments were similar in each language version, with notable differences observed in the Japanese version, where users more often focused on removing copyright-violating content.

As noted in previous studies referring to behavioral strategy arguments, individuals with broad activity profiles tend to pay less attention to conflict situations. Stronger reactions are observed in individuals who have invested more in developing specific projects (Ocasio, 1997; Klapper & Reitzig, 2018). Similarly, individuals more involved in AfDs or the development of articles submitted to AfD for not meeting standards exhibit stronger reactions. However, comments tend to prioritize rules over personal attachment to the article's subject, which suggests that attachment to jointly developed rules is high.

Future research could delve into the stages of differentiation between language versions more closely. Survey research would help determine the intentions of the most engaged users in AfD from other major language versions.

Although a more precise comparison of individual strategies would require describing the actions' history of the most active users engaging in AfD, based on years of participatory observation, we conclude it is likely that individual actions become routinized over time. We also conclude that AfDs contribute to the development of institutionalized policies and guidelines (in particular, ones related to notability).

Most rules and procedures were copied from the English version, but the pace of their implementation varied. Language versions also differ in enforcing rules developed locally. While it is technically possible to identify when a rule was written, it is harder to determine when it began to be treated as a standard. Recognizing strategies and the complexity of actions on AfD could lead to better handling of conflict situations and optimization of actions by Wikipedia editors, who, as a community, spontaneously manage processes related to removing low-quality content from the encyclopedia.

At the individual level, a variety of behavioral strategies can be observed on AfD (Articles for Deletion) pages. However, at the community level, specific rules and norms tend to crystallize. In the initial years, these rules are frequently modified, but over time, due to organizational inertia, they become increasingly institutionalized, making any changes more challenging to implement. One could argue that certain strategies, once they gain popularity, become stable and are difficult to displace with new patterns, even when solutions from more developed language versions are proposed.

According to Dunbar's social brain hypothesis, the dialectalization and emergence of new languages were linked to the need to distinguish between "us" and "them" in growing human communities (Dunbar, 2011). In the context of Wikipedia, communities that initially create rules collectively (globally) tend to separate over time, thereby strengthening their own identities. This phenomenon leads to a resistance to innovation, a trend observed in many organizations. Consequently, Wikipedia, which began as a grassroots alternative to traditional encyclopedias, is becoming increasingly similar to traditional organizational models.

Abstract: The formation of intellectual capital (IC) of natural sciences at scientific institutions (SIs) in Latvia is highly topical. The object of the research is the formation of IC of natural sciences at SIs while the subject of the research is the comparative analysis of the efficiency of the involvement of academic staff and PhD students in the formation of IC of natural sciences at SIs of Latvia. The objective of the research is to study the involvement of academic staff and PhD students in the formation of IC of natural sciences at SIs in Latvia in the period from 2013 to 2018. The following tasks were determined to reach the objective: to study the formation of IC of natural sciences at SIs; to identify the concept of the efficiency of the involvement of academic staff and PhD students in the formation of IC of natural sciences; to calculate main indicators thereof, and, to carry out the comparative analysis of indicators characterising the efficiency of the involvement of academic staff and PhD students in the formation of IC of natural sciences at SIs in Latvia. Research methods used in the paper are content analysis, economic analysis, and economic experiment.

Keywords: Intellectual Capital Indicators, Natural Sciences, Scientific Institutions, Efficiency, Academic Staff

1. Introduction

The aim of the research is to study IC of natural science and the efficiency of its formation at SIs in Latvia. Every six years, the Ministry of Education and Science of the Republic of Latvia (MoES) organises an international evaluation of SIs registered in Latvia. The last International Evaluation of Scientific Institutions' Activity (IESIA) refers to the period from 2013 to 2018. In order to establish the dynamics of efficiency indicators of academic staff involved in the formation of IC in natural science at SIs of Latvia (MoES, 2021), the authors used the output secondary data of findings across the set of evaluation of SIs of natural sciences per period from 2013 to 2018 offered by "Technopolis-group" (TG). Consequently, it provides an opportunity for the authors to calculate the efficiency indicators of IC in na-tural sciences at SIs of Latvia and to compare their results.

Data of the comparative analysis will help to develop support programs to increase the efficiency of involvement of the academic staff in the IC formation. In addition, the comparative analysis will reveal whether the score of natural

sciences at SIs of Latvia in the IESIA of TG coincides with the place of SIs of Latvia in the ratings of IC indicators, and whether the overall score of SIs of Latvia also reflects the efficiency of the involvement of the academic staff of SIs of Latvia in the IC formation.

Hypothesis: The overall score of SIs shows the efficiency of the IC formation at SIs of Latvia.

2. Theoretical Background

The Research of the role of human capital in educational-training process at the university (Contu, 2017) presented different aspects of IC. Spica et al (2017a) state that IC is an economic category, the spiritual value created by the human potential, and it can be accumulated and converted into the value of other capitals. By investigating certain information about the management of education and science, we can increase the capacity and significance of the country's total economic capital movement. Rondeau et al (2022) remind that peer reviewed publications remain a traditional form of academic productivity. Spica et al (2017a; 2017b) have worked out four indicators of the efficiency of the formation of IC in the higher education establishment (HEE): (1)The efficiency of the involvement of academic staff in the formation of IC per year in percentages (AIK); (2)The efficiency of the involvement of academic staff with a Doctorate degree in the formation of IC per year in percentages (DIK); (3)The efficiency of the involvement of students in the formation of IC per year in percentages (SIK); (4)Mutual efficiency of the involvement members of the academic staff with Doctorate degrees and the academic staff without Doctorate degrees in the formation of IC per year in times, (DE).

3. Research Methodology

In order to calculate the AIK, DIK, SIK, and DE of the HEE Spica et al (2017a; 2017b) have worked out four formulas: (1) AIK = (ZPS : AS) x 100; (2) DIK = (ZPS : DS) x 100; (3) SIK = (ZPS : SS) x 100; (4) DE = DIK : AIK. Where: ZPS represents the number of scientific publications of the HEE per year; AS represents the number of academic staff in full-time jobs per year; DS represents the number of academic staff with Doctorate degrees holding in full-time jobs per year; SS represents the number of students per year.

The authors modified the above mentioned formulas for the purposes of the study. Namely, they calculate IC efficiency indicators for total numbers of full time equivalent (FTE) academic and research personnel (KIK), for FTE academic personnel (AIK), for FTE academic and research personnel (PIK) and for PhDs completed at SIs (SIK). In addition, all the said IC efficiency indicators were calculated for different forms of IC such as total number of self-reported outputs of IC (KS), articles in peer reviewed scientific edited journals and conference proceedings included in WoS or SCOPUS (WS), articles in peer reviewed edited journals, and conference proceedings not included in WoS or SCOPUS (RS), monographs (MS), and Latvian patent (LPS), and European patent and International patents (EPS). The authors calculated mutual efficiency indicators (PE) regarding involvement of the FTE academic and research personnel (PS) and the FTE academic personnel (AS) in the formation of IC in times.

In the present research, the authors used the following data from the IESIA: output data on the number of FTE academic personnel (AS), the number of FTE academic and research personnel (PS), the total number of FTE academic and research personel (KS), the number of PhDs completed (SS), the number of articles in peer reviewed scientific edited journals and conference proceedings included in WoS or SCOPUS (WS), the number of articles in peer reviewed scientific edited journals and conference proceedings not included in WoS or SCOPUS (RS), the number of monographs (MS), the number of Latvian patents (LPS), and the number of European and International patents (EPS), and total number of self-reported outputs (KS) in period from 2013 to 2018 per SI of natural science in Latvia. Authors revised the above WS, RS, MS, LPS, EPS and KS for the year.

To calculate the efficiency of the involvement of academic staff in the WS formation used formulas:

AIK = (WS : AS) x 100 (1)

PIK = (WS : PS) x 100 (2)

KIK = (WS : KS) x 100 (3)

SIK = (WS : SS) x 100 (4)

PE = PIK : AIK (5)

In order to calculate the efficiency of the involvement of academic staff in the RS formation used formulas:

AIK = (RS : AS) x 100 (6)

PIK = (RS : PS) x 100 (7)

KIK = (RS : KS) x 100 (8)

SIK = (RS : SS) x 100 (9)

PE = PIK : AIK (10)

The efficiency of the involvement of academic staff in the formation of MS calculated according to formulas:

AIK = (MS : AS) x 100 (11)

PIK = (MS : PS) x 100 (12)

KIK = (MS : KS) x 100 (13)

SIK = (MS : SS) x 100 (14)

PE = PIK : AIK (15)

To calculate the efficiency of the involvement of academic staff in the formation of LPS used formulas:

AIK = (LPS : AS) x 100 (16)

PIK = (LPS : PS) x 100 (17)

KIK = (LPS : KS) x 100 (18)

SIK = (LPS : SS) x 100 (19)

PE = PIK : AIK (20)

Besides, to calculate the efficiency of the involvement of academic staff in the formation of EPS used formulas:

AIK = (EPS : AS) x 100 (21)

PIK = (EPS : PS) x 100 (22)

KIK = (EPS : KS) x 100 (23)

SIK = (EPS : SS) x 100 (24)

PE = PIK : AIK (25)

In this study, one scientific publication or one patent are accepted as one unit of IC. Further, using the modified formulas 1 to 25, were calculated: KIK, AIK, PIK, SIK, PE. Then, according to the results obtained through the author's calculations, a corresponding rating place was assigned to each SI of Latvia per year and each of the above indicators KIK, AIK, PIK and SIK.

Each place in the rating was then assessed with an appropriate score, where the lowest score is 1 point, while the highest score is 5 points. Thus, the SI, which took first place in - KIK, AIK, PIK and SIK received 5 points in the ranking, took second place - received 4 points, took third place - received 3 points, took fourth place - received 2 points, and took fifth to seventh place - received 1 point.

The above mentioned assessment system allows to compare the quantitative efficiency indicators of SIs of natural science in Latvia calculated by the authors to IESIA overall assessment criterion - quality of the SI research performance. The relevant TG Panel was the score of research performance of each SI using a scale where score 5 means an outstanding level of research, score 4 means a very good level of research, score 3 means a good level of research, score 2 means an adequate level of research, and score 1 means a poor level of research (MoES, 2021).

The score assigned to the overall assessment by the relevant TG Panel was based on the assessment of five sub elements A to E, where element A characterises the quality of the research, element B - the impact on the development of the specific field of science, element C - the economic and social impact of the research, element D - the research environment and infrastructure of the institution, element E - the institution development potential. The Panel was provided with scores against each sub-element and the overall score and was also provided with narrative descriptions of their scores, the overall score and the sub-elements (MoES, 2021).

The follow-up authors compared the results of their own estimates of SIs quantitative scores to the qualitative scores of the relevant TG Panel, and calculated the differences between the scores. For this purpose, the authors calculated the average score for each SI recording the efficiency indicators of the involvement of academic staff in IC formation and compared these scores to scores of the research quality of each SI and overall score developed by the TG Panel.

4. Results and Discussion

The number of scientific publications and patents are the main results of the IC formation at SIs of natural sciences. TG analysed 7 SIs of natural sciences of Latvia. In the IESIA there were collected output data on 7 public SIs of Latvia including 6 Latvian university, and one Latvian State Institute were collected.

During the period analysed in the IESIA, there were only 7 such SIs in Latvia: Latvian Institute of Aquatic Ecology, Daugavpils University (DU/LIAE); Institute of Solid State Physics, University of Latvia (ISSP); Latvian State Institute of Wood Chemistry (LSIWC); Research programme “Biology”, Daugavpils University (DU/Bi); Cluster of Natural Sciences, University of Latvia (UL/N), Ventspils University of Applied Sciences Natural Sciences Research Platform (VeU/N), Research programme “Mathematics, Physics, Chemistry”, Daugavpils University (DU/MPC).

It follows from the IESIA that in Latvia, 4 SIs of natural sciences have corresponding fields of science in earth and rela-ted environmental sciences, 4 SIs corresponding fields of science in physical sciences, 3 SIs corresponding fields of science in biological science, 3 SIs corresponding fields of science in chemical sciences, 2 SIs corresponding fields of science in materials engineering, 2 SIs corresponding fields of science in mathematics, and, 2 SIs corresponding fields of science in computer and information sciences. In turn, such corresponding fields of sciences as nanotechnology; che-mical engineering are operated by 1 SI in each field of science.

According to the authors' estimates, from the IESIA data show that the total number of self-reported outputs of SIs of natural science in Latvia is taken in the largest proportion by the WS - 80,72%, which is followed by the RS - 15,97%, the MS - 0,88%, the LPS - 1,70%, the EPS - 0,73%.

4.1 The Efficiency of the Involvement of Academic Staff in the WS Formation at SIs of Natural Sciences

These indicators of SIs and their place in the rating of SIs of natural sciences in Latvia as well as its scores are summarized in Table 1. The table of the SIs indicators, ratings, and score was drawn up by authors. The summarized indicators show that in general, in Table 1, the figure rests in the range from 26% to 659% in respect of the SIs in Latvia. The highest indicator is SIK in the VeU/N, while the lowest indicators is PIK in the DU/LIAE. Comparing the figures collected in Table 1, the authors conclude that the AIK indicator rests in the range from 389% to 550%. The lowest KIK indicators of 27% is for theDU/LIAE, the highest KIK indicator of 128% are for the ISSP, and for the DU/Bi; the highest SIK indicator of 659% is owned by the VeU/N while the lowest SIK indicator of 179% is held by the UL/N. The PS of the SIs of natural sciences are only 0,2 times to 0,4 times efficient in the WS formation.

In Table 1, the authors created the rating and score of the SIs of natural sciences in Latvia based on the AIK, PIK, KIK, SIK indicators of the efficiency of the academic staff and PhDs involvement in the WS formation. According to the AIK indicator, the first place, and highest score is taken by the UL/N; according to the PIK indicator, the first place, and highest score is taken by the DU/Bi; according to the KIK indicators, the first place and highest score is taken also by the DU/Bi; and according to the SIK indicator the first place and highest score is taken by theVeU/N.

On the other hand, when comparing the average score of KIK without SIK, the highest score is obtained by the DU/Bi and the comparison of the average score of KIK with the SIK shows that the highest score goes also to the DU/Bi.

The authors compared the SIK indicators of all students of HEE in Latvia to SIK indicators of PhDs students of SIs of natural sciences in Latvia, and found that SIK indicators of the PhDs students were considerably higher. It follows from the study by Spica et all (2018) that the highest SIK indicators were held by Daugavpils University (1,45% in 2013) and the University of Latvia (1,82% in 2014). Meanwhile, between 2013 and 2018, the highest annual SIK indicator for PhDs students of SIs of natural sciences in Latvia was held by the VeU/N and represented 659%.

Table 1: The efficiency of the involvement of academic and research staff in the WS formation at SIs of natural sciences in Latvia per year in period from 2013 to 2018

SI	AIK (%)	AIK rating	AIK score	PIK (%)	PIK rating	PIK score	KIK (%)	KIK rating	KIK score	Average of AIK & PIK score	PE in times	SIK (%)	SIK rating	SIK score	Average of AIK & PIK & SIK score
DU/LIAE	0	0	0	26	7	1	27	7	1	0,5	0	239	6	1	0,7
ISSP	0	0	0	128	3	3	128	2	4	1,5	0	625	2	4	2,3
LSIWC	0	0	0	66	6	1	66	5	1	0,5	0	255	5	1	0,7

SI	AIK (%)	AIK rating	AIK score	PIK (%)	PIK rating	PIK score	KIK (%)	KIK rating	KIK score	Average of AIK & PIK score	PE in times	SIK (%)	SIK rating	SIK score	Average of AIK & PIK & SIK score
DU/Bi	494	2	4	173	1	5	128	1	5	4,5	0,4	578	4	2	3,7
UL/N	550	1	5	113	4	2	94	4	2	3,5	0,2	179	7	1	2,7
VeU/N	415	3	3	74	5	1	63	6	1	2,0	0,2	659	1	5	3,0
DU/MPC	389	4	2	159	2	4	113	3	3	3,0	0,4	606	3	3	3,0
Average	733			109			95				0,2	241			

When analying the results obtained by SIs in the IC formation in the field of natural sciences, the same methodology was used as in the fields of social sciences, and, humanities and art sciences. Thus, the quantitative results of SIs in these fields can be compared. One of the main criteria for the quantitative evaluation of SIs is the efficiency of the involvement of the SIs academic staff in the formation of WoS and SCOPUS publications.

The comparison of the results of the three fields of science leads to conclusion that the highest score of the KIK indicator in the field of social sciences is 278% (Spica et al, 2022) while the highest score of the KIK indicator in field of natura science is 128%, and, the highest score of the KIK indicator in field of humanities and art sciences is 53% (Spica et al, 2023). In addition, it should be noted that the highest score of the KIK indicator in the field of humanities and art sciences is two times higher than 27% received by the DU/LIAE, which is the lowest score in the field of natural science.

A similar trend is observed when comparing the efficiency of the involvement PhD degree holders in the formation of WoS and SCOPUS publications in the three above-referred fields of science. Here, the highest rate of the SIK indicator in social sciences is 667% (Spica et al, 2022) while in natural sciences the highest rate is 659%, and, the highest rate of the SIK indicator in humanities and art science is 450% (Spica et al, 2023). In turn, the lowest rate of the SIK indicator in the field of natural sciences is 179%; the lowest rate of the SIK indicator in the field of social sciences is 58% (Spica et al, 2022); the lowest rate of the SIK indicator in the field of humanities and art science is 13% (Spica et al, 2023). This means that the lowest rate in the field of natural sciences, however, is almost 14 times higher than the lowest rate in the field of humanities and art science, and, almost 3 times higher than the lowest rate in the field of social sciences.

4.2 The Efficiency of the Involvement of Academic Staff in the RS, MS, LPS, EPS Formation at SIs of Natural Sciences

In Table 2, in respect of SIs of natural science in Latvia, the figure rests in the range from 1% to 165%. The highest indicator is the SIK in the LSIWC, but the lowest indicators are the PIK and the KIK in the DU/LIAE.

Table 2: The efficiency of the involvement of academic and research staff in the RS formation at SIs of natural sciences in Latvia per year in period from 2013 to 2018

SI	AIK (%)	AIK rating	AIK score	PIK (%)	PIK rating	PIK score	KIK (%)	KIK rating	KIK score	Average of AIK & PIK score	PE in times	SIK (%)	SIK rating	SIK score	Average of AIK & PIK & SIK score
DU/LIAE	0	0	0	1	7	1	1	7	1	0,5	0	11	7	1	0,7

The AIK indicators were collected only for the 4 SIs of natural sciences, and the authors conclude that the highest AIK indicator of 116% is held by the DU/Bi, while the lowest AIK indicator of 68% belongs to the VeU/N; the highest PIK indicator and KIK indicator of 43% is held by the LSIWC, while the lowest PIK indicator and KIK indicator of 1% belongs to the DU/LIAE; the highest SIK indicator of 165% is held by the LSIWC, while the lowest SIK indicator of 11% belongs to DU/LIAE.

In Table 3 the figure rests in the range from 1% to 17% in respect of the SIs in Latvia. The highest indicator is SIK in the DU/Bi and the VeU/N, but the lowest indicators are PIK and KIK in the UL/N and the DU/MPC.

Of the 7 Latvian SIs in the field of natural sciences, the 4 SIs have the MS, the 5 SIs have the LPS, and, only the 3 SIs have the EPS.

Average	15			2			2				0,2	5			

In Table 4 the figure rests in the range from 1% to 61% in respect of the SIs in Latvia. Comparing the figures collected in Table 4, the authors conclude that the highest AIK, PIK, KIK and SIK score is held by the DU/MPC, while the lowest AIK, PIK, KIK and SIK score belongs to the DU/Bi.

In Table 5 the figure rests in the range from 1% to 11% in respect of the SIs in Latvia; the highest PIK, KIK and SIK score is held by the LSIWC, while the lowest PIK, KIK and SIK score belongs to the UL/N.

Table 5: The efficiency of the involvement of academic and research staff in the EPS formation at SIs of natural sciences in Latvia per year in period from 2013 to 2018

SI	AIK (%)	AIK rating	AIK score	PIK (%)	PIK rating	PIK score	KIK (%)	KIK rating	KIK score	Average of AIK & PIK score	PE in times	SIK (%)	SIK rating	SIK score	Average of AIK & PIK & SIK score
ISSP	0	0	0	1	2	4	1	2	4	2,0	0	7	2	4	2,7

UL/N	4	1	5	1	3	3	1	3	3	4,0	0,2	1	3	3	3,7
Average	7			1			1				0,2	2			

In the tables from 1 to 5, the awerage indicators PE are the same, and the average SIK indicators are the highest, while the average KIK indicators; the average AIK indicators are the highest, while the average PIK indicators.

The comparison of the results of the three fields of science leads to conclusion that the highest average rate of the PE indicators is 1,8 (Spica et al, 2022) in social sciences, the second highest average rate of the PE indicators is 1,7 (Spica et al, 2023) in humanities and art sciences, and, the lowest average rate of the PE indicators is 0,2 in natural sciences. In addition, it should be noted that the highest average rate of the PE in the field of social sciences is nine times higher than the lowest average rate in the field of natural sciences.

4.3 The Comparison of the Results of Qualitative and Quanatitative Evaluation of SIs of Natural Sciences

Table 6: The Comparison of the results of qualitative and quantitative evaluation of Latvian SIs in the field of natural sciences using the IC form for period from 2013 to 2018

SI	Quality score by TG (QTG)	Overall score by TG (OTG)	Total average score of AIK & PIK using IC form (TAAP)	Difference of score (QTG-TAAP)	Difference of score (OTG-TAAP)	Total average score of AIK & PIK & SIK using IC form (TAAPS)	Diference of score (QTG-TAAPS)	Difference of score (OTG-TAAPS)
DU/LIAE	3	3	0,5	2,5	2,5	0,7	2,3	2,3
ISSP	4	4	1,5	2,5	2,5	1,7	2,3	2,3

DU/Bi	3	3	4,5	-1,5	-1,5	4,0	-1,0	-1,0
UL/N	4	3	3,5	0,5	-0,5	2,7	1,3	0,3
VeU/N	3	3	1,5	1,5	1,5	2,3	0,7	0,7
DU/MPC	2	1	3,5	-1,5	-2,5	4,0	-2,0	-3,0

Table 7: The Comparison of the results of qualitative and quantitative evaluation of Latvian SIs in the field of natural sciences using the overall IC for period from 2013 to 2018

SI	Quality score by TG (QTG)	Overall score by TG (OTG)	Total average score of KIK using IC overall (TAKO)	Difference of score (QTG-TAKO)	Difference of score (OTG-TAKO)	Total average score of KIK & SIK using IC overall (TAKOS)	Difference of score (QTG-TAKOS)	Difference of score (OTG-TAKOS)
DU/LIAE	3	3	0,4	2,6	2,6	0,4	2,6	2,6
ISSP	4	4	2,2	1,8	1,8	2,3	1,7	1,7
LSIWC	4	4	3,0	1,0	1,0	3,0	1,0	1,0
DU/Bi	3	3	3,0	0,0	0,0	2,7	0,3	0,3
UL/N	4	3	2,6	1,4	0,4	2,2	1,8	0,8
VeU/N	3	3	1,2	1,8	1,8	1,7	1,3	1,3
DU/MPC	2	1	2,6	-0,6	-1,6	2,7	-0,7	-1,7

When comparing the qualitative ratings of TG group to the quantitative assessments perfomed by the authors, it can be concluded that they differ from minus 3,0 points to plus 3,5 points in total.

The study shows that the KIK, AIK, PIK, and SIK of SIs of natural sciences in Latvia were lower than the results compiled by the relevant TG Panel except for one to two SIs of natural sciences, and, except for the DU/Bi, where QTG, OTG, TAKO scores coincided.

5. Conclusions

The study did not result in confirmation of their hypothesis. The hypothesis is accepted *pro tem* for other branches of SIs of Latvia.

The present research includes further development of study on the contents of IC of natural sciences and the efficiency of its formation at the SIs in Latvia, performed comparative analysis characterising the Latvian SIs of natural sciences as awhole, specified the system of IC efficiency indicators and presented its quantitative interpretation.

In order to improve the quality of the IESIA of SIs of natural sciences is encouraged to supplement its methodology with quantitative analysis of IC efficiency indicators.

Abstract: This paper is a part of the ORCHESTRA project (Horizon Europe 2021-2024), where the vision is a future where it is easy to coordinate, negotiate and synchronize traffic across all modes (road, rail, sea, and air). Multimodal Traffic Management (MTM) orchestrates traffic across modalities, and with that optimizing capacity in the total transport network. Thus, we may reduce negative impacts of traffic, such as emissions and delays, and still get people and goods to their destination on time. This paper aims to present piloted traffic manager training and reflect upon traffic manager's future competence and training needs, labelled Traffic Orchestrators (TO). The paper presents critical traffic orchestration concepts, measures, and recommendations regarding future TO education. In addition, to learn how to use management tools specific related to their own governance area (GA), TOs also need knowledge on coordination and negotiation with other TOs managing traffic in affected surrounding areas. The pilot form TO training modules for (I) Basic and fundamental competencies, (II) Future scenario handling (normal operation, foreseen events, unforeseen events), and (III) Follow-up modules, refresh studies and specification.

Keywords: Knowledge Creation, Polycentric Multimodal Traffic Management, Education, Inter-Organizational Coordination, Resilience

1. Introduction

This paper is a part of the EU project ORCHESTRA, 2021-2024, addressing the problem that traffic caused by transport has many harmful effects, such as congestions and emissions. These challenges are hard to handle due to a lack of coordination both within and across different transport modes (road, rail, sea, and air). The paper addresses the gap of knowledge and competencies that traffic managers possess today and future requirements for inter-organizational coordination and pro-active traffic orchestration.

The long-term vision of ORCHESTRA is future *Multimodal Traffic Management* (MTM) through *traffic orchestration*, i.e. by coordination and synchronizing traffic management across all modes to cope with diverse demands and situations and to increase optimization and resilience. The general objective is to provide European policymakers, public authorities, transport providers and citizens with new knowledge and technical and organizational solutions to enhance traffic orchestration. The definition of *traffic* is the accumulated vehicles that use infrastructure as a means of travelling from place to place, while *transport* is the movement of people and goods from one place to another using vehicles in all modes (road, air, rail and sea). This paper aims to present a framework for future education, and to reflect upon competence and training needs of future traffic managers, labelled *Traffic Orchestrators* (TO). TOs are key stakeholders in the coordination and cooperation of traffic across governance areas (GA) and network modes. The paper addresses the key questions: (1) What knowledge and competencies do future traffic managers need, and how does it differ from today? (2) How should knowledge creation processes be? (3) How should a future training program look?

1.1 The System of Interest and Key Concepts

ORCHESTRA describes an MTM ecosystem (MTME) and a future polycentric management architecture (PMA). Based on existing structures, policies, regulations, GAs and actors – *polycentric management* aims to bridge communication, coordination and collaboration between several centres through data sharing, described by a PMA and an MTME. Multimodal transport of people and goods may facilitate traffic capacity across networks for optimal transport, avoiding sub-optimization within one modality. MTM includes managing and synchronizing traffic across all transport modes optimizing resources and minimizing negative impacts.

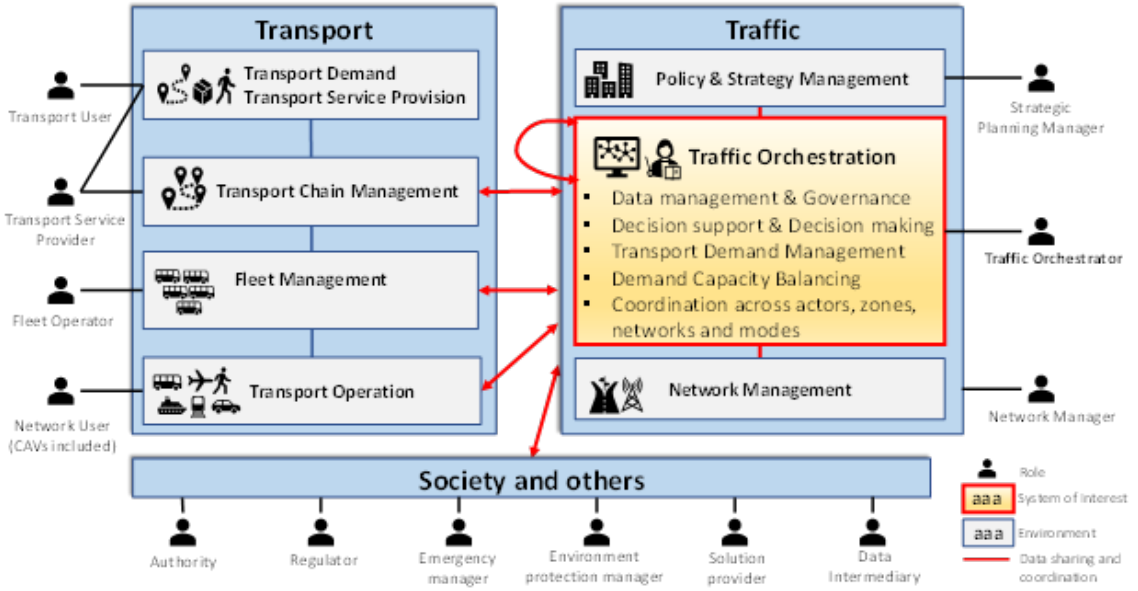

Figure 1: Multimodal Traffic Management Ecosystem (MTME) with System of Interest in its environment).

Figure 1 illustrates the ecosystem constituting Transport, Traffic, and Society and others (Natvig et al, 2024). Stakeholder archetypes represent generic roles with defined responsibilities. Real actors may play one or more roles. A *Traffic Orchestrator* is the executive stakeholder using new measures for:

- *Coordination, cooperation and negotiation across actors, zones, networks, and modes* aiming to arrange for optimization and resiliency using the total transport system.
- *Transport Demand Management* (TDM) aims to arrange everyday traffic flow according to policy and overall strategy of the transport system.
- *Demand Capacity Balancing* (DCB) aiming to cope with current and upcoming situations involving an imbalance between transport demand and capacity in the network.

TOs differ from fleet managers or vehicle operators in the way that they don't manage the fleet or the vehicle but *orchestrate the traffic* generated by fleets and vehicles when transporting people and goods. Traffic orchestration requires knowledge beyond the individual TO's defined governance area (GA), including understanding traffic flows between GAs, co-handling incidents, consequences and ripple effects across networks and GAs. A TO does, therefore, need training in using tools specific to manage traffic within their own GA, and to coordinate and negotiate with other TOs in surrounding GAs.

2. Theoretical Perspectives

One main ORCHESTRA result is to develop enabling toolkit supporting the realisation of MTME, including designing training modules and piloting training adapted to the two Living Labs. The resilience perspective will highlight the following questions: (1) What knowledge and competencies do future traffic managers need, and how does it differ from today? Theories on knowledge creation are presented regarding (2) How should knowledge creation processes be designed? (3) How should a future training program look? In the context of MTM, an educational design model is used.

2.1 Resilience

Resilience is identified as an important aspect for MTM and PMA and is central in the education of future TOs. Numerous definitions of the resilience concept are proposed. The definition used in the ORCHESTRA project is: *"A system is resilient if it can adjust its functioning prior to, during, or following events (changes, disturbances, and opportunities), and thereby sustain required operations under both expected and unexpected conditions"* (Hollnagel, 2019). One main characteristic of a resilient system is *adaptability*, i.e. the adaptive capacity to adjust patterns of activities in the entire ecosystem, for some stakeholders or organisations. Resilient traffic orchestration lies in the PMA, and stakeholder's and organisation's willingness to adapt, negotiate, communicate, and co-manage traffic through harmonising regulations, policies and defined work processes

between organisations and governance areas. Training modules are designed to clarify basic competencies for traffic orchestration of the MTME, and competencies to facilitate resilience in actual traffic orchestration under normal, changed, disrupted and disaster conditions.

Key characteristics of a resilient system are *monitoring* critical issues to know what to do; *anticipating through simulations* potential scenarios to know what to look for; *responding* in actual situations to know what to do; and *learning* of experiences and historical events to know what has happened and to be better prepared in the future. In addition to efficient recovery to a normal stage, to be resilient, a system must develop the ability to adapt both to new conditions and to future changes and surprises. Future work on MTM must build on knowledge about e.g. the safety of CAVs, traffic planning and management, and cyber security.

In MTM, resilience is closely linked to the ability to utilize any available capacity when needed. Today's traffic management is reactive, and done in silos, creating sub-optimization by not being able to efficiently be prepared for events, and utilise spare capacity in neighbouring governance areas or networks. Defined and learned operations for cooperation, proactive measures, coordination and negotiations can enable better utilization of total capacity across networks.

The traffic managers should be trained on how to interpret recommendations of technical tools to avoid disruptions, and on how to take the best decision in case a human intervention is advised (Søråsen, 2024; Grosse et al, 2021). Data sharing and orchestration measures will be significant characteristics to facilitate a pro-active, and more resilient multimodal transport management.

2.2 Knowledge Creation

Future MTM will constitute collaboration and coordination across management levels, organizations, and stakeholders. Learning objectives will transform from current silos focus into polycentric considerations, and from reactive to pro-active orchestration of traffic. *Organizational knowledge-creation* should focus on the active, subjective nature of knowledge (Nonaka & Takeuchi, 1995). Knowledge constitutes "*explicit*" or codified knowledge that is transmittable in formal, systematic language and "*tacit*" knowledge deeply rooted in action, commitment, and involvement in a specific context (Nonaka, 1994). In an organisation explicit knowledge may be seen in newsletters, documents and lectures. Tacit knowledge consists partly of technical skills (*know-how*) and cognitive elements (e.g. mental models and images of reality and the future; *what is* and *what ought to be*), Organisational knowledge creation is often described as a spiral with possible transfer between individuals, to groups, organisation and inter-organisation.

In addition to acquiring knowledge, knowledge creation regarding traffic management involves imagination and understanding future practices for management, including dynamic and continuous adaptation to changing circumstances. *Social construction perspectives* hold that individuals learn and develop when participating in social activities. These are regarded as mutual processes between the individual and society. Later approaches are often cited as e.g. situated learning, socio-cultural theory, cultural-historical activity theory, and distributed cognition (Stene, 2021). All regard the *context* as essential to what humans learn and how they develop. Socially developed *artefacts* are considered mediators between individuals and social contexts. While language is seen as the most significant artefact in learning, thinking, and reflection, dialogue and communication are essential. Artefacts are usually perceived as cultural tools and may also include e.g. serious games, written text, maps, illustrations, and diagrams.

Collaboration may support *scaffolding,* implying what a person can learn by assistance, guidance, or help from others. Reflective practice can be viewed as reflection-in-action and reflection-on-action (Schön, 1998), making a distinction between reflection *during* engagement in an activity and reflection *after* the event.

2.3 Design and Evaluation of Training Programs

This section presents a general theoretical, didactical model used for designing training programs. While pedagogy studies the learning processes at a social level (strategies, methods and techniques), didactics focuses more on the learning processes in a school or organisation.

The didactical model includes six elements for planning and designing training programs (Stene, 2010; Timoshenko et al, 2021). The elements are interrelated, i.e. the specification of one element will influence the other elements. Likewise, when changing or modifying one element we must consider implications for the other elements. (1) *Objectives* may be separated into learning objectives and training objectives/purposes. *Learning objectives* are competencies that the participants should have acquired at the end of the education program (or

specific module). These may be defined knowledge, performance, or attitudes. Requirements to goals are that they should be relevant, realistic, meaningful, and clear (to the participants). This element is associated with "Why" the learning is necessary. *Training purposes* are defined from the perspective of the educator or responsible institution and targets the intended effects on the system. (2) *Learning qualification* means the knowledge, attitudes, and performance the participants face the training with. (3) *Framework conditions* are conditions which make learning possible or place a limitation on learning, for instance teaching aids, time, room facilities and artefacts. (4) *Content* describes the curriculum of the training subject and issues to be covered. The element is related to "What" to learn. (5) *Learning process* concerns "How" to learn. This includes both the teaching and instruction methods used by a facilitator or teacher (e.g. lectures, instructions, demonstrations) and the participants' working methods (individually or in teams). (6) *Evaluation* may involve both the learning process, the goal and the participant's learning.

3. Methodology

3.1 Designing the Training

3.1.1 Design of MTM Training Program

ORCHESTRA includes two work packages that emphasize future MTM training. Kalbere & Stene (2023) present the theoretical approach and suggested program including modules, while Nguyen, Stene and Skuggevik (2024) specify the piloted training trials related to the Living Labs for freight and personnel transport.

3.1.2 Validation of the MTM Program

Validation intended to ensure quality, efficiency and sustainability of the training. To get feedback on the design, strategy and modules, a general program was presented at a Community of Practitioners (CoP) workshop constituting both partners and external stakeholders. Further, partner feedback on drafts of modules and digital training were given in a web-meeting and a plenary face-to-face meeting.

3.1.3 Preparing Training Trials

Prior to the Norwegian training, the authors specified the schedule in the context of the Arendal project (see 3.2) and ORCHESTRA projects, developed a playscript, and specified the six educational elements (see 2.3).

3.2 Training Period and Population

The piloted trials were performed in the January - February 2024 in Norway and Italy. In Norway the training was a two-day physical workshop (face-to-face) that included 10 participants and two facilitators. The participants represented six different organisations involving both external institutions (Agder County, Arendal Harbour, Arendal Municipality) and project partners (ROSAS, HIP, ITS-Norway). The training trials were designed and facilitated by two project partners and the authors of this paper.

In Italy the training was a three-hour digital workshop with six project partner organisations. They included 11 participants (Deep Blue, SEA, TU Delft, Enav, FSTecnology) and two facilitators (ROSAS). The training in Norway served as a blueprint for this shortened, digital version.

4. Piloting Traffic Orchestration Training

This chapter's main part concerns the didactical aspects of the practical and specific training trials. It describes key concepts and measures and the TO training strategy.

4.1 Concepts and Measures

TOs will use *Transport Demand Management* (Figure 2) according to the policy of respective governance areas. The policy will be the condition for measures that are chosen to orchestrate traffic. TOs need to be able to understand the flows and conditions of the information across roles inhabited by actors in the specific MTME and assess the consequences of implementing different measures. Measures used in ordinary situations may include information, traffic calming, access control, priority, and monitoring.

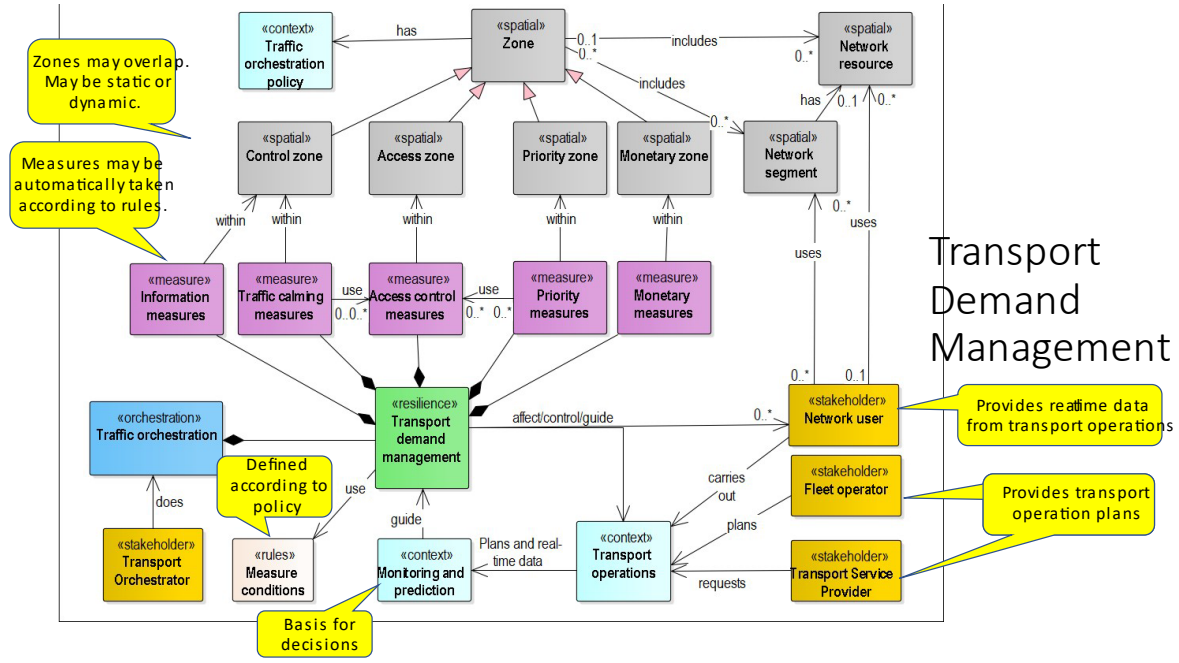

Figure 2: Traffic orchestration using Transport Demand Management (Natvig et al, 2023).

Demand Capacity Balancing may be needed when accidents, increased risks, or events with an unknown cause suddenly strain capacity (Figure 3). In addition to measures used in Transport Demand Management, TOs may need to use more individual measures and measures for capacity adaption. Incidents may also affect neighbouring governance areas, requiring TOs to coordinate and negotiate through coordination measures. To understand the consequences of the implementation of various measures, simulations of "what if" scenarios explore possible plans of operation, giving TOs decision support to effectuate pro-active measures.

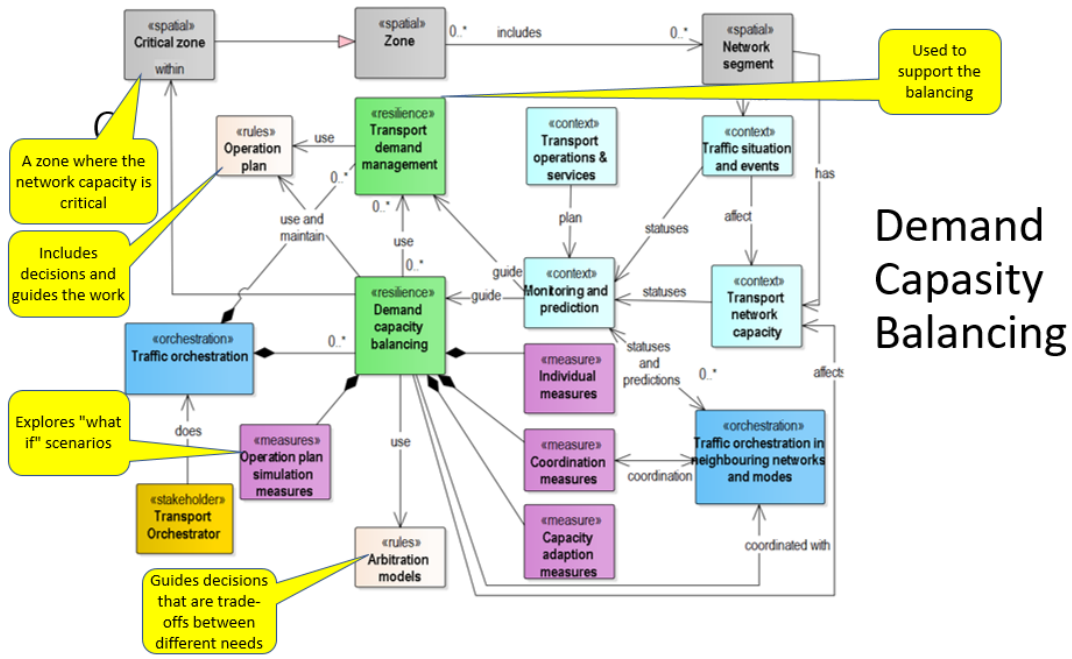

Figure 3: Traffic orchestration using Demand Capacity Balancing (Natvig et al, 2024).

These concepts and measures are the fundamental conditions for the content for the traffic orchestration training and must be understood and continuously rehearsed.

4.2 Training Strategy for Multimodal Traffic Management

The purpose of the TO training program is to educate future TOs on how to manage traffic effectively, i.e. improving resilience of highly automated coordination systems (in normal, disrupted or disaster mode of operation) through better connection and cooperation with the infrastructure and surrounding vehicles. The TO Training Program constitutes three *main parts* (Table 1).

I. *Basic and fundamental competence* includes systems, in addition to practical, operational competencies needed for future traffic orchestration, i.e. performance and skills as a basis for doing traffic orchestration. These may include practical skills, knowledge and/or attitudes.
II. *Resilience competence and traffic orchestration* includes competences to ensure resilience in MTM according to PMA. It is recommended to specify training related to three scenarios: (a) Normal operation, (b) Foreseen events and (c) Unforeseen events.
III. *Specific competencies and refreshment/updating* studies include supplementary competencies, refreshment studies, and specific studies (e.g. specific to contexts and/or local geography).

Table 1: Traffic Orchestrator Training Program.

III. Specific Competencies - Refreshment and updating studies		
I. Resilience Competence - Traffic orchestration Scenarios		
Normal operation	Foreseen events	Unforeseen events
I. Basic and fundamental competencies • Rules, standards, and regulations • Multimodal Traffic Management • Technical tools and equipment (For operation and decision support) • Technology – Traffic flow and data exchange		

The main *participant* to be trained is the TO, who aims to arrange for the most optimal flow of traffic in accordance with policy and in compliance with regulations.

The program includes potential measures, tools, and simulations for traffic orchestration within and between GA. *Resilience* is a significant aspect, and the modules are designed to give necessary competencies about traffic orchestration management principles and measures, in addition to support competencies regarding management in actual (future) scenarios under normal, changed, and disaster conditions.

4.3 TO Training Trials

This section first describes the intended training purposes and learning outcomes of the TO Program, and then the didactical elements in the training trial modules. The section mainly describes the Norwegian training trials because the digital Italian version is mainly a shortened blueprint of this.

The *training purpose* is to prepare, teach and enable future traffic managers (TOs) in an MTME. TO training should enable traffic managers to understand how to orchestrate traffic in their own governance area (GA), using different measures, and cooperate and negotiate with surrounding GAs. In Norway, the purpose was to access the training in the local context, get insights from participants in the actual on-site environment, provide targeted feedback and identify areas for improvement. The intended *learning outcomes* (for the participants) are: (a) *Effects* of completing the program; To increase traffic orchestration performance and skills in future traffic management, handle measures and tools in a resilient manner, and (b) understand *Impacts* of these changes; To improve the resilience.

Framework elements: Three basic training modules were selected, in addition to two resilience modules. Table 2 presents the module names and the duration in the two countries. Most didactical elements (see 2.3) are specified for each module. However, *learning qualifications* are the same for all modules; all participants should have experience with traffic management. Regarding *evaluation*, the participants gave a general evaluation at the end of the last module, in addition to pre- and post-evaluation of each module.

Table 2: Training trials – Modules in Norway and Italy

Time	Modules in Norway	Time	Modules in Italy
Day 1 (8 hours)	A: Introduction B: Traffic orchestration across governance areas C: Simulations, measures and examples of tools	Day 1 (3 hours)	A: General MTM Concept and Traffic Orchestration B: How to effectively use the ORCHESTRA tools and simulations C: Practical use case for tools and simulations for MTM
Day 2 (6 hours)	D: Traffic orchestration according to plan E: Traffic orchestration when incidents occur		

4.3.1 Module A

Learning objectives: After the module participants should have (a) An overview of all training modules and (b) An insight into the ecosystem (MTME), MTM (Multimodal Traffic Management), Roles and responsibilities of MTM, and Possible future scenarios. *Content* and *Learning process:* (a) Introduction to the TO Training Program – Participants presented themselves; TO program and learning objectives for Module A; Pre-evaluation by the participants. (b) MTM Model and concepts (See Natvig et al, 2024) – The facilitators presented the ORCHESTRA project vision, objectives, MTME, and future multimodal traffic scenarios (See Vaillant et al, 2022). The participants commented and asked questions. (c) Future scenarios and the need for MTM – Dialogue and reflections based on illustrations and figures from Vaillant et al, (2023), video of the exploitation project in Arendal (https://www.linkedin.com/company/orchestra2020/), followed by reflections on challenges related to building new industry areas in Arendal illustrated by maps of future transport chains and stakeholders, (d) Reflections and dialogue regarding main topics in Module A, (e) Closing (summing up and post-evaluation).

While facilitators were most active in the beginning by presenting and asking questions, (c) – (e) emphasized involvement, reflection and dialogue.

4.3.2 Module B

Learning objectives: (a) Understand TO methods: TDM (Transport Demand Management, Figure 2), DCB (Demand Capacity Balancing, Figure 3), (b) Understand MTME and PMA: TO (key functions) between GAs, How traffic orchestration can be conducted with the use of local/relevant examples, Key stakeholders and roles, (c) Introduction to traffic orchestration measures and examples of tools. *Content* and *Learning process:* (a) Opening session with a recap of Module A and objectives of Module B, (b) Board Game - Basic traffic orchestration concepts and measures (https://orchestra2020.eu/the-orchestra-board-game/). Two situations were played (Normal traffic; Dry port transport), followed by a post-lecture on main orchestrator concepts and principles. (c) Traffic orchestration – Examples from the Living Labs and exploitation project. Maps were used to reflect on the Living Lab at Herøya (stakeholders, GAs), in addition to how the project is applied in a local context in Arendal. (d) Reflections and dialogue regarding main topics in Module A, (e) Closing.

4.3.3 Module C

Learning objectives: Insight into (a) Potential tools for traffic orchestration and (b) Benefits of simulations (of traffic flow and changes): Decision support, Understanding multiple measures for handling complex situations, Simulation of historical situations and incidents, "What Ifs", and documentation for historical events and potential causes, (c) Connectivity and automation (digital and manual operations of CAV, coordination and data sharing between GA). *Content* and *Learning process*: (a) Opening session, (b) Simulations and tools (See Søråsen, 2024), (c) Simulations and tools in HIP Living Lab, (d) Connectivity and automation in the future, (e) Closing.

4.3.4 Module D

Learning objectives: (a) In-depth understanding of usual cases and everyday operations within MTM using TDM (future normal variations in traffic flow and changes with increased automation, coordination across modalities etc.), (b) In-depth understanding of different TO measures, tools and simulations supporting decisions and actions, (c) Understanding of roles and responsibilities of TOs in GAs – and to be able to translate general roles to actual actors and places. *Content and Learning Process:* In this module, most of the time was used for

discussions and reflections. (a) Opening, (b) Repetition of examples from Module B, (c) Future scenarios for the Herøya and Arendal cases (d) Closing.

4.3.5 Module E

Learning objectives: (a) In-depth understanding of operations within MTM using DCB when incidents occur, (b) In-depth understanding of different TO measures, tools and simulations supporting decisions and actions, (c) Understanding of roles and responsibilities of TOs and GA – and to be able to translate general roles to actual actors and places (d) Insight in how to handle the foreseen incidents (possible incidents that have been thought of). *Content and Learning process:* Discussion of tools and orchestration measures when incidents occur, and how to re-plan and return to operation. (a) Opening, (b) Repetition of examples from Module D, (c) Future scenarios when incidents occur, (d) Closing.

5. Discussion

5.1 What Knowledge and Competencies do Future Traffic Managers Need?

The TO training needs are based on ORCHESTRA's anticipated future traffic scenarios. In addition to understanding general *future* trends, knowledge of *past* and *current* challenges is critical for specifying, updating and determining significant competencies.

5.1.1 Traffic Orchestration – Collaboration and Synchronisation of Plural Managers

Multimodal management will be needed, enabling negotiation for optimal use of capacity across networks during planned operations and when incidents occur to foresee and prepare for capacity problems. TO's role and responsibility is to orchestrate according to policy. That will imply a responsibility to orchestrate the traffic within a GA in a way that will prevent negative consequences in surrounding GAs and across networks. When incidents occur that will affect neighboring GAs, traffic orchestrators must be trained in regulated procedures for cooperation and collaboration, being able to evaluate automated decision support and understand the consequences measures will create for themself and other TOs. This will be practiced best when TOs from neighboring GAs train together. Using coordination measures will enable simulations to indicate the effect of traffic flows, emissions, and other important effects on policy goals.

5.1.2 Simulations of Scenarios – Practicing of Explicit and Tacit Knowledge

Resilience depends on the ability of pro-active measures, and the flexibility in the use of different measures, combinations of measures and an understanding of the immediate effects and chain effects in own, and neighboring GAs.

Training using simulations may facilitate both explicit and tacit knowledge creation. Simulations will be crucial to manage challenges and surprises in actual traffic orchestration. Probable everyday operations and events in local contexts provide the opportunity for discussions and simulations of previously used measures and potential new measures that can be taken to manage incidents and get back to planned operation with minimal negative impact. This gives the traffic orchestrator practice in recognizing the best probable measures and likely consequences. Training and results of simulation may in return give input to automated decision support.

5.2 How Should Knowledge Creation Processes be?

5.2.1 Learning Process

Learning is embedded in practice. The training emphasizes active participants using dialogue and discussions. Learning and development take place when participating in social and culturally shaped contexts. Reflection is regarded as significant in learning and knowledge creation. Experience from practice is significant in both reflection-on-action (past experiences or future intended/unintended acts) and reflection-in-action (experiences when engaged in an activity).

Since context is considered significant for learning, is it central to create good arenas for learning and experience transfer. The training in Norway was physical and in Italy digital. Dialogue face-to-face makes it easier to collaborate and make common reflections by making it possible to notice non-verbal communication and to

make use of tactile collaboration e.g. by using games and the scenarios cases from Herøya and Arendal to create and move signs and symbols on physical maps.

5.3 What Knowledge Strategies may Facilitate MTM?

Knowledge strategies are often linked to organizational outcomes and implemented in one organization. In addition, MTM should include strategies for inter-organisational outcomes of synchronizing management systems, including regulations and plans, stakeholder responsibilities and operations.

5.3.1 How to Cope with a Continuously Changing World?

Digitalization and increased data sharing between vessels, sensors and infrastructure will change the interaction between human and automatic management, requiring dynamic updates of an educational program. Further, knowledge management updates will require rehearsal and repetition of new modules.

Determination of what competencies TOs will need in the future will require continuous updates of documents about e.g. past and current incidents and risks, new digital management tools and measures, and changes of regulations and standards. In addition, foresight science and future trend-analysis may be used to determine resilience competences to handle future normal traffic variations (known-known), and foreseen (known-unknown) and unforeseen events (unknown-unknown).

5.3.2 Knowledge Strategies

Bratianu (2022) presents several organisational strategies, and some perspectives are in accordance with a resilience perspective and may be applicable to create inter-organisational strategies, e.g. integrated knowledge strategies of reactive and proactive components including known and unknown. Resilience should be an important aspect in future TO education, constituting a *reactive* (learning from experiences and historical events) and a *proactive* approach (anticipating potential scenarios to know what to look for). The scenarios and examples used in the training pilots are based on concrete, local cases. Design and updates of scenarios are essential and should aspire to reflect relevant and recognizable cases.

6. Conclusions

The *main conclusion* is that future traffic management requires new knowledge creation due to the shift from reactive traffic management to proactive traffic orchestration (preparation and handling before an incident occurs).

6.1 Piloted TO Training

- The training trials have provided insights into the effectiveness of the modules and their practical application in real-world scenarios.
- The aim of competent traffic orchestration is to find optimal MTM solutions in highly complex situations, foresee most events, execute dynamic measures when needed and thus to ensure the resilience of transport systems.
- Scenarios and exemplification of measures make it possible to discuss and make decisions for various outcomes of historic and foreseen events.
- Artefacts like boardgames, maps, and illustrations are well suited to learning principles and concepts on a general level.
- Contexts may facilitate learning and insight through using scenarios and storytelling related to personal experiences and local context.
- The participants should have traffic management experience.
- The training period for program should be extended, including time between each module, e.g. making room for reflections, exercises or the context related lessons.

6.2 Recommendations for Future TO Training

- Clarify new sets of knowledge, skills, and performance necessary for proactive traffic orchestration.
- A program should clarify both general competence needs, and design context-specific modules related to local challenges.

- It is essential to emphasize cooperation between TOs in neighboring GAs, e.g. roles and responsibilities.
- Develop and use simulations as an active artefact, making TOs able to test measures for optimal management of capacity and handling incidents. Scenarios should include ordinary operations and crisis to prepare TOs for unforeseen situations.

Creating Expert Knowledge on Aligning Tax Systems With Corporate Business Strategies

Marcin Stępień
University of Technology Faculty of Management, Czestochowa, Poland

marcin.stepien@pcz.pl

Abstract: The article presents the possibilities of creating expert knowledge on aligning tax systems with corporate business strategies which can help identify new perspectives for the management of companies in the changing legal environment in which they operate. The lack of comprehensive theoretical research on creating expert knowledge regarding the alignment of tax systems with business strategies has led to an attempt at theoretical analysis and empirical research to fill an identified gap on this matter by deepening the understanding of the knowledge creation processes in this area. The considerations made are based on empirical research conducted in 250 companies that use tax systems in their business strategy. The research procedure involved conducting a survey among randomly selected large and medium-sized Polish enterprises, using the CATI Support method, taking into account the Mann-Whitney U test. This article supports the current view that a higher level of alignment between tax systems and business strategy is more likely to affect large companies than medium-sized ones. What is more, the issue of creating expert knowledge on aligning tax systems with corporate business strategies is important and topical, as there are differences in the perception of the alignment between tax systems and corporate business strategy between corporate executives and tax professionals.

Keywords: Enterprise Business Strategy, Company Tax Policy

1. Introduction

The high dynamics of changes in the area of tax regulations in Poland have resulted in companies being forced to take steps to align their business strategies with existing tax systems. The combination of the two key areas, tax and strategic, requires knowledge to recognize the functioning mechanisms of the strategic areas of business management in the context of possible tax solutions. This means that maintaining the advantageous stability of the company in relation to the legal environment requires the creation of expert knowledge on aligning tax systems with corporate business strategies. Building a company's tax policy on the potential of expert knowledge on aligning tax systems with corporate business strategies can be a source of competitive advantage for the company. Therefore, the study attempts a theoretical analysis and empirical research to investigate whether tax policy is part of a company's business strategy, and whether the companies adjust tax policy with business strategy, by increasing the understanding of the processes of creating expertise in this area. On the other hand, the study draws attention to the perceptions of the alignment of tax systems with corporate business strategy by both managers and tax professionals. The empirical research was conducted on a sample of 250 companies, large and medium-sized, which use tax policy during implementation of their business strategy. The research procedure was carried out on the basis of a survey questionnaire using the CATI Support method. Mann-Whitney U was used to check that the study groups were drawn from the same population. This study assumes that a higher level of alignment between tax policy and business strategy is more common for large companies than for medium-sized ones. It was also assumed that the problem of creating expert knowledge on aligning tax systems with corporate business strategies would be characterized by a dichotomy, consisting of differences in the perception of this alignment by corporate management and by tax professionals.

2. The Role of Taxation Knowledge in the Implementation of Corporate Business Strategy

It is assumed in the literature that the tax system is constituted by legal norms on taxes in a broad sense (Saskia, Pierk, 2020, Slemrod, Gillitzer, 2014). In this context, the tax system is defined as all taxes in force together in a country, linked by a main idea in such a way that they form an organizational whole, both legally and economically (Harpaz, 2021). This means that a tax system is an ordered set of taxes applicable to taxpayers at a given time and in a given country (Bierbrauer, et al, 2021).

Knowledge of the applicable tax system is becoming a significant determinant in running a business. Moreover, effective business management should be based on analysis of potential tax solutions (Shao, Xiao, 2019, Shevlin, et al, 2019, Wang, Zhu, 2023, Lawle, Worley, 2006) as they affect the accuracy of financial and operational decisions taken within the company. The choice of tax options, i.e. the development of a tax policy, requires adequate expertise, which is essential to assess the relationship between the potential of the company and the potential of the tax system. Therefore, an important element of a company's tax policy is to analyze the impact

of changes in tax laws, their interpretation, the ways in which tax authorities apply legal norms, as well as announcements concerning the expected shape of the tax system (Heimberger, 2021). A detailed analysis of the tax environment allows for the implementation of a tax policy designed to support the company's general operating strategy, while minimizing tax risks and charges and ensuring the company's security.

The company has a choice of two options when it comes to building a tax policy and responding to existing tax legislation (Kerzner, 2021). It can take a more conservative or aggressive approach. Conservative tax policy is the fulfilment by the taxpayer of all tax obligations arising from the scope of taxation in order to avoid disputes with the tax authorities (Zwick, 2021). It is about ensuring the greatest possible tax security by correctly identifying tax obligations and determining tax liability (Khmyz, et al, 2023). The company itself does not look for ways to help minimize the tax liabilities, it does not try to take actions to anticipate the possible tax consequences of its decisions. A more aggressive approach is also to comply with all the taxpayer's obligations, using at the same time all possible ways that can help to minimize the tax burden on the way to achieving the company's goal (Baudot, et al, 2020). Prior analysis of the tax legislation, as well as specific tax liabilities, identification of tax risks and threats, helps to achieve this purpose.

Summarizing the theoretical considerations, it is worth indicating that a properly designed tax policy should encourage, on the one hand, the processes of expertise creation and, on the other hand, the implementation of the adopted strategy by companies. Therefore, focusing attention on the objective of creating a competitive advantage in the market, it should be noted that it should be considered through the prism of tax policy, seen as the activities of a company, covering all its spheres of functioning together with the entire value chain.

3. Research Procedure, Research Methodology and Characteristics of the Study Population

The research procedure involved conducting a survey among randomly selected large and medium-sized Polish enterprises. The sampling frame was the databases of medium and large companies, taking into account the records contained in the Bisnode commercial database. Companies were randomly selected from a database of around 1 million records. The CATI Support computer system then drew consecutive telephone numbers for the companies from the operator. The sampling scheme was probabilistic - simple random selection. The study was performed through the following steps:

- Design of survey questionnaires.
- Preparation of a database of companies from which companies will be drawn for the survey. From each company drawn, one manager and one specialist from the accounting and tax department will be surveyed.
- Conducting 250 interviews with management, proportionally distributed among medium and large enterprises.
- Conducting 250 interviews with specialists from accounting and tax departments in the same companies.
- Preparation of a consolidated database of respondents' answers to survey questionnaires. Conducting quantitative analyses of the data obtained using the PS IMAGO package and Excel spreadsheet.

Respondents were asked to rate each statement relating to a particular problem in the surveyed company on a 5-point Likert scale: from 1 - „ I completely disagree" to 5 - „I completely agree". The entire population consists of corporate executives and tax professionals. One managerial representative and one tax professional were surveyed from each company. Some of the analyses were carried out for the entire research sample and some separately for subgroups of managers and accounting and tax professionals. The sample includes 250 questionnaires written by managers and 250 questionnaires written by tax experts. The surveys come from 250 companies (no questionnaire was rejected – due to technically correct answers in all questionnaires). A total of 500 complete surveys were received).

Table 1: Structure of the sample by size of enterprises and type of respondent

Employee Groups			Frequency	Percentage	Percentage of valid
Management	Valid	medium-sized enterprise	242	96.8	96.8
		large enterprise	8	3.2	3.2
		Total	250	100.0	100.0
Tax professional	Valid	medium-sized enterprise	244	97.6	97.6
		large enterprise	6	2.4	2.4
		Total	250	100.0	100.0

Source: own elaboration

Based on the data summarized in Table 1, it can be concluded that the majority of respondents, both managers and tax experts, represent a group of medium-sized companies. Table 2 presents the structure of the research sample, taking into account the organizational and legal form of the companies surveyed.

Table 2: Structure of the sample by legal form of enterprises

		Frequency	Percentage	Percentage of valid	Cumulative percentage
Valid	State-owned enterprise	41	8.2	8.2	8.2
	Cooperative (production, trade, services)	15	3.0	3.0	11.2
	Public limited company	15	3.0	3.0	14.2
	Limited liability company	302	60.4	60.4	74.6
	Civil partnership	30	6.0	6.0	80.6
	General Partnership	32	6.4	6.4	87.0
	Limited partnership	20	4.0	4.0	91.0
	Other legal form	45	9.0	9.0	100.0
	Total	500	100.0	100.0	

Source: own elaboration

Based on the results of the research presented in Table 2, it can be concluded that the survey primarily found that the legal form of the surveyed enterprises was limited liability companies (60.4% of the entities surveyed). Partnerships under Polish tax law (civil, general, limited partnerships) were a total of 16.4% of the surveyed companies.

4. Analysis and Evaluation of the Alignment of Tax Policy with the Business Strategy of the Companies Surveyed

Based on the data presented in Table 3, it can be concluded that an analysis of the significance of differences using the Mann-Whitney U test indicates that large companies are characterized by a higher level of alignment between company tax systems and business strategy than in medium-sized companies. This may be due to the fact that large companies have a greater ability to generate expert knowledge about the alignment between tax systems and the company's business strategy. Moreover, large companies have the capacity, firstly to finance expertise, which is expensive, and secondly, they have the capacity to acquire this expertise in the required time, which is an important variable in the decision-making process. The research shows that, in the large companies, managers continuously monitor whether the implemented tax policy is adjusted to the established objectives of the company's business strategy. It is worth noting that the obtained survey results suggest that the majority of managers of large companies (>80%) have knowledge of what tools can be used in building and implementing a company's tax policy. In addition, it should be noted that, according to respondents, the majority of managers of large companies (>80%) are aware of how tax policy affects the work of subordinate organizational units.

Table 3: Level of adjustment of tax policy to the business strategy of medium-sized and large enterprises

Company size		At all levels of management, there is an open and comprehensible dialogue with employees about the tax policies being implemented.	The tax policy is adjusted to the needs and expectations of the management.	The tax policy is adjusted to the needs and expectations of the tax authorities.	Management checks if the objectives of the company's business strategy are coordinated with the objectives of the company's tax policy.	All planned implementations of tax policy objectives are included in the operational plans of employees responsible for tax policy implementation.	The company has identified factors influencing its tax policy.	The majority of managers (>80%) are aware of how tax policy affects the work of subordinate organizational units.	The majority of executives (>80%) are aware of the tools that can be used in building and implementing the company's tax policy.	Management continually checks that the tax policy is adjusted to meet the priority objectives of the company's business strategy.
medium-sized enterprise	U Manna-Whitneya	13000,000	14161,000	18838,500	14354,000	14077,000	12558,000	11938,500	13007,000	13014,000
	Z	-11,480	-10,853	-8,130	-10,741	-10,879	-11,776	-12,410	-11,631	-11,600
	Asymptotic significance (two-sided)	0,000	0,000	0,000	0,000	0,000	0,000	0,000	0,000	0,000

	Asymptotic significance (two-sided)	0,350	1,000	0,133	0,836	0,574	0,098	0,135	0,548	0,176
	Exact significance [2*(one-sided)]	.414[b]	1.000[b]	.228[b]	.852[b]	.662[b]	.142[b]	.181[b]	.573[b]	.228[b]

Source: own elaboration

In order to clarify the process of creating expert knowledge on aligning tax systems with corporate business strategies, respondents were asked whether the coordination of business strategy objectives with tax policy objectives affects the implementation of the company's business strategy. Additionally, respondents were asked whether tax policy objectives were taken into account in business plans, which have an impact on the understanding of the nature of the implementation of the company's business strategy. In the counterpoint, respondents were asked whether identifying the factors influencing the implemented tax policy helps to understand the essence of the implementation of the company's business strategy. The results from the understanding of the essence of the implementation of the company's business strategy are presented in Table 4.

Table 4: Understanding of the importance of implementing the company's business strategy in %

Understanding of the importance of implementing the company's business strategy			
Evaluation	coordination of the company's business strategy objectives with tax policy objectives	taking account of tax policy objectives in operational plans	identification of factors influencing the implementation of tax policy
I completely disagree	3,0	2,4	3,0
I disagree	2,4	2,4	3,8
I have no opinion	12,8	14,0	15,0
I agree	30,4	31,2	32,4
I completely agree	51,4	50,0	45,8

Source: own elaboration

Considering the survey results presented in Table 4, it is noted that the coordination of corporate business strategy objectives with tax policy objectives is an important element in the implementation of corporate

business strategy according to 81.8% of respondents. Only 5.4% of respondents disagree that coordinating business strategy objectives with tax policy objectives is an important element of implementing a company's business strategy, while 12.8% do not see a correlation. In the opinion of 81.2% of respondents, the inclusion of tax policy objectives in business plans occurs in a high degree, 14.0% of surveys and only 4.8% of respondents do not include tax policy objectives in their business plans. According to 78.2% of respondents, understanding the essence of the implementation of a company's business strategy requires the identification of the factors influencing the tax policy implemented. 15% of respondents have no specific opinion on this matter. In contrast, 6.8% of respondents stated that there are no identified factors in their company that influence the implemented tax policy.

In order to investigate whether the managers of the surveyed companies and the tax professionals working or cooperating with the surveyed enterprises have the same understanding of the essence of the implementation of the company's business strategy, both communities were asked about the coordination, consideration and identification of the factors influencing the implemented tax strategy (Table 5 and 6).

Table 5: Understanding of the importance of implementing the company's business strategy according to managers in %

Understanding of the importance of implementing the company's business strategy			
Evaluation	coordination of the company's business strategy objectives with tax policy objectives	taking account of tax policy objectives in operational plans	identification of factors influencing the implementation of tax policy
I completely disagree	0,8	1,6	1,2
I disagree	0,8	0,0	0,8
I have no opinion	6,8	7,6	8,8
I agree	15,6	15,2	14,8
I completely agree	76,0	75,6	74,4

Source: own elaboration

Analyzing the responses of the managers of the surveyed companies (Table 5) in terms of their understanding of the importance of the implementation of the company's business strategy, it is noted that for 91.6% of the respondents the coordination of the company's business strategy objectives with tax policy objectives is important or very important. Only 6.8% of respondents do not perceive an impact. Notably, only 1.6% of respondents disagree or completely disagree that it is important or very important to coordinate the company's business strategy objectives with tax policy objectives. When considering the company's tax policy objectives in the business plans, 90.8% of respondents stated that the impact was significant. 7.6% of respondents do not perceive such an impact and 1.6% of respondents disagree with the above statement. According to 89.2% of the surveyed executives, understanding the essence of the implementation of the company's business strategy requires the identification of factors influencing the implemented tax policy According to 8.8% of managerial respondents, there is no definite opinion and 2% of respondents stated that their company has no identified factors influencing the implemented tax policy. Table 6 shows the responses from the understanding of the essence of the implementation of the company's business strategy given by the tax professionals.

Table 6: Understanding of the importance of implementing the company's business strategy according to the tax professionals in %

Understanding of the importance of implementing the company's business strategy			
Evaluation	coordination of the company's business strategy objectives with tax policy objectives	taking account of tax policy objectives in operational plans	identification of factors influencing the implementation of tax policy
I completely disagree	5,2	3,2	4,8
I disagree	4,0	4,8	6,8
I have no opinion	18,8	20,4	21,2
I agree	45,2	47,2	50,0
I completely agree	26,8	24,4	17,2

Source: own elaboration

Based on the research carried out on a group of tax experts, it can be noted that only 45.2% of the respondents in this group believe that the coordination of the company's business strategy objectives with tax policy objectives is important, and only 26.8% believe that it is very important. At this point, it is worth noting that tax professionals do not fully agree with managers on the ability to coordinate business strategy objectives with

corporate tax policy objectives. The opinion of 18.8% shows that they do not recognize such an impact. Furthermore, according to 9.2% of respondents, the coordination of the company's business strategy objectives with tax policy objectives is weak or very weak.

When considering the results of the survey regarding the reflection of the company's tax policy objectives in the business plans, it should be noted that for 47.2% of the respondents in the group of tax experts, the impact is important and for 24.4% very important, which is also different from the opinion presented by the managers. Surprisingly, as many as 20.4% of respondents in the tax expert group do not perceive an impact and, according to 8% of respondents, there is little consideration of corporate tax policy objectives in business plans.

The survey found that 17.2% of respondents in the group of tax professionals completely agree that understanding the essence of the implementation of a company's business strategy requires the identification of factors influencing the implemented tax policy. Half of the respondents agree with of the above statement and 21.2% of the respondents have no specific opinion. Only 11.6% of respondents in the tax expert group said they disagreed that identifying the factors influencing the implementation of tax policy helps them to understand the essence of the implementation of the company's business strategy.

As the variables studied were mainly qualitative variables (measured on nominal and ordinal scales) a chi-square test of independence was used to examine the strength and possibly the direction of associations between variables, as presented in Table 7. The contingency coefficient, used for variables measured on a nominal scale, was used to assess the strength of the relationship between variables. If the value of this coefficient is 0, it means that there is no relationship between the variables (the variables are unrelated). If the value is close to 1 it means that there is a very strong relationship between the variables.

Table 7: Tests of significance of the dependence in the area of understanding the essence of business strategy implementation between the tax professionals and managers

Employee groups and:	Chi-square statistics	df	Asymptotic significance (two-sided)	Contingency coefficient
coordination of the company's business strategy objectives with tax policy objectives	122,357[a]	4	0,000	0,443
taking account of tax policy objectives in operational plans	134,524[a]	4	0,000	0,460
identification of factors influencing the implementation of tax policy	167,155[b]	4	0,000	0,501

a) 0% of cells (0) have an expected count less than 5. The minimum expected count is 6.00.

b) 0% of cells (0) have an expected count less than 5. The minimum expected count is 7,50.

Source: own elaboration

Table 7 presents the results of testing the relationship between the group of tax professionals and the group of managers in the area of understanding the essence of the implementation of the company's business strategy from the following perspective: coordination of the company's business strategy objectives with tax policy objectives, taking into account tax policy objectives in operational plans and identification of factors influencing the implementation of tax policy. Based on the results obtained, it can be concluded that there is a statistically significant relationship between employee group membership and views on the understanding of the essence of the implementation of the company's business strategy from the discussed perspectives in both groups.

5. Discussion

Attempting to create expert knowledge on aligning tax systems with corporate business strategies firstly requires the development of a tax policy that is in line with the current tax system in the relevant legislation. A company's tax policy should be adjusted to its business strategy.

On the basis of the empirical research carried out, it is noticeable that there are significant differences between the assessments made by the group of managers and the group of tax professionals. Based on the survey, it can be concluded that 68.8% of the tax expert respondents are of the opinion that tax policy is part of the company's business strategy. Among managers, the above view is shared by more than 92%. This may suggest that respondents from the tax expert group, are aware that the tax system is directed to optimize the tax liability to the state budget, and not to minimize the tax burden on companies. It can also be inferred that among the

management representatives, there is a high level of trust in the knowledge of tax professionals, or their knowledge of taxation is characterized by a high level of optimism. This indicates the existence of a dichotomy in the perception of the alignment between corporate tax policy and business strategy in the group of managers and the group of tax experts.

Addressing the noted research gap, it is important to highlight that the differences in perceptions of the alignment of corporate tax systems with business strategy between business executives and tax experts, results from their different perspectives, goals and scopes of knowledge of the two groups. From a management process perspective, it should be noted that the company's managers focus their activities on implementing the overall strategy, achieving business goals and realizing long-term vision. This group views the tax system as a tool to support business objectives, such as increasing revenue, entering new markets, or enhancing profitability. In contrast, tax experts perceive the tax system as a legal solution that applies to a business entity. Therefore, the primary goal of tax experts is to ensure compliance with tax regulations while minimizing tax risks.

Considering the range of knowledge and specialization between business managers and tax experts, it is worth emphasizing that the first group is characterized by general knowledge of tax systems but may not necessarily be familiar with the substantive details of this field. Therefore, managers may underestimate the importance of certain tax aspects that can affect the compliance and efficiency of tax systems. The range of knowledge and specialization for tax experts is characterized by detailed subject matter expertise. They are aware of subtle differences in the interpretation and application of tax laws, which affects their assessment of how the tax system fits into their business strategy.

The company's goals and adopted priorities are also viewed differently by managers and tax experts. The priority of managers is to execute business strategy, while tax issues are often seen as secondary by this group. This makes executives more likely to take tax risks if it helps achieve business goals. Moreover, managers' assessment of tax risks is often treated as one of many business risks, so this group is more willing to accept them in exchange for potential benefits. For tax experts, the goal and priority is to minimize tax risks and comply with regulations. Therefore, tax experts are characterized by greater conservatism and a desire to avoid risk, even at the expense of reduced business flexibility. In addition, tax experts tend to view tax risk as a significant threat that can affect a company's reputation and financial stability.

Differences in perceptions of the alignment of corporate tax systems with business strategy affect the communication processes between the various functional units of the company. This may be because managers do not always understand the importance of substantive issues arising from tax systems that are relevant to tax experts, and experts may not know the full strategic context for their business. It should be emphasized that managers have the final say in shaping business strategy and may be less concerned with tax issues as they focus on value-added. However, the task of tax experts is to focus on compliance and risk, not necessarily on the potential strategic benefits that the tax system might bring to the business strategy.

It should be added that the assumption made that a higher level of adjustment between tax policy and business strategy is more often the case for large companies than for medium-sized ones has been confirmed. This is due to the interpretation of the results obtained, which allow us to notice a slightly higher awareness of the implemented tax policy as part of the company's business strategy, in the group of large companies. This may indicate that, in large companies, the creation of tax expertise is part of the company's business strategy.

6. Summary

Research on the creation of expert knowledge on aligning tax systems with corporate business strategies was made on the basis of the literature on the subject, taking into account the current state of the law in Poland and empirical research. The considerations highlighted in this study enabled the achievement of the research goal, which was to investigate whether tax policy is embedded in a company's business strategy, and whether the companies studied adapt tax policy to business strategy, by deepening the understanding of the processes of creating expertise in this area.

The research carried out led to the following conclusions:

- an examination of the level of alignment between tax systems and the business strategies of medium-sized and large enterprises suggests that a higher level of adjustment between tax policies and business strategies is more common for large enterprises than for medium-sized enterprises, as large enterprises have a greater capacity to generate expertise on the adjustment between tax policies and the enterprise's business strategy,

- coordination of business strategy objectives with tax policy objectives is an important element in the implementation of corporate business strategy,
- the existence of a dichotomy between a group of tax experts and a group of management representatives in coordinating the company's business strategy objectives with tax policy objectives was identified.

Creating expertise on matching tax regimes with a company's business strategy can contribute to new perspectives on the management of companies operating in a changing legal environment. The legal environment, including tax laws, is dynamic and changes with economic and political developments. Therefore, expert knowledge enables managers to understand current changes in tax law, anticipate future changes and adjust their business strategies. Expert tax knowledge allows managers to identify tax optimization opportunities. This enables managers, together with tax experts, to strive to minimize the tax burden in a legal and efficient manner, resulting in a more competitive and profitable business. Aligning tax systems with business strategy allows them to be fully integrated. Executives can develop strategies that achieve business goals on the one hand and take into account tax benefits and risks on the other. This integrated approach can increase management efficiency and contribute to better use of available resources. What's more, the volatility of tax laws creates risks for businesses. Therefore, the knowledge of tax experts helps identify potential tax risks and develop strategies to minimize their impact on business, which translates into financial stability and security. Expert tax knowledge can help identify tax credits, subsidies and other incentives to support innovation. Executives can then integrate these incentives into their business strategy, allowing them to increase investment in research and development, creating new products and services and improving their competitive position. In the era of globalization, many companies operate in international markets. In this context, expert knowledge enables managers to understand different tax regimes and their impact on international operations, allowing for better management of corporate structure, finances and capital flows.

In conclusion, it is important to state that the creation of expert knowledge on aligning tax systems with corporate business strategies can contribute to the creation of new perspectives on the management of companies in the changing legal conditions of their operation. However, the processes of creating expert knowledge about the adjustment of tax policies with companies' business strategies are perceived differently by tax professionals and managers. Furthermore, differences also exist when the issue of creating expert knowledge on aligning tax systems with corporate business strategies is considered through the perspective of company size, leading to further research and exploration in this area.

Relevance of Higher Education for Adults in a Work-Life: A Case Study From Norway

Trygve Stølan, Hanne Haave, Linda Kiønig and Tone Vold
Inland Norway University of Applied Sciences, Norway

Trygve.stolan@inn.no
Hanne.haave@inn.no
Linda.kionig@inn.no
tone.vold@inn.no

Abstract: This case study is conducted in the spring semester of the first year, testing out organizing the mandatory assignments allowing to coordinate the two courses offered: "Project Management" and "Digital work forms in organizations", and facilitate for the students to utilize their own organization as a basis for the case in the assignment. The study programme of Bachelor in Organization and Management consists of a total of eight courses, each semester offering two courses parallel to each other. The students are adult employees and attend two-day seminars five times per semester. The research for this paper will be qualitative in conducting semi-structured interviews. The aim of the research will be to unveil if this has had an impact on the perception of relevance, and their learning outcome. The results will show how successful this "merger" regarding the assignment between the two different courses, based on how the students perceive the outcome to support the relevance regarding their job situation. Moreover, how they perceive the learning outcome from looking at the same case from the perspective of two different curricula will be interesting and may influence the way one organizes future training in higher education institutions.

Keywords: Relevance, Learning, Facilitation, Assignment From one's own Organization

1. Introduction

At the Inland Norway University of Applied Sciences, Rena, the adaption of study programmes has been an ongoing process. The adaption is mainly about meeting the needs of adult students, of whom many are in a worklife. This lifelong learning perspective, combined with providing the students with up-to-date course content, and contributing to the students' perception of relevance of the courses, has been the primary focus from the lecturers' point of view.

Both lifelong learning and the worklife relevance of education are promoted as guidelines for higher education by the Norwegian Government in the white papers (White Paper 16 (2019-2020), White Paper 14 (2019-2020)). To help facilitate this, a high degree of student involvement and engagement is suggested.

At the Inland Norway University of Applied Sciences, Rena, the concepts of a "flipped classroom" and "student involvement" have been developed over several years (Vold, 2014, Nematollahi et al., 2015, Bishop and Verleger, 2013). Hence, there are already opportunities for the students to utilize their own workplaces in their mandatory assignments, which have been tested out and implemented as a standardized work form in the course delineation.

In this study, the student involvement was taken to another level, as some of the students preferred the approach to utilizing their own organization as a case to a degree, in which they suggested integrating and combining the mandatory assignments in two different courses. Even if the courses in the bachelor's degree are designed to complement and build on each other, a joint mandatory assignment has never been tested out. They are to write a thesis at the end of their BA, in which they are encouraged to utilize the courses they have been exposed to, although the courses leading up to this have never been a subject of being combined.

In the following, we will present the two different courses in which a joint mandatory assignment has been tested out, how this pilot was planned and the theoretical foundation that we build for our understanding of the reasoning behind this undertaking. We then present the methodological approach to our data collection, before we present and discuss our data. We conclude on the result of our pilot project, point towards improvement points and present our suggestions for other scholars who would like to test this at their own university.

1.1 The Case Study

The two courses ("Project management" and "Digital work forms in organizations") are taught as seminar-based in the spring semester, with each seminar lasting two days with one course per day. Both courses have

mandatory assignments. In the course "Project management", the assignment has been based on up-to-date cases from the news. In the course "Digital work forms in organizations", the mandatory assignment has for several years offered a choice of either working on a case developed by the teacher – or utilizing their own organization as a basis for the case development.

Both lecturers are generally open to- and encourage student involvement and input. During this semester, the student representatives suggested merging the two assignments, and utilizing the learning from both courses into one assignment. The argument they presented was that they would profit from using one case to discuss the two different perspectives that the two courses offer.

Perceiving this as a novel idea and a possibility to develop the courses, the two mandatory assignments were merged, keeping the opportunity for students who wanted to write two assignments, or who only attended one of the courses, to write separate assignments. It was decided to form an assignment that would have the students tying the curriculum in both courses to one of the group members of their own organization.

The students were encouraged to work in groups of 3-5 students. The feedback would be given to the groups from the different lectures, which meant we had to make them hand in the assignments in both courses in the LMS system (Canvas).

Forty-three students chose to use this opportunity. Some students misunderstood, and chose a case developed by one of the teachers (hence, not writing about their own organization), and still write one assignment with the two perspectives.

2. Theoretical Foundations

The relevance of education is often tied to the perceived connection of curriculum to one's own personal background. This was recognized by the American pragmatists Dewey (1938) and James (2020) as they, amongst others, have pointed out the importance of interest of an area and its connection to learning. Hidi and Renninger (Renninger and Hidi, 2011, Hidi and Renninger, 2006) have developed a four-phase model of interest development. For example, the first phase: "triggered situational interest" is about being triggered by- and gaining interest by being exposed to a case or text. This phase may evolve into the phase of "maintained situational interest", which is about being continuously exposed to the area of interest by perceived meaningful tasks, instructional conditions and learning environments. In turn, this may develop into the "individual interest" phase, and then into a "well developed individual interest" phase. The "individual interest" is based on the individual's emerging interest characterized by positive feelings and stored knowledge and is about reengaging and developing their own "curiosity" about a certain topic or content. The process has a resemblance to Bloom's taxonomy (Bloom et al., 1956), which is about developing cognitive skills from merely remembering content to producing new and original work. However, this still requires some external support in the form of encouragement by peers or experts, e.g., teachers. Obtaining this level of individual interest will probably allow one to be able to pursue the work or questions they seek answers for, even if they face difficulties (Hidi and Renninger, 2006). The fourth phase of the model is about a "well-developed individual interest" (Hidi and Renninger, 2006). This enables a student to endeavour on larger tasks, as the individual interest promotes the perseverance of long-term work. However, the student may benefit from external support and a supportive learning environment.

Highly inspired by John Dewey, David A. Kolb (1984) developed the experiential learning cycle which describes how to prepare for, executing and gaining experience, and to reflect on and conceptualize as a preparation for new active experiencing. This is often referred to within the field of Organizational Theory (Filstad, 2022), and combining the theory with the students' assignments, e.g., allowing them to reflect on actions that have taken place to better understand theory, which may also trigger the individual interest of the students, as it provides them with a link to their own experiences. The actions may be tied to the curriculum in the different courses. In Project Management, it may be about how to pinpoint milestones in a project, while in the course of Digital work forms in organizations, it may be about the introduction of a digital tool, and how this has affected the organization.

In many ways, this relates to Bloom's taxonomy (Bloom et al., 1956) by introducing knowledge, supporting comprehension, encouraging application and a following analysis and synthesis, and lastly encouraging the students to evaluate. The knowledge is presented in the courses through lecturing, video recordings, podcasts and other available materials. The comprehension is about relating the curriculum (knowledge) to examples,

and then tying it to their own background by applying the acquired knowledge. Then, through the assignments, they are to analyse and synthesize the outcome, as well as evaluate this outcome.

Reflection is therefore a common theme within both organizational theory and learning theory (Boud et al., 1985). Reflecting in order to learn and understand is also important to help facilitate in a classroom setting. Assignments and groupwork may aid in the facilitation of reflection. Schön (1987) has contributed to understanding reflection, and how it supports in understanding and developing knowledge. His seminal work on developing reflective practitioners includes reflection in different versions. Reflection in an action obviously requires being in a situation or an action. Nevertheless, reflection on action may refer to reflecting on something that has taken place. Also, allowing the space of time between the reflection and the action may influence the outcome of the reflection and support critical thinking (Moon, 2004, Moon, 2008).

Making students work in groups may support theories of social learning (Vygotsky, 1978). Learning with and from others, and their experiences, may also contribute to a sense of connection and the development of friendships. To develop a mandatory assignment together with others may also encourage a sense of respect, a feeling of achievement and confidence (level 4 in Mazlow's hierarchy of needs) (Maslow, 1981). Developing the inner potential (level 5), in addition to the use of "peak experiences" (Feigenbaum, 2024), may also connect to the development of the individual interest (Hidi and Renninger, 2006) of the learners.

Making students work in groups may also resemble the way they have to work within their organizations. In an organization, this may refer to Communities of Practices (CoP) (Lave and Wenger, 1991). CoPs are often created to solve different problems, as the members are "pursuing shared enterprises" over time (Wenger, 1998). The members are engaging in social learning, as they seek meaning and identity within the social practice.

Learning in teams has also been described within the frames of Organizational Theory. Senge (1992) has explained that learning in teams is one of five disciplines that will support developing a learning organization. Team learning is about collaborating in a group to obtain a common goal. This requires interaction and coordination between the group members, something which in turn supports a learning process, both within the group and the individuals in the group.

3. Methodological Approach

Regarding case studies, Yin (2003) suggests to select a topic, identify research questions and clarify the boundaries of the case study. The data in this paper is collected using a qualitative approach (Patton, 2002) as a follow-up of an educational pilot project. We were three researchers conducting a group interview with four students, using a semi-structured interview guide. Our informants were chosen by use of purposeful sampling (Patton, 2002), and were recruited among a group of adult students taking part in the project. The informants were two women and two men, of whom three had a longer work-life experience, with one being relatively newly educated. Of the four interviewees, two are students' representatives, and thus more interested in participation and commitment to their studies.

During the group interview, one of the researchers had the role as a moderator, while all three took notes of the informants' conversation and discussions. Posterior to the meeting, we reflected on what we thought had come out of the discussion. Later, we wrote out and shared our notes, the next step being to analyse the material by themes and categories, and discuss our findings against relevant theories.

4. Results and Discussion

The project is basically about trying out a particular educational scheme by combining the assignment in two courses and allowing cases from students' own worklife practices. The success of the project depends on how the students respond to the assignment. As a follow-up, we wanted to investigate the effects on the students perceived learning outcome, as well as the relevance of the study for their worklife.

4.1 Combined Assignment in two Courses

The students were positive about having the opportunity to choose between different tasks in the work requirement. "*It's nice to be able to choose"* as one of the respondents articulated. When it comes to how the assignments were communicated and presented, the students' opinion was that due to the short time for preparation and design, the assignments were somewhat unclear or imprecise. Nonetheless, this still mostly went well with the students. We found that a prerequisite was a very good dialogue between students'

representatives and the teachers, who take them seriously and meet the students' expectations and questions. The teachers do facilitate the students to obtain the optimum yield from their studies.

4.2 Cases from Students' own Worklife

To work with tasks from their worklife depends on the students having recognition and experience relevant to the knowledge. This in turn can lead to sharing experiences with other students in their group, *"How have you done this in your workplace? Oh, then I can do this in mine"*. Even the student with less work and project experience reports being able to gain insight and learn from other people's experiences – and this shows that even those with little work experience benefit from- and learn from others. They recognize the situation presented by theories in the studies and are able to obtain having their own knowledge confirmed. For example, they mentioned, *"How to structure the knowledge you have?"* and *"How to handle conflict processes?"* This suggests the direct connection to their work and thus background, as per Dewey (1938) and Kolb (1984). These reflections (Boud et al., 1985, Moon, 2004, Moon, 2008, Schön, 1987) show that they are able to turn the learning into knowledge and start analysing, synthesizing, and even evaluating their learning (Bloom, 1956, Anderson and Krathwohl, 2001).

4.3 Work Forms: The Students own Informal Organization of the Learning Process

Another prerequisite we found is that the students are organized as a team and have developed their own informal studies. They meet regularly via Teams, with one meeting before the gathering and one after. They prepare themselves by going through the curriculum. They also work together during the assemblies, right after the lecture. This is about building relationships and has a great educational benefit. This resembles both CoP (Lave and Wenger, 1991), as they are "joining forces" for a common goal, and Team Learning (Senge, 1992) as they collaborate and learn from each other.

4.4 Learning Outcomes

Regarding learning outcomes, we asked the students, *"What is your experience in terms of the learning outcomes, what types of tasks do you learn the most from?"* As the studies are organized as being seminar-based, our informants find that these intensive sessions work better because they provide the opportunity to go from theory to practice. They also find that group work offers significant learning opportunities, as they find it useful to join other fellow students to share experiences and discuss. They claim that groupwork supports an enhanced learning outcome. The applicable part of the study is of course also the individual. One student claimed that they started out as "unskilled" managers who want to bring in theory that can be used – and translated it into their own practice. By going through the learning processes, they develop as managers. This, again, shows a learning outcome of working in groups/teams learning with, and from each other (Vygotsky, 1978, Senge, 1992, Wenger, 1998, Lave and Wenger, 1991).

4.5 Relevance of the Study

In our opinion, our study shows that in the content of the case study (testing out a joint mandatory assignment in two courses and utilizing the same basis of the assignment) that the students use to obtain an enhanced learning outcome. This includes utilizing the students' own backgrounds, and according to our informants learning both from and with each other is a vital contribution to how they can utilize the knowledge, and draw relevance of the study. The students report that they can relate experiences from their own work practice to the theories of the studies and learn from them to become better managers. One of the students has worked with a digitalization development project in his own organization and recognizes the topic in both project management and digital working methods. One comment that confirms this is: *"Heuristically intuitive: I have done this at work, and this is how I can improve myself."* They are generally very positive regarding linking knowledge from the study to their own work. They recognize the situation, they get their knowledge confirmed, and they recognize oneself in the study.

5. Conclusion

The project is basically about seeing the effects of a particular educational scheme, and what the students get in return. Success depends on whether the students respond. The subject teachers organizing is the starting point, as they take up the idea of a joint task/practical case and implement it. The sample of informants is

significant, as these students seem to be more than average interested in participation and commitment to their studies.

The findings from the interviews show us that the students' individual starting points/experiences are of importance. The students own informal organization of the learning process is of great importance for their perceived learning outcome. Working in self-organized students' groups with the assignments enhances the learning outcome, and contributes to the relevance of the education.

Abstract: Purpose: This study deals with a tourism organisation from Poland, which experienced not only the COVID-19 pandemic, but also the close war situation in Ukraine which caused a significant decrease in tourist traffic and revenues. Since, based on the literature, knowledge management can be useful for crisis management, this study aims to explore the role and usefulness of KM during crisis situations in tourism. Methodology: Qualitative in-depth analysis was conducted by using data collected via semi-structured interview with the CEO of a local tourism organisation in Poland. The research output is presented in the form of a single case study with that organisation as the unit of analysis. Findings: The case highlighted that: a) a crisis may not be the most appropriate time for the implementation of KM from the scratch in an organisation; b) having some minimal KM experience can be essential for a more structured and complex KM approach; c) organisations may benefit from lessons learned during the crisis to get insights for developing KM. These findings suggest that practitioners and policymakers facilitate KM awareness among tourism organisations to enhance resilience in coping with future crises. Research limitations: This is a single case study and thus it cannot be easily generalised or provide a comprehensive overview of the whole sector. It is also a case study from a single country, affected by two serious crises which limits the applicability of the results to other countries. Practical implications: The study provides useful insights for practitioners in tourism organisations aspiring to improve internal processes of knowledge management and thus mitigating the future tourism crises. Originality/value: This paper contributes to the body of knowledge in terms of the role and relevance of KM during the tourism crisis. It provides food for thought for researchers investigating the knowledge and crisis management processes within the tourism industry.

Keywords: Knowledge Management, Tourism Crisis, Tourism, Case Study

1. Introduction

Knowledge management has proven its applicability and usefulness in many different organisational contexts and areas. According to some studies, knowledge management can support many organisational activities, such as innovation management (Andreeva and Kianto, 2011; Vaccaro et al, 2010), organisational performance (Junges et al, 2015), or sustainability (Martins et al, 2019). Knowledge management has also been useful in many different sectors, for example for the organisations from the KIBS (knowledge-intensive business services) sector (Zieba, 2021), construction industry (Fong and Choi, 2009) or tourism industry (Anand et al, 2023; Martínez-Martínez et al, 2015).

Knowledge management has also been indicated as potentially useful in case of a crisis or disaster situation in tourism (Mistilis and Sheldon, 2006). Defining a crisis in tourism is a challenging task as there is no one single agreed-upon definition in the literature – and the definitions that appear usually are used to describe a particular crisis context (Santana, 2004). Sönmez et al (1994) affirms that a tourism crisis in general is "any occurrence which can threaten the normal operation and conduct of tourism related businesses; damage a tourist destination's overall reputation for safety, attractiveness and comfort by negatively affecting visitors' perceptions of that destination". Examples of crises can be natural disasters, like earthquakes, tsunami or volcano eruptions.

Although there are some studies indicating the usefulness of knowledge management in a crisis situation in the tourism industry (Barišić et al, 2020; Orchiston and Higham, 2016; Racherla and Hu, 2009), it is still unclear how tourism organisations manage their knowledge during a crisis. To fill this knowledge gap, this paper is going to explore the topic in a sample tourism organisation from Poland. The case study presents managing knowledge by this kind of organisation in a crisis situation caused by COVID-19 and the war in a neighbouring country (Ukraine). This research is preliminary and exploratory in nature, as it is based on a single case-study.

This paper develops as follows. First, knowledge management in the crisis in tourism is described. Second, the methodology of the study is presented and third, the findings are described. The paper ends with the discussion section and conclusion and future research avenues.

2. KM in Crisis in Tourism

The relationship between knowledge management (KM) and crisis management has been extensively examined, with numerous studies underscoring the significance of robust KM practices in effectively handling crises (Anand et al., 2023). However, research has been diverse and somewhat scattered across various subjects of analysis, such as: military and war scenarios from the perspectives of states and peacekeeping organisations (Bolisani and Damiani, 2010), natural disasters (Dorasamy et al, 2013), medical emergencies (Wickramasinghe et al, 2006), economic crises (Ponis and Koronis, 2012), and disruptions in logistics and supply chains (Ponis and Ntalia, 2016).

Knowledge in crisis can serve as means of support in mitigating the effects of the crisis events. It may assist organisations in overcoming early challenges arising from a crisis, supporting the development of new knowledge, and facilitating the application of lessons learnt (Ng et al, 2022). Additionally, it can hinder possible damages and reinforce defence mechanisms (Kir Kuščer et al, 2021), as well as contribute to ensuring the safety of workplace and employees (Schiuma et al, 2021). Ongoing knowledge exchange, in the form of systematic updates of the tourism industry, can successfully foster organisations during the crisis response stage (Orchiston and Higham, 2016).

Knowledge management can function as an invaluable instrument, enhancing organisational resilience and fortifying their defensive strategies (Paraskevas et al, 2013), therefore creating a centralised knowledge repository (Racherla & Hu, 2009) becomes vital for tourism companies to deal with the crises effectively. Mistilis and Sheldon (2006) affirm that knowledge is needed at various stages: before, during and after a crisis. Nevertheless, while reviewing the tourism literature, it can be stated that scholars focus on selected KM processes in relation to specific crisis phases and research on KM issues in the context of overall crisis management is limited.

While the existing studies on the relationship between KM and crisis management employ varied methodologies and perspectives, there is broad agreement on two key points. Firstly, KM practices enhance learning abilities, resilience, and preparedness of organisations in managing crises (Raman and Jennex, 2010). Secondly, the success of KM in crisis management often relies on the preemptive implementation of strategic and structured approaches (Ponis and Koronis, 2012; Wang and Belardo, 2005).

This insight presents two significant challenges for tourism organisations, a sector where the link between crisis management and KM has also been investigated to a small extent (Mistilis and Sheldon, 2006; Stolarek-Muszyńska and Zieba, 2022). This sector tends to be less organised and resilient, making it vulnerable to global disruptions, as evidenced by the recent COVID-19 crisis (Kahveci, 2023; Nilsson et al, 2023). The approach to KM in these organisations is often informal, unstructured, not strategically planned, and can be described as "emergent" – typically a response to immediate problems that need solving (Zieba et al, 2016). Unfortunately, this tendency results in inefficient responses in times of crisis due to delayed reactions.

3. Methodology

The purpose of this study is to explore in-depth the role and usefulness of knowledge management during crisis situations in tourism. As this aim is strictly context-related and “the boundaries between phenomenon and context are not clearly evident” (Yin, 2003), this research adopts a case study approach.

The study addresses the following research questions:

> RQ 1: To what extent does a tourism organisation apply KM processes during a crisis and whether this is a conscious and/or planned or unconscious and/or unplanned approach?
>
> RQ 2: How aware is the decision-maker of the tourism organisation of the potential support the KM processes offer during the crisis?
>
> RQ 3: What are the challenges related to knowledge management during the crisis?

With the view of the exploratory focus, this study is based on qualitative in-depth analysis (Creswell, 2014) and research output is presented in the form of a single case study with the organisation as the unit of analysis. Mariotto et al (2014) argues that research may benefit from the single case study approach as it provides a deep understanding of the topic that is being investigated. Primary data for this study was collected via semi-structured interview which took place in November 2023. The full interview was recorded and transcribed *verbatim* (Poland, 1995) in Polish and afterwards translated to English.

The interview was conducted with the CEO from a local tourism organisation in Poland which represents an entity within the structure of a public-private association. The organisation coordinates local marketing activities for the destination and plays a key role in the integration of the local government units and tourism industry companies from i.e., lodging sector, gastronomy, tour operator, transport, etc. As part of the subject research, a representative of the local tourism organisation operating in the metropolitan area has been chosen for in-depth analysis.

4. Findings

This section is aimed at answering the research questions based on what emerged from the analysis of the investigated case. First of all, it has to be recalled that in the last years the examined tourism organisation reported facing three relevant crises related to: the COVID pandemic, the war in Ukraine, and inflation (these are the crises the organisation faced in the opinion of the respondent). Further challenges are due to the changes in the financial structure of the local government which are affecting the amount of the local government's contribution to tourism organisations, which constitutes the majority of the organisation's budget.

According to the opinion of the organisation member, the three crises have had different impacts. In particular:

> "COVID pandemic brought out good qualities in the industry, such as the willingness to cooperate, to join forces - so this was also very beneficial in terms of even local development, gaining partners, association members, and strengthening cooperation with other organisations in the POT-ROT-LOT system".

> "The war in Ukraine. I would say, there was a positive aspect that we were able to test in practice the organisational efficiency of the organisation as such and the team".

> "…this inflation hurts us doubly. … our costs are rising … running the Tourist Information, just compared to last year, they have already risen by 50%".

All summed up, in the organisation's opinion the most prominent crisis was the one caused by the war in Ukraine.

> [The most significant crisis was] "the war in Ukraine because, due to the proximity of the border …. Tourists either postpone their visit to our city or cancel it altogether. …. our tourist influx is reduced".

Therefore, in what follows, the authors will mainly refer to the crisis caused by the war in the neighbouring country.

As concerns RQ1 - To what extent does a tourism organisation apply KM processes during a crisis and whether this is a conscious and/or planned or unconscious and/or unplanned approach – it must be said that the new, and unexpected conditions, forced the examined organisation to collect and process a lot of information concerning the Ukrainians-related touristic demand.

> "…here we can see … the impact of information management - by collaborating with members, such as cultural institutions, museums, hotels, restaurants, etc. Knowing that suddenly we have a lot of users of tourist infrastructure whose first and main language is Ukrainian. We really started to gather this information: how many of these people are there, and on the other hand gather information about adapting the tourist offer in Ukrainian, and also encouraging the creation of such an offer."

This was an unplanned activity, made easy for the organisation's flat structure and its strict relationships with the various stakeholders, which allowed to gather information, rapidly:

> "… directly from the Ukrainian refugees … or … in restaurants, hotels, accommodation places, or public utility buildings that normally operate for tourists and residents, but during the crisis also provided services directly to refugees".

Summing up, the examined organisation applied some KM processes during the crisis, but they did it in a completely unconscious way, which they confirmed by stating that:

> "… [KM] had absolutely no significance".

Coming to RQ 2 - How aware is the decision-maker of the tourism organisation of the potential support the KM processes offer during the crisis? – first it must be underlined that the organisation was completely unprepared to face the crisis, apart from the knowledge of Ukrainian language:

" … we were linguistically ready. We were actually able to provide services in Ukrainian …"

In spite of this, the organisation did not change, or at least they affirm that nothing has changed in their way of doing KM:

> "… it's hard to say that there were any additional actions undertaken … it was business as usual in terms of work … so we just continued with the team's regular schedule".

At the same time, they state that they were:

> "… organizationally agile enough to quickly respond to the emerging needs …"

and that the President of the Board was involved in communicating crucial information to the external partners.

The previous assertions further confirm that managers were involved in KM without having a clear perception of KM itself.

Concluding with RQ 3 - What are the challenges related to knowledge management during the crisis? – it was considered crucial to have all the needed information concerning the emerging new situations as soon as possible.

As concerns the activities performed by the organisation to assist refugees, and particularly the creation and managing of a helpline, they affirmed that a challenge was faced:

> "… how to collaborate with NGO. If we had [such knowledge], we would have approached cooperation in a way that better protected our organisation's interests".

Effective and rapid knowledge sharing was a particularly crucial element in acting in a crisis.

> "… I would say knowledge sharing [is an important KM element in crisis management]. Because in this particular crisis, our organisation had no knowledge about the reception of refugees. But possibly... more about knowledge sharing by other organisations with us, like [organisation name], [organisation name], which quickly helped us to make up for the shortcomings and effectively carry out the activities we started".

It must be underlined that cooperation was considered an effective way to face the KM related challenges raised by the crisis, and this was one of the most important lessons learnt by the organisation.

> "Oh, I was saying that it gave us experience in cooperating with organisations outside the tourism industry."

Cooperation also enabled the organisation to collect and process the information needed to face the crisis. This concerned also the pandemic related crisis.

> "… in the pandemic crisis, the important role of how we collected information from the industry locally was really visible. We exchanged this local-level knowledge with other organisations, and using the knowledge of these other organisations, we were able to adapt our local actions. That was very evident and very important at the time."

5. Discussion

As it can be seen on the basis of the results from the case study, some elements of knowledge management were visible in the crisis situation, although these elements were implemented rather unconsciously, meaning that the organisation did not have the awareness of the knowledge management concept itself, its elements and the usefulness of its implementation. The examined organisation has implemented elements of KM rather intuitively, responding to the needs from the environment, without planning - this kind of approach can be called "emergent approach to KM", as defined by Zieba et al (2016). It can be expected that the introduction of some basic elements of KM might constitute a base for further development - on that basis an organisation can make a reflection and draw some conclusions which can support the company in the next crisis.

It is also possible that a crisis situation is not a perfect moment for KM implementation due to various turbulences and the resources the organisation needs to appoint to deal with this crisis. It would be more advisable to implement KM earlier and adjust it to the present needs in a crisis situation (e.g., knowledge sharing with external partners indicated by the examined organisation that was implemented during the crisis). Organisations may implement some KM activities as an effect of the crisis, but during it, under the pressure, they may just implement some ad hoc activities, responding directly to the current needs.

What could be recommended for organisations dealing with crises is a self-reflection activity done after the crisis itself. Organisations could examine then what worked and what did not, as well as focus on the type of knowledge that is crucial from their perspective for crisis management. As a crisis situation is a difficult one and probably implementing changes is quite challenging then, organisations could learn afterwards and implement new solutions on the basis of lessons learnt during the crisis.

6. Conclusion and Future Research Avenues

This study endeavoured to investigate in-depth the role and usefulness of knowledge management in a tourism crisis. Two large crises, namely COVID-19 and Russian invasion on Ukraine, have proved the vulnerability of the tourism industry in Poland and clearly demonstrated that tourism organisations need to be prepared and equipped with tools and crisis knowledge in order to mitigate the impact of hazardous events, both short and long-term.

The findings from the case study point out that KM is somehow present during managing crises by tourism organisations. Even though the organisation is not aware about the knowledge management concept and the theory behind it, it can still benefit from the KM elements. Managing knowledge can be useful in the crisis (Mistilis and Sheldon, 2006), but it is vital to prepare before such hazardous events and implement KM processes earlier, as the crisis moment itself is not the best one for KM introduction due to urgent diverse organisational challenges.

This paper contributes to the body of knowledge in terms of the role and relevance of KM during the tourism crisis. It offers food for thought for researchers investigating knowledge and crisis management processes within the tourism industry. The study provides also useful insights for the practitioners from the tourism organisations sector aspiring to improve internal processes of knowledge management and thus, mitigating the future tourism crises better and easier.

As this study adopts a case study approach, it is subject to the methodology-related limitations. Research output is limited to the analysis of a single organisation and thus it does not give a comprehensive overview of the whole sector. It is also a case study from a single country, affected by two serious crises and it also limits the applicability of the results to tourism organisations from other countries.

Future research avenues may focus on expanding the initial findings from a single case-study to multiple cases in order to explore similarities or differences within the tourism industry. The subsequent research studies could entail validating the qualitative results with the use of quantitative approach. Additionally, tourism organisations from other countries could be examined, especially the ones facing similar crises (COVID-19 or other pandemic and wars in neighbouring countries). By examining tourism organisations from other countries and comparing the results, the cultural aspects of dealing with the crisis with KM support could be detected.

Abstract: In recent years, the integration of artificial intelligence (AI) technologies has gained widespread attention in the education sector. This study explores the impact of ChatGPT, a deep learning-based natural language model, on teaching and learning processes in Higher Education Institutions (HEIs). In the education sector, the use of ChatGPT can be a double-edged sword, on the one hand, it can lead to innovation in the sector, on the other hand, there are also risks associated with it. By reviewing scientific papers published since the launch of ChatGPT in November 2022, this study identifies and discusses the main research themes investigated as well as opportunities and risks of integrating ChatGPT in HEIs. On this basis, it provides a more comprehensive understanding of the potential role of ChatGPT and similar solutions in shaping the future of higher education. The findings inform educators, education policy makers and researchers about the ongoing discourse on the integration of AI technologies in higher education and offer practical recommendations for optimizing the benefits of ChatGPT while considering potential risk factors to optimize student learning and the learning experience in HEIs.

Keywords: ChatGPT, Artificial Intelligence, Higher Education, Higher Education Institutions, Systematic Review, Future Prospects

1. Introduction

Technological advancements, especially the new generation of artificial intelligence (AI), have emerged as pivotal change agents of work, life, and communication modes (Hill-Yardin et al., 2023). AI technologies, characterized by their capacity to process big data and simulate human-like intelligence and actions fundamentally reshape all industries and the whole society (Strzelecki, 2023; Yu, 2023; Montenegro-Rueda et al., 2023).

Generative AI differs from traditional AI models, as instead of making predictions based on identified patterns, these advanced AI models produce novel outputs and can support self-learning, meaning that they can continuously enhance people's knowledge base and improve their decision-making processes through iterative interactions with data (Yu, 2023). Furthermore, as they are powered by transformer designs, Large Language Models (LLMs) like ChatGPT (Generative Pre-trained Transformer) skillfully navigate the complexities of natural language processing and generate contextually relevant responses to prompts and inquiries. ChatGPT is a conversational AI chatbot proficient in mimicking human-like communication with the end user (Dempere et al., 2023). With around 100 million users only a few months after its release, ChatGPT has become the fastest-growing app in history (Strzelecki, 2023).

In the context of education, ChatGPT can revolutionize teaching and learning processes (Lim et al., 2023). Trained on extensive data, it can comprehend linguistic nuances and generate human-like coherent text autonomously. In HEIs, Chat GPT can positively affect various academic activities, for example, create interactive learning experiences, assist students in comprehending teaching materials (Wang et al., 2017), and facilitate personalized learning (Fuchs, 2023; Dempere et al., 2023.). ChatGPT's intuitive conversational interface facilitates real-time interaction, empowering students to seek academic assistance and clarify their doubts in real-time. Moreover, its adaptive algorithms serve individual learning styles and preferences, fostering a tailored learning experience. Personalized learning has proven to improve student's learning engagement and academic achievements (Wu, 2017). ChatGPT can also assist teachers in HEIs in creating customized learning plans tailored to the individual student's needs and enable data-driven insights into student performance and adaptive assessment (Fuchs, 2023). In general, a tailored approach to individual student needs could improve student services, student life, and student overall experience and in that way help HEIs to increase student retention (Dempere et al., 2023).

However, the integration of ChatGPT in post-secondary education is not without challenges. Although ChatGPT has the potential to improve the quality of academic writing and make research more accessible to non-experts, it also brings challenges regarding the authenticity and reliability of generated solutions and authorship issues

(Dwivedi et al., 2023). The major concerns related to using ChatGPT in HEIs are unethical data gathering, privacy issues, unlawful use of data (Dampere et al., 2023), academic dishonesty, plagiarism, and cheating (Yu, 2023; Gill et al., 2024), decreasing human interaction in the learning process (Fryer et al., 2017), over-reliance on AI and ChatGPT that can negatively impact students' cognitive abilities (Shiri, 2023; Dwivedi et al., 2023), augmenting preexisting prejudices through data training (Fuchs, 2023), AI-generated hallucination errors, that are AI-generated responses not explained by training data (Strzelecki, 2023) and finally the absence of regulation surrounding ChatGPT (Strzelecki and ElArabawy, 2024).

With potential innovations but also great challenges brought by ChatGPT into education, we have witnessed tremendous speculation among stakeholders in academia (Fuchs, 2023). Therefore, this paper positions itself within a rich debate about the possibilities and challenges of using ChatGPT in HEIs to contribute to the understanding of the positive and negative aspects of using ChatGPT in HEIs and anticipate future integration of ChatGPT and AI tools in the education sector.

2. Method

A literature review was conducted to develop a better understanding of the topic, identify gaps in knowledge, suggest promising avenues for future investigation, and locate contributions to the field of research (Donthu et al., 2021). The Web of Science database was used to identify relevant articles due to its high quality and scientific rigor, which is widely recognized in academic circles. The terms 'Chat GPT' and 'education' were used to search for relevant articles. This search resulted in 34 documents. These articles were analyzed using the VOSviewer software tool. The application of the tool led to the automatic removal of 13 articles because they were not relevant to the topic under study. A cluster analysis was performed on the remaining 21 articles.

3. Results

In this section the results of the cluster analysis are presented. To determine the most important research themes that were pursued in the reviewed articles,, bibliographic coupling was used. A minimum of five articles per cluster was required, resulting in three clusters. The analysis produced the cluster network depicted in Figure 1, which includes cluster (1) Transformation in Digital Communication, cluster (2) Chat GPT in Academia, and cluster (3) ChatGPT in the Study of Medicine.

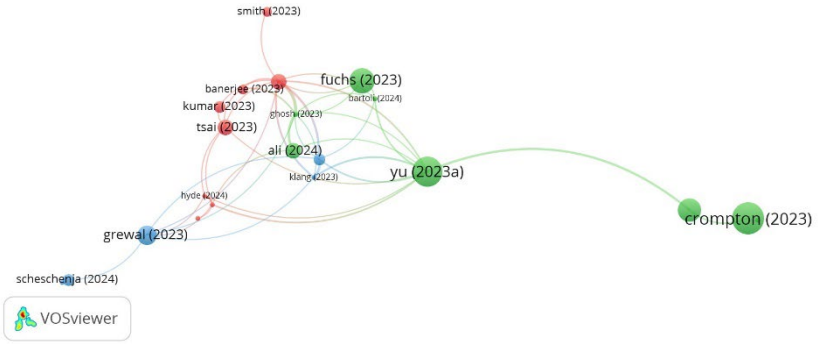

Figure 1: Bibliometric Network

3.1 Cluster 1 – Transformation in Digital Communication N = (8)

In the current digital landscape, language models like ChatGPT, which are based on advanced architectures such as GPT, play a central role in redefining the interaction between humans and machines (Chen et. al, 2024). These models not only understand linguistic contexts in an enhanced way but can generate contextualized texts, ranging from virtual assistants to autonomous content creation as well (Tsai et. al, 2023).

Despite the advances in technology, ethical considerations play a significant role in their development. It is crucial to address challenges such as bias in training data to ensure equitable application (Preiksaitis and Rose, 2023).

These technologies have vast applicability, transforming not only everyday interactions with virtual assistants but also the dynamics of digital content generation (Kumar et. al, 2023). However, ethical challenges highlight the need for constant improvement, especially regarding fairness in the use of these tools (Hyde et. al, 2024).

Current research aims to enhance the contextual comprehension of these models and effectively address the ethical challenges they pose. In the future, there is an anticipated shift towards even more natural human-machine communication, with research focusing on interpreting multimodal inputs and processing complex linguistic contexts (Smith et. al, 2023).

3.2 Cluster 2 – Chat GPT in Academia N = (8)

The use of artificial intelligence has brought about significant changes in academia, and ChatGPT, as a powerful language model, has played a crucial role in this context (Bartoli et. al, 2024). Its ability to understand and generate text contextually and coherently makes it a valuable tool for students and researchers.

However, the implementation of ChatGPT in academia poses certain challenges. Ethical issues surrounding the responsible use of technology, transparency in relation to algorithms, and concerns about possible biases built into the model are currently areas of debate (Borger et. al, 2023). Additionally, the effective integration of ChatGPT into educational processes requires careful consideration of how to balance aiding human creativity with preserving academic integrity.

However, ChatGPT presents exciting opportunities for learning and collaboration. ChatGPT can be used as a brainstorming tool to generate ideas and explore concepts (Yu and Guo, 2023). Additionally, its ability to understand specific contexts can facilitate interaction with students by offering clear explanations of complex topics and providing personalized support.

As Fuchs (2023) reiterates AI continues to evolve, so it is crucial to embrace a balanced approach to incorporating ChatGPT into academia. Exploring the capabilities of ChatGPT to enhance creativity, support teaching, and boost research can result in significant advances. However, it is imperative to address ethical concerns and ensure that ChatGPT is a tool that augments, rather than replaces, the human experience in academia (Yu, 2023).

3.3 Cluster 3 – ChatGPT in the Study of Medicine N = (5)

The integration of ChatGPT into the field of medicine marks a significant shift in the way students and healthcare professionals access information and collaborate on research. This advanced language model presents ample opportunities to improve medical learning and practice (Lower et. al, 2023).

Its capacity to handle large amounts of data and retrieve contextual information enables swift access to current medical knowledge. Students can explore a variety of topics, including diagnoses and innovative treatments, to improve their understanding and make informed decisions (Grewal et. al, 2023).

In the clinical field, ChatGPT serves as a valuable support tool. It can assist in formulating diagnoses by reviewing clinical data and suggesting evidence-based treatment options. Additionally, it facilitates clinical discussions among healthcare professionals, promoting the exchange of knowledge and perspectives (Lockie and Choi, 2023).

However, implementing ChatGPT in medicine presents challenges. Ethical issues, such as patient privacy and the reliability of the generated information, require careful attention (Lower et. al, 2023). It is also important to recognize the limitations of the model and understand that it does not replace clinical experience and human judgment (Lockie and Choi, 2023).

As ChatGPT becomes more integrated into the field of medicine, it is crucial to maintain a balance between the advantages of this technology and an ethical approach that acknowledges its limitations (Lockie and Choi, 2023; Lower et. al, 2023).

4. Opportunities for Integration of ChatGPT in Higher Education

In this section, the potential opportunities of integrating ChatGPT in higher education are presented.

4.1 Personalized Learning for Students

ChatGPT comes closer to the idea of personalized learning as it can accommodate the needs, interests and abilities of individual students and in turn could lead to higher engagement and better learning outcomes (Fuchs, 2023). Personalized learning is facilitated by incorporating students' language patterns and feedback (Dampere, 2023). The students could have access to personalized learning plans adjusted to their needs (Fusch, 2023).

4.2 Boosting Learning Efficiency and Supporting Cognitive Initiative

ChatGPT has significant advantages in improving learning efficiency (Yu, 2023) and supporting the cognitive preparing students for work in AI era (Yu, 2023). Responding immediately to students' inquiries, ChatGPT provides personalized tutoring and speeds up students' learning (Hwang and Chen, 2023). It may be like a 'study buddy' to help students reflect on learning materials (Strzelecki and ElArabawy, 2024). This technology is not only a tool that assists in crafting emails and writing essays (Dampere, 2023), but it can also unleash students' creativity and critical thinking (Yu, 2023; Tan, 2023). ChatGPT may inspire students to generate alternative ways of thinking and expressing ideas (Strzelecki and ElArabawy, 2024). The application of ChatGPT may enhance students' cognitive learning, as it prompts students to articulate their thoughts, analyze information, evaluate arguments, and formulate logical responses, thus fostering their critical thinking.

4.3 An Important Resource for Educators

The results indicate that ChatGPT supports the learning process, i.e. represents a new and interesting resource for educators. ChatGPT provides them with a versatile teaching tool that can be used not only to design and deliver more innovative teaching, but also to increase students' motivation to learn and engagement in class (Yu, 2023). This technology can also help educators to design personalized learning materials, improve the quality of teaching and support students' learning experiences (Yu, 2023; Strzelecki and ElArabawy, 2024). ChatGPT can support the instructors in creating personalized learning plans that include content, activities, and assessments adjusted to the individual student's needs (Fusch, 2023).

5. Risks of Integration of ChatGPT in Higher Education

This section presents the risks identified in the reviewed papers regarding the integration of ChatGPT in higher education.

5.1 Potential Escalation of Plagiarism and Cheating Among Students

ChatGPT brings a great academic integrity risk in the education sector (Yu, 2023; Strzelecki and ElArabawy, 2024). Students may use ChatGPT-generated content and present it as their work without proper acknowledgment (Mhlanga, 2023). In that way, students misrepresent their knowledge, skills, abilities, and academic achievements violating academic integrity. Using ChatGPT to complete assignments may lead to academic dishonesty and cheating behaviors (Strzelecki, 2023; Yu, 2023). Based on identified academic dishonesty risks, many schools and HEIs have been alarmed by the launch of ChatGPT and even banned the usage of ChatGPT and AI tools considering it academic fraud and cheating (Yu, 2023; Dempere et al., 2023). While some from academia suggest that students write by hand during class sessions to ensure full control over students' performance and achievements, others emphasize the relevance of teaching digital literacy (Dempere et al., 2023). It becomes obvious that HEIs have to adjust teaching and examination standards to ensure that students adhere to academic integrity when using new AI technologies (Mhlanga, 2023).

5.2 Over-reliance on ChatGPT

Scholars have also pointed out the challenges of over-reliance on ChatGPT and AI tools. Excessive dependence on ChatGPT and AI may hinder the development of essential cognitive abilities, such as understanding ability (Yu, 2023), analytical and critical thinking skills (Dwivedi et al., 2023; Fuchs, 2023), problem-solving skills (Tan, 2023), and research abilities (Shiri, 2023). Students, who do not do their assignments until the last minute, may create their work entirely based on ChatGPT and without their independent thinking and problem-solving skills. In this case, students are just passive learners who accept the responses generated by ChatGPT, without critical thinking and questioning the relevance and accuracy of the information provided (Fuchs, 2023). Recent surveys revealed that most American college students use Chat GPT to complete homework tasks and to write papers and essays (Dampere, 2023; Yu, 2023; McGee, 2023). This trend of over-reliance on AI technology in learning may significantly limit students' learning outcomes and development (Yu, 2023) and their ethical awareness (Tan, 2023).

5.3 Reducing Human Interaction

The integration of ChatGPT in HEIs also poses a risk of reducing human interaction in learning (Dampere, 2023). As ChatGPT provides immediate responses to students' queries, there is a risk that students rely solely on the

ChatGPT information and guidance, bypassing interactions with their teachers (Yu, 2023). Replacing human interaction in the learning process may impede students' ability to develop strong and trustful relationships with their instructors and lower their engagement and learning outcomes (Fryer et al., 2017).

5.4 Misinformation and Stereotyping

This risk includes the inaccurate transmission of information and unverified content (Tan, 2023), spreading misinformation and unpredictable outputs referred to as hallucinations (Dampere, 2023). Hallucinations have been caused by data beyond its training set. If the training data is not adequate, i.e. it is of low quality, the AI-based tool might learn incorrect or incomplete patterns, which further leads to inaccurate responses (Strzelecki and ElArabawy, 2024). Misinformation may negatively affect learning outcomes if learners do not scrutinize the information generated by ChatGPT (Tan, 2023). Moreover, if the AI system is trained on biased data, it might reinforce existing biases and inequalities in higher education (Fuchs, 2023). Therefore, it reinforces existing biases and perpetuates inequalities in education. For example, if the system is trained on biased or incomplete data, it might generate responses reflecting these biases, thereby leading to a reinforcement of existing inequalities and a failure to challenge and disrupt discriminatory practices in higher education.

5.5 Lack of Regulations

Although many risks have been related to over-reliance on ChatGPT and similar AI tools, many scholars agree that banning these tools is not an adequate solution (e.g. Dwivedi et al., 2023, Yu, 2023). However, it is critical to develop digital literacy in the education sector and ensure that teachers and students use ChatGPT correctly and responsibly facilitating their independent thinking and creativity (Yu, 2023; Fuchs, 2023).

6. Conclusion

Based on a literature review this paper explored the impact of the ChatGPT on teaching and learning processes in Higher Education Institutions. The articles included in the study were subjected to a cluster analysis, which resulted in three different clusters, namely: (1) Transformation in digital communication, (2) ChatGPT in science and (3) ChatGPT in medical studies. The review also allowed the identification of opportunities and risks associated with the integration of ChatGPT in the teaching and learning processes. Concerning the opportunities, the current body of learning suggests that it facilitates personalized learning, boosts learning efficiency, and supports cognitive initiatives. Moreover, both educators and students appear to benefit from its use as it complements or supports teaching or learning-related activities. In terms of potential risks, the results suggest that the use of ChatGPT can reinforce or trigger plagiarism and cheating. Over-reliance on ChatGPT also harbors the risk that students, instead of trying to solve a task themselves, "outsource" it to ChatGPT and thus reduce or forget their ability to approach a problem. This over-reliance could also lead to less interactions with other students or teachers. The findings also addressed the issue of content quality/accuracy and possible consequences. The lack of regulations in this regard was listed as a further risk.

In summary, it can be concluded that while the integration of ChatGPT and similar tools can improve the teaching and learning processes of HEIs, there is a concurrent need to navigate ethical considerations and strive for continual improvement in their development and application. The results emphasize the importance of permanent communication and education measures aimed at both groups, i.e. students and teachers. Both groups need the necessary tools to be able to use ChatGPT in a targeted manner for learning and teaching. The focus should be less on bans and more on the development and empowerment of capable and informed individuals. However, this work cannot be undertaken by universities alone, but requires close cooperation with upstream learning institutions, starting with kindergartens. This means that there is a need for ChatGPT usage regulations that cover the entire development/learning process of a person from kindergarten, through school, training, university, and beyond. The study provides the basis for further studies on the topic. For example, it would be interesting to use an experimental design to find out whether and to what extent the learning success of students differs between those who study scientific skills ChatGPT supported and those who study ChatGPT without support. A similar design could also be set up with university lecturers to find out whether the learning objectives are achieved similarly, better or worse by using ChatGPT.

Measuring The Process of Knowledge Transmission and Absorption in The Organization

Katarzyna Szymczyk
Czestochowa University of Technology, Czestochowa, Poland

katarzyna.szymczyk@pcz.pl

Abstract: The aim of the paper is to identify the degree of knowledge sharing and measure the scale of behavior related to giving and receiving knowledge in the organization. The author of this study focuses on presenting and analyzing the results of a quantitative survey conducted among 131 academy employees. Academic teachers and non-academic staff participated in the study conducted in March-April 2024 based on a questionnaire developed by R.E. De Vries, B. Van den Hoff, and J.A. De Ridder in 2006. A five-point Likert scale was used to measure the knowledge transfer and absorption scale. The study results showed that the transmission of knowledge and its absorption generally occur evenly. This means that employees, on the one hand, share knowledge, but on the other hand, they are also willing to use and acquire knowledge from others. This may result from a specific behavioral model created because of the conditions imposed in the organization, or it was created due to the need for cooperation and co-help in sharing knowledge to facilitate and improve work. The presented study is preliminary and requires further development to enrich the actual knowledge-sharing subjects' theory and practice. Yet, the presented data can be useful in comparative analyses and other deepening studies on similar matters.

Keywords: Knowledge Management, Knowledge Transmission, Knowledge Absorption, Organization

1. Introduction

The concept of knowledge management in an organization, according to the universal definition in a narrow sense, is a set of activities aimed at identifying, preserving, disseminating, and using the explicit and implicit knowledge of the company's personnel to increase the efficiency and effectiveness of employees' activities. In a broader sense, this concept also considers employee motivation, sociological and social aspects, intelligence, and communication skills. Therefore, knowledge should be treated as the vital intangible resource of a given organization. Based on the acquired knowledge, an organization can learn and improve. It must not only gain knowledge, e.g., from the business environment but can also transfer it both within and outside the organization (Demarest, 1997; Kowalczyk & Nogalski, 2007; Yi, 2009; Karaś & Piasecka-Głuszak, 2013; Witherspoon et al., 2013; Kokot-Stępień & Krawczyk, 2023). Sharing knowledge is integral to the organization's performance (Yeboah, 2023; Asrar-ul-Hag et al., 2016; Yi, 2009). It occurs in two aspects: transferring and acquiring knowledge. Sharing knowledge in an organization potentially takes place differently in large, hierarchical, and complex organizations than in smaller organizations with less formalized structures and fewer employees. Sharing knowledge will be different in small and medium-sized enterprises than in large enterprises, which are strictly hierarchical corporations, and will be different in state institutions, associations, cooperatives, groups of mutual interest, etc. Any organization's flow of information and knowledge is crucial to its proper functioning (Asrar-ul-Hag et al., 2016; Witherspoon et al., 2013; Ipe, 2003). However, knowledge management and sharing may be more complicated and sometimes even more difficult in an organization with a complex structure. This is mainly due to the hierarchical levels that prevail. The knowledge exchange between company managers, starting from owners, managers, directors, and lower-level employees, may be slower, limited, or incomplete. In organizations with a simple structure in which owners or managers have closer contact with employees, the exchange of information usually runs more efficiently and faster. In the workplace, where access to knowledge and information often depends on management decisions, the company may contribute to a situation where employees do not have the necessary knowledge or do not know where to obtain it and might be less willing to share their knowledge. This happens, especially when there is high competition between employees in the workplace or when a given organization has not introduced an appropriate organizational culture based on building mutual trust, cooperation, and a sense of belonging to the organization. It is worth mentioning, however, that despite the limitations in acquiring and sharing knowledge among employees, they may still want to acquire and share knowledge with others to improve their work and develop the skills and competencies needed for their development. It is essential for company owners and managers that all employees have access to knowledge and can share it, and for this purpose, it is worth using tools to measure the scale of knowledge sharing. Measuring the scale of knowledge transfer and acquisition may help modify the strategy of managing personnel and information flow in the organization, which should ultimately bring tangible benefits for the organization's functioning from the inside to the outside.

2. Knowledge Sharing Measuring

In knowledge management, the issue of sharing knowledge between superiors and employees, between employees, and between employees and their superiors deserves particular attention. This issue can be considered in two ways: the process of transmission and absorption of knowledge. Recognizing and understanding the process of knowledge sharing and its measurement may help identify the degree of effectiveness of the organization's operation from the inside, understanding interpersonal relations, the level of trust between employees, and the intensity of cooperation as the potential causes of its lack in favor of unhealthy competition. The extent to which an organization functions as a team, a well-coordinated group, or even an organism of interconnected vessels may be intensely dependent on the skills, needs, and willingness to share knowledge, exchange information, and learn from each other. Sharing knowledge can benefit the organization by improving its functioning and strengthening it from the inside, ultimately translating into its functioning externally and allowing it to maintain or gain a competitive advantage. Therefore, every organization should learn to identify and measure the knowledge transmission and absorption process and take action to improve this process. The knowledge-sharing literature contains many studies worth mentioning. Much research concerns enterprises and industry, but many studies have also been conducted in public institutions like universities. It is worth noting the works of Cheng et al. (2009), Alhammad et al. (2009), Sadiq Sohail & Daud (2009), Zawawi et al. (2011), Fullwood et al. (2013), Chmielecki (2013), Wei Chong et al. (2014), Ramayah et al. (2014), Yasir et al. (2017), ÅšwigoÅ (2017), Akosile & Olatokun (2020), Javaid et al. (2020), Al-husseini & Abdel Baqi, 2023. In this study, the author discusses issues related to knowledge sharing, mainly its transmission and absorption. The author presents the analysis of quantitative research results based on a survey questionnaire conducted in 2024 on a group of high-, middle- and low-level employees of a state organizational unit - a university. Knowledge Sharing (KS) behavior scale developed by R.E. De Vries, B. Van den Hoff, and J.A. De Ridder in 2006 was used to prepare the survey questionnaire. Knowledge sharing considers knowledge transfer (donating) and accumulation (collecting) (De Vries et al., 2006). Donating and collecting knowledge are crucial in building organizational culture and job satisfaction. De Vries et al.'s knowledge-sharing model measures the level of transfer and accumulation of knowledge and allows for analysis of what knowledge-sharing practices look like in each organization, whether they are appropriately implemented, and whether a given organization adequately manages the knowledge-sharing processes. De Vries et al.'s model also allows for determining the extent to which the organization members are eager to give/donate and absorb/collect knowledge from other members. Considering the advantages of the above-mentioned authors' model, this study used it to measure the organization's transfer and absorption of knowledge.

3. Study

Quantitative research based on a survey questionnaire conducted in March-April 2024. The research sample included university employees, both academic teachers and non-academic employees. Knowledge Sharing (KS) behavior scale developed by R.E. De Vries, B. Van den Hoff, and J.A. De Ridder in 2006 was used to prepare the survey questionnaire. Knowledge transmission and absorption were measured using a five-point Likert scale. The questionnaire was emailed to the offices of the Deans of selected universities with a request to send it to employees. Ultimately, 131 people participated in the study. The return of surveys could potentially be higher, which is a reason to repeat the study, and the collected results should be treated as a preliminary study. The relatively small number of employees who participated in the survey may be due to the time the survey was conducted, namely the pre-Easter period. The other reason may be reluctance or lack of time to complete the survey. Considering this analysis is a preliminary study, the collected results may be helpful for comparative analyses in similar studies. The study included 57% women, 42% men, and 1% non-binary persons. Most respondents are employees who are academic teachers - 80% of the respondents, and the remaining 20% are employees who are not academic teachers. Not academic teachers are generally employed in administering a given faculty. The detailed distribution of respondents by job position is presented in Figure 1.

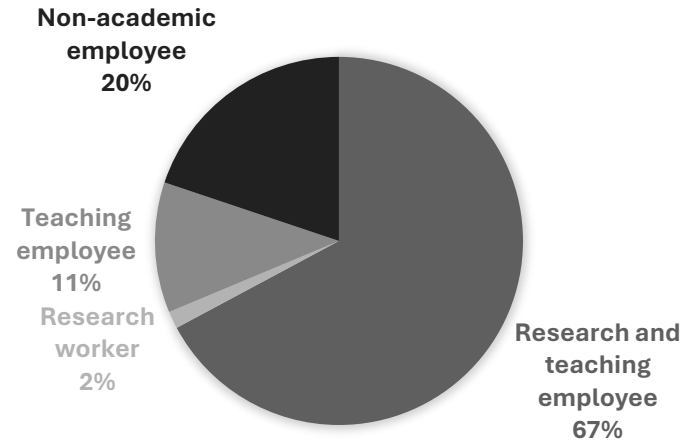

Figure 1: Division of respondents by form of employment

Most respondents in the research sample have been working for at least 16 years or longer. There were relatively few people working for six to 15 years—20%. Less recorded are people who have been working at the university for a short time and no longer than five years. Figure 2 presents a detailed breakdown of the collected results.

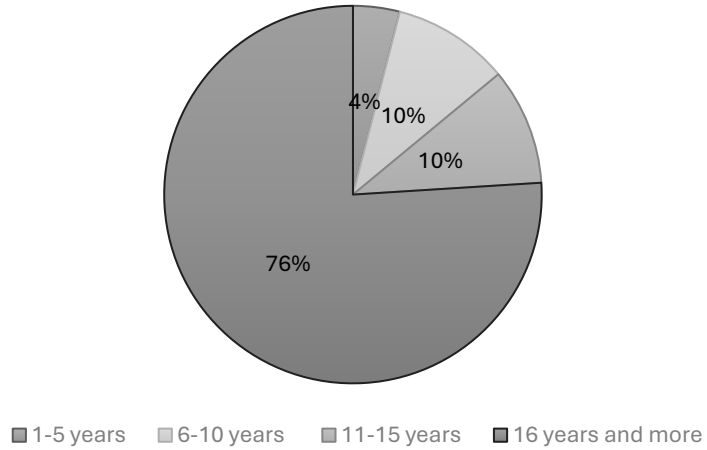

Figure 2: Percentage of survey respondents by length of employment

58% of respondents hold functional positions, and the remaining 42% do not have such. Teaching is a functional position, including heads of institutes, departments, laboratories, etc., deputies of these heads, deans, vice-deans, rectors, vice-rectors, chancellors and deputies, heads or directors of administrative units, etc.

4. Results

As mentioned, the survey questionnaire was prepared using the Knowledge Sharing (KS) behavior scale developed by R.E. De Vries, B. Van den Hoff, and J.A. De Ridder in 2006. The study aimed to determine to what extent employees of a given organization, in this case, a university, are willing to share their knowledge with their coworkers/collaborators and to what extent they can acquire knowledge from their coworkers. The survey contained a total of eight questions. It was divided into two parts. The first part concerned transferring knowledge to colleagues, while the second concerned acquiring knowledge from colleagues:

1. The Knowledge Transmission

When I learn something new, I share it with my coworkers.

I share all the information I have with my coworkers.

I think it's important that my coworkers know what I do.

I regularly tell my co-workers what I do.

2. The Knowledge Absorption

When I need some knowledge, I ask my co-workers about it.

I like to be informed about what my co-workers know.

When I need to learn something, I ask my co-workers about their skills.

When a coworker is good at something, I ask him/her to teach me how to do it.

The study was conducted in Polish. Knowledge transmission and absorption were measured using a five-point Likert scale:

1 - I strongly disagree

2 - I rather disagree

3 - I have no opinion/it's hard to say

4 - I rather agree

5 - I strongly agree

The questions included the concept of a collaborator, as in an organization such as a university, employees have contact with other employees, but not all of them remain in close contact; they cooperate, they take part in the same tasks, they stay in the same rooms and carry out the same or similar tasks. projects. Therefore, the study emphasized that the respondents expressed their opinion on sharing knowledge with people with whom they cooperate daily, are in the workplace, or are in relatively close contact with them rather than with other employees working in the same building.

4.1 The Knowledge Transmission

Almost 70% of the respondents admitted that when they learn something new, they share it with their colleagues. 21% had no opinion on this matter. 10% of respondents indicated that they do not share their acquired knowledge with their colleagues in such situations. The detailed distribution of respondents' answers is presented in Figure 3.

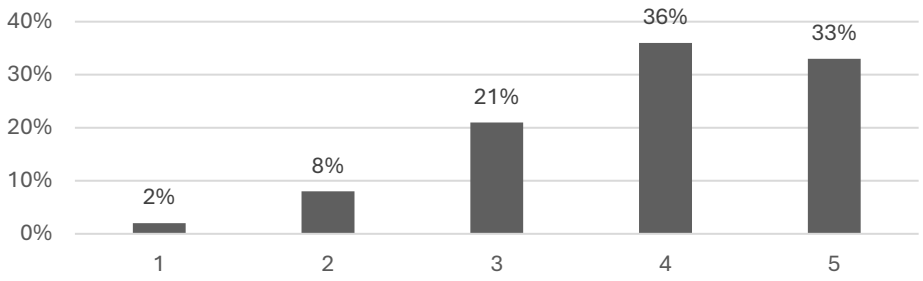

Figure 3: When I learn something new, I share it with my coworkers. N=131

57% of respondents said they share all their information with their coworkers. In this case, 20% had no opinion, while 23% admitted they were unwilling to share all their information with their coworkers. The detailed distribution of responses obtained from respondents participating in the study is presented in Figure 4.

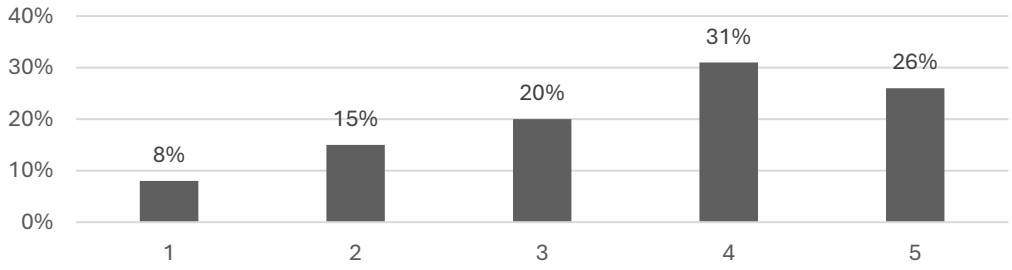

Figure 4: I share all the information I have with my coworkers. N=131

67% of respondents strongly agree or agree with the statement that it is important for co-workers to know what a given employee does. Figure 5 presents the detailed distribution of respondents' answers.

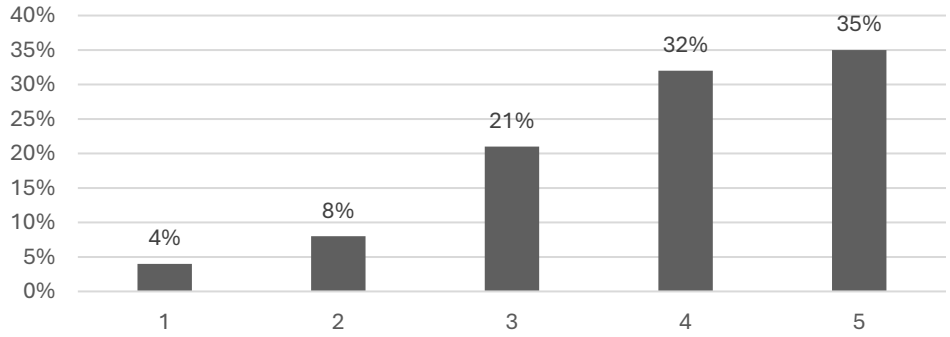

Figure 5: I think it's important that my coworkers know what I do. N=131

Regarding whether an employee regularly informs coworkers about what he or she does, 54% definitely or rather agreed, 24% have no opinion on this matter, 13% said rather not, and 9% said they do not regularly inform coworkers about what they do. deals with. The detailed distribution of responses obtained from respondents participating in the study is presented in Figure 6.

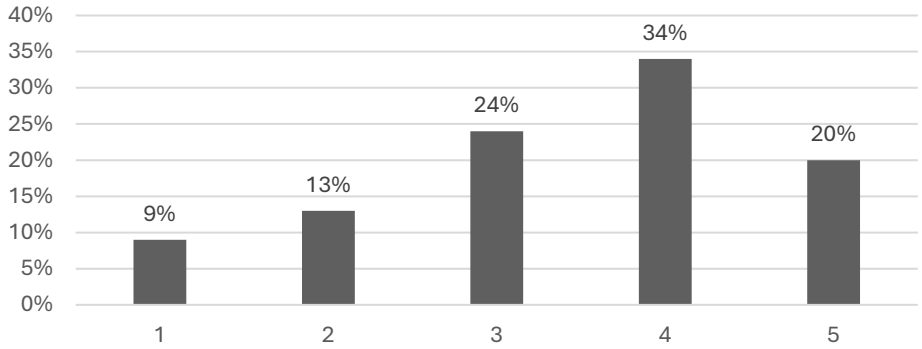

Figure 6: I regularly tell my co-workers what I do. N=131

4.2 The Knowledge Absorption

Most respondents admitted that they ask their co-workers if they need any knowledge. 31% of respondents strongly agree, and 44% agree that they turn to their coworkers for knowledge when they need to learn something. 6% of respondents said that when they need to acquire knowledge, they do not ask their coworkers about it, and only 2% admitted that they do not do it. 17% have no opinion on this matter. The answers obtained from respondents are presented in Figure 7.

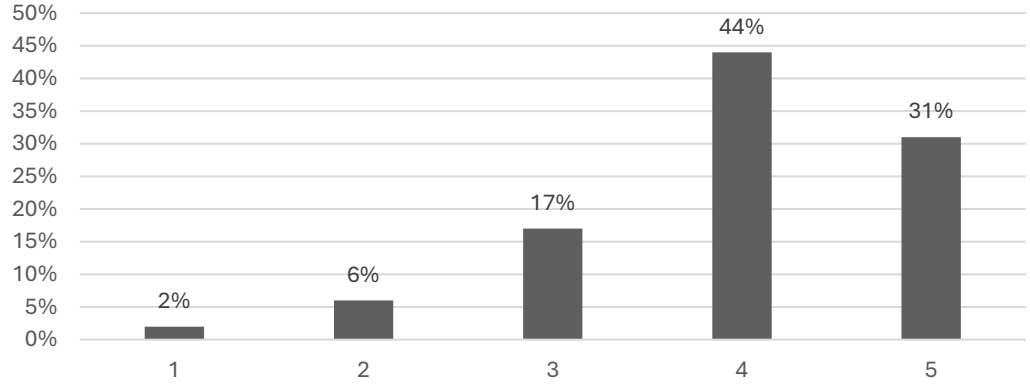

Figure 7: When I need some knowledge, I ask my coworkers about it. N=131

41% definitely, and 29% would rather be informed about what their coworkers know. 13% probably do not want such information, and only 2% do not want to be informed about what their coworkers know. 15% of respondents indicated that they had no opinion on this issue. The collected responses are presented in Figure 8.

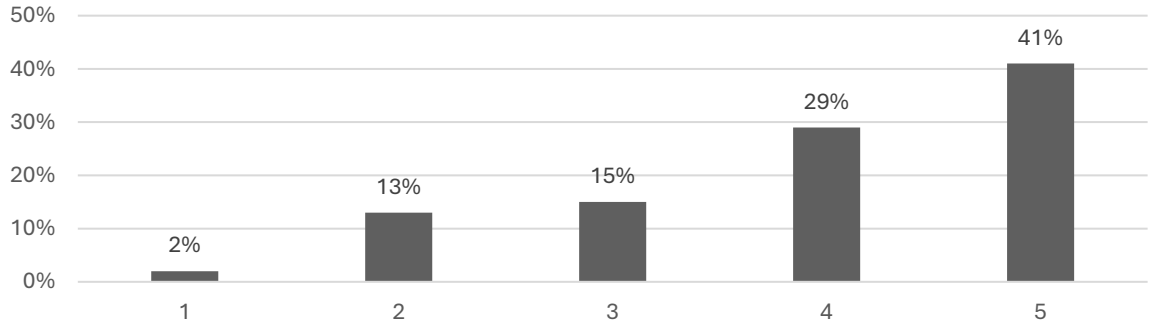

Figure 8: I like to be informed about what my coworkers know. N=131

60% of survey respondents admitted that if they need to gain knowledge and learn something new, they turn to their coworkers to learn about their skills. 20% of respondents had no opinion on this matter, 15% admitted that they disagreed, and 5% strongly disagreed with the statement that if they need to learn something new, they turn to their coworkers and ask about their skills. The collected responses are presented in Figure 9.

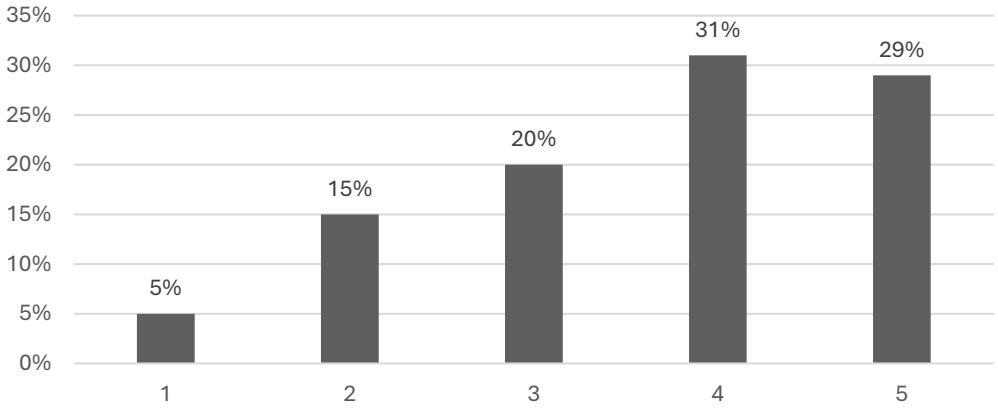

Figure 9: When I need to learn something, I ask my coworkers about their skills. N=131

54% of respondents admitted that they strongly agree, and 21% rather agree that if a coworker is good at something, they ask him or her to teach them what they know. 75% of study participants expressed positive opinions on this issue. 15% had no opinion on this matter. A total of 10% expressed reluctance to learn from others. Figure 10 presents the collected answers.

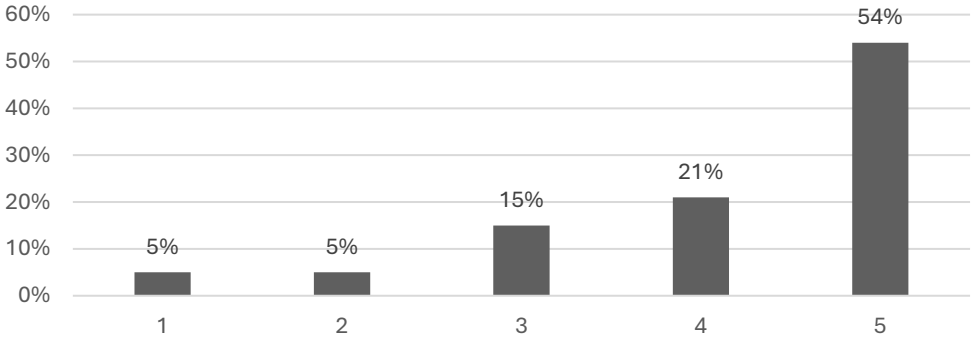

Figure 10: When a coworker is good at something, I ask him/her to teach me how to do it. N=131

The next part of the study summarizes the collected results and discusses the conclusions drawn from the research.

5. Discussion

The collected research results were sorted into knowledge transmission and knowledge absorption. Positive and negative behaviour in both groups were listed. The answers of respondents participating in the study who did not express opinions were not considered. A summary of the collected responses in percentage terms is presented in Table 1.

Table 1: Summary of survey results, including positive and negative behaviour

	The Knowledge Transmission		The Knowledge Absorption		
	Positive behaviour	Negative behaviour		Positive behaviour	Negative behaviour
When I learn something new, I share it with my coworkers	70%	10%	When I need some knowledge, I ask my co-workers about it	75%	8%
I share all the information I have with my coworkers	57%	23%	I like to be informed about what my co-workers know	70%	15%
I think it's important that my coworkers know what I do	67%	12%	When I need to learn something, I ask my co-workers about their skills	60%	20%
I regularly tell my co-workers what I do	78%	22%	When a coworker is good at something, I ask him/her to teach me how to do it	75%	10%

By analyzing selected research results, some conclusions can be drawn. First, it is worth noting that the study indicated the respondents are relatively willing to share their information and knowledge with their coworkers (70%). When they need this knowledge, they are eager to ask their collaborators about it (75%). However, when it comes to sharing all information with coworkers, the percentage of respondents willing to do so is somewhat lower (57%) than that of respondents who want to be informed about what they know and what their collaborators know (70%). Interestingly, most respondents indicated that they regularly notify their co-workers about what they do (78%), and 67% said that it is important for co-workers to know what a given employee does. Most respondents (75%) also admitted that if a co-worker is good at something, they ask him for help and to teach them how to do something. Slightly less, but more than half, 60% of respondents admitted that if they need to learn something, they ask their co-workers about it to learn about their skills. Respondents who expressed rather negative opinions on the above-mentioned issues are a minority. The most negative responses, 23%, were indicated about sharing all information with coworkers. There was also some controversy about regularly informing coworkers about what a given person is doing - 22% of people participating in the study had a negative attitude toward this issue. Similarly, when one needs to learn something and asks coworkers about their skills, 20% of respondents reacted negatively to such action. Respondents replied most positively to the issues of learning something and sharing this knowledge with coworkers, regularly informing them about what they are doing, acquiring knowledge from their coworkers, and learning something new from them. The study also shows that employees are relatively willing to be informed about what their coworkers know.

The respondents' positive behavior regarding knowledge sharing was also considered regarding gender. In this case, only respondents' responses were considered in which they strongly agreed or agreed with the presented statements. Women are more eager to be informed about what their colleagues are doing. The willingness to ask co-workers about their knowledge and skills to learn something is also greater among women than men. As employees, they seem to be much more communicative and open, and they are more willing to inform their co-workers about what they are doing than men. The issue of providing all information to co-workers and transferring what a given employee has learned occurs similarly for both women and men. The detailed responses are presented in Figure 11.

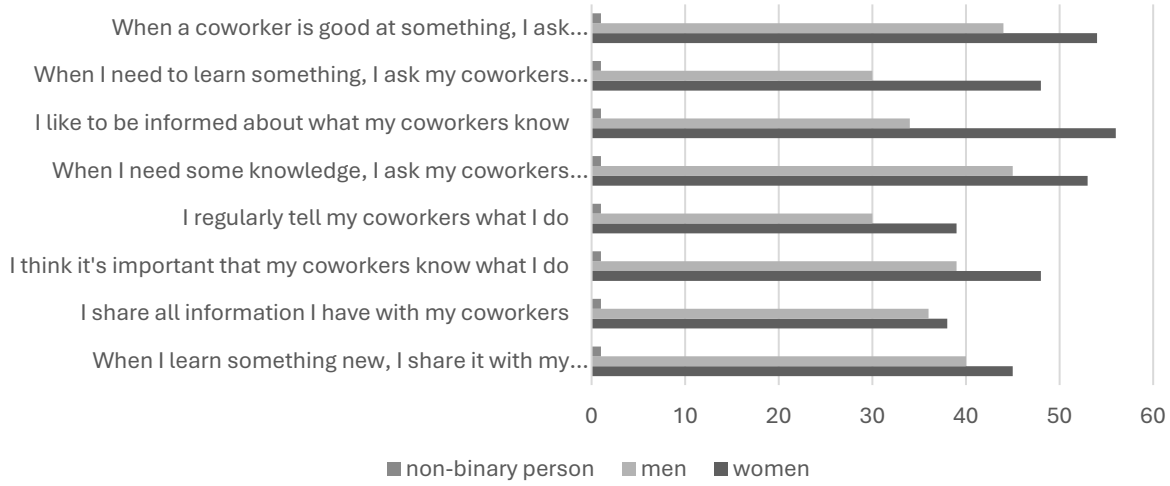

Figure 11: Positive behavior regarding knowledge sharing by gender

Considering the functional position the respondents hold or not, the research noticed that people who hold a functional position, compared to people who do not have such positions, are less willing to share and acquire knowledge from coworkers. People who do not perform any function are more willing to learn from others, ask about their skills and expertise, and provide them with the knowledge and information they have. The detailed share of responses is shown in Figure 12.

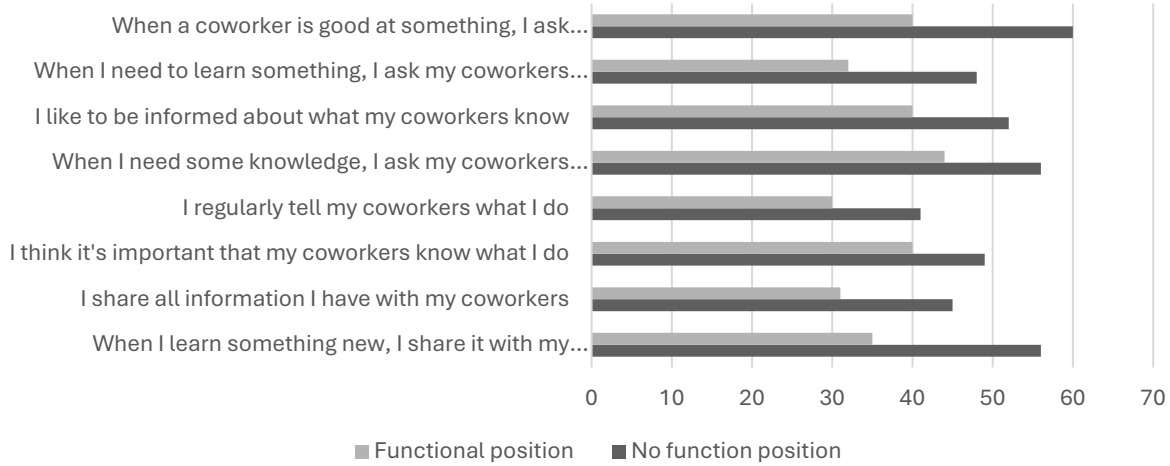

Figure 12: Positive behavior due to functional position.

Based on the collected research results, it can be generally stated that the transmission of knowledge and its absorption in the group of university employees occurs similarly. There were no vast differences between knowledge transmission and absorption. Respondents in the study indicated that they are willing to share knowledge and simultaneously seek knowledge from their coworkers and are eager to acquire it. However, female workers are keener to share and absorb knowledge from their coworkers than male workers. Workers who do not hold functional positions at work are more willing to gain knowledge from coworkers, learn from them, and are more eager to give their knowledge or share the information they learned than workers who hold functional positions. Of course, it should be emphasized here that the research is preliminary, and it is difficult to draw general conclusions for the entire university population. Nevertheless, this is already an overview of knowledge sharing in an organization with a hierarchical and complex structure.

6. Conclusions

The article analyzes the results of research on knowledge sharing in organizations. The study focused on the issue of knowledge transmission and absorption. A survey questionnaire was prepared using de Vries et al.'s

model to conduct the study. The research sample included employees of selected faculties of universities in Poland. Both non-teaching staff and academic teachers took part in the study. The survey questionnaire was made available via e-mail, and the number of respondents ultimately amounted to 131. The study was conducted in March and April 2024. The study aimed to determine to what extent employees of organizations with a complex structure are willing and able to transfer their knowledge to co-workers and acquire and collect knowledge from them. Therefore, the above-mentioned model was used to measure the behavior of organization members in terms of knowledge transmission and absorption. Based on the collected research results, it was found that there are no fundamental differences between transmission and knowledge absorption. The survey shows that employees are relatively willing to share knowledge with coworkers and are also willing to acquire knowledge from coworkers. The research results may indicate that the university, as an organization with a specific organizational structure, imposes behavioral models in which knowledge transfers to coworkers and the collection of knowledge from coworkers occurs evenly. This may indicate that the key to efficient operation in this type of organization is cooperation, and there is a relatively strong need to share knowledge, both in giving and receiving terms. However, the presented study is preliminary and requires extension and comparative analyses to draw more precise conclusions. Therefore, the presented research results can be used for research of a similar nature for comparative purposes or internal analyses of knowledge management issues in the organization.

Stewardship for Managing Societal Challenges

Emőke Takács and Toon Abcouwer
ERI Hungary - European Research Institute Hungary, Budapest, Hungary

t.emoke@eri.net.in
toon@abcouwer.nl

Abstract: Technological developments have made us live in a complex and constantly changing world. The focus was mainly on a more accessible and better life for individuals, leaving nature and surroundings out of consideration. However, the impact on nature and the environment makes it clear that striving for environmental sustainability is starting to be a bare minimum. Also, the disproportionate impact on marginalised communities is an unintended side-effect. There is increasing emphasis on sustainable practices, conservation of resources, mitigating the effects of climate change, and addressing environmental injustices. Aside from that, mitigating the growing divides in the world requires a different view of our contemporary world. Some of us face increasing anxiety, and others are enthusiastic about the future. It is this future that makes knowledge management play a crucial role in adapting to these new circumstances. Using the existing knowledge based on being proud of the past and, at the same time, being curious and innovative to develop new knowledge to manage unpredictable future events are equally relevant. We recognise that the different settings of change require different types of management styles. Most scientific literature assumes that management is skilled enough to operate well in certainty, while leadership is needed when risk arises. We propagate to integrate the concept of stewardship as a required means in a setting of uncertainty. So far, this concept has gained little attention in knowledge management. Our paper deals with developing skills and competencies for stewardship, managing knowledge to prepare for the unforeseeable futures. In current dynamics, enriched with complexity, it is inevitable to manage knowledge, develop resilience and new skills, respect one another, and build sustainability. Also, new competencies are recognised to manage in current times of change.We combine the paradigms of understanding the different phases of change with the specific types of knowledge management and the competencies required to address the challenges and divides of today. It involves collaboration and shared values among 'We': governments, organisations, communities, and 'Me', individuals to enact meaningful change for 'All', now and in the future.

Keywords: Change, Knowledge Management, Stewardship, Resilience, Sustainability, Competencies

1. Introduction

The never-ending human developments throughout history, have created a complex and constantly changing world, which we all keep adapting to (Beck, 2006; Folke et al., 2002). People react differently to changes. Some of us face growing anxiety, and others are enthusiastic about the future, depending on how confident we are in managing it. Our confidence depends much on how certain we are in the results of change: if we find it a threatening risk for our lives, or if we are completely uncertain about the effects of the changing circumstances, which we are also unsure about (Abcouwer et al., 2022). We face uncertainty independent of how much we try to be prepared for the unknown future and do our best to be knowledgeable (for a description of certain, risk and uncertain see Gigerenzer, 2015). To sustain our equilibrium and present successes, we need several types of skills, knowledge and knowledge management (E. Takács & A. W. Abcouwer, 2020).

In a well-functioning organisation, management is skilled at operating in certainty, where the situation is known, just as the effects of the daily interventions. Leadership is necessary when the equilibrium is disturbed by risks. Stewardship seems to be efficient in uncertain circumstances (Takács et al., 2019). Science studies management and leadership thoroughly, but what is 'stewardship' Can we develop stewardship? What knowledge, skills and competencies does it require to manage unforeseen events? Managing knowledge, developing resilience and new skills are inevitable in our dynamically changing complex world (E. Takács et al., 2022).

Based on our research activities, we first explain why stewardship is necessary today by analysing the aspects of continuous change, identifying the roles for managing different challenges and the skills to sustain in the future. The diverse theoretical insights with practical recommendations of the European Commission highlight the urgent need to change our attitudes, knowledge management practices, leading to the acknowledgment of the importance of Stewardship for managing societal challenges.

2. Complexity of Challenges and Adapting to Change

Human nature insists on solving the arising problems, but it is becoming clear that the causes we presume for the dynamic societal changes are not manageable on their own. Dealing with challenges one by one only makes us realise the interplay of many underlying issues and cannot reach solutions. As the concept of

intersectionality[1] highlights, no singular problems exist, but they interrelate (Runyan, 2018). The unique dynamics and effects of the intersecting issues create complexity that cannot be solved separately or in a unified way. Understanding complexity by intersectionality helps us to use a broader perspective on knowledge management, while understanding the change process helps managing the challenges more successfully.

The Adaptive Cycle of Resilience (ACoR) model (E. Takács & A. W. Abcouwer, 2020) is based on the dilemma of what we want, must and can do in the given situation (Heene, 2002). The sign of eternity illustrates the ongoing change process starting with an equilibrium, disturbed by challenges, which we need to find new combinations to operationalise so we can reach a new equilibrium. We recognise that in certainty, managers can optimise operations, but when uncertainty arises, creative leaders can support the adaptation to the new circumstances by coming up with new ideas to put in operation and reach certainty again (Takács et al., 2021). These new ideas should be based on new insight and new knowledge that has to be managed carefully.

Figure 1: Developments and the Adaptive Cycle of Resilience (Takács & Abcouwer, 2011)

Change does not stop but evolves. Adaptability and sustainability are crucial challenges for all of us in such a rapidly changing world. We need to deal with the ever-changing societal challenges, and besides adaptivity, different skills, knowledge and attitudes are necessary in the four mentioned stages of change. We identified management, leadership and stewardship as the ones that can handle the challenges successfully.

3. Dealing with Change: Management, Leadership, Stewardship

In the constantly changing environment, different skills, knowledge and attitudes are needed.

In equilibrium (or certainty), managers work well. They know what they want, must and can do to keep the operations balanced. When challenges arise, and we leave our certainty in our abilities (can), we need strengths and faith that we can handle the problem. It certainly requires leadership, just as when we need to find the solution to handle the change. To operationalise and conserve the new ways of working, going concerned is again efficiently manageable with the knowledge and skills of the managers (E. Takács & A W Abcouwer, 2020). But what is Stewardship? When does it play a role in change management and what new requirements for knowledge arise?

Stewardship goes beyond business activities. It also regards organisations' effects on the world around them, looking at values, ethics, and morals. Stewardship guards all resources (time, money, goods and services) with the human responsibility to care for and manage the natural world. Ownership, responsibility, accountability, and reward describe managers and leaders with stewardship (Contrafatto, 2014). They search for solutions to transform ownership, governance, and finance by reconsidering the so-called "truths" accepted by society and redesigning the organisations' operations. They work on adapting to change and sustain while considering all stakeholders: 'Me', the individuals; 'We', the organisations and the groups of individuals; and 'All', the world (Abcouwer & Takács, 2022; Abcouwer et al., 2022). Stewardship changes the focus from 'solving one thing here

[1] According to the concept of intersectionality, different systems, like inequality, are based on multiple forms of discrimination that "intersect" and create unique dynamics and effects.

and now' to a broader and longer perspective thinking, which results in a sustainable present and future for the people (Me), the organisations (We), and our environment (All).

Figure 2: Management-Leadership-Stewardship (Takács et al., 2021)

Managers' concerns work with knowledge transfer because in certainty, it is easy today to find and manage the proper knowledge to handle the problem at stake. In risk and uncertainty, we need the leadership's innovative thinking and courage to solve the arising challenges. Being adaptive requires stewardship to keep answering unknown questions. Shifting to stewardship requires good knowledge management and sensitivity, to be able to get a better understanding of the unknown futures ahead.

A leader who is consciously involved in life-long learning and knowledge management should easily reach stewardship. Those who care for their organisations also pay attention to their people. Knowledge is power, and more and more the value and the primary source for individual and organisational development. We highlighted the importance of knowledge exchange, which is necessary for successful learning and management. The use of information and knowledge is becoming more relevant than its ownership (Brouwers et al., 2022). Experiences built under changing circumstances should focus more on knowledge exchange, although disputes around ownership have increased. Recognising and valuing human capital and building trust and security in the organisation can be a gain for both the individuals and the organisation - and once we recognise the importance of stewardship, - also for the world. Leaving ownership of information and focusing on building new knowledge and practices together leads to questioning and revising accepted (scientific/"true") knowledge sources, which is also characteristic of innovative leaders. To set a favourable environment in the organisation, hierarchy must be changed to trust, cooperation, learning, security, inclusion, equality, flexibility, inspiration, and renewal. Moving the focus to using and interpreting knowledge is a differentiating factor that forms the basis for creating value. Stewardship, backed by wisdom, is conducive to a service mindset. Leadership alone is less likely to invoke cooperation and collaboration. (Dell'Era et al., 2020) In a cooperation, where decision makers share ownership and communicate their interpretations, we explore a new role for the "we" (the organisational value), compared to the traditional orientation where organisations are for fulfilling the shareholders' value or interest.

Stewardship is the careful and responsible management of the things entrusted to our care (Chapin III et al., 2009) a collective work to advance healthy, equitable, sustainable communities describes leaders—both people and organizations—who take responsibility for forming working relationships to drive transformative change in regions and communities (Institute for People Place and Possibility (IP3), n.d.). Importantly, stewards must have a vested interest in promoting an equity orientation regarding purpose, power, and wealth.

Table 1: Differences between Management-Leadership-Stewardship (own source, adaptation of (Lunenburg, 2013))

Category	Management	Leadership	Stewardship
Thinking process	focus on issues looking inward	focus on people looking outward	focus on all the creatures (ecojustice) looking in- and outward

Category	Management	Leadership	Stewardship
Goal setting	executing plans improving the present seeing the trees	articulating a vision creating the future seeing the forest	understanding complexity live in the present with ownership, responsibility and accountability for the future
Employee Relations	controlling subordinates directing and coordinating	empowering colleagues trust and developing	encouraging equality accept, respect and reward
Operations	doing the things right managing change serving super-ordinates	doing the right things creating change serving subordinates	doing as best as can understanding and adapting to change serving the world with all included
Governance	uses authority avoids conflicts acts responsibly	influence uses conflict acts decisively	motivates, encourages respects and accepts responsible and decisive

Can we learn to be a steward? What skills and competencies are needed?

Individuals can serve as stewards to advance community well-being, and stewardship is best accomplished when people work together across differences and sectors to expand the vital conditions that all people and places need to thrive. Stewardship has the most significant impact as a mechanism for shared responsibility and collective action when the work has expanded, aligned with breadth and depth, and, in turn, expanded reach and impact.

4. Skills and Competencies

4.1 EC (2022) European Sustainability Competence Framework

GreenComp (Bianchi et al., 2022) is a reference framework for sustainability competencies. It provides a common ground to learners and guidance to educators, advancing a consensual definition of sustainability as a competence.

It responds to the growing need for people to improve and develop the knowledge, skills and attitudes to live, work and act sustainably. It is designed to support education and training programmes for lifelong learning. It is written for all learners, irrespective of age and education level and in any learning setting – formal, non-formal and informal.

The competencies are grouped around four areas. The competences to

- embody sustainability values
- embrace complexity in sustainability
- envision sustainable futures
- act for sustainability.

These four areas require different kinds of knowledge that must be carefully managed. In the following figure, we describe the areas in more detail to give an indication of what kind of knowledge must be available to embrace the sustainability competencies.

Figure 3: Sustainability competencies (own source, adaptation of the European Sustainability Competence Framework)

Embodying sustainability values require the competences of valuing sustainability, supporting fairness and promoting nature, as humans are part of nature, so should respect the needs and rights of other species and the nature itself to restore and regenerate healthy and resilient ecosystems.

Embracing complexity in sustainability can be achieved by developing the competences of systems thinking, critical thinking with thorough analyses, and framing the current or potential challenges as a sustainability problem in terms of difficulty, involved people, time and geographical scope to identify suitable approaches to anticipating and preventing problems and mitigating and adapting to already existing problems.

Envisioning sustainable futures are very important for youths with their future ahead. Competences as futures literacy for developing alternative scenarios and identifying the steps needed to achieve them, adaptability and creativity, and exploratory thinking can support decision making in complexity and result in novel ideas and methods.

Acting for sustainability with political agencies, collective actions and individual initiatives and potentials for sustainability to actively contribute to improving prospects for the community and the planet.

Sustainability competencies show the individuals' responsibilities ('Me') for their communities ('We') and the environment ('All'). They can help people become systemic and critical thinkers, as well as develop agencies and form a knowledge basis for everyone who cares about our planet's present and future state.

5. The 'Me-We-All' Approach

We recognise that single challenges do not exist, so solving problems one by one will not lead to sustainable solutions. ACoR shows the ever-changing circumstances phase by phase, with skills, competencies, learning and management styles to handle them appropriately. We see how complex it is to live with and manage changes and how vital information management and education are. Like intersectionality, we must consider different aspects and look at problems with a broader view to identify equal opportunities for everyone. When decisions consider all stakeholders, 'Me-We-All', - *"Me": the People, "We": the organisations and "All": the society or our environment* - they can intersect to reach resilience and sustainability in dynamics. For such abilities besides education, we also need supporting values at these three levels (Schwartz, 2012). Organisational values cannot be the guiding principles, purposes and directions anymore, they are something the members create and shape with the consideration of 'Me-We-All' (Abcouwer & Takács, 2022; Abcouwer et al., 2022).

Figure 4: Changing values (Abcouwer et al., 2022)

When leaders change their values towards ethical and sustainable measures, they find stewardship to deal with the changing circumstances.

- Managers who regard intersectionality will understand differences, and with tolerance, acceptance, and focused education they can decrease any divides, strengthen cooperation of diverse teams, and opt for more creative ways to deal with challenges.
- Appropriate competencies and new methods in education can improve awareness and build trust and engagement in the organisations, leading to better performance at all levels for 'Me-We-All'.
- Sharing and caring can reach economic empowerment to steward the organisation's future.
- Equity, creativity, technology and digital inclusion can contribute to an equitable and more sustainable future.
- Considering Environmental Sustainability is an absolute must. Neither 'Me' nor 'We' or 'All' can survive without it.

Stewardship plays an essential role in this process. For a sustainable present and future, managers and leaders must acquire the ethical values that form the basis for responsible planning and management of resources. Careful and responsible management considers not only the businesses but also the environment and nature, their human capital, their knowledge and information, their culture and diversity. Stewarding the future is motivated beyond economic values. They build the organisation's capacity via education and cooperation to act for 'Me-We-All'. By understanding and making available sources, stewardship helps to create individual (Me) and organisational (We) wealth and contributes to the well-being of the people (Me and We) and the society (All).

Intersectionality (Runyan, 2018) also teaches that differences need to be accepted and included. Offering equal prospects and ways to all is not a solution either. Standard paths served mass production during industrialisation and mechanisation, to provide solutions for living, working, teaching and access to products and services. The answer in stewardship is something completely different. It "re-norms" and changes standards. It is to offer equal outcomes and other paths that can be unique to many people. Caring for individual cases is much more complex, but letting stewardship enter our views gives power, determination and fair opportunities for equal

prospects and outcomes. According to Thomas Sowell (Sowell & Friedman, 1981; Sowell & Weiner, 2010), Diversity, Equity, and Inclusion in practice support discriminatory trends because the practical ramifications of the ideology was not thought through, turning the results the other way around. "Undeserved inequalities call for redress", he says, where the chances for opportunities and success are equal, regardless of educational level, gender or cultural background. Believing that with stewardship, the abilities of individuals can be useful, they can contribute in their own unique way to work out solutions in a diverse problem space. Stewardship facilitates changing Equality to Equity offering everyone choices on accommodating individual differences for equal outcomes. So, not the same shoes for everyone, but shoes that fit the person. Management can ensure equity once they understand the root causes of outcome disparities. Then, they can eliminate barriers to full participation and bring fairness to the procedures and processes. It is also a different approach to striving for diversity. A sustainable society for everyone requires acceptance, trust and a broader view of reality than only for the privileged ones.

Equity (Minow, 2021; Sowell, 2001), referring to the common stock of the organisations, brings ownership and intellectual property in sight. For sustainability, as the world's ability to host our successors, managers and leaders should not limit themselves to traditional certainties, like intellectual property, value and ownership (Van den Broek et al., 2023). Such open-minded, careful and attentive stewardship will base cooperation in front. Instead of owning solutions, members of diverse teams contribute to results with their abilities, competencies and equal opportunities (Takács & Abcouwer, 2023).

6. Developing Stewardship for Managing Present Societal Challenges for a Liveable Future

Education plays a crucial role in shielding children and youth with sustainability competencies so they can be responsible stewards in organisations, that care for future generations (E. k. Takács et al., 2022).

Changing school cultures and developing school leadership teams is the first action to take (Hahn, 2021). Understanding the nature of change and the need for adaptivity can support the development of management, leadership and stewardship skills, competencies and attitudes (Takács & Abcouwer, 2021).

This understanding is very important not just for schools which develop future leaders, but also for organisations, which are already responsible for managing change in a way that does not harm any individuals, society, or the world. Being aware of the differences between Management, Leadership and Stewardship, understanding the role of motivation can ensure sustainable change management for organisations (Abcouwer et al., 2021).

The European Sustainability Competence Framework (Bianchi et al., 2022) can guide school leaders and organisational managers to embody sustainability values, embrace complexity in sustainability, envision sustainable futures, and act for sustainability. On all these issues, knowledge must be available to be able to support decision-making on these fields (E. Takács & A. W. Abcouwer, 2020). We find that a change must happen both in school cultures and organisational cultures when we want to ensure futures for the people (Me), organisations (We) and the Earth (All). The need for different types of knowledge is apparent for understanding the challenges we will face in future (E. Takács & A W Abcouwer, 2020). Our paper wished to provide a basic understanding of such a change with some helpful insights and instructions.

Knowledge Transfer Dynamics in Family Businesses Through Digitalisation: A Systematic Literature Review

Alessia Talarico, Antonio Lorena, Ludovica Zoccali and Marzia Ventura
University Magna Græcia of Catanzaro, Catanzaro, Italy

alessia.talarico2@studenti.unicz.it
antonio.lorena87@gmail.com
ludovica.zoccali@studenti.unicz.it
marziaventura@unicz.it

Abstract: In the current unpredictable and constantly evolving scenario, knowledge is a strategic resource for businesses (Argote L., Ingram P., 2000), particularly in the case of family businesses (Zapata – Cantu L. et al., 2023). In this context knowledge transfer is most important and technology and innovation can concretely support the transfer of information, both inside and outside organizations; but family businesses are not very technology-oriented (Bouncken R. & Schmitt F., 2022). So, the aim of this study is to understand how digitalization could impact on knowledge transfer dynamics in family businesses and in particular on codifying explicit knowledge, on transfer of tacit knowledge and on generational succession in family businesses.

Keywords: Knowledge Transfer Dynamics, Family business, Digitalization

1. Introduction

In recent years many authors, such as Drucker, point out that the only significant resource for businesses is knowledge (Nonaka et al., 1996) and how management of this knowledge is essential for organisations and their survival in the existing context (Omotayo, 2015). Furthermore, it is also one of the most important sources for competitors of an organization to gain an advantage. Indeed, the relationship between knowledge and performance can be better comprehended by focusing on the four fundamental components of knowledge management: knowledge creation, knowledge acquisition, knowledge coding and knowledge transfer; the last is the element in which this study focuses on. Specifically, knowledge transfer is an efficient process used to increase the productivity of an organisation (Argote, 2000) and to obtain the best results and achieve an elevated level of innovation (Riege, 2007). According to Argote and Ingram (2000), knowledge transfer affects one unit through the experience of another. In particular, knowledge transfer improves the behaviour and activities of an organisation's members, (Omotayo, 2015) and therefore cannot be considered as simple as the movement of knowledge between people or from one place to another (Riege, 2007). Indeed, although most studies of business organisation address the issue of knowledge transfer dynamics by focusing on the characteristics and attitudes of the parties involved, it has emerged that these dynamics are influenced by the intrinsic nature of knowledge and its complexity (Szulanski, 1996). This complexity depends on the different understandings of knowledge. While the traditional Taylor and Herbert's theory point that is explicit, formal and systematic (Nonaka et al., 1996), others such as Nonaka and Takeuchi, who in agreement with Michael Polanyi, recognize a tacit knowledge that is hard to communicate, to transfer or to share with others.

In this context, digitalization, which can be defined as a socio-technical process of mass adoption of digital technologies (Yonghong et al., 2023), can concretely support the transfer of information, both inside and outside an organization (Bouncken et al, 2022), as it can eradicate the boundaries between an enterprise and external organizations (Yonghong et al., 2023). Indeed, digitalization and technology help organizations to connect, to cooperate, to communicate, to gain knowledge (Yonghong et al., 2023) and to facilitate the relationship with internal and external agents. It also allows for the reduction in information asymmetries (Nieto et al., 2023) rendering the information received more productive, fostering a greater learning from and with a variety of partners (Brynjolfsson et al., 2023). For these reasons digitalization is vitally important to organizations, undeniably becoming a priority for managers and policy-makers (Legner et al., 2017). Not all companies however, are digitally oriented and a clear example of this are family businesses (Nieto et al., 2023). It is in fact family businesses that are the object of this present research. Admittedly, some authors, namely Lubatkin and Schulze, point out that they are less innovative when compared to other types of enterprises (Bouncken et al, 2022). And in order to survive they must constantly learn, create, transfer and apply knowledge in an effort to adapt more easily to changes in the environment in which they operate (Zapata – Cantu L. et al., 2023). They need to manage the diffusion of information inside the organization, allowing the transfer of knowledge to increase the success of the family firm's succession process (Valenza et al., 2021) and beyond the perimeters of

the family business, outside, between organizations into its own external environment. It is necessary to deepen the various types of knowledge which can be transferred (Mustake et al., 2017) and to also understand which forms are most important for the growth of the organization (Valenza et al., 2021). In this regard different studies illustrate how the differences between family and non-family firms depend on their own socio-emotional characteristics (Gómez-Mejía et al., 2007), as it particularly influences the tacitness level of family firm's knowledge and when this is very high, it can be very difficult to digitalize knowledge transfer (Brynjolfsson et al., 2023).

Based on the arguments discussed, the aim of this study is to understand how digitalization can impact on knowledge transfer dynamics in family businesses that are complex and influenced by various factors including the nature of the knowledge, the roles of family members, and the impact of digitalization.

2. Methodology

The methodology adopted in this study consists of a systematic review of the literature (Tranfield et al., 2003). This methodological approach, based on predefined criteria, is the reference standard for synthesizing evidence thanks to their methodological rigor.

2.1 Search Strategy and Selection Criteria

Three major academic databases were selected for the purpose of this study: Scopus, Web of Science and Google Scholar. These databases, having extensive archives of scholarly articles, conference proceedings and critical academic publications in the fields of business management and digital technologies allow for a thorough and robust analysis.

As the objective of this research is to understand the dynamics of knowledge transfer in family businesses through digitisation, three specific initial keywords were chosen to capture the relevant literature and the essentials of the study: "digital*", "knowledge transfer dynamic*" and "family business*". Using these keywords, a comprehensive search strategy was developed, employing the Boolean AND operator to refine the search queries and improve the accuracy of the results

The search focused on peer-reviewed articles published up to July 2024 to ensure the inclusion of contemporary and relevant studies on the interaction between digitalization, knowledge transfer dynamics, and family businesses published in English. Attention was also paid to research that includes empirical data, theoretical frameworks, and case studies relevant to the topic. These criteria were applied to ensure the relevance, quality, and focus of the selected studies, resulting in a refined set of articles for detailed analysis.

The initial search founded no results in all databases used. For this reason, the second step was to modify the string replacing the keyword "family business*", step by step, with "family firm*", "family enterprise*", "family organization*" and "family compan*". Also in this case the search founded no results. Due to this, alternating this different synonyms in the string in all databases selected, the keyword "knowledge transfer dynamics" was replace with "knowledge transfer" to include a major number of articles in which the selection was made in function of the knowledge transfer dynamics concept. The results were then rigorously screened based on titles and abstracts to assess their relevance to the research questions.

2.2 Thematic Analysis and Synthesis

The articles selected after initial screening were subjected to in-depth full-text review through careful reading. The purpose was to check the relevance of the article to the research objectives and to include in the final analysis only those studies consistent with the topic under study.

Each article was read thoroughly to confirm its direct relevance to the research questions concerning the interplay between digitalization, knowledge transfer dynamics and family businesses. Detailed information was extracted from each article using a standardized data extraction form. This form included fields for authors' names and affiliations, year of publication to ensure the timeliness of the data, research methodologies, key findings, theoretical frameworks, and the identification of research gaps.

The data collected were systematically organized into specific thematic categories. This process allowed similar findings and theoretical references to be grouped together to promote a coherent synthesis.

Specifically, the mechanisms through which digitization influences the transfer both tacit (implicit, uncoded) and explicit (codified, easily shared) knowledge dynamics within organizations were attended to. It emerged, in this regard, how digital tools and platforms can support communication, collaboration and knowledge sharing especially in family businesses. With the chosen strings, the process of systematically analysing and organizing the extracted data provided a comprehensive understanding of the current state of research of digitization to support knowledge transfer dynamics within family businesses. This process simplified the detection of key trends and existing gaps in the literature, paving the way for future research directions. To increase the reliability and validity of the results obtained, data from the three databases were compared and cross-referenced for consistency and robustness of the identified themes. The comparison of the results obtained from the different sources was intended to reduce bias and strengthen the credibility of the conclusions.

Finally, a synthesis of the data obtained was made to more easily identify any gaps in the literature from which future theoretical studies could be drawn. The purpose was to contribute to a comprehensive understanding of the current state of research on the topic studied to better clarify the impact of digitization on knowledge transfer dynamics in family businesses.

3. Results

The search strategy yielded varying results across the three academic databases, highlighting the importance of utilizing multiple sources for a comprehensive literature review. The following table shows results obtained.

Table 1:

Keywords	Scholar	Web of Science	Scopus	Total results
Digital*, Knowledge transfer dynamic*, family business*	0	0	0	**0**
Digital*, Knowledge transfer dynamic*, family firm*	0	0	0	**0**
Digital*, Knowledge transfer dynamic*, family enterprise*	0	0	0	**0**
Digital*, Knowledge transfer dynamic*, family organization*	0	0	0	**0**
Digital*, Knowledge transfer dynamic*, family compan*	0	0	0	**0**
Digital*, Knowledge transfer, family business*	314	2	4	**320**
Digital*, Knowledge transfer, family firm*	152	0	2	**154**
Digital*, Knowledge transfer, family enterprise*	37	0	0	**37**
Digital*, Knowledge transfer, family organization*	6	0	0	**6**
Digital*, Knowledge transfer, family compan*	2	0	1	**3**
Total results	**511**	**2**	**7**	**520**

After the initial retrieval of 520 articles, a meticulous screening process was conducted to assess the relevance of each article. This rigorous screening aimed to filter out articles that did not directly address the research questions or did not meet the quality and focus criteria established for this review. After this careful evaluation, 45 articles were identified as highly relevant and suitable for in-depth analysis.

The result produced by Scopus, Web of Science and Google Scholar (restricted to 45 after the screening process) offer a nuanced and complete view of the current state of research in this field on basis of the chosen search string. This summary underscores the necessity of utilizing multiple databases to obtain a holistic understanding of the literature landscape and to ensure that no significant studies are overlooked.

It should be noted that the choice of keywords influence the results obtained. So, making variations in the keywords might produce different results by capturing other relevant studies that were not identified using the strings of the present study. This suggests that a more flexible and iterative approach to keyword selection could enhance the comprehensiveness of the literature review.

4. Finding and Discussion

From the reviewed literature, different common denominators emerged. The results of the analysis will be presented below focusing attention on: knowledge and knowledge transfer dynamics in family business and the impacts of digitalization on knowledge transfer dynamics in family business.

4.1 Knowledge and Knowledge Transfer Dynamics in Family Business

In general, knowledge assets, which are challenging to replicate and transfer, have become the primary source enabling organizations to achieve superior results compared to their competitors. Unlike the assets which traditionally formed the basis for competitive advantage, knowledge assets now play a crucial role in driving organizational success (Zapata-Cantu et al., 2022). For these reasons family businesses must stay open to new ideas and continuously update their knowledge to align with emerging market trends and technologies, preventing stagnation and ensuring profitable use of their knowledge base (Andersén, 2015; Filippini et al., 2012; Wang, 2016, Putz et al, 2023). The presence of dynamic changes means that no single solution or routine can be long-term, as such rigidity can hinder business development (Wang, 2016; Putz et al, 2023). In this context, what is important is knowledge renewal that can be sourced from suppliers, customers, employees, and intermediaries and their networks (Boyd et al, 2012; Klewitz et al., 2012; McAdam et al., 2010, Putz et al, 2023). So, intra and inter-organization relationships became essential to exchange information inside and outside (Zahra et al, 2007; Zapata-Cantu, 2021). However, other authors indicate that family firms are less inclined to share knowledge (Mazzola et al., 2008; Botero et al., 2021; Zapata-Cantu et al, 2021) when there is a lack of trust, commitment, predecessor involvement in the training of a successor and organizational culture (Zapata-Cantu et al, 2021). Also, strong social relationships within firms facilitate the adoption of new technologies and resource sharing, enhancing business performance (Meng et al.). Collaboration among family members promotes the dissemination of technological ideas, strengthening continuous innovation and business resilience (Gamba, 2019; Meng et al.). Engaging with stakeholders allows companies to quickly identify and integrate new market trends, crucial for developing new products and services (Chaudhary et al, 2018; Chen et al., 2009; Fredrich et al., 2019). Effective knowledge transfer within companies requires strong communication, facilitating mutual learning and innovation (Szulanski, 1996; Tsai, 2001) especially for tacit knowledge transfer, which is fundamental in creating a strong competitive advantage, as Letonja and Duh (2016) point out.

In this regard, taking into account the importance of relational social capital, i.e. the positive attitudes existing between the parties involved (Nahapiet and Ghoshal, 1998) and cognitive social capital, i.e. the codes, languages and narratives shared between the parties involved (Lane and Lubatkin, 1998) in knowledge transfer dynamics, the role of family members in the knowledge transfer process is crucial; the older generation, often the repository of tacit knowledge, plays a central role in guiding and mentoring the next generation, Zapata-Cantu et al. (2023) emphasise that these older members must be actively involved in the transfer process to ensure that valuable tacit knowledge is not lost. The successors, typically the next generation, are responsible for integrating and applying this knowledge to move the company forward. Valenza et al. (2021) emphasise the importance of successors being properly prepared and involved in this process to facilitate a smooth transition and continued business success. Valenza et al. (2021) point out that ensuring critical knowledge is preserved and passed on to the next generation is vital for maintaining the longevity and success of the business. Maintaining a repository of both tacit and explicit knowledge helps family businesses stay competitive, as underscored by Zapata-Cantu et al. (2023).

Regular evaluation of the knowledge transfer processes is essential for continuous improvement. Feedback mechanisms allow for the assessment of the effectiveness of these processes, enabling businesses to adapt and refine their methods based on changing needs and feedback from participants. This ongoing adaptation ensures that knowledge transfer remains effective and aligned with the evolving goals and challenges of the family business.

4.2 The Impact of Digitalization on Knowledge Transfer Dynamics in Family Business.

One of the main observations that emerges from the analysis of the selected literature is that knowledge transfer dynamics in family businesses are influenced by digitisation despite the fact that this type of business is less oriented towards this process than other types of organisations (Zapata-Cantu et al.). Digitisation helps, in fact, to break down internal organisational and external boundaries, fostering better collaboration and communication also with one's partners (Bouncken et al. 2022).

The sourcing, sharing, and processing of information through digital technologies improves the connectivity and dissemination of information within and outside the company (Radicic and Petković, 2023). Through digital platforms advanced technology tools can increase a company's efficiency and better support customers by streamlining organizational processes (Ardito et al, 2021).

In particular, family businesses, which generally have a wealth of industry-specific skills and knowledge-spanning generations (Sirmon et al, 2003; Iwu et al., 2024), can demonstrate a remarkable ability to adapt to new technologies, using digital tools to improve decision-making and management processes. Additionally, these factors could improve the competitiveness of the family business (Prasanna e al, 2019) benefiting from both external and internal environmental knowledge (Breivik-Meyer et al, 2020; Iwu et al, 2024). These benefits encourage family businesses to cooperate (Chirico et al, 2020, Iwu et al, 2024). Digital technologies also support the creation of collaborative environments that enhance intergenerational communication and promote the sharing of competencies, essential for succession and the professionalization of successors (Del Rio Castro et al., 2021, Nieto et al, 2023).

The transfer of tacit knowledge in the digital age poses a challenge. According to Brynjolfsson et al. (2023) tacit knowledge is interpersonal in nature and requires direct interaction that may be difficult to pursue by digital means alone. Furthermore, there are many benefits of effective knowledge transfer, for example, as Riege (2007) argues, improved innovation capabilities that lead to better performance and competitive advantages.

The ability to leverage digital technologies to improve knowledge management and support innovation is seen as a key element for the long-term success of family businesses (Zapata-Cantu et al., 2022).

4.3 Implications, Limitations and Future Research Directions

The findings emerging from the present study could influence future research on the impact digitization has on knowledge transfer dynamics in family businesses. Due to the great importance of digital technologies in improving knowledge management processes, there is a need to identify digital tools and platforms specifically for family businesses. For example, possible solutions could be the adoption of artificial intelligence tools, data analytics and collaborative platforms that have a relevant impact on knowledge creation, sharing and utilization processes. In addition, it is necessary to understand how the specific characteristics of family businesses (e.g., their dependence on socio-emotional wealth and intergenerational dynamics) may limit or promote digital transformation in this type of organization.

Future research should also be conducted by seeking to understand how the characteristics of family businesses may influence the impact of digital technologies on knowledge transfer dynamics. Thus, the role of family governance structures, the involvement of multiple generations in decision making the impact of family values and culture on digital orientation should be considered.

What emerges from this study is the importance of external networks and collaborations that enable family organizations to enrich their knowledge base. For this reason, it is very important to focus on the mechanisms that these enterprises adopt to create relationships with external stakeholders, such as suppliers, customers, and industry associations, to enrich their digital skills and knowledge.

Understanding how family businesses can leverage resources from the external environment to enhance innovation and competitive advantage requires an understanding of these relationships.

Knowledge transfer is a complex process, especially that of tacit knowledge, so future research should deepen, emphasizes the need for further research into methods and practices that can facilitate this process in the digital age. It would be interesting to understand how digital technologies can be designed and applied in organizational settings to support the transfer of tacit knowledge, which in family businesses is represented by the experiences and knowledge of family members. This would make it easier to understand the impact of digitization in family businesses.

The present study was conducted comprehensively on the chosen keywords but nevertheless has limitations. The first is that using specific keywords may unintentionally exclude relevant literature studies using different terminologies. More keywords or a different string should be considered in the future to include studies other than those found with the present study.

For the future, it would be advisable to conduct the studies without neglecting the geographical and cultural context in which family businesses operate, as these aspects influence the adoption and orientation toward digitization in knowledge transfer and by identifying digital tools and platforms that can best contribute to this

process. Finally, future research could be conducted taking into account that the effectiveness of digitization affects the characteristics of family businesses that influence the effectiveness of digitization in knowledge transfer, for example, socio-emotional wealth, governance structures, and intergenerational dynamics.

By overcoming these limitations, future research directions could help to better understand the impact of digitization in knowledge transfer in family business.

Abstract: Business firms face challenges in maintaining their sustainability in the global market. As a result, it is increasingly necessary for them to focus on ensuring sustainable performance by balancing financial, social and environmental outcomes. One of the efforts companies make to achieve sustainable organisational performance and gain a competitive advantage is by increasing their utilisation of knowledge. According to the knowledge-based view, performance differences among organisations result from their different knowledge stocks and their different capabilities for knowledge use and development. Therefore, the ability to acquire and manage knowledge internally becomes essential. It enhances the organisation's competencies, sustains them, and contributes to achieving a competitive advantage. As a vital resource for organisational success, managing knowledge through practices is necessary. Organisational design refers to how power is distributed in an organisation. Previous research has examined the effects of knowledge management on absorptive capacity and organisational performance. However, few studies have investigated how the relationship between decentralised organisational design and knowledge acquisition capabilities works. To fill this gap, this study aims to investigate the relationship between decentralised organisational design and knowledge acquisition capability in achieving sustainable performance. A sample of 125 responses was collected from companies in the state of Santa Catarina, Brazil, through an online questionnaire. The data were analysed using partial least squares structural equation modelling applied to validate the model and test the hypothesis, through the free and open source SEMinR package of the R language. The results indicate that a decentralised organisational design has a positive and significant impact on a company's knowledge acquisition capability. Therefore, for companies to achieve sustainable organisational performance, they must adopt appropriate organisational design methods that allow for a clear distribution of tasks and responsibilities, as well as promote learning and problem-solving and encourage the creation of a culture of knowledge sharing among employees.

Keywords: Knowledge Management Practices, Organisational Design, Knowledge Acquisition, Sustainable Performance, SEMinR.

1. Introduction

Companies strive to enhance organisational performance through effective knowledge utilisation, a strategic resource as per the knowledge-based view of the firm (Grant, 1996). Knowledge acquisition (KA) capacity, a component of absorptive capacity (ACAP), is vital for enhancing skills and gaining a competitive edge (Zahra and George, 2002).

Given knowledge's critical role in organisational success, effective management through various practices is essential (Andreeva and Kianto, 2012; Inkinen, Kianto and Vanhala, 2015; Qader et al, 2022). Knowledge management (KM) practices facilitate value extraction from knowledge-based assets, supporting efficient and effective knowledge management for organisational benefit (Andreeva and Kianto, 2012; Inkinen, Kianto and Vanhala, 2015). Inkinen, Kianto and Vanhala (2015) categorise KM practices into areas like supervisory work, information technology (IT), and organisational design (OD).

OD significantly impacts KA within companies. It encompasses the arrangement of people and positions to facilitate work processes (Syed-Ikhsan and Rowland, 2004). OD complexity, formalisation, and centralisation are key factors (Lin, 2008). Centralised ODs limit decision-making to a select few, whereas less centralised structures foster dispersed decision-making and individual autonomy (Raziq et al, 2020).

Decentralised OD serves as a crucial KM practice to enhance knowledge utilisation within an organisation. This approach involves delegating authority and decision-making responsibilities to knowledge workers, forming and utilising cross-functional teams, and endorsing diverse communities of practice (Inkinen, Kianto and

Vanhala, 2015). Susanty, Yuningsih and Anggadwita (2019) suggest that while hierarchical structures impede knowledge dissemination, endorsing multiple communities of practice fosters a robust knowledge development environment that can bolster organisational performance.

Previous research has explored the impact of KM practices on ACAP and organisational performance (Inkinen, Kianto and Vanhala, 2015; Qader et al, 2022; Susanty, Yuningsih and Anggadwita, 2019). Additionally, studies have delved into the direct influence of ACAP on innovation and financial performance (Kostopoulos et al, 2011; Liu et al, 2021).

Nevertheless, there remains a scarcity of studies examining the interplay between decentralised OD and KA capacity. Hence, this study endeavours to elucidate the connection between OD and KA capacity and to assess how these practices can foster firms in attaining sustainable performance.

In addition, in the context of emerging countries, such as Brazil, besides global competition, companies face other institutional and regional challenges that are characteristic of these countries (Dávila, Andreeva and Varvakis, 2019). However, the literature lacks studies that investigate KM practices in this context.

This paper is structured into five sections, in addition to this introduction. Section 2 provides a concise definition of each construct and research hypothesis, followed by the methodological approach outlined in section 3. Subsequently, section 4 elaborates on and discusses the results, while section 5 presents the primary conclusions.

2. Literature Review and Research Hypothesis

This section provides a brief review of KM practices and ACAP, with a focus on the constructs of OD and KA capacity. The review is followed by the presentation of the research hypothesis.

2.1 Knowledge Management Practices and Organisational Design

KM practices are not confined to a single approach (Hussinki et al, 2017; Inkinen, Kianto and Vanhala, 2015; Kianto and Andreeva, 2014). They are organisational aspects that can be consciously manipulated by management to efficiently utilise knowledge for organisational benefit (Andreeva and Kianto, 2012).

Targeted at achieving organisational objectives, these practices can confer a competitive advantage (Hussinki et al, 2017). They can be classified into dimensions such as Organisational Development (OD), strategic knowledge management, organisational culture, human resource management practices, and information and communication technology (Kianto and Andreeva, 2014).

OD involves decisions related to work distribution and task coordination to foster learning and problem-solving (Abdelwhab Ali et al, 2019; Inkinen, Kianto and Vanhala, 2015; Kianto and Andreeva, 2014). These decisions can either facilitate or hinder knowledge processes (Abdelwhab Ali et al, 2019; Kianto and Andreeva, 2014).Research indicates that a highly centralised environment can impede knowledge sharing (Raziq et al, 2020). To enhance knowledge sharing, managers should consider a less centralised structure, promoting open workspaces, increased communication, and informal meetings (Abdelwhab Ali et al, 2019).

In the Brazilian context, Dávila, Andreeva and Varvakis (2019) found that OD mechanisms had the most significant positive impact on innovation performance, compared to ICTs, rewards, and organisational culture.

2.2 Absorptive capacity and Knowledge Acquisition

To Cohen and Levinthal (1990), the ACAP refers to a firm's ability to recognise the value of new information, assimilate it, and apply it to commercial ends. They argue that firms that conduct their research and development are better equipped to use externally available information effectively.

Based on these authors, Zahra and George (2002) define ACAP as the dynamic capability related to knowledge creation and utilisation that enhances a firm's ability to gain and sustain a competitive advantage. The ACAP of an organisation depends on the ACAP of its members (Cohen and Levinthal, 1990).

According to Flatten et al (2011), a firm's ACAP is composed of four distinct but complementary capabilities: (i) acquisition, refers to the firm's ability to identify and acquire external knowledge and information from the environment; (ii) assimilation, involves the firm's ability to understand and interpret the new knowledge and information acquired; (iii) transformation, refers to the firm's ability to integrate and recombine the new

knowledge with existing knowledge to create new ideas and products; and (iv) exploitation, involves the firm's ability to use the new knowledge and ideas to improve its products or services and gain a competitive advantage.

Zahra and George (2002) categorise the four dimensions of ACAP into two categories: (i) Potential ACAP, which refers to the ability to recognise and acquire external knowledge that is valuable to the organisation. This includes the KA capacity (gathering new knowledge) and assimilation (integrating new knowledge with existing knowledge); and (ii) Realised ACAP, which refers to the organisation's ability to effectively utilise the knowledge that has been acquired and assimilated. This includes the processes of knowledge transformation (modifying existing knowledge to create new knowledge) and exploitation (using existing knowledge to create value for the organisation).

The greater the organisation's capacity to acquire and assimilate information obtained from external sources, the greater the possibilities to respond to the high competition of the external environment (Flatten et al, 2011). In this article, we focus specifically on KA capacity, which plays a key role in enabling organisations to renew their stock of knowledge and continuously innovate.

According to Zahra and George (2002, p. 189), "acquisition refers to a firm's capability to identify and acquire externally generated knowledge that is critical to its operations". Flatten et al (2011, p. 100) define acquisition as "a firm's ability to identify and obtain knowledge from external sources".

2.3 Knowledge Management Practices and Absorptive Capacity

Studies that address the relationship between KM practices and absorptive capacity are scarce (Dávila and Dos Anjos, 2021). Such studies show that there is a positive relationship between these constructs (Valentim, Lisboa and Franco, 2012).

Valentim, Lisboa and Franco (2012), when investigating 4,534 firms in Portugal, concluded that these firms are committed to the use of KM practices executed through collaboration with business partners, favouring experience-based learning processes, knowledge transfer to staff and/or knowledge absorption by staff.

Dávila (2016) analysed the relationship between KM Practices, ACAP, and organisational performance. The results showed that KM practices related to strategic management of knowledge, organisational culture and organisational design influence potential ACAP; while KM practices about strategic management and information and communication technologies influence realised ACAP.

Considering knowledge as a resource capable of helping companies overcome economic challenges and the importance of acquiring and managing this knowledge through an adequate organisational structure, to achieve sustainable performance, we propose the following hypothesis: The decentralised OD is positively associated with the firm's KA capacity.

3. Method

This article takes a positivist approach and employs a quantitative methodology to explore the relationship between OD and the KA capacity.

3.1 Sample

To answer this research question, we collected research data in the state of Santa Catarina, Brazil, using scales previously validated in an international context. Santa Catarina is located in the southern region of Brazil, which Hofstede et al (2010) describe as more hierarchical, less formal, more individualistic and more achievement-oriented.

The target companies were selected through a database of the Federation of Industries of Santa Catarina. The data were collected with top or middle-level managers of the companies. From this, we obtained 146 responses, representing a response rate of 9.3%. After excluding 21 incomplete or uncodified responses, we had a usable sample of 125 for further analysis.

The most represented industries were food and drink (32.8%), textile and clothing (19.2%), capital equipment (7.2%), metal-mechanical industry and metallurgy (6.4%), and chemical (4.8%). In terms of the number of employees, the largest group (44%) was micro and small businesses with up to 99 employees. Most respondent companies have been in the market for between ten and thirty years (45%) (Table 1).

Table 1: Profile of Firms and Respondents

Respondent characteristics	Frequency	(%)
Sector		
Food and drink	41	32.8
Textile and clothing	24	19.2
Capital equipment	9	7.2
Metal-mechanical industry and metallurgy	8	6.4
Chemical	6	4.8
Others	37	29.6
Number of employees		
20-	6	4.8
20-50	35	28.0
51-99	14	11.2
100-200	17	13.6
201-500	16	12.8
501-1000	9	7.2
1000+	28	22.4
Age		
10-	13	10
10-30	56	45
31-100	49	39
100+	7	6
Respondent's position		
Director	39	31.2
Owner	12	9.6
Manager	33	26.4
Others	41	67.2
Total	125	

3.2 Measures

In this study, the dependent variable was the KA capacity, which was examined through three indicators from Flatten et al (2011). The independent variable was DO, which was investigated using five indicators from Kianto and Andreeva (2014). Both the dependent and independent variables were measured using a five-point Likert scale, with 1 representing "strongly disagree" and 5 representing "strongly agree".

3.3 Analysis

To ensure the accuracy of our results and control for common method bias (CMB), we implemented a series of solutions following the recommendations of Podsakoff, MacKenzie and Podsakoff (2012). Our hypothesis was tested using partial least squares structural equation modelling (PLS-SEM), which was chosen due to its suitability for small sample sizes and lack of distributional assumptions (Hair et al, 2021). To perform the analysis, we used the SEMinR package in the R programming language, which offers user-friendly syntax and intuitive functions (Hair et al, 2021).

As the indicators from both scales are highly correlated, it was necessary to evaluate the reflective measurement model. This evaluation is based on several criteria, including indicator reliability, internal consistency reliability, convergent validity, and discriminant validity (Hair et al, 2021).

Having assessed the reflective measurement model, the structural model was evaluated. It was, therefore,

necessary to analyse the significance and relevance of the relationships in the structural model, as well as the explanatory and predictive power of the model (Hair et al, 2021).

4. Results and Discussion

This section presents the application of CMB remedies, the results of the analysis of the measurement model and the structural model, for testing the hypothesis developed.

4.1 Remedies for Common Method Bias

We utilised some procedural remedies suggested by Podsakoff, MacKenzie and Podsakoff (2012). The online survey was managed and conducted by the Federation of Industries of Santa Catarina. By doing so, we ensured that the respondents were provided with the same data collection standards they were accustomed to (e.g. ethics, privacy, communication style, and channel), thus increasing the likelihood of obtaining honest responses. We selected respondents who possessed knowledge of innovation and business management issues. On the statistical side, we tested a model that included an additional unmeasured latent factor to represent CMB. As recommended by Liang et al (2007), we confirmed that the loadings on the unmeasured latent factor were lower than the loadings on the construct factors. Additionally, we verified that the variance inflation factors (VIF) for each construct factor in each latent variable were lower than 3.3 (Kock, 2015). Taken together, these procedural and statistical procedures reduced the risk of CMB being a significant concern in this research. We also compared the responses from early and late respondents to test for nonresponse bias using discriminant analysis (Armstrong and Overton, 1977), and no significant differences were detected.

4.2 Measurement Model

In reflective measurement models, it is essential to estimate the relationships between the reflexively measured constructs and their indicators, which are known as loadings. Indicator loadings above 0.708 are recommended as they suggest that the construct explains more than 50% of the indicator's variance, indicating acceptable indicator reliability (Hair et al, 2021). Table 2 displays the loadings for each indicator.

Table 2: Loadings for each indicator

Constructs and Indicators	Loadings
OD - Organisational Design (Kianto and Andreeva, 2014)	
OD1 People from different parts of our organisation interact informally with each other in a frequent manner	0.735
OD2 In our organisation, open dialogs are common among/between employees and manager	0.763
OD3 In our projects, our organisation uses teams consisting of people with skills and expertise from diverse fields	0.875
OD4. In our organisation, we frequently use cross-functional teams and projects	0.838
OD5 In our organisation, we have purposeful overlap of functional responsibilities	0.689
KA - Knowledge Acquisition (Flatten et al., 2011)	
KA1 The search for relevant information concerning our industry is every-day business in our company	0.713
KA2 Our management motivates the employees to use information sources within our industry	0.880
KA3 Our management expects that the employees deal with information beyond our industry	0.761

Only the indicator OD5 remained below the recommended value of 0.708, indicating that the variance explained by its construct is 47.5% (0.689^2). However, even though the indicator loading was slightly below the recommended value of 50%, we chose to keep the indicator, considering that its exclusion could affect the content validity of the construct, which refers to how well each indicator represents a facet of the construct (Hair et al, 2021).

Internal consistency reliability is evaluated to determine whether the indicators that form the scales consistently measure their respective constructs. In PLS-SEM, three main measures are used for this purpose: (i) Cronbach's alpha; (ii) composite reliability (rhoC); and (iii) consistent reliability coefficient (rhoA) (Hair et al, 2021). While Cronbach's alpha is considered conservative, rhoC can be considered too liberal, and the true reliability of the construct is usually found between these two extreme values, as assessed by rhoA (Hair et al,

2021). To sum up, the recommended values for these three measures range from 0.7 to 0.9.

The assessment of convergent validity is based on the average variance extracted (AVE) values (Hair et al, 2019). Convergent validity is the extent to which a construct converges to explain the variance of its indicators (Hair et al, 2021). The minimum acceptable AVE is 0.5, which means that the construct explains 50% or more of the variance of the indicators that make up the construct (Hair et al, 2019).

Table 3 displays the three measures of internal consistency reliability and the measure of convergent validity.

Table 3: Measures of internal consistency reliability and convergent validity

Constructs	Cronbach's Alpha	rho_C	rho_A	AVE
Organisational Design	0.842	0.864	0.887	0.613
Knowledge Acquisition	0.700	0.759	0.830	0.621

All measures of internal consistency reliability are observed to be within the recommended values. Moreover, the measure of convergent validity (AVE) was higher than the recommended value.

SEMinR provides two methods to evaluate whether the measurement constructs exhibit discriminant validity: the Fornell-Larcker criterion and the heterotrait-monotrait (HTMT) correlation ratio (Henseler, Ringle and Sarstedt, 2015). However, it has been noted in the literature that the Fornell-Larcker criterion is not a reliable method for detecting discriminant validity issues (Henseler, Ringle and Sarstedt, 2015; Hair et al, 2021).

Thus, in this study, we employed the heterotrait-monotrait ratio (HTMT) of correlations to analyse discriminant validity (Henseler, Ringle and Sarstedt, 2015). As the constructs are substantially different, Henseler, Ringle and Sarstedt (2015) propose that the HTMT should be less than 0.85. The HTMT between the two constructs in our study was 0.524.

The bootstrap analysis utilized 10,000 samples, applying the percentile method to derive confidence intervals at a 5% significance level, with estimated t-values (T Stat.) surpassing 1.96 (Hair et al, 2021). Table 4 displays that the upper bound of the 97.5% confidence interval is below 0.85, as suggested by Hair et al (2021).

Table 4: Bootstrapped HTMT

Constructs	Original Est.	Bootstrap Mean	Bootstrap SD	T Stat.	2,5% CI	97,5% CI
OD -> KA	0.524	0.532	0.106	4.965	0.324	0.732

Therefore, all measurements of the reflexively measured constructs are reliable and exhibit high levels of convergent validity. Once it has been established that the measurement of constructs is reliable and valid, the next step involves evaluating the results of the structural model.

4.3 Structural Model

The procedure for assessing the structural model involves evaluating issues related to collinearity, the significance and relevance of relationships, and explanatory power (Hair et al, 2021). However, in the case of this model, which has only one independent and one dependent variable, evaluating collinearity is unnecessary.

The assessment of significance involves using bootstrapping standard errors to calculate t-values of path coefficients (β) or confidence intervals (Hair et al, 2021). Therefore, Table 5 shows that the relationship between OD and KA is statistically significant at the 5% level based on bootstrapped standard errors, as the t-value (T Stat.) is greater than the critical value of 1.96, and its β is 0.432.

Table 5: Path coefficient estimates, significance, and confidence intervals

Constructs	β	Bootstrap Mean	Bootstrap SD	T Stat.	2,5% CI	97,5% CI
OD -> KA	0.432	0.455	0.076	5.668	0.302	0.598

Given that β is equal to 0.432, it suggests a positive relationship between OD and KA. Specifically, an increase of one standard deviation unit in OD corresponds to a 0.432 standard deviation unit increase in KA.

The coefficient of determination (R2) represents the fraction of variability in the dependent variable (KA) that can be accounted for by the independent variable (OD) in the model. This indicates the extent to which the

independent variable can explain the variation in the dependent variable. R2 ranges from 0 to 1, with higher values indicating a better model fit (Hair et al, 2021). In this case, the R2 value is 0.187 (adjusted R2 = 0.180), which indicates that OD explains approximately 19% of the variance in KA.

Finally, Figure 1 displays the bootstrapped model along with some details explained above, including: (i) the loading and significance of each indicator; (ii) the value (0.432), significance, and confidence intervals of β between OD and KA; and (iii) the R2 value of KA (0.187).

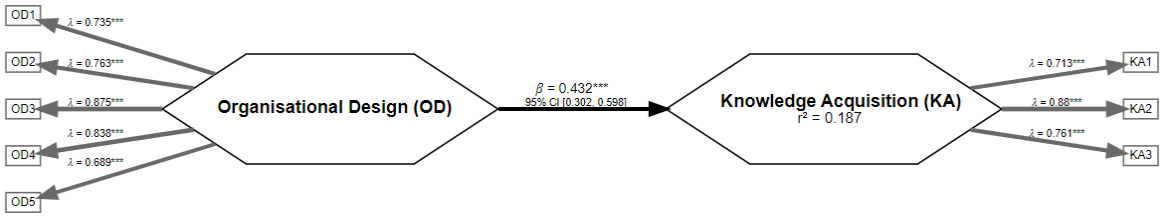

Figure 1: Bootstrapped Model

The findings of this empirical study reveal that OD plays a crucial role in KA capacity. To attain sustainable organisational performance, companies need to adopt appropriate OD strategies that enable the effective distribution of tasks and responsibilities, encourage learning and problem-solving, and promote a culture of knowledge sharing among employees. Furthermore, the implementation of a decentralised OD can lower hierarchical barriers, enhance collaboration and communication among employees, and foster an environment conducive to knowledge creation and transfer. These factors collectively contribute to strengthening companies' ability to acquire and utilise knowledge efficiently, ultimately resulting in improved sustainable organisational performance and increased capacity to adapt to changes in the business environment.

5. Conclusion

In an ever more dynamic and uncertain world, particularly in emerging economies, it is becoming progressively crucial for firms to engage in more effective KM. This empirical study has shown that OD has a positive and significant effect on the KA capacity of companies based in Santa Catarina, Brazil. Consequently, the implementation of OD can enhance KM efficiency within companies, such as by empowering knowledge workers to make decisions, creating cross-functional teams, and recognizing diverse communities of practice, all of which significantly contribute to the KA capacity of companies.

The hierarchical structure can sometimes impede knowledge flows, but a decentralised OD can enable companies to establish a resilient environment for knowledge development that can enhance sustainable organisational performance.

Through investigating the influence of OD on KA capacity, this study highlights the significance of establishing a conducive setting for knowledge workers to excel and enhance their knowledge. Furthermore, by exploring the association between these two constructs and sustainable performance, the study can contribute to the literature on KM and sustainability.

5.1 Theoretical and Practical Contributions

The results of this research have significant theoretical and practical implications. From a theoretical standpoint, investigating the influence of OD on KA capacity contributes to the overall understanding of KM. In practical terms, managers can use the findings to identify KM practices that can be adopted to enhance business capabilities.

From a practical perspective, the relationships between OD and the KA capacity can provide clues to how companies can promote the use of knowledge to leverage their sustainable performance.

This study proposes that managers should prioritise key dimensions of KM. Organisations can tailor their strategies to delegate decision-making responsibilities and encourage horizontal communication. Executives should promote initiatives to enhance OD to improve the KA capacity and, consequently, the company's performance.

5.2 Limitations and Future Research Directions

The results of this research have a limited scope due to the small sample size. Additionally, as an applied research, it is cross-sectional. Future studies could adopt a longitudinal approach to investigate the factors that affect OD and its association with KA capacity.

Our study's research context is based on a specific country. Future research should examine our research hypothesis in a cross-country context to understand how OD and KA capacity operate across different cultural and institutional contexts.

Examining Misinformation and Deep Fakes

Namosha Veerasamy, Zubeida Khan and Danielle Badenhorst
CSIR, Pretoria, South Africa

nveerasamy@csir.co.za
zdawood@csir.co.za
dbadenhorst@csir.co.za

Abstract: Misinformation in the form of deep fakes and phishing links can not only spread false information but can only be used a weapon in the hands of cyber criminals. To combat this problem, the authors investigate fake news and misinformation, in a South African context. In the paper, the use of cyber scams that contain misinformation will also be unpacked. This aims to create an awareness and defensive approach to tackling emerging cyber threats that prey on misinformation. This paper tackles a growing concern by examining the pervasiveness of fake news by looking into the extent that fake news infiltrates various media channels and its potential impact on public perception and decision-making. The paper will also explore the anatomy of fake news by dissecting the common tactics and strategies employed by purveyors of fake news and highlight red flags that can help the public identify misinformation. Maintaining academic integrity is pivotal to the research and publication community. This paper will also promote the use of trusted sources and verification of information. The paper aims to promote media literacy by sharing strategies to enhance media literacy and critical thinking skills, empowering individuals to discern credible information from misleading content. This paper proposes a human-centric framework to empower individuals in South Africa to become discerning consumers of information. Recognizing the limitations of Artificial Intelligence (AI)-based detection methods and the unique challenges of the South African context (multilingualism, resource constraints), the framework emphasizes critical thinking and media literacy skills. It outlines a step-by-step process for evaluating information sources, including source credibility analysis, content verification, and cross-referencing. The effectiveness of the framework is demonstrated by a relevant use-case.

Keywords: Misinformation, Deep Fakes, Fake News, Disinformation, Mal-Information, Artificial Intelligence, Cybersecurity, Cybersecurity Learning Factory

1. Introduction

“Fake news is not a new phenomenon. It has been around since news became a concept 500 years ago with the invention of print—a lot longer, in fact, than verified, “objective” news, which emerged in force a little more than a century ago. From the start, fake news has tended to be sensationalist and extreme, designed to inflame passions and prejudices (Soll 2016)”. Fake news can be extremely dangerous, powerful and persistent. Wild fake stories can promote prejudice, distrust and circulate unverified content. Thrilling counts of monsters, politicians and criminals have been provoking and enthralling audiences. Trust in news establishments can be questionable and may continue to decline. Fake news has now become a powerful force as we are bombarded with content without any accuracy and objectivity. As fake news grows, there is also associated terminology like misinformation, disinformation, mal-information. These concepts are examined next.

Misinformation refers to false or inaccurate information, especially that which is deliberately intended to deceive (Oxford, 2024).

Disinformation is a form of propaganda involving the dissemination of false information with the deliberate intent to deceive or mislead (Oxford b 2024).

Mal-information is information that is based on reality but is used to inflict harm on a person, organisation or country such as catphishing or swatting (Mediadefence.org 2024)

Fake news are false stories that appear to be news, spread on the internet or using other media, usually created to influence political views or as a joke (Cambridge 2024)

Fake news is false information that has been purposefully crafted, contains sensationalism, can be emotionally charged, misleads or fabricates information that mimic mainstream news. Fake news can be wholly fabricated or a mix of fact and fiction.

According to Wardle, there are seven types of fake news (Wardle 2017):

- Satire Or Parody ("No Intention To Cause Harm But Has Potential To Fool")
- False Connection ("When Headlines, Visuals Or Captions Don't Support The Content")
- Misleading Content ("Misleading Use Of Information To Frame An Issue Or An Individual")
- False Context ("When Genuine Content Is Shared With False Contextual Information")

- Impostor Content ("When Genuine Sources Are Impersonated" With False, Made-Up Sources)
- Manipulated Content ("When Genuine Information Or Imagery Is Manipulated To Deceive", As With A "Doctored" Photo)
- Fabricated Content ("New Content Is 100% False, Designed To Deceive And Do Harm")

The proliferation of fake news and misinformation can have vast consequences. Some examples include (University of Exeter Library 2024):

- Distrust in the media
- Undermining the democratic process
- Platforms for harmful conspiracy theories and hate speech
- Spread of false or discredited science

Information today has grown in volume, variety, veracity, value and velocity. In today's information landscape, the spread of fake news poses significant threats to individuals, organisations, and society at large. The challenges posed by the proliferation of fake news in the digital age is on the rise. The use of misinformation and fake news can have dire consequences. Harmful misleading intentions, influence, creation of bias, manipulated content and propaganda are some of the negative outcomes. Various collaborative efforts can be applied in order to try and combat the issues of fake news and misinformation. This paper provides valuable insights on how to overcome this issue of fake news and misinformation in the growing digital era.

Fake news raises a serious concern about the continued reliability and truthfulness of information that form the underlying base for knowledge domains. With the rise of additional technologies like Artificial Intelligence, these platforms support the growth and development of deep fakes and other malicious tampering of information.

The remainder of the paper is structured as follows. The next section of the paper looks at existing works, followed by a section on the use of misinformation for the proliferation of cyber scams. Thereafter the paper delves into deep fakes and the use of AI in Section 4. The subsequent section, Section 5, explores the detection and battle against fake news. Finally, the authors conclude and discuss future work.

2. Detection of Misinformation at an Elementary Level

When fake news or misinformation is encountered, users may easily trust that the content is true, even though it may be inaccurate. Readers face an ongoing struggle to determine whether the content they find in digital channels is actually true reporting or a fabrication.

Diverse methodologies and frameworks to detect mis-, disinformation and fake news **can be applied**. This section provides a brief overview of common techniques for detection of misinformation and fake news.

Many frameworks attempt to calculate scores of credibility to distinguish real or fake news. Bhattarai et al. (2021) introduced an interpretable fake news detection framework based on the Tsetlin Machine, using conjunctive clauses to capture lexical and semantic properties of news text. This approach not only classifies news as fake or real, but also calculates a credibility score for fake news (Bhattarai et al., 2021). Zhang et al. (2019) proposed a text analytics-driven approach for fake news detection that transforms news from a document-based corpus into a topic and event-based representation. Fake topics and fake events can be detected with their two-layered approach, with a 92.49% classification accuracy and 94.16% recall (Zhang et al., 2019).

Other approaches consider tools that could be employed by laypeople or focus on cognitive aspects of fake news and its proliferation. Choy & Chong (2018) propose a LeSiE (Lexical Structure, Simplicity, Emotion) framework, with the goal of equipping laypeople with the ability to identify fake news without requiring complex tool. They consider the anomalous lexical structure, over-simplification and increased cognitive simplicity, as well as emotionally arousing material found in fake news artefacts. Batailler et al. (2021) discuss the application of signal detection theory to fake news, separating the ability to accurately distinguish real from fake news from biases in judging news veracity. Their framework considers the influence of partisan bias and cognitive reflection on fake news identification (Batailler et al., 2021).

The frameworks in the literature often rely on machine learning trained on specific datasets that may not reflect the multilingual and multicultural reality of South Africa. South Africa has a history of political and social tensions caused by misinformation. A human-centric approach could be more relevant and reachable for citizens to critically evaluate information.

A further abuse of misinformation is the generation of cyber scams. Trusting users may view adverts, phishing emails and other promotions without any knowledge that the content is fraudulent. The next section looks at the application of misinformation in the creation of cyber scams.

3. Cyber Scams Using Misinformation

Awareness also needs to be created on the use of misinformation and disinformation in the generation and proliferation of cyber scams. This section provides a brief overview of just a few of these scams to shed light on other malicious practices that benefit from misinformation and disinformation.

False information can also be used for false advertising and fraud. False information can be used to trick people into handing over money, credentials or other benefits. Scams make use of fraudulent and illegal means to confuse/deceive people. The next section looks at a few of these schemes that utilise false information and advertising as part of a dishonest scheme (Brooks 2023). Such scams deceptively pose as legitimate business practices.

Various phishing scams may contain misinformation in order to trick users into divulging their personal information. Phishing emails can claim to update user account details or verify certain credentials. Phishing emails may impersonate banks, service providers, online shopping sites and a host of organisations that users traditionally transact with.

Office supply scams occurs when scammers pose as legitimate companies offering office supplies. Fraudsters impersonate legitimate companies offering office supplies. Businesses place orders and pay, but the supplies never arrive.

Fake invoicing occurs when businesses are targeted with seemingly legitimate invoices and payment requests. Due to the high volume of invoices processed, companies can be vulnerable to these scams.

Charitable solicitations occur when charitable requests may stem from scammers that are trying to take advantage to steal money. The fundraising or sponsorship invite may be fake and form part of a fraudulent charity scam; this tends occur following a disaster or high-profile event.

With many of these scams, AI technology is the catalyst to create fake requests and deceive the users into believing that the invitation is legitimate. The next section looks at the use of AI in creating fake content.

4. AI, Deep Fakes and Fake News

AI plays a major role in the dissemination of fake news, mis- and disinformation. Potential offensive uses of AI in fake news includes the creation of deepfakes, and automated content generation (Cybenko & Cybenko, 2018). AI technologies, particularly deep learning algorithms, enable the creation of convincing deepfakes. Deepfakes are algorithmically produced, hyper-realistic fake images, videos or audio recordings. Deepfakes have various applications, ranging from entertainment and education to malicious uses such as spreading misinformation, propaganda, election rigging and more.

Deepfakes have been used to create fake videos of political leaders, potentially influencing voter behaviour and destabilising political environments. For example, fabricated videos of politicians saying or doing things they never did could sway public opinion (Vaccari & Chadwick, 2020). Deepfake technology allows for the creation of content that can be rapidly spread, undermining trust in media institutions, which can be particularly damaging when used to spread propaganda or false narratives to large audiences (Rana et al., 2022). Beyond politics, deepfakes pose threats to individuals' privacy and security, including potential harassment and blackmail (Rana et al., 2022; Pantserev, 2020).

Furthermore, AI can be utilised to aid automated content generation; fake news articles or social media posts mimicking the style or appearance of legitimate news can be automated, making it difficult to individuals to discern between the validity of the content (Cybenko & Cybenko, 2018). Social media bots and amplification can be AI-driven and leveraged to amplify fake news stories, providing undue credibility. These bots can like, share and spread misinformation across platforms at a scale impossible for humans, increasing the reach of fake news using social media engagement algorithms (Meyers et al., 2020). Further, AI algorithms can analyse cast amounts of data to identify biases or preferences of individual users, and then microtargeting these users with fake news stories that the user would be more likely to believe or share, further propagating misinformation (Kumar et al., 2021). Advanced NLP techniques allow AI to write or modify fake news stories, making them more compelling

or tailored to specific audiences. This can include altering headlines or content to make them more clickable or shareable, thereby increasing their spread (Mohseni et al., 2020).

AI tools can also help with the generation of malicious content. Users can phrase the request in an innocent manner but thereafter use the response to create various scams like phishing, fake invoicing, charitable solicitations, or office supply scams. AI tools now provide for a seamless approach to content creation for scams as the outputs are now phrased appropriately and remove the obstacles of poor grammar or other tell-tale signs.

5. Detecting Fake News

Combatting misinformation requires critical thinking skills, fact-checking, and responsible sharing of information. Since AI and deepfakes are used to assist in the generation of fake news, detecting fake news requires a multifaceted approach. While automated software can be helpful in identifying certain red flags, critical thinking remains essential. A skilled person should be able to analyze the source of the information, examining its credibility and potential biases. Ultimately, fostering a questioning mindset is the key solution in detection fake news.

Therefore, the scope of this framework is about detecting fake news as a person, i.e., a human-centric approach, empowering individuals with the critical thinking skills and knowledge to discern credible information from misleading content. Human -centric approach focuses on the needs, preferences and experiences of human beings. When faced with material, content and information, users are engaged in a human-centric experience as they need to intuitively digest and make sense of the subject matter. Automated, programmable analysis is not always ideal as users need to rapidly look through the information and make judgements, decisions and responses.

Other studies use software-based detection approach. There are several unique characteristics about fake news in South Africa that deems a human-centric approach preferred:

- Fast-paced cyberthreat landscape: This shift in focus aims to equip users with the long-term ability to navigate the ever-evolving landscape of online information.
- Lack of resources: In a disadvantaged country such as South Affrica, some individuals do not have access to high-speed internet, or advanced devices needed to run complex AI-based detection software.
- Mult-lingual environment: South Africa has eleven official languages. AI detection tools trained on one language might miss fake news spread in another. A human-centric approach equips South Africans to analyse information regardless of language.
- Local culture: Understanding the cultural nuances of South Africa can help in identifying fake news that might play on specific cultural anxieties or biases. For instance, South African communication styles can sometimes be indirect or use humour. Understanding these nuances can help South Africans avoid misinterpreting online content as fake news simply because it uses sarcasm or satire. A human-centric approach allows for this contextual understanding.
- Digital literacy: While most South Africans have mobile devices and intermittent internet access, they lack the lack the technical skills to navigate complex online platforms or apps. For example, many users make use of online platforms like WhatsApp in South Africa as a means of rapid communication. However, users may still lack knowledge about whether the messages received can be trusted. Human-centric tools can get better outreach for South Africans in order to empower them to become more discretionary and not just simply spread messages without verifying it.

5.1 i-Fakt (Identify fake truth) Human-Centric Framework

The ability to discern fact from fiction has become a critical skill. The proposed human-centric framework I-Fakt empowers individuals to navigate the complexities of the digital age by fostering media literacy and critical thinking. The rationale behind selecting this approach is rooted in the unique socio-cultural and technological landscape of South Africa. This includes 11 official languages, and a digital divide. The factors for this are now provided.

- Socio-Cultural Context: South Africa's diverse linguistic and cultural environment calls for a flexible and adaptable framework that can be applied across different languages and cultural contexts, catering for unique cultural nuances faced by the citizens. AI-based tools, often trained on datasets from specific languages and cultural backgrounds, may not be effective for this.

- Resource and Technological Constraints: Many South Africans lack access to high-speed internet at all times, and advanced technological devices required for sophisticated AI-based tools and technologies. A human-centric approach, which uses readily available resources is more practical and sustainable in this context.
- Digital/ Media Literacy Levels: While mobile device usage is high, digital literacy levels vary significantly, across the country. A framework that prioritizes education by critical thinking and media literacy is better suited to improving the awareness around misinformation and disinformation.

By following the steps of the framework, one can develop the tools needed to become a discerning consumer of information. A high-level overview is provided in Figure 1, and each pillar is unpacked in the following section.

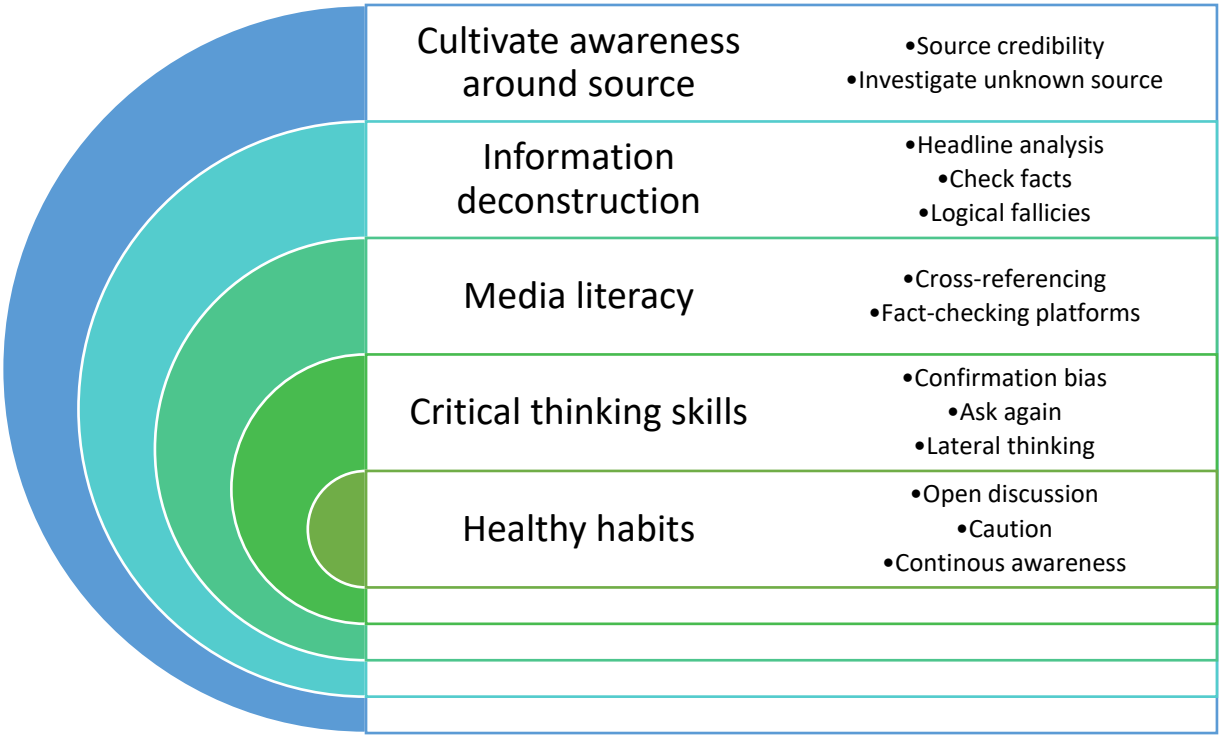

Figure 1: I-Fakt (Identify Fake Truth) Human-centric fake news detector framework

5.1.1 Cultivate Awareness Around Source

The onset of the framework lies in understanding where information and news stems from. The parameters of this pillar are as follows:

- Understanding Source Credibility: Learn to identify reputable news organizations with a history of fact-checking and ethical reporting. Explore resources that evaluate news source credibility. For instance,
- Investigate Unknown Sources: Before engaging with unfamiliar websites or social media pages, research their background and mission statement. Look for red flags like unusual domain extensions, unprofessional design, or lack of "About Us" or further information.

5.1.2 Information Destruction

Once the credibility of the source has been established, it is crucial to inspect the information itself, to understand the intent and veracity of the information.

- Headline analysis: Individuals need to be wary of sensationalized headlines with excessive exclamation points, strange grammar and uppercase letters. One must look for headlines that accurately reflect the content of the article.
- Check facts: Individuals should not solely rely on the information presented in the piece in question but should look for evidence to support claims, such as data from credible sources. For instance, consider a social media post claims that a new government policy will drastically reduce child grant payouts. This

sparks outrage and panic among many South Africans. An individual should check governmental policy websites to confirm this fact.
- Logical fallacies: Fake news commonly presents common logical fallacies such as appeals to emotion. For instance, a headline claiming that consuming South African herbs is a miracle cure for HIV/AIDS! Would appeal to individuals' sense of hope.

5.1.3 Media Literacy

This pillar of the framework empowers one to become a proactive participant in the digital information landscape by delving into techniques for verifying information beyond a single source.

- Cross-referencing: Individuals should not accept information at face value but should verify the information by searching for it from other established news outlets such as News24, The Daily Maverick, etc. If no reputable sources report the story, it could be fake.
- Fact-checking platforms: Utilize fact-checking websites like Snopes, PolitiFact, and Africa Check to verify information and debunk common fake news narratives.

5.1.4 Critical Thinking Skills

This pillar equips and individual to develop a questioning mind and foster intellectual curiosity.

- Confirmation bias: Individuals need to be aware of their own biases and how they might influence the interpretation of information. For instance, an individual, already having a negative perception of a political party, is more likely to accept negative information about the party in question at face value. One should seek out diverse perspectives to avoid falling victim to confirmation bias.
- Ask again: Approach online information sceptically. Individuals should question such as who is presenting such information, and do they have an agenda/ ulterior motive?
- Lateral thinking: Individuals should consider alternative explanations for the information presented. For instance, a certain celebrity did not attend the South African Music Awards. A voice note shared on messaging apps claims that he had been arrested for a serious crime. South Africans can apply lateral thinking by checking reputable news websites and social media accounts of the celebrity for any official statements before spreading fake news.

5.1.5 Healthy Habits

- Open discussion: Discuss this with peers and family members critically to consider whether the news is factual or not.
- Caution: Individuals should not share the piece of news without fact-checking. By sharing unverified information, individuals unwittingly contribute to the spread of fake news. This makes it more difficult for accurate information to reach people who need it.
- Continuous awareness: Regularly reading up and learning about current cybersecurity trends and engaging in discussions about media literacy and information verification reinforces healthy habits and strengthens the collective defence against misinformation. The cybersecurity learning factory [] could be rolled out around South African communities to encourage continuous awareness.

This framework empowers South Africans to become discerning consumers of information in the digital age. It emphasizes critical thinking and media literacy as key tools to assist in detecting fake news.

5.2 Use Case

A South African comes across the following post on X (formerly Twitter): *BREAKING! Disgraced again! [Politician's Name] caught in massive bribery scandal!!! Full story: [http://www.politicianscandal.co.za] #SouthAfrica #Corruption #PoliticalParty.*

As the citizen scrolls through Tiktok, he comes across a video, showing a clip with a voiceover: *"Did you hear about [Politician's Name]? Caught in a bribery scandal. See the full story at the link in my bio. #SouthAfrica #Corruption"*

An individual should consider each pillar of the framework and apply it to the post as follows.

- Cultivate Awareness Around Source: The source, on both X and Tiktok, leads to an unknown website with a sensational headline and lacks context. This raises red flags about credibility.
- Information Deconstruction: The headline is accusatory and uses exclamation points to evoke outrage. No evidence or details about the scandal are provided. The video on uses dramatic music and selective editing to amplify the claim without providing supporting evidence.
- Media Literacy: A search for the story on established news websites (in the South African context- News24, Daily Maverick, SABC News) reveals no mention of the incident. Checking Africa Check also shows no record of the claim in the above example.
- Critical Thinking Skills: Considering the political landscape, this accusation might be aimed at damaging the politician's reputation. Checking the politician's social media might reveal a response. One could also check if the politician has addressed the issue on their official TikTok or other social media accounts.
- Healthy Habits: Based on the analysis, the post and video is likely fake news. An individual should not share it and encourage others to be critical of online information.

The human-centric framework is an adaptable solution for combating misinformation. This use-case validates the framework's applicability across various contexts.

6. Conclusion

Knowledge on the topic is critical to preventing the spread of fake news and misinformation. Many readers may get caught up in the virality of certain feeds, posts and articles without any awareness that the information is sensationalism. The proliferation of fake news and misinformation poses a significant threat to South Africans. This research has examined the pervasiveness of it, its potential consequences, and strategies for detection. The authors found that AI plays a growing role in creating and disseminating fake news through techniques like deepfakes and automated content generation. Effectively detecting fake news as South Africans is challenging due to unique factors such as evolving threat landscape, cultural nuances, etc., and requires a human-centric approach based on critical thinking. This paper presented a human-centric framework empowering individuals to become discerning consumers of information in the digital age, alongside an illustrative use-case. Through this research, it is envisaged that users can be empowered with the techniques to fact check and verify information.

7. Future Work

Future work would involve extending the framework to include psychological factors. Understanding the psychological factors that make people susceptible to believing fake news can assist with improving judgment and reducing susceptibility to fake news and misinformation. Another direction is to consider the cybersecurity learning factory as a vehicle to demonstrate usage of the framework. The cybersecurity learning factory is an innovative educational platform designed to provide engaging and interactive learning experiences in cybersecurity. The aforementioned human-centric framework could be integrated into to the Cybersecurity learning factory to include experiential learning into modules based on the framework. These modules can teach South Africans how to identify fake news sources, analyse information critically, and verify information through credible resources.

Abstract: To respond to changes in the global competitive context, organizations must base their competitive advantage on the enhancement of new knowledge within production and decision-making processes. At the same time, the continuous processes of innovation and technological advancement define a higher rate of knowledge obsolescence. With these premises, organizations find themselves constantly introducing new knowledge into their processes and, at the same time, setting aside knowledge that has now become obsolete. Corporate museums represent organizations that collect organizational artifacts of a parent organization. The main theoretical contributions on the phenomenon of corporate museums have offered a focused contribution on the marketing and corporate communication perspective. In fact, there are few studies on corporate museums in knowledge management studies. From the theoretical perspective of knowledge management, corporate museums represent a place where the knowledge of a parent organization is collected and narrated through its organizational artefacts. This study aims to analyze corporate museums as a place for collecting, exploitation and transferring the organizational memory of a parent organisation. The study is based on the analysis of a case study. A corporate museum connected to the agrifood sector was analysed, through interviews and analysis of company documents. The findings of this study can be traced back to theoretical contributions and practical implications. From the perspective of theoretical contribution, this study analyzes the corporate museum as "ba", or as a place for collecting and sharing knowledge. From the perspective of managerial implications, the results highlight that the corporate museum can take on a strategic role in the valorisation and diffusion of organizational memory. It follows that the museum can be considered as a BA capable of generating new knowledge and innovation to be transferred within the parent organization. The results of this study offer new theoretical and empirical contributions to studies on knowledge management, on the phenomenon of corporate museums linked to the agrifood sector. The agrifood sector has demonstrated a greater need to enhance and implement knowledge in its organizational processes, through mechanisms that take into consideration the peculiarities of the sector.

Keywords: Knowledge Transfer, Corporate Museum, Agrifood Sector, Story Telling, Organizational Memory, *(*max 5 words)

1. Introduction

In recent years, companies have learned that they must base their competitive advantage on the valorization of knowledge. Knowledge, therefore, can be understood as a strategic lever to increase and maintain competitive advantage (Mårtensson, 2000; Vesperi and Gagnidze, 2023). Consolidated literature on knowledge management has highlighted that some sectors have a greater propensity to enhance and implement knowledge in their internal processes. Within KM studies, it is possible to identify empirical observations linked to specific sectors such as automotive (Canonico, et al., 2021) or hospitality (Hallin and Marnburg, 2008; Fauzi, 2020). At the same time, it is possible to distinguish contributions within knowledge management studies on public administrations (Syed-Ikhsan and Rowland, 2004; Massaro, et al., 2015) or small and medium enterprises (Lim and Klobas, 2000; Yew Wong and Aspinwall, 2004; Durst and Runar Edvardsson, 2012; Durst, et al., 2023).

Despite the strategic role that the agrifood sector plays in the global economic system, the attention of KM scholars has been scarce. In fact, knowledge management studies appear scarce on the agri-food sector and agri-food organisations. For this reason, the agri-food sector and agri-food organizations represent a new challenge for KM scholars. It is possible that agri-food organizations are micro and small (Ménard and Klein, 2004) with low propensity for innovation and low investments in research and development and characterized by low-knowledge managerial practices. From the point of view of valorising knowledge, agri-food organizations represent an interesting case study as they simultaneously combine the valorisation of traditional knowledge and the need to innovate. With the aim of valorising traditional knowledge, some agri-food organizations have created corporate museums.

There are still few studies dealing with corporate museums linked to agri-food organisations, making use of theoretical frameworks based on organizational theory, and in particular linking corporate museums to knowledge transfer and organizational memory.

This study aims to offer some initial reflections to fill this gap in the literature. This study - in the context of management and organizational theory studies - analyzes the strategic role of the company museum as a form of organizational memory and heritage capable of transferring knowledge. To achieve this objective, a qualitative descriptive methodology based on the analysis of secondary sources is used. We present the rest of this work as follows: after this (i) introduction, (ii) the main theoretical elements on Corporate Museum, Organizational Memory and agri-food organizations are discussed. Below, (iii) the methodological process is illustrated. Finally, (iv) the main conclusions and suggestions for future research.

2. Theoretical Background

2.1 Corporate Museum

The first corporate museums began to spread in the early 1900s. Corporate museums can be defined as corporate spaces dedicated to conserving, enhancing, and archiving organizational artifacts of the parent company. Analyzing the literature, various purposes and objectives attributed to corporate museums emerge. It is possible to trace the final aim of the first corporate museums to the "collection" of corporate artifacts (Iannone and De Chiara, 2019; Martinez, 2020). From the perspective of knowledge management (KM), corporate museums can share and transmit the knowledge and values created within the parent organization. The corporate museum, therefore, contains and represents the organizational memory of another organization. The representation and narration of organizational memory allow the organization to improve dialogue with its external and internal stakeholders (Sandberg & Tsoukas, 2020).

In the vast and varied landscape of KM studies, only a few studies have investigated the phenomenon of corporate museums using the theoretical frameworks of organizational theory, based on the constructs of organizational memory and knowledge transfer. This article explores corporate museums using the theoretical perspective of knowledge management, as a form of organizational memory, and when they are strategically used as a tool to transfer knowledge from the organization. The concept of organizational memory can be traced back to the concept of depository (Huber, 1991; Grant, 1996; Alavi & Leidner, 2001). Following this approach, memory can be defined as a set of knowledge present within an organization in the form of documents, informational material, or any other form that can facilitate internal activities and be easily accessible. From this perspective, the artifact takes on a particular meaning. The corporate museum becomes a tool for transferring knowledge and daily practices through the narration of the culture and organizational memory of the parent company.

Some elements of organizational culture are codified and shared in the organization's formal documents (such as official company documents, strategic plans, internal communications, disciplinary procedures). These documents become organizational artifacts, often displayed and used in corporate museums. These artifacts make an organization distinguishable from other organizations.

Corporate museums are not just passive archives of objects and documents but play an active role in constructing and communicating corporate identity. They can serve as marketing tools, enhancing the company's image with customers and the public. They can also act as training tools for employees, providing a deeper understanding of the company's history, values, and practices. Through curated exhibits and narratives, corporate museums can emphasize the company's innovations and successes, creating a sense of pride and belonging among employees.

Moreover, corporate museums can serve as platforms for dialogue and collaboration between the company and its various stakeholders. They can host events, conferences, and workshops that facilitate the exchange of ideas and knowledge. These spaces can also be used to promote corporate social responsibility, showcasing the company's efforts in sustainability, ethics, and community involvement.

A crucial aspect of corporate museums is their ability to adapt and evolve over time. With the advent of digitalization, many corporate museums are integrating digital technologies to enhance the accessibility and interactivity of their collections. Through virtual tours, digital archives, and interactive applications, corporate museums can reach a wider and more diverse audience, overcoming the physical limitations of traditional exhibition space.

In conclusion, corporate museums represent a key element in knowledge management and the construction of organizational memory. They not only preserve the company's past but also actively contribute to shaping its

present and future by facilitating knowledge transfer, improving communication, and strengthening corporate identity.

2.2 BA and Knowledge Management

The concept of "Ba" was introduced by Ikujiro Nonaka and Noboru Konno in their 1998 paper, "The Concept of 'Ba': Building a Foundation for Knowledge Creation." This concept is integral to understanding how knowledge is created and shared within organizations. Rooted in Japanese philosophy, "Ba" refers to a shared space for emerging relationships. It is a dynamic context, physical or virtual, that fosters knowledge creation, sharing, and utilization.

“Ba” is a Japanese term that roughly translates to “place” or “space”, but in the context of Nonaka and Konno’s work, it embodies more than just a physical location. It represents a shared context in which knowledge is shared, created, and utilized. According to Nonaka and Konno, “Ba” is a space where individuals come together and interact, and through this interaction, knowledge is created and expanded. “Ba” can be physical (such as meeting rooms), virtual (such as online forums), mental (such as shared experiences), or any combination of these. The key characteristic of “Ba” is its ability to provide a context that encourages participants to share their tacit knowledge, which is personal, context-specific, and hard to formalize, making it difficult to communicate to others. Nonaka and Konno identified four types of “Ba” each corresponding to a stage in the SECI (Socialization, Externalization, Combination, Internalization) model of knowledge creation:

- Originating Ba: This is the space where individuals share experiences, feelings, and mental models. It is primarily associated with the socialization phase, where tacit knowledge is shared through direct interaction and shared experiences. For example, informal meetings or social gatherings within an organization can serve as Originating Ba.
- Interacting Ba: This space supports the externalization phase, where tacit knowledge is articulated into explicit concepts. Interacting Ba facilitates dialogue and collective reflection, enabling individuals to express their tacit knowledge in a form that can be shared with others. Workshops and brainstorming sessions often act as Interacting Ba.
- Cyber Ba: This virtual space supports the combination phase, where explicit knowledge is systematized and combined. Cyber Ba utilizes technology to enable the sharing and combination of explicit knowledge across time and space. Online databases, intranets, and knowledge management systems are examples of Cyber Ba.
- Exercising Ba: This space supports the internalization phase, where explicit knowledge is absorbed and converted into tacit knowledge by individuals. Exercising Ba provides the context for learning by doing, where individuals internalize knowledge through practice and experience. On-the-job training and simulations are examples of Exercising Ba.

“Ba” plays a crucial role in the SECI model of knowledge creation. It provides the necessary context for the conversion of knowledge from tacit to explicit and vice versa. By facilitating the interaction and exchange of knowledge among individuals, “Ba” helps to create a shared understanding and collective knowledge within an organization.

Understanding and leveraging “Ba” can significantly enhance an organization's ability to create and manage knowledge. By intentionally creating and nurturing different types of “Ba” organizations can foster a culture of continuous learning and innovation.

In conclusion, the concept of “Ba” as articulated by Nonaka and Konno is a foundational element in the understanding of knowledge creation within organizations. By recognizing and fostering different types of "Ba," organizations can create an environment that supports continuous knowledge creation, sharing, and utilization, leading to sustained innovation and competitive advantage.

3. Methodology

To analyze the phenomenon of corporate museum enterprises it is necessary to also consider the involvement of the parent organization. In fact, analyzing the corporate museum, without taking into consideration the influence and relationship with the parent organization, could lead to a limited vision and create distorted results. For this reason, the complexity of the analysis phenomenon is amplified. To resolve these critical issues, consistently with studies with similar objectives (Nissley and Casey, 2002; Vacca, 2014; Vesperi, et al., 2022), this study adopted a qualitative methodology with an exploratory approach. The present study is based on a

qualitative methodology, through an exploratory analysis, with semi-structured narrative interviews. The qualitative nature allows us to explore a phenomenon that is not well defined and understand aspects that are still unseen. Therefore, a qualitative approach seems suitable for the analysis of a complex phenomenon, such as that of corporate museums. The qualitative methodology based on a case study, therefore, was considered an appropriate method to obtain an overall view on corporate museums and the relationship with the parent company. This methodology has the main advantage of adopting an exploratory and qualitative research design to investigate the phenomenon in detail (Eisenhardt, 1989; Locke, 2020, Budhwar, et al., 2023), considered complex, recent and poorly defined. A company museum connected to a parent company operating in the agrifood sector has been identified.

The data and information were collected between January 2024 and April 2024, integrating multiple sources. We used internal company documents, such as annual reports, internal company reports and company websites. In agreement with the company and the interviewees, all names have been made anonymous and the documents not directly traceable, to guarantee their confidentiality. The manager of the corporate museum was interviewed. 3 interviews were conducted. The interviews, with the interviewee's consent, were transcribed and shared. This allowed us to eliminate interpretative errors and distortions. Furthermore, this allowed us to increase the quality of the interviews, collect comments on the interviews and their content. The interviews were reanalyzed using a narrative approach (Boje, 2001; Czarniaswka, 2004). We analyzed the interviews as texts, identifying the relational dynamics between the corporate museum and the parent company and practices related to knowledge management.

4. Results and Discussion

Since there is a vast literature on knowledge management (KM), but observations on corporate museums still appear scarce; the main objective of this study was to fill this gap. Especially within knowledge management studies, corporate museums are still little explored. This condition has strongly influenced this study. In fact, it was necessary to carry out an exploratory study.

The focus on corporate museums is justified as they represent containers of organizational artifacts, strongly connected to the parent companies. The analysis of corporate museums is characterized by the sector in which the parent company operates. The results of this study confirmed what has just been highlighted. In fact, the interviews revealed the strong bond and the knowledge transfer relationship between the parent organization and the corporate museum. Knowledge is conveyed to the corporate museum in the form of artifacts.

Analyzing knowledge within the corporate museum represents an indirect way to analyze knowledge within the parent company. Understanding the historical evolutions of the parent organization, therefore, appears necessary to understand the different forms of knowledge that are present within the corporate museum. This is the prerequisite for the analysis of the corporate museum. The observed case study has highlighted that the corporate museum is able to simultaneously collect, archive and valorize different types of knowledge, represented in different forms. The representation of knowledge, in the form of organizational artefacts, represents the evolution of KM practices used within the parent company.

The interviews have highlighted different aspects. In particular, the attention has emerged.

The second aspect is the strategic use that is attributed to the corporate museum. In fact, the interviews have highlighted that the corporate museum must not represent a collection of organizational artefacts, but must valorize the knowledge present within the corporate museum and generate advantages for both the corporate museum and the parent organization. In fact, the main studies on corporate museums have limited themselves to defining corporate museums as marketing tools. Without any advantage for the museum itself. The museum, according to these studies, is a tool that shifts all the benefits of its activity to the parent organization. From the interviews, however, it emerged that the corporate museum must be a stable and autonomous organization. The interviews highlight that the corporate museum must generate a competitive advantage for the museum and at the same time for the parent organization. In fact, through the valorization of knowledge considered obsolete by the parent organization, the corporate museum must generate value (not only economic) for itself and for the parent organization. The interviewees, in fact, highlighted that the corporate museum should return new knowledge to the parent organization. In this context, a BA is generated that allows the reuse of obsolete knowledge to undertake new paths of innovation and knowledge creation. The interviewees stated that the corporate museum must represent a shared space with the employees of the parent organization in order to spread the values of the organizational culture of the parent organization and, above all, encourage the development of new ideas, creativity and innovation that return to the parent company in the form of

innovation. The process of creating new knowledge within the corporate museum still appears not completely clear. The interviewees expressed the intent to achieve this goal. At the same time, no certain element has emerged. Until now, no concrete results have been presented regarding the use of the corporate museum as a BA. Our results highlight that it is therefore not possible to analyze the corporate museum independently, but we must understand the deep relationship between the parent company and the corporate museum. From the interviews it was possible to distinguish the phases of acquisition, archiving and sharing of knowledge within the corporate museum. This study is not without limitations. These limitations, however, can offer KM and corporate museum scholars potential opportunities for future research directions. The main limitation of this study is related to the methodology adopted. The study did not take into account elements such as the economic sector, the geographical area and the economic and socio-cultural conditions. For this reason, future studies could focus their attention by trying to consider discriminating variables such as the economic sector and the relative level of diffusion or rate of obsolescence of the widespread technology, organizational size or organizational knowledge.

Carl-henrik.wahl@inn.no
Ole.ranglund@inn.no
Linda.kionig@inn.no

Abstract: In June 2024 the worlds' largest songwriting camp took place in a small town in Norway. The main organizer is a small music production company called the Woods. Although having organized more than 100 "ordinary" music camps, this was -by far- be the largest one, with approximately 153 participants from approximately 20 countries. The logistics alone is nothing less than challenging. This study will focus on the knowledge management perspective regarding the organizing, and we have through a qualitative study interviewed the main organisers. Our perspective has been to unveil how they plan for, coordinate and organize the participants as well as keeping track of the different groups' progress regarding developing songs.

Keywords: Project Management, Knowledge Sharing, Coordinating Processes

1. Introduction

Sometimes songs take a long time to be finished. Then it needs to be recorded and produced before the marketing and publishing. At The Woods, who is a company specializing in producing and publishing music, they have been organizing "music camps" to effectively develop songs. "Music camps" are camps organized as seminars lasting approximately 2-3 days (often from Friday afternoon to Sunday afternoon). The purpose of the camps is to write songs (lyrics and melody) that can be published. Most times the songs need further work such as a better production, but this varies.

After having organized nearly one hundred music camps, the Woods decided to organize a world record attempt by organizing the worlds largest music camp, Rena Song Festival.

For this they engaged the municipality, the university, hotels and hostels, restaurants and other providers in the municipality of Åmot.

After a year of preparations, the invitations went out and 153 participants showed up, making this the worlds largest music camp.

From an organizational perspective, the knowledge management in such a temporary organization is interesting to unveil. This paper investigates how knowledge is disseminated within this organization and how knowledge has been distributed during the preparations for the record attempt and during the camp. For the person that was the initiator and has been the "driving force" behind the project, it has been important to avoid crisis and to be as prepared as possible in beforehand. He has been agile regarding the fact that crisis might still occur, crisis that is beyond what is possible to plan for. The planning has however been meticulous in order to foresee most of what may go wrong.

Our research question is thus; *Rena Song Fest – how to organize the world's largest songwriting camp?*

Through group interviews and individual interviews, we have sought to identify how the people working in this temporary organization have perceived how their level of knowledge and access to knowledge have facilitated their work execution before and during the camp.

2. Theoretical Foundations

Knowledge Management is about sharing, disseminating and saving knowledge (Hislop, 2009, Davenport and Prusak, 1998). Knowledge sharing and communication have in this project been seen as vital to secure that this music camp runs smoothly. Knowledge can be shared in several ways within the context of organizational theory.

However, it is important to know what type of knowledge this is about. Tacit knowledge requires different approaches to sharing than explicit. Tacit knowledge is implicit and difficult to express as it may be about skills, wisdom or intuition (Polanyi, 1967, Davenport and Prusak, 1998). Explicit knowledge is thus what is possible to articulate, to write down and store.

The knowledge-creation process is about turning tacit knowledge such as ideas, experiences, impressions into externalized knowledge, combined with previous knowledge with the co-workers and then internalized (Castellani et al., 2021, Nonaka and Takeuchi, 1995, Nonaka, 1994). This model is otherwise called the SECI-model. This model is often referred to within theory of "Learning organizations" (Filstad and Blåka, 2007) as learning in organizations often depends on "unlocking" the tacit knowledge and sharing it with others in the organization.

Learning in organizations and organizational learning are terms that has been debated (Örtenblad, 2018). In some definitions it is a focus on the individual as a learner whilst other definitions are focused on the organization (Örtenblad, 2018, Marsick and Watkins, 1999).

Argyris and Schön (1996) proposes another take on organizational learning. Their single and double loop learning has had huge impact on how to view how organizations learn. The single loop is about acting on a result, for example something that has gone wrong, a complaint, etc. The double loop is about searching the reasoning for why the result occurred (for example a faulty product can stem from different types of predating issues, such as using faulty but cheap screws in a product) fixing the reasons for the results rather than just fixing what has been wrong (providing a new product if a product is faulty).

Crisis may still occur, and it may damage the reputation of an organization (Coombs, 2007). A crisis may be defined as a "sudden and unexpected event that threatens to disrupt an organizations and poses both a financial and reputational threat" (Coombs, 2007). As the organizing company (The Woods) is mainly attracting customers due to a good reputation, it was vital that any crisis could be solved so that anything that may damage their reputation is solved as soon as possible.

Situational Crisis Communication Theory (SCCT) provide a framework that allows for understanding how stakeholders may react to a crisis. Stakeholders in this setting, may be the attendances at the music camp. Being on top of information going out to stakeholders are thus important. With the emergence of social media, news travels faster than ever. Stakeholders would also like to know how any crisis is treated to avoid a new happening. Emotions are also an important feature to pay attention to within handling crisis. According to Coombs (2007) *"behavioural responses are positive when a person is judged not to be responsible and sympathy is evoked"* (p. 166). This means that if the stakeholders perceive The Woods representatives to have done what they can to avoid crisis, they are more inclined to be positive and forgiving. Stakeholders with a previous bad relationship may amplify how they feel about the company.

It is also about how a message is framed as it may shape the perception of how a problem is defined, what caused it, who is responsible and how has it been solved (Coombs, 2007). It is also important to understand and assess the incidents recognized as crisis.

The SCCT model shows the different issues regarding a crisis. It shows that the crisis history and prior relationship reputation will affect the organizational reputation. Any crisis response strategies will influence crisis responsibility and organizational reputation as well as any Emotions. Emotions will influence behavioural intentions. If they are negative before entering the camp, they will be even stronger if something negative occur.

As the table 1 in the Appendix shows, there are possibilities of countering bad reputations.

Even if the staff working at Rena Song Fest establish what can be labelled an "ad hoc" organization (Morgan, 1998, Jacobsen and Thorsvik, 2002), it is still important to seek to avoid any crisis and unexpected events. It is about being "better safe than sorry" and thus take all possible precautions. Hence, the easiest way according to Gangdal and Angeltveit (2014) is to develop a culture within the organization based on routines, collaboration, cooperation and a unified understanding of what to be done, how it should be done and why these things should be done. It is about having clear goals, a common understanding of what the challenges may be, and how to arrive at common solutions. It is also about being able to place the responsibilities of the different tasks, work towards a common understanding of solutions, establish routines for detecting and preventing unwanted incidents and also develop a culture in which the participants encourage and dare to correct eachother. This, according to Gangdal and Angeltveit (2014) provides the manager with space and time that can be spent being ahead and prevent unwanted incidents.

3. Method of Inquiry

This paper is one of several reports from a longitudinal research project following the Woods song camps production management. We have used a qualitative approach that has included group interviews and individual interviews (Patton, 2002, Creswell, 2003). The group interviews were with the staff that were to support the people attending the music camp. The individual interviews have been with the representatives from The Woods. The interviews were conducted using a semi-structured interview guide to pursue relevant themes (Denzin and Lincoln, 2005, Jacobsen, 2015). The data material has been analyzed by reading through transcripts from the recorded interviews to identify any interesting issues that throw light on the research themes. Our findings give us insight in project management processes; the planning beforehand and how the Rena Song Fest was carried out. Along the process we have discussed our findings in the research group, and our findings are also presented and discussed with the Woods project team. This check-back validates the understanding of our findings (Guba and Lincoln, 1989).

4. Results and Discussion

4.1 Planning the Rena Song Fest Project – Seeking to be "Better Safe Than Sorry"

The responsible organizers claim that they have planned for a long time, checking and double checking every detail in their plan. For example, all the food and beverage services were checked out, the hotels and hostels were contacted to double and triple check about the accommodation. Lists over who would share room with whom were distributed prior to the camp, and they even booked rooms that were not occupied, just in case something would happen, and they would need an extra room.

This shows that they have sought to be highly detailed in their planning process. This is in line with what Gangdal and Angeltveit (2014) suggest regarding seeking to be ahead of unforeseen happenings.

There were mandatory meetings where the staff was trained in issues that may emerge. Also, they had to attend regular meetings to report on progress and situation both before and during the Rena Song Fest.

This show that within their "ad hoc" organization, they shared knowledge (Nonaka and Takeuchi, 1995) and through their common discussions and seeking to unveil challenges, were prepared to handle situations and solve problems that emerged (Gangdal and Angeltveit, 2014).

Equipment was organized well in advance and 38 studios distributed across the centre of the municipality (at the Inland University of Applied Sciences, Rena, at the County Hall and at The Woods) were set up several days before the start of the camp. All equipment was tested to check that the participants would be able to work as they expected allowing them to focus on the creative part of the song writing.

The preparation that the employees at The Woods have done to avoid crisis we find to be very (Coombs, 2007). They also seem to have sought to eliminate any occurrence of crisis. This may be due to their previous experiences with up to 100 music camps, although they have much less attendance. This record attempt would represent new experiences, but some issues they knew they had to attend to prior to the music camp. This indicate that their *tacit knowledge* allows for substantial preparations, both regarding accommodation, food&beverages, studio facilities and issues that may arise. Hence, the *tacit knowledge* the representatives from The Woods have obtained aid the process of sharing knowledge with what is now a part of the extended ad hoc organization (Nonaka and Takeuchi, 1995, Nonaka, 1994). By giving the staff instructions and explaining what to do, what to avoid, what to report and how to solve (known) possible problems the representatives at The Woods have sought to externalize the tacit knowledge allowing the staff to combine this knowledge with prior experience and by working in the music camp, they have the potential to internalize this knowledge.

These preparations also show that they act according to Argyris and Schön's single and double loop learning model (Argyris and Schön, 1996). In fact, they seem to anticipate and solve any problems before they arise.

4.2 Running the Rena Song Fest – Hands on and Problemsolving

The employees from The Woods experiences from previous camps had also led to dividing the attendants into groups based on self-reported levels of competences regarding the different areas that are required to develop songs (singer, songwriter, producer, musicians, etc.). However, some producers fell ill and could not attend. This was solved by the "reserve staff" at The Woods, that were to be "stand in's" and provide urgent help to groups that struggled now had to be producers in some of the groups. As this occurred at the last minute, literally the

same day as the camp started, this was the only solution. However, as these producers (from The Woods) originally were to be "spare" they were able to support the groups that were short of a producer. This is yet another example of being able to avoid crisis and bad reputation (Coombs, 2015).

The staff claim that they have been properly informed, and that they were clear about the "line of command". The introduction and information provided prior to the camp were interpreted as a bit boring, but as the camp progressed, they found the information useful. They claimed to know what to do on eventualities and if they were not able to solve the problem themselves, they knew who to contact.

This implies what we have suggested above; the knowledge sharing and sharing of what to the employees at The Woods have of tacit knowledge has been externalized, and the informants amongst the staff claim that they have understood (combined) and internalized the knowledge (Nonaka and Takeuchi, 1995, Nonaka, 1994).

In one case, there was an emergency as one of the places for staying overnight for the attendants to the music camp had trouble checking in the people arriving. Although this was originally taken care of by sharing lists and overviews of the distribution of sleeping spaces, it turned out that there were misinterpretations. This is a situation that may quickly have escalated to a crisis that potentially could have harmed The Woods' reputation (Coombs, 2007). However, it was rapidly solved by the representative calling the responsible from The Woods who arrived at the "hostel" a few minutes later and the matter was solved within a short time. It was also resolved by *apologies* (see table 1 in appendix), *reminders* and partially by *ingratiation* in the SCCT crisis respond table (see table 1 in appendix).

The examples above shows what Gangdal and Angeltveit (2014) suggest regarding enabling managers to be ahead of the problems and are allowed time and space to solve any emerging problems proves very useful. This is due to substantial planning and preparations, in combination with knowledge sharing and hands on management.

4.3 Posterior Actions

Posterior to the music camp, there have been several reflection meetings. One issue that arose that was unavoidable was the lack of producers at the music camp. According to the employees at The Woods, the learning they have from this is to offer courses for attendants that would like to become producers prior to the camp. This may solve any problems with lack of producers. This is an example of doing something with the reason for a possible crisis to emerge(Coombs, 2007) and strongly resemble double loop learning (Argyris and Schön, 1996). Also, the feedback from the participants at the music camp has been excellent and many of them have signed up for new camps at The Woods. Hence, their reputation may very well have been strengthened rather than damaged from the project.

A meeting with the other stakeholders (minus the participants) (such as the municipality, the university, etc.) is planned. This meeting may serve as a learning area for the rest of the stakeholders. This dissemination goes beyond the organization but may benefit the society and the involved parties at the Rena Song Fest.

5. Conclusions

The way knowledge has been managed by distributing and disseminating vital information and experiences, the management at Rena Song Fest have been able to avoid a lot of crises that would have emerged with less planning and preparations. The knowledge sharing has been vital and functioned as they hoped. The staff making up the "ad hoc" organisation has learned a lot from the project and the learning is kept and managed within the organisation (The Woods). The formidable undertaking had less "mishaps" than one could expect, due to the diligence of the employees at The Woods regarding preparations ahead of the Rena Song Fest. This has also resulted in participants at the Rena Song Fest signing up for more (ordinary) music camps at The Woods. The learning that the organization take away from this experience will benefit the organization as they will now have experiences with large music camps. As the number of participants exceeded what has been listed as "the worlds largest song camp", although only by three, Rena Song Camp is officially the largest song camp organized in the world.

Their approach to planning by "being better safe than sorry" has allowed the management to handle emergent crisis and also to avoid any major crisis to develop into e.g. reputations that could potentially be harmful.

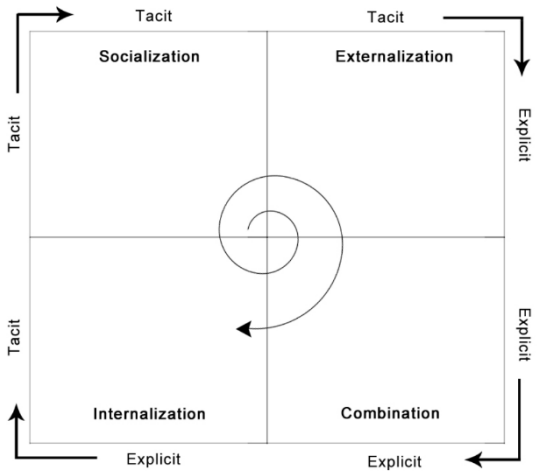

Figure 1: The SECI-model (Nonaka, 1994; Nonaka&Takeuchi, 1995)

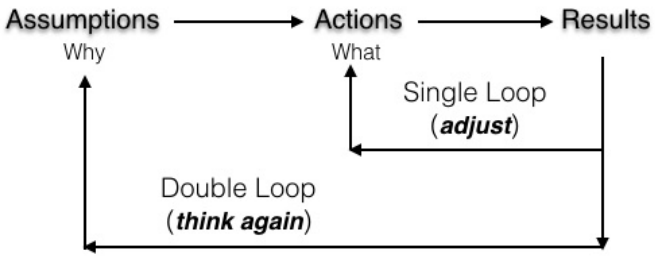

Figure 2: Single and Double loop learning (Argyris & Schön, 1996)

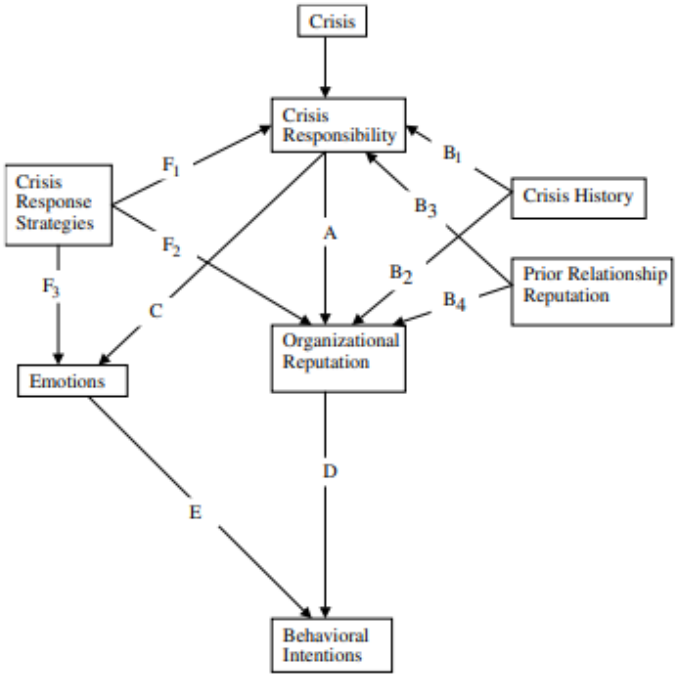

Figure 3: SCCT model (Coombs, 2007, p. 166)

The SCCT crisis response strategies are listed in this table:

Table 1: Table on SCCT crisis response strategies (Coombs, 2007, p. 170)

Primary crisis response strategies
Deny crisis response strategies
Attack the accuser: Crisis manager confronts the person or group claiming something is wrong with the organization.
Denial: Crisis manager asserts that there is no crisis.
Scapegoat: Crisis manager blames some person or group outside of the organization for the crisis.
Diminish crisis response strategies
Excuse: Crisis manager minimizes organizational responsibility by denying intent to do harm and/or claiming inability to control the events that triggered the crisis.
Justification: Crisis manager minimizes the perceived damage caused by the crisis.
Rebuild crisis response strategies
Compensation: Crisis manager offers money or other gifts to victims.
Apology: Crisis manager indicates the organization takes full responsibility for the crisis and asks stakeholders for forgiveness.
Secondary crisis response strategies
Bolstering crisis response strategies
Reminder: Tell stakeholders about the past good works of the organization.
Ingratiation: Crisis manager praises stakeholders and/or reminds them of past good works by the organization.
Victimage: Crisis managers remind stakeholders that the organization is a victim of the crisis too.

Making Tacit Knowledge Explicit: Disseminating Knowledge in a World Record Attempt

Abstract: The organizers of the world record attempt regarding gathering the largest number of singersongwriters in the world in a song writing camp (RENA SONG FEST 2024). From previous investigations, we know that there are certain steps in the development of a song, and that to develop a song that can be produced, they need to finish each step within a time frame. This has been a tacit knowledge. Hence, to organize for a vast number of groups they need to disseminate this knowledge to the ones that are to supervise and aid the groups towards a product that can be developed for production. In this paper we investigate how the managers at Woods developed a process for implementing and disseminating the knowledge needed to mentor the different groups taking part in the song writing camp. This two-tier mentorship will revisit the SECI-model and allow us to investigate if and how the organizers utilize this model to aid the supervisors in their work with the different songwriter groups.

Keywords: Tacit Knowledge, Explicit Knowledge, SECI-Model, Communities of Practice, Practical Knowledge, Ad-Hoc-Organization.

1. Introduction

Rena Song Fest 2024 was a world record attempt seeking to organize the largest songwriting camp. The theme of the camp was Eurovision Song Contest. As they managed to organize 153 participants, they are, for now, leading the competition. Rena Song Fest 2024 took place from the 27th to the 30th of June in Rena in Åmot municipality. This municipality holds approximately 5000 inhabitants in total of whom approximately 2000 lives in and around the centre called Rena.

Hosting such an event has required a lot of input from several stakeholders. The initiative was taken by the founder and managing director of The Woods, a music production company situated at Rena. The Woods have arranged approximately 90 music camps, but with less participants per camp. Hence, this world record attempt requires a different approach to organizing the camp and would be organized together with daWorks, BYRÅ and The Song Farm.

The goal of the music camp is to make as many songs as possible during the three days of the camp. This require that as many groups as possible can develop as many songs as possible.

The Woods have long and substantial experience regarding developing and producing songs utilizing song camps. The Woods have developed these camps from merely gatherings of people interested in making music to their professional and renowned music camps with different themes. They have used every song camp to improve on their professionalism. After each day of every camp, the staff that acts as supervisors for the different groups have reflected and discussed how to improve for the next camp. The experiences and thus knowledge base has increased for each camp held.

However, the size of the world record attempt required more supervisors than The Woods had access to. Hence, they needed to train more supervisors for this job. The experiences the supervisors at The Woods have gained are, however, not always explicit knowledge. The supervisors at The Woods have generally discussed without being recorded much of their acquired knowledge and this knowledge may thus be characterized as tacit knowledge. Our research question is: How did the Rena Song Fest organizers manage the process of implementing and disseminating the knowledge needed to supervise the different groups taking part in the song writing camp?

This paper shows how knowledge, both tacit and explicit can be shared in different tiers of a larger ad hoc organization. Through qualitative research we have investigated how the SECI-model (Nonaka and Takeuchi, 1995) developed by Nonaka and Takeuchi has been used to disseminate knowledge throughout the temporary organization for Rena Song Fest 2024.

2. Theoretical Foundation

Knowledge has been defined as: "the individual ability to draw distinctions within a collective domain of action, based on an appreciation of context or theory, or both" (Tsoukas and Vladimirou, 2001). This means that the individuals can make distinctions at the same time as they appreciate collective understandings and what is generally accepted as appropriate. Tsoukas and Vladimirou (2001) also claim that knowledge consists within a rule based context. The rules or the norms are determined within an organization by members of a Community of Practice (p. 980). This imply that the "individuals draw and act upon a corpus of generalizations in the form of generic rules produced by the organization" (p. 979). Further, the "community" must have a shared opinion and interpretation of these rules. They have to agree on what this means and how to apply it. Organizational rules allow for obtaining goals.

Lave and Wenger (1991) introduced the concept of a Community of Practice (CoP). They define CoP as a group of people who share a concern or a passion for something they do and learn how to do it better as they interact regularly. This concept emphasizes that learning is a social process and occurs through participation in a community.

Polanyi (1967) claim that practical knowledge is personal, and involves personal participation to be generated. He further explains that we can learn to use a tool so well that we do not think about how we use it to perform an action or task, meaning that the use becomes tacit knowledge.

It is also worth noticing the importance of heuristic knowledge developed by employees while performing their tasks. This type of knowledge cannot be managed in the same way as formally available information because it relies heavily on employees' experiences, perceptual skills, social relationships, and motivation. Managing this aspect of organizational knowledge requires fostering a sense of community at work, encouraging employees to improvise and take initiatives, and actively maintaining a sense of corporate mission. In other words, managing heuristic knowledge involves more sensitive management of social relations rather than corporate digital information (Tsoukas, 1998). Additionally, effective management of organizational knowledge necessitates a reciprocal relationship between propositional and heuristic knowledge: while propositional knowledge is integrated into organizational members and becomes tacit through application, heuristic knowledge needs to be formalized (as much as possible) and made available within the organization.

The SECI-model is generally discussed and elaborated within the frames of organizational theory or learning organizations (Filstad and Blåka, 2007, Irgens, 2011, Jacobsen and Thorsvik, 2002). Nonaka and Takeuchi (1995) described how knowledge can be shared through socialization, externalization, combination and internalization. The model itself mainly focuses on how to make tacit knowledge explicit. Tacit knowledge is knowledge that is internalized and difficult to articulate (Polanyi, 1967) whilst explicit knowledge can be recorded and stored for sharing. The SECI-model show how tacit knowledge through socialization and externalization can become explicit and combined with the learners' previous knowledge and through working with this knowledge can internalize it. The figure (Figure 1) shows an overview of this process. The socialization and externalization are about discussing with others sharing circumstances and other information that enables the tacit knowledge to become possible to obtain by others. By testing and utilizing this information it is possible to combine the new knowledge with previous knowledge and then internalize it.

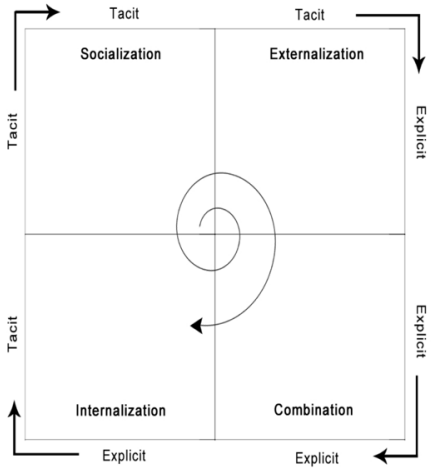

Figure 1: The SECI-model (Nonaka, 1994; Nonaka&Takeuchi, 1995)

However, this is contested by Cook and Brown (1999) as they use the example of riding a bike. When one has learned to ride the bicycle, this is tacit knowledge. It is, however, difficult to explain *how* to ride the bicycle. The explicit knowledge can be used to help acquire the tacit knowledge, but tacit knowledge, they claim, can never become explicit (Cook and Brown, 1999).

Also, there is a distinction between what each individual can do and what a group as a whole can do. The collective knowledge in a group thus consists of the individual's knowledge. The group's collective knowledge guides its actions, just like an individual's knowledge guides their actions. The work done by the group, based on its shared knowledge, is different from the work done by an individual based on their own knowledge (Cook and Brown, 1999).

3. Method of Inquiry

In this study we have had a qualitative approach. Data has mainly been collected by using semi-structured interviews (Patton, 2002, Dalen, 2011). This allows pursuing interesting statements that may enrich the data. We have interviewed the head of supervisors from The Woods and have also collected data from supervisors in the extended ad-hoc-organization. Since the interviews were registered on tape, we analysed the data by first listening to the recordings and sorting data into main categories and subcategories to identify patterns of the transition of knowledge in the ad-hoc organization. In order to secure validity and reliability, we have performed a checkback (Guba and Lincoln, 1989) presented the data to the interviewees.

4. Results and Discussion

The Woods and their partners have shown high ambitions in planning and going through with the Rena Song Fest. When planning Rena Song Fest, they were eager to avoid problems and "crises" as possible throughout the song camp. Due to the head managers insistence of preparing and planning rather than solving crises during the camp, they have been meticulous and detailed in their planning process. The head manager of Rena Song Fest insisted on establishing good relations with the stakeholders, the service providers and the staff. The staff, being a mixture of people hired by Rena Song Fest and "regular" employees at The Woods, thus needed to be as well trained as possible prior to the event.

We identified three stages in the process that supported the knowledge dissemination. The first was the importance of planning and being prepared by continuously asking themselves what could go wrong? They built an ad-hoc organization and delegated responsibility among the staff. In addition, they wanted to manage operate in a dynamic way to be prepared for unforeseen situations. This required communication and sharing of information. Both the participants of the Rena Song Fest and the members of the ad-hoc organization were very well informed about the "line of command" something they claim contributed to the management being closely updated on any undesired events. This in turn allowed the management to be "hands on" regarding solving the problems either by them selves or by delegating it to others.

Secondly, they arranged common meetings with the staff starting with a meeting ahead of camp start, "long and boring" according to the head supervisor. Here he presented all details regarding the camp. Thus, the whole group of supervisors were informed about "what, where, when and how". In this way all the mentors got the same information about what was going on. This gave them a basis for acting on possible problems arising during the event. These meetings, although "long and boring" contributed to the fact that all of the staff at the ad-hoc organization were informed as well as possible at all times. This allowed for the staff to feel included, as in a CoP (Lave and Wenger, 1991) and also a feeling of mastery (Senge, 1992) as they could answer questions from the participants of the camp.

Thirdly, The Woods head manager also shared with the group of new supervisors their knowledge about how to systematically run a song camp session, running the steps of the production processes, in a way that leads to a successful product. Daily evening evaluating meetings with the crew supported the group as a Community of Practice (Lave and Wenger, 1991).

The mentors from The Woods claim to have had quite substantial training during the previous camps. They each also claim to have developed their knowledge together with the others. An example they give is about timing and focus. Most artists want to make the perfect song with the perfect chorus and verses. However, the time limits do not always allow for finetuning of this. Hence, they must learn to settle for "the second best" in order to finish. They have also developed a model for what needs to be finished at approximately what time. This is they claim a result of reflection and being forced to explain what has become tacit knowledge.

This is an example of how they have utilized the SECI-model as described by Nonaka and Takeutchi (1995). By discussing and explaining amongst each other at the end of each day at the camp and after the camps they have been able to share this and make this a knowledge amongst the mentors.

The new mentors that have been trained has been taught about the timing but does not yet have this as their *internalized tacit knowledge.* This may be due to their lack of experiences regarding being mentors at several camps and thus have no other experiences to *combine* their new knowledge with other than having taken part in camps as participants. This thus supports the claim of Cook and Brown (1999) that tacit knowledge cannot become explicit.

The knowledge shared is decided by the group of mentors at The Woods. Hence, they may be viewed as a Community of Practice (Lave and Wenger, 1991) who set the rules for what is to be the governing interpretations and actions to be taken with this as a point of departure regarding what the new mentors are to work by. This is in line with what Tsoukas and Vladimirou (2001) states.

Posterior to the camps, the new mentors claim to have learned a lot not only from what they have been taught by the mentors at The Woods, but also from working as mentors at Rena Song Fest 2024. This is thus their own individual practical knowledge according to Polanyi (1967). If one consider the knowledge shared by the mentors from The Woods to be “a tool”, this also means that if they are able to utilize this more than this time, they may develop tacit knowledge on the mentorship (Polanyi, 1967).

In the aftermath an evaluation show that the experiences form the song camp is vital to both the daily production practice of the firms, but also has great significance for doing similar projects in the future.

4.1 Importance to Other Fields and Organizations

These investigations have been important as the outcome can be used in different settings as well as in new world record attempts when writing songs for the Eurovision Song Contest. It may also have significance regarding organizing supervisors in large groups for example in education both physically and online. Bringing this knowledge into such a setting provide guidelines for how to organize for developing supervisors for the purpose of for example educating within the frames of massive open online courses (MOOCS). Training supervisors for work in this type of setting thus require that there is a CoP of trained supervisors that set rules for what should be within the scope of what supervision should be about, and which is based on a common understanding drawn from the individuals’ tacit knowledge about supervision. Allowing the new supervisors to utilize their learning as “a tool” this may, combined with the experiences they obtain, become the new supervisor’s tacit knowledge.

5. Conclusion

The world record attempt called Rena Song Fest 2024 was a huge success. Not only did they manage to organize for the most participants ever on a song camp, but The Woods as the main organizer (together with daWorks, BYRÅ and The Song Farm), has gained valuable experience on how to perform song camps with large numbers of participants. The aim of this paper was to investigate the two-tier mentorship and how the knowledge development amongst the experienced and the new mentors would unfold.

The experienced mentors shared their knowledge which was based on the individuals’ tacit knowledge but what had been negotiated within the frames of what can be called a Community of Practice. This provided some rules and guidelines based on the collective knowledge. The new mentors were thus provided with “a tool” that they could use when executing mentorship in the groups they were assigned.

The experienced mentors used the SECI-model, but the new mentors need more experience in order to internalize the use of their “tools” (knowledge from the experienced mentors) and make this their tacit knowledge.

The outcome of this project may be applicable in different settings, for example in the education of large numbers of students.

Enhancing Teaching and Learning Through Digital KM at an Open University

Narubodee Wathanakom
Sukhothai Thammathirat Open University, Bangkok, Thailand

narubodee.wat@stou.ac.th

Abstract: This study investigates the utilisation of digital knowledge management (KM) in enhancing teaching and learning at an open university, with a particular focus on Sukhothai Thammathirat Open University (STOU) in Thailand. As a leading open university in Southeast Asia, STOU faces unique challenges in providing higher education opportunities to Thai people both locally and internationally. STOU recruits staff based on qualifications, attitude, and personal values to align with the open university mission and vision. STOU's mission requires its academic and non-academic staff to have differentiated competency, necessitating specialised skill sets in open education, including self-learning textbook writing, mastery of e-learning, and other digital resources planning. This study highlights STOU's capacity-building innovations in digital KM. Qualitative interviews were conducted with lecturers who participated in teaching and learning KM though qualitative interview with lecturers who participates in the KM on teaching and learning. The result of the study revealed that the key to success for enhancing teaching and learning was driven by the leveraging of a global standard framework called the UK Professional Standard Framework, together with certain KM activities such as face-to-face training, extensive online repository of resources, mentoring, and the utilisation of digital platforms. These initiatives equip academic staff with the necessary skills to effectively engage in the digital education landscape and encourage them to improve their teaching and learning. Robust KM practices at STOU significantly improve student passing rates, engagement, and satisfaction. The study offers practical recommendations to optimise digital KM via process-driven practices to contribute to the advancement of higher education in Southeast Asia.

Keywords: Knowledge Management, Open University, Digitalisation, Teaching and Learning

1. Introduction

In the 21st century, strategic knowledge management (KM) enables local and international organisations to create and sustain their unique business propositions and to gain a competitive edge by generating superior product quality, efficiency, and innovation (Almalki, & Al-Shammari, 2023). Knowledge is an intangible asset that increases an organisation's productive and adaptive capabilities (Marquardt, 2011). KM encompasses the efficient and systematic management of knowledge processes, extending beyond mere acquisition to include representation, storage, learning, sharing, reuse, creation, and innovation within an organisation or sector (Nawaz & Gomes, 2014). KM also facilitates the development of knowledge assets and in turn the achievement of organisational mission, goals, and objectives. State-of-the-art KM practices benefit organisations by encouraging knowledge sharing, creativity, and continuous improvement of product or services (Otundo, 2023). Further, KM is related to aligning people, technology, and business processes to create value for customers, as well as enable decision-making, risk management, quality enhancement, cost reduction, and improvement in service quality (Fan & Shum, 2023). This is because KM encourages a collaborative working environment through continuous exchange of information among stakeholders to augment organisational success (Saini, Jain, & Jain, 2023). KM design increasingly leverages new technologies such as crowd computing, AI, big data, the internet of things, and other digital tools (Safaee & Yadegari, 2022). Moreover, KM is associated with an organisation's learning culture (Priyadharshini & Lakshmi, 2021). A strong learning culture is necessary for effective KM, since employees who are more engaged and motivated tend to innovate and create new knowledge with the aim of improving existing working processes (Garvin, Edmondson, & Gino, 2008). Therefore, organisations must employ KM strategies to align people, processes, and culture to maximize its impact.

KM also plays important roles in both for-profit and non-profit organisations, including higher educational institutions. Petrides and Nodine (2003) mentioned that KM practices can empower faculty by helping them collect data and exchange information about which teaching methods work best in different learning settings. As knowledge-driven organisations in teaching, learning, research, publication, and community service (Fullwood & Rowley, 2017), the goal of every university is to produce highly capable graduates to meet the requirements of society and future employers (Umaroh, Putra, Fahrudin, & Arsyad, 2023). Sukhothai Thammathirat Open University (STOU), Thailand's premiere open university, aims to provide lifelong higher education opportunities for Thai people worldwide through distance learning (Sukhothai Thammathirat, 2024). Effectively leveraging the latest digital technology and educational innovations in service of the open university mission requires a unique set of competencies to support online students with diverse learning styles, including KM, pedagogical expertise, and online learning design (Bezuidenhout, 2015; Gulati, 2008); technological skills to

manage online learning tools (e.g., LMS) (Alvarez et al., 2009; Arinto, 2013); the ability to facilitate remote learning and keep distance learners engaged through student-centered learning (Berge, 2009; Chakraborty & Nafukho, 2014); and continuous professional development that keeps pace with the latest knowledge, trends, and technology to elevate KM learning experiences (Aziz & Selamat, 2016).

Previous research on KM in higher education has discussed KM processes, the utilisation of digital technology, cloud-based services, the influence of KM on academic staff satisfaction and teaching motivation, and KM culture (Dneprovskaya & Shevtsova, 2023; Younas, Noor, & Arshad, 2022; Hakiman, Munadi, & Ernawati, 2019; Duong, Kien, & Khoa, 2022; Shaukat, Ahmad, Naveed, & Rehman, 2023). However, there are gaps on the integration of processes, technology, and learning culture towards effective KM, especially in an open university where academic and non-academic staff requires unique competencies to provide teaching and learning in a KM learning environment. Drawing on the United Kingdom Professional Standard Framework (UKPSF) for higher education for the context of an open university, my article addresses this gap by presenting KM initiatives that integrate processes, technology, and learning culture.

2. Literature Review

Knowledge management was defined by Nonaka and Takeuchi (1995) as the process of creating, sharing, and utilising knowledge within an organisation to achieve a competitive advantage. They introduce the concepts of tacit and explicit knowledge and discuss the importance of converting the former (i.e., personal, experienced-based, and context-specific knowledge) into the latter (i.e., formalized and structured knowledge). They also highlight systematic storage and accessibility as aspects of effective KM.

Alavi and Leidner (2001) view KM as a structured, company-wide approach to gathering, organising, and sharing employee knowledge with the goal of making this information accessible throughout an organisation to improve individual performance and overall company effectiveness. They propose a comprehensive framework for KM within organisations that consists of four main processes: knowledge creation, knowledge storage and retrieval, knowledge transfer, and knowledge application. Knowledge creation is the process of generating new knowledge within an organization and includes the sharing of tacit knowledge through social interaction (e.g., face-to-face conversations, shared experiences, and apprenticeships) and converting tacit knowledge into explicit knowledge through articulation, dialogue, and documentation. Knowledge storage and retrieval emphasises the importance of organisational memory and involves capturing, organising, and storing organisational knowledge in repositories for future access and use. This process preserves valuable knowledge assets, such as databases, document management systems, expert systems, or knowledge repositories. These systems should be designed to facilitate easy access, retrieval, and maintenance of knowledge. Knowledge transfer is the process of sharing knowledge among individuals, groups, and organisations. This includes both formal knowledge transfer (e.g., training programs, documentation, knowledge-sharing platforms, and communities of practice) and informal knowledge transfer (e.g., social interactions, mentoring, and informal networks). Knowledge transfer can be cultivated through a culture of trust and collaboration, providing incentives for knowledge sharing, and investing in technological infrastructure that supports knowledge exchange. Knowledge application is the process of utilising knowledge to make decisions, solve problems, and improve organisational performance. The value of knowledge lies in its application, not just its possession. Knowledge application can occur at various levels within an organisation, from individual decision-making to team problem-solving and organisational strategy formulation. Organisations can enhance knowledge application by aligning KM initiatives with business objectives, providing training and support for knowledge users, and creating a culture that encourages experimentation and learning from failures. Knowledge application can also be facilitated by embedding knowledge into organisational processes, routines, and systems to make them more accessible and actionable.

The UK Professional Standards Framework (UKPSF) is a comprehensive set of guidelines and standards developed to enhance the quality and consistency of teaching and learning in higher education. It provides a universal framework for recognizing and benchmarking teaching excellence and professionalism among higher education practitioners. The UKPSF is managed by Advance HE, an organisation dedicated to supporting higher education institutions in their efforts to improve teaching and learning, and consists of three key domains: areas of activity, core knowledge, and professional values.

The first domain outlines five key areas of activity that higher education professionals are expected to engage in: design and plan learning activities, teach and support learning, assess and give feedback to learners, 4) develop effective learning environment, and engage in professional developments. The second domain, core

knowledge, refers to six areas to support teaching and learning: an understanding of subject, appropriate methods of teaching and learning, understanding of how students learn, use of appropriate learning technologies, methods for evaluating teaching effectiveness, and quality assurance and enhancement. The third domain, professional values, refers to core values that support teaching and learning: respect of individual learners, promotion of participation, evidenced-informed approaches, and wider contexts acknowledgement. The UKPSF plays a vital role in enhancing the quality of teaching and learning in higher education. By providing a structured and comprehensive framework for professional development, it supports educators in delivering high-quality education and fostering a positive learning experience for students. Because the open university manages KM learning in a highly diverse learning environment, the UKPSF is an appropriate framework. The UKPSF supports professional development for academic and non-academic staff, knowledge sharing and collaboration, usage of technology in KM, and the achievement of expected learning outcomes of the open university program.

3. Methods and Methodology

3.1 Population and Key Informants

The research population is comprised of lecturers who joined the UKPSF KM Program at Sukhothai Thammathirat Open University, which included 40 persons in 2022. Since this research focuses on the school of management science, the key informants are five lecturers from school of management science at STOU who successfully earned accreditation and a fellowship or a senior fellowship with the UKPSF in the first quarter of 2024.

3.2 Research Instruments

A semi-structured questionnaire was developed for this study concerning the KM practices and processes of UKPSF accreditation to propose a model to expand this practice further in other academic schools or universities with similar settings. All questions were reviewed by three subject matter experts to ensure content validity, passing an index of Item Objective Congruence (IOC) threshold score higher than 0.5. All questions received a score of one.

3.3 Data Collection

The data was collected through unstructured face-to-face interviews with five lecturers from school of management sciences who joined the KM program and could successfully earn UKPSF accreditation.

3.4 Data Analysis

After transcribing the recorded interview audio and validating the transcripts, I identified common themes that emerged across the interviews and coded the data accordingly. Following this, I summarised the findings according to each theme and identified key quotations from the informants. I then drew final conclusions according to the research objective.

4. Results

4.1 STOU KM Process

From the in-depth interview with lecturers who participated in the KM it was found that STOU relies heavily on their human capital to deliver quality education to a diverse student population. The research found that STOU placed a strong emphasis on KM and streamlined the whole process through a dedicated department of human resources development for KM learning, which became the center of excellence for KM. The center is involved in assessing development needs, providing new staff induction, teaching and learning capability enhancement, and allocating special funds for individual and team development. There two targets group of KM initiatives: academic staff and non-academic staff. The focus on these two groups is distinct, such that academic staff's KM goal is to enhance teaching and learning design and execution for online or KM learning environments, while non-academic staff needs to possess service skills to support students in the form of communication, customer service and technology guidance. The goal for both target groups is to enhance organisational learning to promote a culture of continuous learning and collaboration among academic and non-academic staff to deliver

best-in-class KM education to students. Since there are various initiatives for both groups, this article will focus on the KM initiatives for academic staff, specifically the case from the faculty members at the school of management science, the largest academic school in STOU by number of students, as well as academic staff.

As one of its key management initiatives over the past three years, the university has supported the school of management science to train 12 academic staff on the UK professional standards framework and get certified with appropriate levels of teaching and learning design experiences (associate fellowship, fellowship, senior fellowship and principal fellowship). This framework is proven to develop staff on the knowledge, skills, and values required for effective teaching and learning in higher education. The university has worked closely with this business school to execute KM, which the school has expanded upon by linking KM with the practical design and implementation of teaching and learning for lecturers. Based on my interviews with the key informants, I conceptualise effective digital teaching and learning KM for open universities as a four-step model, consisting of a technology-based training program, the creation of a community of practice, omni-channel mentorship programs, and assessment and certification of lecturers.

Step 1: Developing a Technology-Based Training Program. The kick-off training program aligns the UKPSF with KM processes and covers an introduction to the three dimensions of the UKPSF discussed above (areas of activity, core knowledge, and professional values) to ensure all lecturers understand the framework and its application in their practices. At STOU, training sessions were delivered through interactive workshops by senior lecturers who acquired senior fellowship status with practical activities, case studies, and group discussions to facilitate active learning and engagement. The participants were required to actively participate in the quizzes and teaching and planning writing activities. The participants reported that the session is very work-intensive yet inspiring. This is evident from the following participant quotes:

"I now have a clearer grasp of the different dimensions of teaching and learning, and how they interconnect with each other."

"The session helped me gain a deeper understanding of how effective teaching and learning practices should be in higher education in the context of open education."

"This kick-off session inspired my passion for continuous learning and professional growth. I am eager to develop my teaching skills to be a better teacher, aligned with the visions and missions of STOU to be the leading open university in the world."

"I learned how to design more engaging and inclusive learning experiences for my students with diverse backgrounds."

To support the learning of the participants, the training utilised e-learning modules and knowledge repositories in the form of a digital library, soft files, and video for specific topics/episodes, such as key steps to apply for UKPSF accreditation, the three UKPSF dimensions, and how to apply the UKPSF to the open university. that allow participants to review before the session and revisit after the session. The participants reported that these resources support their teaching and planning autonomy since they could not capture 100% of the content during the face-to-face training. These repositories are easily accessible and searchable, allowing lecturers to find relevant resources quickly through STOU e-services, such as intranet and Microsoft Team virtual rooms to facilitate communication and collaboration among participants. These platforms enhance the training experience through knowledge sharing, discussions, and peer support. This approach aligns with the UKPSF's emphasis on teaching and learning activity. Lecturers in STOU develop teaching and learning through writing self-study textbooks that must facilitate independent learning and cater to the unique needs of distance learners. The content must comprehensively cover all necessary information, explanations, and examples to enable students to learn independently. This means that the lecturer requires unique competency in analyse backgrounds of learners before designing the self-study textbooks. The textbook is supplemented with e-learning modules on STOU's Moodle LMS, online tutorials and workshops, and real-life case studies for students. To link the UKPSF with teaching and learning tasks in an open university context, subject matter experts ran a series of online snippet videos and workshops on writing a self-study textbook, preparing e-learning for students, conducting online tutorials, utilising educational technology, and developing effective formative and summative assessments. One of the most popular workshops for lecturers is how to use Class Point, an online engagement technology plugin to support learning and engagement, as well as using AI-based tools for education.

Step 2: Creating Communities of Practice. Communities of practice are groups of lecturers who share a similar interest and field of expertise to learn how to improve their teaching and learning through regular interaction. The CoPs are planned with regular (mainly virtual) meetings to discuss experiences, share insights, and provide

support among lecturers and guided by the master mentor who has achieved senior fellowship in the prior year. Some CoPs were organized during the afternoon as virtual coffee breaks where lecturers gather to discuss their teaching and learning practice where best practices were being shared to the rest of team as the inspiration. Participants reported they felt inspired by their peers' examples of new techniques with impressive results. This CoPs becomes the support system and source of comfort since they feel safe to share their concerns and ideas with the community. Apart from learning though their experiences, lecturers can also learn from their peer experiences to avoid some mistakes that could happen if they follow the same path.

"Through the community, I have been able to enhance my teaching skills, learn more about flipped classroom and project-based learning to apply for business management students."

"When I face challenges or problems or even doubts in my teaching, I know I can turn to the community for help and encouragement."

"I learnt from my peers that students may not turn on their camera during an online course because of their anxiety or discomfort with being on a camera."

"I adopted the new ways of supervising my MBA student dissertation with a weekly flipped classroom workshop with my students, helping them to progress with their research faster."

"I am new to STOU and have never written a self-study textbook before and I got peer guidance on the whole process from researching for a reference, preparing outlines, writing style, and pre- and post-test creation."

The CoPs support peer learning, where lecturers can learn from each other's experiences, case studies, common challenges, and collaboratively develop practical solutions on teaching and learning. This approach aligns with the UKPSF's emphasis on collaborative learning and professional values. In the CoPs, there is a master mentor and instructional design and technology experts who can provide guidance, answer questions, and share advanced knowledge. This access ensures that the learning is both deep and broad, covering all aspects of the UKPSF. During the CoP session, lecturers are encouraged to critically reflect about their practices via online reflective journal Microsoft team to document their experiences, challenges, and insights related to the three UKPSF dimensions. These journals can be shared within the CoPs, contributing to collective knowledge.

Step 3: Establishing an Omni-Channel Mentorship Program. Because effective mentorship supports professional development and knowledge transfer, STOU established a mentorship program aligned with the UKPSF that pairs mentors and mentees. These pairings consider compatibility in terms of subject matter, teaching style, and professional goals. The mentor is a senior lecturer with more than 5 years of experience who has been qualified at the minimum fellowship status. The mentee will be paired with a mentor in a related field in the subcategory of business management. The mentorship program is designed to provide a seamless experience through multiple channels, enhancing flexibility in terms of appointment scheduling and technology such as Line (the most popular social media platform in Thailand), Microsoft Teams, in-person discussion, and resource support in the form of videos and digital documents to cater to the diverse needs and preferences of lecturers in the program. The mentorship program can happen with a mix of face-to-face and online to suit the convenience and availability of mentor and mentee, but the only condition is that mentee should agree on the topic of discussion with pre-readings before the session to make it effective for both. The mentorship programs focus on providing support on teaching and learning practices of the participants and resolving some struggles or issues with empathy and co-created solutions. Sometimes, mentees invited mentors to join and observe their teaching class to provide comments and rooms for improvement. The mentorship program resulted in faster career progression and effective reflective practices, as evidenced by the following responses:

"Weekly meetings with my mentor have provided a structured space to reflect on my teaching experiences, critically analyse my methods, and identify areas for improvement. This mentorship process has helped me become more self-aware and proactive in seeking feedback from students and colleagues to continuously enhance my teaching effectiveness."

"I systematically evaluate my instructional strategies, assessment methods, and student engagement techniques in light of the framework's guidance."

"I have developed the habit of maintaining a reflective journal, documenting my teaching experiences, challenges faced, and lessons learned. This process lifted me up when I felt down and struggles with learning design issues."

Step 4: Assessing and Certifying Lecturers. This final step in the KM process focuses on the assessment and certification of educators under the UKPSF, which requires lecturers to develop portfolios that demonstrate their engagement with the UKPSF dimensions. These portfolios should include evidence of their activities, reflections, feedback, and any other relevant materials. The draft will be sent for internal peer review among certified senior lecturers. This robust process aims to improve teaching and learning, as well as reflective writing, with the goal of creating a safe learning environment for lectures to improve themselves. This helps improve the structure of participants' writing and allows them to develop their teaching and learning portfolio before submitting to UKPSF. Once the final version is ready, it will be sent to UKPSF to review and assess before certified under the appropriate category of the UKPSF (Associate Fellow, Fellow, Senior Fellow, Principal Fellow). This certification acknowledges their commitment to teaching excellence and professional development. Apart from getting the accreditation from UKPSF, the improved teaching and learning among participants resulted in a significantly higher passing rate of students, with 90% of research-based graduate students finishing their degree as planned with great results, as well as an increase in student satisfaction (4.5 out of 5.0) in key areas. A best-practices case of organising entrepreneurial marketing bootcamps was recognised and published in tier 1 Thai Journal called ThaiJo to disseminate the entire learning plan to the academic community.

5. Conclusions

The results of this study on STOU's teaching and learning KM demonstrate the efficacy of the UKPSF for organizing and replicating the KM process. However, the context of open universities is different from other universities; there is a need to customise KM processes to meet UKPSF requirements. Open university KM processes must also be flexible enough to meet the needs of diverse participants from different academic fields. Digital KM processes are especially critical to improving KM accessibility and flexibility. As a result, I propose the following four-step model for the effective organisation of digital KM for open universities, which can also be applied to other universities: Step 1: Developing a Technology-Based Training Program, Step 2: Creating Communities of Practice, Step 3: Establishing an Omni-Channel Mentorship Program, and Step 4: Assessing and Certifying Lecturers. Because KM continues to evolve, these steps can be enacted as an ongoing, circular process. This will help ensure that academic staff can continuously improve their teaching and learning to align with the mission and vision of the university. The primary contribution of this study to the field of KM is the proposed application of KM to enhance teaching and learning in the higher education context via the proposed digital teaching and learning KM model depicted in Fig 1.

Analysis of the Effectiveness of Technological KM Tools in the SME Sector Using the DEA Model

Dariusz Wielgórka
Częstochowa University of Technology, Faculty of Management, Częstochowa, Poland

dariusz.wielgorka@pcz.pl

Abstract: Knowledge management has emerged over the past decade as one of the key issues at the heart of modern organisations. The Industrial Age has been replaced by the Knowledge Age. It is a time when strategic management of knowledge and resources is a critical success factor for the organizations. Good Knowledge Management (KM) practices can equip the organizations to be more innovative and provide better integration and sharing of knowledge, which is the basis for starting new organizations or revitalizing mature organizations. The issue of knowledge management is primarily considered in the context of large organisations. In contrast, relatively little attention has been paid in the literature to the specifics of knowledge management in small and medium-sized enterprises. Small and Medium Enterprises (SMEs), the backbone of the economy, significantly benefit from KM practices. The operation of modern organizations in the SME sector requires constant adaptation of management methods and development strategies to new economic conditions. This is particularly important in the process of digital transformation, which has been making significant transformations in the area of economy for a few years now. This also applies to the issue of knowledge management in business organizations, which can be considered in the area of organizational structures, business processes, personnel, organizational culture, but also ICT technologies supporting this management. Advanced ICT solutions for knowledge management, understood as the systematic and organized use of its resources to improve the functioning of the organization, implemented within the framework of process orientation, come to the rescue. The article implies a research method based on a non-parametric DEA model, in particular CRS, identifying inputs and outputs and used to study the effectiveness of using technological tools for knowledge management in enterprises operating on the Polish SME market. In the literature, there is no use of the DEA method to study the effectiveness of technological tools for knowledge management in companies in the SME sector. The research objective of the article is to analyse the effectiveness of the use of technological tools for knowledge management in enterprises operating on the Polish SME market. The study was carried out using the non-parametric DEA method, which is based on a two-factor concept - technical efficiency (TE), meaning the ability of a company to produce maximum output (effects) for a given level of inputs, and allocative efficiency (AE), which in turn means that a company can use inputs in optimal proportion to individual prices (input costs). After analysing all possible inputs and effects, it was assumed that the following factors have a primary impact on the individual efficiency of technological KM in the SME sector: sales revenue, number of computer workstations, net profit included in effects, and fixed assets in the form of IT equipment, intangible assets in the form of software and the number of employees using technological KM tools included in inputs. Data for the survey was obtained using the CATI method among 600 randomly selected SMEs operating on the Polish market.

Keywords: Knowledge Management KM, SME, Technological Tools KM, DEA Model

1. Introduction to Technological Tools KM in SME Enterprises

The micro, small and medium-sized enterprise (SME) sector plays an important role in all economies around the world (Barroso, Ferreira, Meidute-Kavaliauskiene, Banaitiene, Falcao, Rosa, 2019). In Poland, there are 2.4 million non-financial enterprises, defined as active enterprises, of which 99.8% are enterprises included in the SME group (according to data for 2021 of the Polish Central Statistical Office (GUS). In recent years, entrepreneurship in Poland has been characterised by three distinct trends. Firstly, over the last few years it can be seen that the entrepreneurship of Poles is not waning. The number of enterprises is growing dynamically. Secondly, the quality of Polish entrepreneurship is improving. Polish companies as a group are contributing more and more to social welfare. The data show that they produce an increasing proportion of Polish GDP. The average company is growing steadily in economic terms. Its productivity, as measured by revenue, added value and production, is increasing. Trends also point to an improvement in the structure of companies from the point of view of legal forms. The share of companies as legal entities is increasing and that of physical persons is decreasing. Thirdly, the openness of entrepreneurs and their orientation towards growth is increasing. Companies, although still too seldom, are internationalising more and more - the proportion of exporters and the average value of exports are systematically increasing, as well as the use of the advantages of an online presence. Polish companies are also investing more and more and developing and implementing innovations, although the scale of development activities is still not high.

In the most general manner, knowledge management (Pritchard, 2010) is defined as a management method, the basic aim of which is the unconventional development of competitive advantage (Glabiszewski, Sudolska, 2009) by contemporary operating enterprises, including non-profit organisations (Perechuda, 2005). The great supporters of the knowledge management concept are T.H. Davenport and S.C. Völpel, who pointed out,

however, that knowledge management primarily plays an important role in improving methods of creating new knowledge, and then in its proper dissemination and use (Davenport, Völpel, 2001). Another definition of knowledge management is proposed by P. Murray and A. Myers, who presented it as a sum of processes enabling the creation, dissemination and use of knowledge, in order to achieve the goals set by the organisation (Ahmad, JianMing, Rafi, 2019) (Strojny, 2000). Knowledge management was also characterised by D.J. Skyrme, who described it as a precise and systematic management of knowledge resources and the related processes of creating, collecting, disseminating and using knowledge to ensure the organisation's proper functioning (Skyrme, 1999). Providing the right conditions to support the implementation of such a system into an organisation depends largely on a number of factors, among which the following stand out: adequate resources, the right management system and organisational structure (Liczmańska-Kopcewicz, 2017), appropriate organisational culture and communication, and a properly designed organisational strategy. For this reason, knowledge is still a resource that, when properly used, can contribute to a given company's competitive advantage in the market (Centobelli, Cerchione, Esposito, 2017) (Bamel, Pereira, Bamel, Cappiello 2021).

Knowledge in small and medium-sized enterprises cannot be created according to the same procedures as in large organisations, which results from the small potential in terms of human resources, capital, technology and development. The knowledge management system should prevent the loss of knowledge possessed by the organisation, but should also create knowledge within the existing resources. This system must be an attempt at a holistic approach to organisational phenomena and processes. The management of an organisation must independently create a knowledge management system in its organisation, adapted to the specifics of the enterprise and its human and financial capabilities. An attempt to comprehensively implement knowledge management in an SME must, taking into account the scale, cover such areas as the IT system, organisational culture and employee management. The functioning of modern SME organisations requires constant adaptation of management methods and development strategies to new business conditions. This is particularly important in the process of digital transformation, which has been making significant transformations in the area of the economy for some years now. This also applies to the issue of knowledge management in business organisations, which can be considered in the area of organisational structures, business processes, personnel, organisational culture, but also in the area of ICT supporting this management. This means that under conditions of extreme competitiveness as part of the digital transformation, the management methods used so far, which are aimed often aimed solely at ensuring stability and predictability. With help comes advanced ICT solutions for knowledge management (Preuss, Cordoba-Pachon ,2009), understood as systematic and knowledge, understood as a systematic and organised use of its resources to improve the functioning of the organisation, realised within the framework of the process orientation by (Unold, 2015):

- knowledge location and acquisition,
- collecting knowledge and processing it,
- its enrichment and sharing.

The knowledge management system consists of the following elements:

- knowledge management strategy - indicating priorities for action, defining the role of knowledge management in the process of achieving the organisation's strategic objectives,
- people and organisational culture - the willingness of employees to share knowledge, supported by organisational culture,
- business processes - the process orientation of the organisation to effectively collect, share and retrieve knowledge,
- information and communication technologies - these provide users with information and communication technologies - these provide users with effective collection, processing and sharing of data (transformed into information and further into knowledge).

In practical terms, this means the need for modern ICT solutions for knowledge management, enabling the support of business processes business processes as part of gaining and strengthening competitive capabilities. During evolution of the information society towards a knowledge society it boils down to treating modern enterprises as intelligent organisations intelligent. An intelligent organisation is one that bases its operating philosophy on the management of knowledge (Waltz, 2003). The term became widespread in the 1990s. due to the development of ICT, the dynamically changing economic environment and increased market competitiveness. An intelligent organisation is an organisation learning organisation, which has the ability to create, acquire, organise and share knowledge, use it to improve the efficiency of its operations and sharing it, using it to improve operational effectiveness and increase competitiveness in the global market. The idea of

such an organisation is based on a systemic approach to the organisation, i.e. treating it as a complex organism based on existing structures and implemented processes with particular emphasis on the role of knowledge. Attributes of smart organisations include (Beckford, 2016), (Grösser, Zeier, 2012), (Schwaninger, 2010):

- speed and flexibility of action,
- the ability to observe the environment,
- the ability to diagnose market signals early and respond to changes in the environment,
- the ability to quickly implement new knowledge-based solutions and thereby achieve the economic benefits.

The classification of tools supporting knowledge management due to the ambiguity of the terms causes many difficulties. In fact, the very definition of a "technological tools" in the knowledge management process is difficult to classify and raises many questions. Both the tools themselves and the functionalities they possess are not easy to classify. Many times the nomenclature of tools overlaps with the nomenclature of functionalities, and the functionality of a tool dedicated to one process is provided by another tool. In addition, technological trends are moving towards flexible tool design tools allowing a given tool to be used for multiple purposes depending on the depending on the concept of the organisation in question. Mechanisms to support knowledge management are based on three core technologies: database, network and web technology. Database technology - understood as the technology associated with the physical and logical structuring and storage of data. From a technological point of view, it is based database mechanisms and programming language systems. Network technology - understood as a set of network connections, mechanisms responsible for the coordination of all processes related to data exchange. This technology consists of two layers: a first hardware layer realised through. The first layer is hardware, implemented by servers, network connections and a number of tools related to synchronisation of the network synchronisation, and the second layer represented by software designed to implement the above-mentioned activities. Web technology - understood as a technology combining database technology. Web technology is implemented through websites and any mechanisms related to the representation of data on websites. The Websites present data, information, knowledge from various sources, often accumulated in many databases and files, sources, which are often combined in multiple databases and files. By means of web technology on websites equipped with the appropriate applications the web technology provides tools to share information and knowledge. Web technology provides tools for a range of knowledge management processes, such as: knowledge sharing between experts, discussion forums experts, discussion forums, corporate portals and many others. However, it is important to remember that the foundations of web technology most perceived by users are database technology and network technology.

Each of the aforementioned technologies enables the implementation of multiple knowledge management functionalities. Many times, knowledge management tools are based on all three technologies.

2. Methodology - Characteristics of an Efficiency Study Using the DEA Model

No studies of the effectiveness of using technological tools for knowledge management in the SME sector were found in the literature. However, a combination of DEA and KM approaches has been noted. Kuah and Wong used a two-level DEA model to measure the performance of Malaysian universities in relation to KM factors (Kuah, Wong, 2013) while Shirouyehzad, Rafiee, Berjis considered KM and safety management criteria as inputs and customer satisfaction and accident rates as outputs of a DEA model to evaluate the performance of 12 automotive companies in Esfahan (Shirouyehzad, Rafiee, Berjis, 2017). However, some studies can be found in which DEA has been applied to select, improve or evaluate Six Sigma projects. In the literature we also find the use of the hybrid DEA technique for the selection of six sigma projects (Hadi-Vencheh, Yousefi, 2018) (Wen, An, Xu, Chen, 2018). In the literature, we will also encounter the PCA-DEA approach to investigate the impact of the six sigma extension on key work characteristics in the automotive industry (Azadeh, Nasirian, Salehi, Kouzehchi, 2017). Therefore, the implication of the DEA method to study the effectiveness of technological tools for knowledge management in the SME sector is an important contribution.

Efficiency analysis using the non-parametric DEA method is based on a two-factor concept, with technical efficiency (TE) (Lang, Welzel, 1996), meaning the firm's capability to produce maximum output (effects) at a given level of inputs, and al-locative efficiency (AE) (Rogowski, 2008) meaning that the enterprise can use inputs in optimal proportion to individual prices (input costs). It is often used to study efficiency (Tavares 2002). The combination of TE and AE gives total economic efficiency (EE) (Sikora, Kulczycki, 2009). In the case of the concept of technical efficiency introduced by Farrell, the difference between the stated level of production of

the enterprise and the limit of its actual production capacity is taken into account (Welzel, 1996). Deviation from an efficient production plan means that the pro-duction of the outputs of a combination of inputs (the results obtained) could have been achieved with less input, which means a waste of resources (Welzel, Lang, 2005). The technical inefficiency caused by this fact increases in proportion to the distance from the effective production limit (Sheldon,1994). An important element in the study of corporate efficiency is the evaluation of economies of scale. Failure to take advantage of existing economies of scale results in efficiency losses for the enterprise (Wielgórka, 2008). From a general point of view, economies of scale illustrate the response of the level of outputs to a proportional increase in inputs. In the case of economies of scale, the quantity of outputs produced increases relatively faster than the level of inputs, which means that unit costs fall. In the opposite case, i.e., declining economies of scale (diseconomies of scale), unit costs rise as the level of outputs rises. In the situation of fixed scale effects, despite the increase in the number of outputs, the cost of producing one unit of outputs remains unchanged (Gospodarowicz, 2000). The DEA method makes it possible to determine the presence or absence of scale effects. Proponents of non-parametric methods, including the authors of the DEA method, are based on the concept of productivity, defining a measure of productivity as the quotient of a single output and a single input. By having one input (x) and one output (y), one can obtain an efficiency curve. This curve contains a set of objects with inputs (x) and outputs (y) that achieved the maximum possible outcomes, given a specific level of inputs. All combinations of inputs and technologically possible outputs lie between the OX axis and the efficiency curve (production frontier), i.e. the input-output relationship curve. DEA was developed specifically to over-come the drawbacks of parametric analyses, by evaluating efficiency based only on avail-able data on the magnitude of inputs and outputs without having to determine their functional relationship, which is very difficult when the number of factors is large. The units under evaluation in DEA are called decision-making units (DMUs) and a DMU is considered to be efficient when no other DMU can produce more outputs using an equal or lower amount of inputs (Ebrahimnejad, Tavana, Nasseri, Gholami, 2019) (Maleki, Ebrahimnejad, Kazemi, 2019). What makes the difference in DEA models is the concept of RTS. In the case of constant RTS, the CRS model will be used. Meanwhile, in terms of variable RTS, the BCC model should be used. Since recognizing the RTS is a long-term procedure, there is a need to collect data from different periods and analyze them (Amani, Valami, Ebrahimnejad, 2018), and regarding the limitations on data collection (we only were allowed to collect data in one period) we were not able to determine the RTS. Objects are considered technically efficient if they are on the efficiency curve, while those that are below the efficiency curve are technically inefficient. Decision making units (DMUs) are the objects of analysis in the DEA method. The main focus of the analysis is the efficiency with which a DMU transforms inputs into outputs. The relationship be-tween the efficiency of a given object and its maximum efficiency achievable under given technological conditions is taken as a measure of technical efficiency. Depending on model orientation, either input-oriented technical efficiency or output-oriented technical efficiency is calculated. The first point in evaluating efficiency using DEA is to define the ap-propriate technology that provides a baseline for the measurements to be made. For this purpose, a set of n decision making units that produce s outputs using m inputs is considered. For each DMU, the input and effect vectors are labelled and, respectively, with x > 0 and y > 0, which means that each decision making unit is assumed to have at least one input and one effect. The production technology thus defined:

$$T = \{(X,Y) : X \geq \sum_{j=1}^{n} \lambda j Xj, Y \leq \sum_{j=1}^{n} \lambda j Xj, \lambda j \geq 0\}$$

is subject to four fundamental assumptions [72]:

1) convexity - when (Xj, Yj) ε T, j - 1, ..., n, and λj ≥ 0 are non-negative scalars such that:

$$\sum_{j=1}^{n} \lambda j = 1$$

, then

$$(\sum_{j=1}^{n} \lambda_1 X_1, \sum_{j=1}^{n} \lambda j Yj) \in T$$

2) inefficiency

- when (X, Y) ε T and then

- when (X, Y) ε T and , then

3) constant economies of scale

- when $(X,Y) \in T$ (kX, kY) ε T for each k > 0

4) of minimum extrapolation, i.e. the condition that the technology must contain all possessed combinations of inputs and outputs.

The development of alternative DEA models has changed some of the assumptions.

In particular, the assumption of constant economies of scale was questioned in the further development of the methodology. The primary model of the DEA method is a non-linear (index) form, containing the weighted sums of inputs x and outputs y for a given DMU. The task of the model is to maximize this quotient assuming that it cannot be greater than 1 for any other decision making unit:

$$\max h_o = \frac{\sum_{r=1}^{s} u_r y_{ro}}{\sum_{i=0}^{m} v_1 x_{1o}} \qquad ST: \frac{\sum_{r=1}^{s} u_r y_{rj}}{\sum_{i=1}^{m} v, xi_j}$$

j = l, …, n; ur,; vi ≥ 0, r = 1, …, s; i l, …, m

After transformations, the normal linear form is obtained:

max Zo

$$ST: -\sum_{j=1}^{n} Y_{rj}\lambda_j + Y_{r0}Z_0 \le 0$$

$$\sum_{j=1}^{n} X_{ij}\lambda_j \le X_{10}$$

$$\lambda j \ge 0$$

r - l, …, s; i - l, …, m; j - l, …, n

Subsequent modifications result in a form of the basic input-oriented CRS model:

$$\min \Theta_0$$

$$ST: \sum_{j=1}^{n} x_{ij}\lambda_j \ge y_{r0}$$

$$X_{10}\Theta_0 - \sum_{j-1}^{n} x_{ij}\lambda_j \ge 0$$

$$\lambda j \ge 0, j = 1,\ldots,n$$

This model is designed to minimize the input demand up to the efficiency limit so that an input efficiency ratio is obtained. When the value of the coefficient is = l, the DMU is fully effective, which is expressed by the 100% transformation of its inputs into outputs. A proportional reduction of inputs is not an option in this case as it would imply a simultaneous loss of efficiency. A score lower than one suggests that the unit is inefficient, as it wastes (1-)*100% of inputs.

In economic terms, the technical efficiency (TE) of the enterprise, calculated by solving the CRS model refers to the situation of the presence of constant economies of scale. This means that a proportional increase in inputs entails a proportional increase in outputs. Companies aim to determine the volume of production at which costs reach the lowest possible level. In the long run, the efficiency curve will approach the shape of the curve with constant economies of scale.

3. Research on the Effectiveness of Technological KM Tools in the SME Sector Using the DEA Model

The research problem is the implication of the DEA method for assessing the effectiveness of the use of technological tools for knowledge management in companies operating on the Polish SME market. The implementation of this non-parametric method requires the definition of inputs and effects and then subjecting these factors to efficiency analysis. After analysing all possible inputs and effects, it was assumed that the following factors have a primary impact on the individual efficiency of technological KM in the SME sector: sales revenue, number of computer workstations, net profit counted as effects, and fixed assets in terms of IT equipment, intangible assets in terms of software and number of employed people using KM technological tools counted as inputs.

A comprehensive survey based on an interview questionnaire, classified as quantitative research, was conducted in 2022. Interviews were conducted with owners, co-owners and persons responsible for management in the segment of SME companies in Poland, from various industries. The survey involved 600 randomly selected SME companies operating on the Polish market, of which 40% were micro-enterprises employing up to 9 people, 30% small entrepreneurs employing up to 49 people and 30% medium-sized entrepreneurs employing up to 249 people. The structure of the survey was weighted to the structure of companies in Poland according to the regon database operator (Central Statistical Office). The research sample prepared in this way enables data analysis at the level of the entire SME population in Poland. The survey was conducted using the CATI (Computer Assisted Telephone Interview) method in 2022. This is one of the methods of collecting information in quantitative research.

Table 1: CRS TE performance measure statistics in the analysis of the effectiveness of technological KM tools in the SME sector from 2017 to 2021

Statistics CRS TE	2017	2018	2019	2020	2021
Standard deviation	0,17	0,19	0,17	0,19	0,20
Minimum value	0,20	0,19	0,23	0,24	0,22
Number of effective SMEs	228	246	258	288	294
Number of ineffective SMEs	372	354	342	312	306
% Effective SMEs	38%	41%	43%	48%	49%

The CATI survey was conducted using a special programme that assisted the caller to the respondent throughout the interview. The interview questionnaire consisted of a core part (essential questions) and a metric (classification questions). The core part of the questionnaire was designed to obtain information about knowledge management in SMEs. The questionnaire contained information about the surveyed enterprises: number of employees, revenue, balance sheet total, legal form, type of activity according to PKD, period of activity, official position of the person completing the questionnaire. One of the stages of the comprehensive study was to assess the effectiveness of the use of technological tools for knowledge management in enterprises operating on the Polish SME market using a non-parametric DEA model, in particular the CRS model assuming the presence of fixed economies of scale.

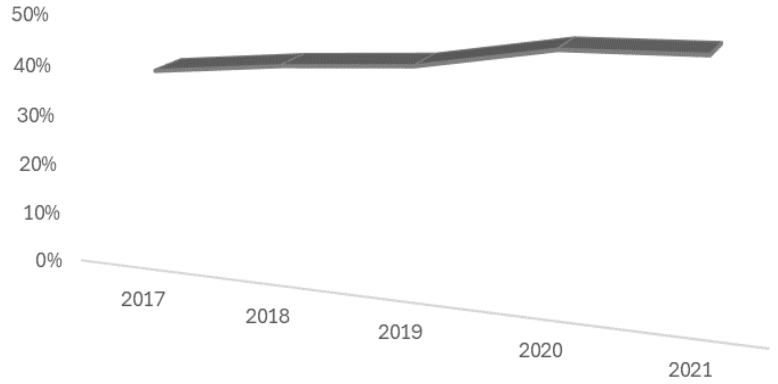

Figure 1: Level of SMEs effectively using technology tools for knowledge management 2017-2021

Measures derived from the estimation of input-oriented models will determine the ratio of the actual output of the SME to that which the SME should have had if it had effectively used the same amount of inputs. Over the period studied, the total number of efficient SMEs effectively using technological KM tools is increasing, which is a positive development (Figure 1).

By estimating the CRS model, technical efficiency (TE) can be calculated, which determines the possible amount of inputs that can be used under given technological conditions to produce at least the same amount of products. In 2021, only 49% of SMEs were effectively using technological KM tools (Figure 2).

In particular, the number of effective enterprises (i.e. effectively using technological tools for knowledge management) increased in the group of small and medium-sized enterprises reaching 52% and 63% of the total surveyed entities, respectively. In the microenterprise group, the number of effective entities represented only 32% in 2021. It should be inferred that larger companies in the SME group make more effective use of technological tools for knowledge management.

4. Conclusion

The research conducted investigated the implications of the non-parametric DEA method for quantifying the effectiveness of the use of technological tools for knowledge management in the SME sector.

The estimation of the DEA model in the area of efficiency coefficients that each SME could achieve ranged from 0 to 1. A coefficient value equal to 1 indicates an efficient SME, while an efficiency coefficient value lower than 1 indicates that the SME in question has room for improvement in the input-output ratio of technological KM tools. During the 2017-2021 period under review, it is important to note an increasing trend in the number of effective SMEs using technological KM tools. The increase in the number of effective SMEs is mainly related to the growing role and awareness of knowledge utilisation in SMEs. However, the lowest level of effective use of technological tools for knowledge management was noted in the microenterprise group. Larger enterprises in the SME group make more effective use of technological tools for knowledge management.

The effective use of technological knowledge management tools in SME companies plays a very important role today. It facilitates and streamlines organisational processes, supports business processes, shapes organisational culture by changing rules, forms, habits of cooperation and communication. Digital solutions are also helpful in building relationships with customers, enabling feedback on the quality of service or purchase preferences. There is huge potential in the SME sector, especially in the group of micro-enterprises which, lacking strong financial backing, are unable to meet the demands of the market. Therefore, it is important to build a financial support programme for SMEs, especially micro-enterprises, to increase the use of technological tools for knowledge management, which will improve the competitive position of this sector. The implication of the DEA method will allow it to be further used in subsequent studies on knowledge management in the SME sector.

Optimizing Educational Opportunities using AI to Ensure Accessibility at Public Sector Institutions in Poland

Anna Wiśniewska-Sałek
Czestochowa University of Technology, Częstochowa, Poland

anna.wisniewska-salek@wz.pcz.pl

Abstract: The use of artificial intelligence in education is a logical consequence of the potential it represents. The solutions offered by AI to eliminate barriers, e.g. for people with special educational needs, provide real help in communicating with them. However, the potential often does not equal the opportunity. It is necessary to check whether the environment in which AI solutions will be implemented is actually prepared for its application/use. The article indicates the main directions of AI development in education by analyzing the types of disabilities among learners. Finding real needs will allow you to optimize opportunities (using AI) for equal access to education. Public institutions were subjected to additional examination. Its aim is to check their actual digitization status, which creates the foundation for implementing modern solutions.

Keywords: Education, AI, People With Special Needs, Accessibility.

1. Introduction

The Constitution of the Republic of Poland adopted in 1997 (Constitution of the Republic of Poland, 1997) guarantees the right to education in Poland. It is provided by Article 70, which refers to, among others, having the right to education, while maintaining its compulsory education until the age of 18. It defines education in public institutions as free and emphasizes the obligation to ensure universal and equal access to education, which is guaranteed by public authorities while maintaining the autonomy of higher education institutions on the principles set out in the Act. Another legal document relating to education in Poland is the Act of December 14, 2016, Education Law (2023). Respects the principles contained in:

- the Constitution of the Republic of Poland,
- Universal Declaration of Human Rights,
- International Covenant on Civil and Political Rights
- Convention on the Rights of the Child.

The structure of the school, special units and counseling facilities and centers are described in Article 2 of this Act, while Article 4 in sections 2 and 3 defines a special unit, section 3 characterizes an individual educational and therapeutic program and section 4 organization of education and upbringing for special education. The special unit is intended for pupils with a certificate of need for special education and is described as a form of education (with reference to Article 127): "Special education covers children and youth who are disabled, socially maladjusted and at risk of social maladjustment, requiring the use of special organization of learning and methods of work. The global dimension of the issue of special education had its original place in the United States Congress in 1975: Public Low 94-142, 94th Congres, Education for All Handicapped Children Act of 1975 (Public Law 94-142, 1975).

In Poland, in accordance with the Education Law (Education Law, 2023), compulsory schooling (7 years) is preceded by one year of pre-school preparation (in the age of 6 years), and then the obligation to study until the age of 18, mainly in secondary schools. The education system also includes: educational and upbringing facilities, continuing education facilities, artistic institutions, psychological and pedagogical counseling centers, youth educational centers, institutions providing care and upbringing for pupils, teacher training institutions, pedagogical libraries, and colleges of social service workers. The stages of education also include in their structures special, integrated, with pre-school integration, special classes, job training, bilingual, sports and sports championship units/schools/kindergartens. Education is generally available, but only in the context of the absence of administrative barriers. In accordance with the Regulation of the Minister of National Education (2023) on the principles of organizing and providing psychological and pedagogical assistance in public kindergartens, schools and institutions, announced on September 5, 2023, the director of the educational unit is responsible for the organization of psychological and pedagogical assistance. (which is related to the limited budget, e.g. for eliminating architectural barriers). As a result, this forces young people with disabilities to choose a place of education depending on the degree of need for special education, and thus, to some extent, to choose, for example, a special school rather than an integrated school. Paragraph 2 of the above-mentioned regulation

specifies the situations qualifying a pupil for psychological and pedagogical assistance in a kindergarten, school or institution: 1) disability, 2) social maladjustment, 3) risk of social maladjustment, 4) behavioral or emotional disorders, 5) special talents, 6) specific learning difficulties, 7) deficit of competences and language skills disorders, 8) chronic diseases, 9) crisis or traumatic situations, 10) educational failures, 11) environmental neglect related to the living situation of the pupil and his family, the way of spending free time and environmental contacts, 12) adaptation difficulties related to cultural differences or changes in the educational environment, including those related to previous education abroad. In order to obtain the right to benefits ensuring equal access to education, a decision on the need for special education must be obtained, pursuant to Article 127 point 18 Education Law (2023).

2. Literature Review

2.1 Inclusive Education

The 1994 Salamanca Declaration recognizes the idea of inclusive education, and the definition of integrational education in the second chapter emphasizes the need to ensure that people with special educational needs have the opportunity to learn in traditional schools where teaching is tailored to their needs. This is an important step towards ensuring equal educational opportunities for all pupils and promoting social integration (UNESCO and Ministerio de Educación y Ciencia, 1994). Inclusive education aims to ensure that every student has equal opportunities for education, regardless of possible limitations such as disabilities or other attributes. The desire to ensure that everyone can benefit from education in a way tailored to their individual needs is the foundation of this approach (Florian, 2014). Inclusive education aims to create a more inclusive and tailored learning environment in which all pupils have equal access to learning and the opportunity to develop their skills. Through integration, the educational system aims to promote understanding, tolerance and acceptance among pupils, which contributes to creating a more diverse and friendly school community (Sharma et al, 2021; Moosa et al, 2022). Although it offers many benefits, integration education faces several obstacles, such as teacher shortages, lack of training for educators, and negative attitudes towards pupils with disabilities. Both pre-school and professional teachers' attitudes toward integration education are crucial to its effectiveness because they have a significant impact on the implementation and robustness of integration practices. Additionally, teachers' attitudes can shape relationships, activities, and teaching methods that directly impact all pupils, including those with special needs (Soeharto et al, 2024; De Boer et al, 2011).

Research conducted by (Unianu, 2013) clearly indicates the need to improve teachers' competences in the field of integration and promote good practices in this field. The quality of education is closely related to the quality of teachers' work, therefore it is crucial to introduce the principles of integrative teaching and develop strategies to support each pupil in achieving educational success. Adapting the teaching process to the individual needs and capabilities of pupils is a key element of optimizing the educational process. Inclusive education is crucial to ensuring equal opportunities and support for pupils with disabilities. This requires the involvement of teachers who have the appropriate knowledge and skills to adapt their teaching methods to the individual needs of pupils (Marimuthu and Cheong, 2015). The lack of an implemented practice of integrated education necessitates the need to take difficult actions to identify barriers and develop appropriate measures that will allow the development of such a model at all levels of the education system. Current efforts focus primarily on primary education, but it is important to expand these practices throughout the system to provide a more comprehensive, inclusive education that is an essential element of an inclusive society (Dimov et al, 2014). Monitoring the academic progress of Children With Disabilities (CWD) in inclusive classrooms is a key aspect of assessing the effectiveness of UN inclusion education policies. Understanding how CWDs achieve outcomes in low- and middle-income countries is important to achieving the goal of providing all children with high-quality primary education by 2030. It is important to ensure that education systems are equitable and appropriately responsive to the needs of children with disabilities, in line with the principles of the UN Convention on the Rights of Persons with Disabilities (Diaz-Sarachagaet al, 2018). However, there is a long-standing debate about whether people with disabilities underperform academically compared to their peers who study in integrated schools (McCoy and Banks, 2012). Researchers agree that pupils with severe disabilities can develop their academic, social and independence skills in an inclusive setting. This integration allows them to participate in the everyday life of the school and community, which contributes to their comprehensive development and greater acceptance by peers (Kurth et al, 2002).

2.2 AI in Education

Modern technologies such as Big Data, Machine Learning and Artificial Intelligence (AI) are used in global education systems, enabling a more personalized and student-centric approach. Thanks to these innovations, the modern education system is better able to meet the individual needs of pupils, which is a significant improvement compared to the often criticized traditional approach (Bhutoria, 2022). Thanks to the ability to analyze data and detect patterns, AI systems can optimize learning paths, tailoring content and teaching strategies to pupils' specific skills and preferences, which contributes to a more effective education process (Zhang and Begum, 2021). The development of education using artificial intelligence opens up significant opportunities for personalized learning for future generations, and the emerging challenges can no longer be underestimated. Issues related to data privacy, availability of digital resources, and accessibility limitations constitute significant obstacles that require attention and solutions for the effective implementation of AI technologies in educational practice (Ivanova et al, 2024).

Personalization of education is consistent with the practical solutions approach to teaching, because it is based on collected data regarding individual skills and needs of pupils. By analyzing this information, the educational system can adapt content and learning methods to specific requirements and goals, which in turn promotes a better learning process. Therefore, it is a practical approach based on research and evidence of the effectiveness of personalization in education (Yonezawa et al, 2012). Personalization in education has a long history and is crucial to effective teaching. Adapting content, activities and interventions to the needs of specific students aims to better understand problems and tailor the teaching process to individual needs, which can lead to better educational outcomes and pupil development. A thorough analysis of pupils' situations and needs is therefore a fundamental part of a personalized approach in education (Hwang et al, 2020). Artificial intelligence is playing an increasingly important role in innovative education systems, enabling interactive learning tailored to the individual needs of pupils. The use of modern tools supported by AI, such as virtual reality or intelligent teachers, allows for personalization of the teaching process and ensuring more effective knowledge transfer (Kabudi et al, 2021). In this context, there is growing interest in integrating artificial intelligence into educational systems to increase their efficiency and quality. Previous literature highlights the lack of research on AI in the context of education as a significant limitation and suggests the need for further research and practical implementation of AI technology in the education sector (Bhutoria, 2022). The integration of artificial intelligence in teaching is currently a dynamically developing field that is attracting more and more interest and investment due to the rapid development of AI technology and advances in education. Bibliometric research on this topic is becoming increasingly important to understand and track this dynamic process and innovation in the field of AI-powered education (Nja et al, 2023; Sajja et al, 2023; Farrelly and Baker, 2023; Bran et al, 2019; Nguyen et al, 2023).

As the education system evolves, there is a need to continually evaluate research and trends in education to adapt teaching methods to meet the needs of pupils. The integration of artificial intelligence technologies may prove to be a key factor in increasing the efficiency of the learning process and ensuring a personalized approach to learning. It is important to track these changes and adapt teaching programs to the new challenges that arise in the digital era (Dogan et al, 2023).

3. Characteristics of People With Special Needs in Polish Regions

The analysis of dynamics was carried out on the basis of data published by the Statistics Poland (Education, 2012; Local Data Bank, 212). The time scope of the study covered the years from the 2012/2013 school year to 2022/2023. The subject of the study are children with special educational needs studying in primary school (age range is 7-14 years) and young people attending secondary schools: general education profile (age range is 15-19 years) and technical secondary school (age range is 15-20 years). The research process used dynamics measures [9] to determine the direction and intensity of changes among pupils with selected types of disabilities over a 10-year period, broken down by school type, compared to the level from the previous period or the level adopted as the baseline (2012/2013).

Characteristics of the data used in the study (legend for charts 1, 2, 3 and table 1):

- Types of disabilities:

A-deaf;
B-hard of hearing;
C-blind;
D-vision impaired;
E-with impaired motor skills including aphasia;
F-with intellectual slight disability;

G- with autism including Asperger syndrome;
H-with multiple disability;
I- socially maladjusted;
J- -threatened with social maladjustment.

- Types of schools:

Primary-pupils with special educational needs by type of disability in primary schools;
General-students with special educational needs by type of disability in general secondary schools;
Technical-students with special educational needs by type of disability in technical secondary schools.

- Voivodeships in Poland:

DŚ: Dolnośląskie Voivodship;
KP: Kujawsko-Pomorskie Voivodship;
LB: Lubelskie Voivodship;
LS: Lubuskie Voivodship;
ŁD: Łódzkie Voivodship;
MP: Małopolskie Voivodship;
MZ: Mazowieckie Voivodship;
OP: Opolskie Voivodship;
PK: Podkarpackie Voivodship;
PD: Podlaskie Voivodship;
PM: Pomorskie Voivodship;
ŚL: Śląskie Voivodship;
ŚK: Świętokrzyskie Voivodship;
WM: Warmińsko-Mazurskie Voivodship;
WP: Wielkopolskie Voivodship;
ZP: Zachodniopomorskie Voivodship.

3.1 Analysis of Dynamics According to the Division Into Types of Disabilities

Figure 1 shows the medium-term rate of change according to selected types of disabilities in Poland, broken down by type of school in the analyzed period.

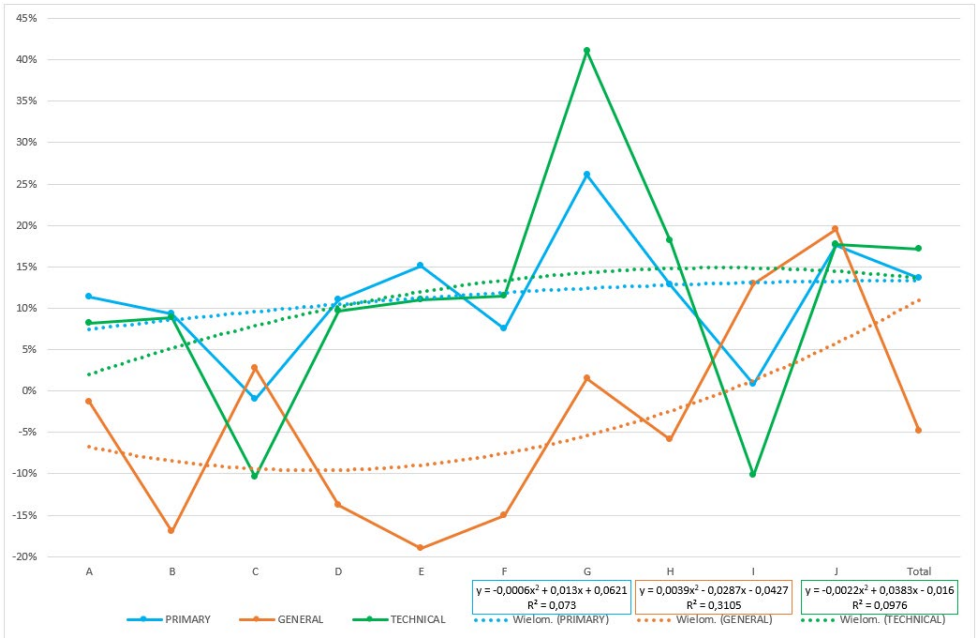

Figure 1: Dynamics of changes by types of disabilities and types of schools in 2012-2023

The dynamics analysis shows that the largest medium-term increases in the number of people diagnosed with autism spectrum disorders (including Asperger's syndrome) are in the group of school children and in the group of young people attending technical schools. The scale of changes in the case of this type of disability is analogously at the level of +912% and +4289% in the 2022-2023 school year compared to the base year (2012-

2013). In turn, the stable dynamics (increases and decreases at the level of the medium-term rate of change of 1%) covers blind people and people with a diagnosis of social maladjustment (for children aged 7-14) as well as deaf people (for young people aged 15-19). The size of these changes concerns a reduction by 18 in the number of blind people and by 168 in the number of people diagnosed with social maladjustment in primary schools (although in the case of social maladjustment, the medium-term rate of change was positive). In the technical secondary school, the decrease in the number of deaf people was 14.3%, which is 20 people (compared to the base year). In Fig. 1, a clear similarity can be seen in the nature of the dynamics of changes according to the types of disabilities for school children and youth in technical secondary schools. Here, the annual changes are in most cases positive. In turn, young people attending general schools show decreasing dynamics every year. One can also notice the relationship between the types of disabilities - those that record declines in the first group discussed show increases in the second group and vice versa. The basic indicator for examining the structure of people with specific types of disabilities is the same for the analyzed population of people aged 7-20 in the period after 2017. Since the 2017-2018 school year, the domination of autism judgments (including Asperger's syndrome) has been visible in all types of schools examined. In turn, in the five years preceding this period, motor disabilities (including aphasia) were most often diagnosed among young people (15-19 and -20), while among children attending primary school, mild intellectual disabilities were mostly diagnosed.

3.2 Analysis of the Dynamics of People With Disabilities - Administrative Division

Analysis of changes in the total number of people with disabilities in Poland, broken down by voivodeships and types of schools in 2012-2023, calculated using the medium-term rate of change (Figure 2).

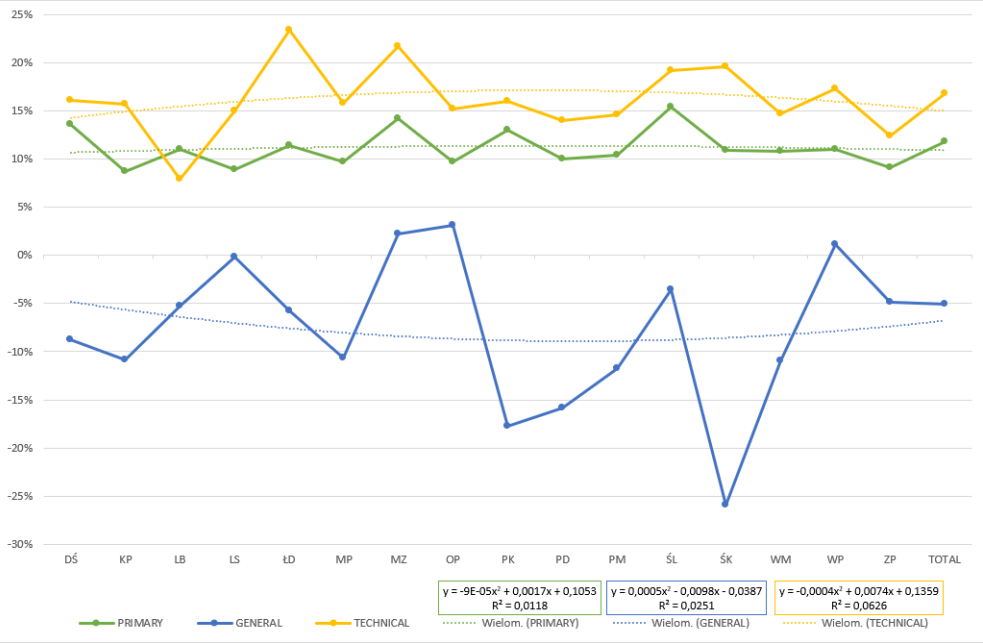

Figure 2: Dynamics of changes in people with disabilities by voivodeship in the analyzed period

The analysis of Polish regions in terms of the discussed types of disabilities allows us to notice similar relationships as in the case of study 3.1. The group of people aged 7-14 and 15-19 shows similar changes in dynamics (annual increases in the number of people with disabilities in individual voivodeships). In turn, the group of young people studying at technical secondary schools records a decline in dynamics and greater fluctuations for a given region in Poland. The highest positive dynamics of changes for primary schools and technical secondary schools occurs in the Mazowieckie and Śląskie Voivodeships (16,370 and 12,279 people with disabilities compared to the base year for primary schools and 1,323 and 1,291 for technical secondary schools, respectively). Youth aged 15-19 recorded the highest dynamics (compared to the base year) in the Pomorskie Voivodeship, and the highest average annual increases in the Mazoweckie Voivodeship (the number of people was -229 and +169, respectively). The analysis of the structure of the population of people requiring special educational needs showed that the largest share in Poland has the population of people learning in the Mazowieckie Voivodeship (on average 14%) and in the Śląskie Voivodeship (on average 12%).

3.3 Analysis of People With Disabilities Compared to Their Peers

The table below shows the percentage of the median of people with disabilities in the total number of people in the same age group in Poland, divided into voivodeships.

Table 1: Analysis of the median age structure

Polish region	Population in age group		
	aged 7-14	aged 15-19	aged 15-20
PL: Poland (total)	1,60%	0,18%	0,15%
DŚ	1,40%	0,20%	0,14%
KP	1,93%	0,19%	0,20%
LB	1,23%	0,14%	0,11%
LS	1,48%	0,17%	0,15%
ŁD	1,24%	0,17%	0,12%
MP	1,25%	0,12%	0,09%
MZ	1,78%	0,26%	0,16%
OP	1,67%	0,16%	0,18%
PK	1,51%	0,16%	0,17%
PD	1,56%	0,17%	0,20%
PM	1,86%	0,26%	0,15%
ŚL	2,05%	0,19%	0,22%
ŚK	1,44%	0,18%	0,17%
WM	1,97%	0,22%	0,21%
WP	1,31%	0,11%	0,11%
ZP	1,66%	0,19%	0,10%

The results of the share of people with disabilities in the total number of their peers indicate that in the Warmińsko-Mazurskie Voivodeship there are the most people in the age group of 7-20 years who require special educational needs, and the fewest in the Małopolskie Voivodeship. The analysis also shows the difference between children and adolescents. The median number of young people with disabilities is in the tens and hundreds, while children number in the thousands. For example, the lowest and highest numbers of people along with the corresponding voivodeship:

- children aged 7-14: min. 1187 (OP); max. 7911 (MZ);
- youth aged 15-19: min. 75 (OP); max. 685 (MZ);
- youth aged 15-20: min. 93 (LS); max. 539 (ŚL).

The analysis of the number of children in Poland in general shows that the highest median number of children is in the Mazowickie Voivodeship and the lowest in the Lubuskie Voivodeship, regardless of the division into children or youth.

4. Accessibility of Public Entities in Poland

Accessibility testing allows you to diagnose whether a facility/institution supports people with disabilities in their functioning in society. In Poland, the Accessibility Plus Program (APP, 2018-2025) has been implemented since July 2018, which is implemented in parallel with two acts: the Act of April 4, 2019 on the digital accessibility of websites and mobile applications of public entities (Journal of Laws “UDC”, 2019) and the Act of July 19, 2019 on ensuring accessibility for people with special needs (Journal of Laws “UzD”, 2019), obliges (mainly) public entities to conduct their activities in the digital sphere (including websites and mobile applications), architectural (including buildings free from barriers, horizontal and vertical communication spaces) and information and communication (including PJM translator, alternative access). The aim of such activities is to enable the use of the services of a given institution/entity, so that people with various types of disabilities (this also applies to people who are temporarily in a situation requiring support, such as pregnant women) can use them on their own.

The accessibility analysis was carried out on the basis of data published by the Ministry of Funds and Regional Policy in the "Report on the status of ensuring accessibility for people with special needs by public entities in Poland" (Report, 2021), presenting the status of accessibility of the surveyed entities as of January 1, 2021. The time range was as of January 1, 2021, but no later than March 31, 2021. The data was obtained using an electronic report form, which was made available on the reporting portal of the Statistics Poland. The acquired data were standardized to facilitate their comparison and interpretation, using the so-called accessibility index. This measure is expressed on a scale from 0 (no requirements met) to 1 (full fulfillment of requirements), and the percentage of elements that make up the whole (percentage of requirements met for the unit) expresses partial accessibility assurance or the percentage of units meeting the requirements for a given characteristic.

Characteristics of the data used in the study (legend for charts 3 and 4):

- Voivodeships in Poland (as specified in point 3 of the article).
- Types of accessibility indexes:

A-Accessibility;

A(Inf/Com)-Information and communication accessibility index;

A(Dig)-Digital accessibility index;

A(Arch)-Architectural accessibility index.

- Types of entities (schools):

A-Edu: Average accessibility index for Education;

Ns: Nursery schools;

Ps: Primary schools;

P-ps: Post-primary schools;

HEdu: Higher education.

4.1 Accessibility Index

Figure 3 presents the results of the analysis of the state of ensuring accessibility for people with special needs by public entities in Poland, broken down by region.

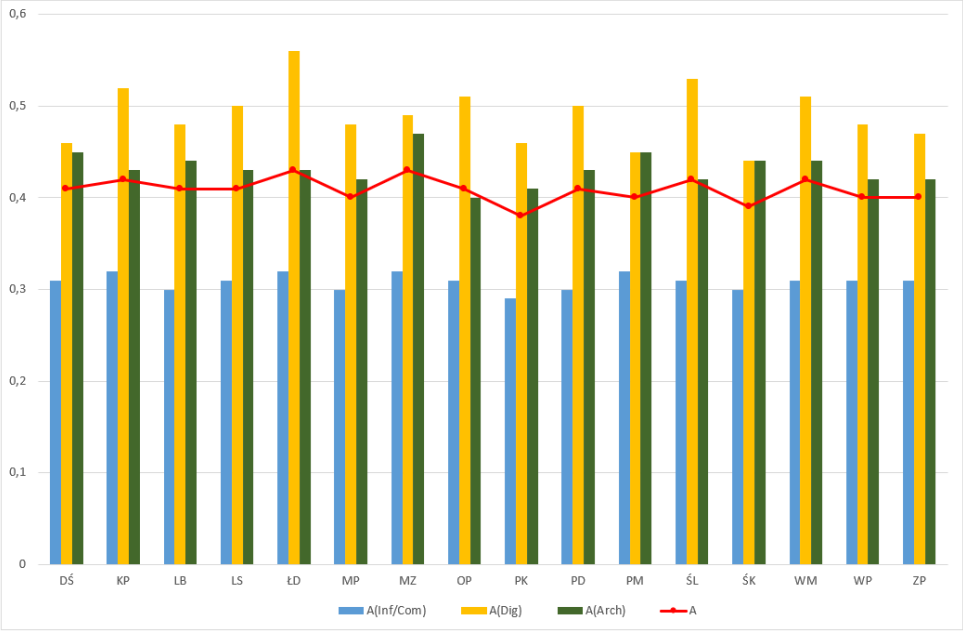

Figure 3: Level of accessibility of public entities located in Poland by voivodeship

The analysis of the accessibility index in public entities shows their small contribution to improving the everyday functioning of people with disabilities. Public institutions in Poland meet the minimum accessibility

requirements in accordance with the Act on ensuring accessibility for persons with special needs (UzD) at an average level of 40%. The requirements belonging to the information and communication group are the lowest met, at the level of 30%, and the highest (less than half on average) are the digital requirements. The Łódź and Mazowieckie Voivodeships are the leaders in the ranking of the overall accessibility index, while the Podkarpackie Voivodeship is at the bottom of the ranking. The Łódź Voivodeship also has the highest index in terms of digital accessibility and communication support. Architectural requirements are at the level of the average national indicator in general, and entities in the Mazowieckie Voivodeship are best adapted.

4.2 Digital and Information and Communication Accessibility Index in Education

The analysis of accessibility in the educational system in Poland, divided into types of schools, is presented in the chart below (Figure 4).

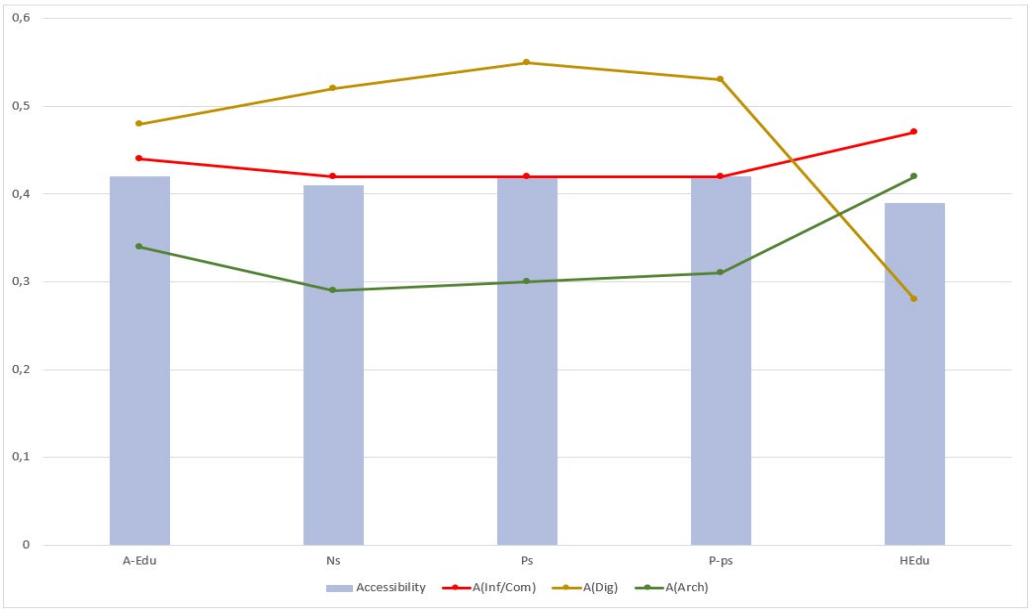

Figure 4: Level of accessibility in educational system institutions in Poland

The analyzed public entities directly related to education show an accessibility index of 0.4 on average, which is close to the national level. The highest ranking index is related to the website and mobile applications, which are compliant with the accessibility requirements specified in the UDC for kindergartens and schools. Public higher education units, unlike pre-school and school education, have a low digital accessibility rate. However, they show a proportionally higher indicator of architectural and information and communication accessibility.

4.3 Optimizing Education

Education to bring results to young people in the form of knowledge and skills is a challenge for both teachers and pupils themselves. Educating pupils with special educational needs is an even more difficult task for both parties, because very often the types of disabilities require dedicated tools and skills to educate them appropriately. However, thanks to technological progress that has led to the development of artificial intelligence, the possibilities of support for such students are increasing. This technology is already present in many aspects of our lives, and using it to assist in special education is an opportunity to optimize access to education. The use of advanced algorithms allows you to adapt the methods and pace of work to the pupil's needs, which creates the opportunity to take care of the child individually, without fear of exceeding his or her physical or intellectual abilities. The Government Education and Science Portal in Poland (ESP, 2023) on its website describes ChatGPT as one of the tools based on artificial intelligence that can support people:

- with visual impairments - no need to browse the websites, which often do not meet accessibility standards;
- with disabilities of the upper limbs - giving up the use of special keyboards, extending the time of searching for often scattered data;
- deaf people - shortening long texts that are difficult to translate into sign language
- with dyslexia - appropriate text reformatting;

- with intellectual disabilities - learning artificial intelligence to present data in the form of ETR (easy to read),
- sensitive to stimuli - removing barriers in browsing websites, such as distracting banners, widgets, or the so-called pop-ups) – all this effectively makes it difficult for people who are sensitive to stimuli to browse the website.

Artificial intelligence can also be helpful in a teacher's work (Czechowska, 2024):

- adapting teaching programs to individual difficulties through non-standard ideas for personalized tasks and materials, e.g. Khan Academy, Bing Chat, ScribeSense, Socratic by Google;
- supporting communication by using appropriate systems or applications, e.g. Replika, Cleverbot, Wordwall, Otter.ai, Braina;
- earlier detection of learning difficulties thanks to the analysis of test results or pupils' work, e.g. IBM Watson Education, immersive reader, DreamBox, One Note;
- support for remote learning by providing materials for homework, e.g. Chrome extensions, Quizizz, easy-to-read and understand texts ZPE or PSONI, Miro, Canva.

Professor Fazlagić (2022), in his publication describing the use of artificial intelligence in the education sector, reviews it according to subcategories:

- supporting the learning process;
- teacher support in administrative processes;
- management of the education system.

The teaching process can support the teacher by using artificial intelligence as a tutor in basic education, providing feedback on learning progress and knowledge/skill deficits, and replace it in consolidating the explained material, e.g. by departing from the standards in situations where the selected area requires improvement by, for example, increasing the intensity of testing tasks in the areas. This solution also allows for the elimination of social or emotional barriers, which are reflected, for example, in stress related to public ridicule resulting from a knowledge deficit. Artificial intelligence can support teachers in their administrative duties by performing automated (in whole or in part) assessment of learning outcomes or attendance. It may also, to some extent, act as a methodological advisor or provide feedback about the pupil to his or her parents/guardians. The administrative dimension itself can also be considered from the perspective of education management, where artificial intelligence verifies the criteria for professional advancement achieved by a teacher, or analyzes data sets affecting the quality of teaching or the education system itself.

5. Conclusions

The conducted research allows for a preliminary diagnosis of the situation of people with a judgment on the need for special education in Poland. Over the last 10 years, a relationship (similar dynamics of change reflected in the quantitative dimension of the study) can be observed between primary and general education, comparing them to the results of technical schools. In this context, there is a noticeable relationship with regard to the highest percentage of annual increases in disability resulting from diagnosed autism, including Asperger's syndrome, and the highest changes in dynamics observed in the region of the Mazowieckie and Śląskie Voivodeships. In turn, for pupils attending technical secondary schools, the highest average annual changes concerned the diagnosed risk of social maladjustment and the highest changes in the Mazowieckie and Pomorskie Voivodeships.

The analysis of time series in terms of their share in the structure of the studied population showed that the largest number of people diagnosed with the need for special education are in the Mazowieckie and Śląskie Voivodeships. However, the division by type of disability highlighted a breakthrough in 2017, after which all surveyed groups showed the highest share of people diagnosed with autism (including Asperger's syndrome). Before 2017, the disability of young people aged 15-19 and 15-20 resulted from the jurisprudence of motor disability (including Aphasia) and for pupils aged 7-14 from the jurisprudence of mild intellectual disability. Compared to peers in the context of the age group, the highest percentage of people with disabilities is among school children, and in the administrative context of the country in the Mazowieckie and Śląskie voivodeships.

Comparing the above research results with the analysis of accessibility, i.e. adapting the architectural, communication, digital and information infrastructure to the needs of people with disabilities, it can be noted that a small share of the accessibility index in Poland at the level of 40% (the highest is in the Łódź and

Mazowieckie Voivodeships) should meet the needs of a seemingly small percentage of people with a certificate, approximately 3% of the surveyed population. In the context of educational institutions, this indicator compares best with digital, which, in the perspective of the use of artificial intelligence in education (including special education), creates the possibility of equal access to education for all. Assuming that the development of education using the possibilities offered by artificial intelligence (both for healthy people and people with disabilities) will take place only among people aged 7-20, it can be estimated that this will allow for the elimination of barriers and equalization of opportunities in access to forms of education tailored to needs.

When building a long-term education strategy, the general situation of the country should also be taken into account, i.e. in the case of Poland, it is an aging society. Related activities aimed at activating seniors, or even the concept of lifelong learning, constitute a direction for further research on whether the accessibility requirements met at the current level will meet the needs of an ever-growing social group.

A Cross-Disciplinary Knowledge Management Framework for Generative Artificial Intelligence in Product Management: A Case Study From the Manufacturing Sector

Aron Witkowski and Andrzej Wodecki
Warsaw University of Technology, Warsaw, Poland

aron.witkowski.dokt@pw.edu.pl
andrzej.wodecki@pw.edu.pl

Abstract: This paper presents a cross-disciplinary knowledge management framework designed to enhance the integration of Generative Artificial Intelligence (GenAI) in product management within the manufacturing sector. The framework focuses on designing, monitoring, and optimizing the business value of GenAI solutions by leveraging best practices from both knowledge management and artificial intelligence engineering disciplines. The study highlights the use of LLMOps methodology for continuous monitoring and multi-agent approach for continuous improvement. The research employs a qualitative case study methodology, focusing on a leading large international manufacturing firm that has implemented GenAI solutions in its product management. The study involves interviews with stakeholders and document collection and analysis. This case study contributes to the literature by providing a structured approach to incorporating GenAI into product management in the manufacturing sector, facilitating cross-disciplinary knowledge sharing. The study advances the understanding of using cross-disciplinary knowledge management framework for advanced AI applications in business projects and encourages further research. The framework serves also as a guide for manufacturing firms aiming to implement advanced AI providing actionable insights for designing, monitoring, and optimizing the business value of GenAI solutions. It underscores the potential of academic researchers as catalysts in such projects and proposes a method for continuous knowledge transfer and improvement through a knowledge flywheel.

Keywords: Knowledge Management, Generative Artificial Intelligence, New Product Development, Cross-Disciplinary Collaboration, Product management, Manufacturing

1. Introduction

Generative Artificial Intelligence (GenAI) plays a noticeable role in different industries, as evidenced by its potential in automating tasks, delivering novel goods, services or business models and generating valuable new content (Daugherty et al., 2023; Kanbach et al., 2024; Przegalinska and Jemielniak, 2023; Reznikov, 2024) The integration of GenAI in product management can potentially enhance innovation and streamline processes. Generative AI, particularly through large language models (LLMs) like the generative pretrained transformer (GPT), augments product processes including ideation, digital design and prototyping or product marketing (Bouschery et al., 2023; Bulut and Mahmoud, 2023; Choi et al., 2023).

The manufacturing sector, facing intense competition and the need for differentiation, can benefit from the integration of GenAI solutions in the product management process. Not only processes but also products undergo changes - one of the critical issues though in the manufacturing industry is the increasing difficulty in achieving hardware-based innovations (Smith, 2013). As a result, companies are shifting their focus towards additional services and connected products to maintain a competitive edge (Parida et al., 2014; Porter and Heppelmann, 2015). GenAI models can also be helpful here, but they come with their own challenges - hallucinations, data drift, ethical issues, and others, making it difficult to determine the business value of a GenAI (Bandi et al., 2023; Kalam et al., 2024; Samuelson, 2023).

This shift necessitates the development of new competencies among different stakeholders involved in product management to design and monitor the real business value generated by GenAI-driven solutions. Product managers must acquire certain new skills to effectively oversee the implementation, optimization and business evaluation of advanced AI-driven solutions. Data scientists, aiming to maintain the quality of GenAI models, must keep track of the latest solutions. However, the heavy workload and project overload often faced by product managers, IT engineers or data scientists pose challenges to acquiring these new competencies.

Therefore, the successful implementation of GenAI solutions requires a robust framework that supports the design, monitoring, and optimization of these technologies' business value. This framework can leverage best practices from knowledge management to ensure that the integration of GenAI not only enhances product management but also contributes to continuous learning and improvement within organizations. In the upcoming sections, we will explore a variety of insights and observations, primarily based on a case study of a leading manufacturing company, highlighting different facets of the relationship between knowledge

management, generative AI and product management. These insights will shed light on the challenges and opportunities encountered when integrating advanced AI solutions into product management processes and the importance of multidisciplinary teams in overcoming these challenges. We will examine the importance of communication and collaboration among various stakeholders, the necessity of aligning business goals with technology objectives, and the influence of emerging technologies on the development of new products. Finally, we will emphasize the lessons learned from these observations and their implications for both practitioners and researchers in the realms of knowledge management, generative AI and product management.

2. Business Value From Generative Artificial Intelligence for Product Management

In this section we focus on the Generative Artificial Intelligence (GenAI) solutions impact on the product success. There are numerous activities in which GenAI can support the product management process. Sentiment analysis and opinion mining are useful for generating new product ideas and designing products. GenAI solutions such as BERT, GPT, LSTM, and N-gram language models often form parts of larger sentiment analysis solutions (Li et al., 2023). These are used, for example, to identify important elements in user-generated content (Wang and Liu, 2023), improve opinion mining through text and emoji fusion (Sai et al., 2023), or detect fake news about products (Peng and Xintong, 2022). Tools like ChatGPT can also generate product ideas and often do so more effectively than humans (Bouschery et al., 2023). GenAI can also be applied to text summarization in various contexts, enhancing recommendation systems by integrating summaries from online reviews (Benham et al., 2022). In product design and development across different industries, GenAI solutions facilitate tasks such as fashion design (Choi et al., 2023), cosmetic color scheme development (Zhang et al., 2023) and bionic-inspired biomedical engineering (Deng et al., 2023). They also aid in IT system design (Van Bossuyt et al., 2023), user interface design (Gupta et al., 2024), and game development (Colado et al., 2023). GenAI also supports product quality control and defect detection, generating new artificial data and reducing testing time, cost and TTM (Time-To-Market) (Morizet et al., 2023). Generative AI solutions are also effective in product marketing and the optimization of products processes. In marketing, GenAI is used for creating targeted advertisements and generating keywords (Bulut and Mahmoud, 2023), as well as in the automatic generation of promotional videos, which significantly streamline the creation of marketing content (Ooi et al., 2023). Additionally, they support customer service by providing potential recommendations for products and services (Sun et al., 2023). GenAI solutions are also effective at the intersection of product management and knowledge management, enhancing the functionality of product databases (Abadi et al., 2023; Niemir and Mrugalska, 2023). These benefits of GenAI integration can only be fully realized if the implementation of GenAI is managed effectively, using appropriate methodologies and evaluation methods.

2.1 Product Success Evaluation Methods

When evaluating product success, two key aspects need consideration: the factors contributing to success and the measurement of success. General product success factors identified in the literature include innovative value, strategic approach, high-quality product development processes, market research, customer focus, and maintaining skilled employees with the necessary resources and infrastructure (Soltani-Fesaghandis and Pooya, 2018). McKinsey (2021) identified several categories that distinguish high-performing AI organizations from others, including clear AI solution management models, team skill development programs, and practical training for non-technical staff. Additionally, factors such as design thinking in developing AI solutions, harmonized data processes, and regular updates and understanding of AI models play a distinct role in the successful implementation of AI in product management.

When it comes to the measurement of success, evaluating the business value of GenAI solutions is crucial for understanding their impact on product success. Three primary evaluation methods can be used: statistical methods, business methods, and experimental methods. Each of these methods has its impact in assessing GenAI models:

Statistical Methods: Common evaluation metrics for generative models include Fréchet Inception Distance (FID) and Inception Score (IS), although these can be prone to biases and may not always provide accurate comparisons between different models (Bandi et al., 2023; Chong and Forsyth, 2020).

Business Methods: These methods focus on the actual impact of GenAI solutions on business processes and product success. Metrics include Key Performance Indicators (KPIs) such as product revenue, process efficiency or product quality, which are more aligned with business objectives.

Experimental Methods: Used to assess the real business value post-deployment through A/B testing or surveys/qualitative interviews and other experimental designs that compare the performance of GenAI-driven solutions with existing methods.

Overemphasis on one area can lead to an unbalanced focus, causing some issues. A predominance of statistical methods may result in evaluations that do not align with business needs or are not easily understood by business stakeholders. A predominance of business method may lead to an overload of business metrics, complicating GenAI model training, evaluation, validation, and experimentation. A predominance of experimental approaches can create challenges in formulating business cases based on historical data and in the training process.

2.2 Lack of Appropriate Methodology

As commercial GenAI solutions are still in their relatively early stages, there is no comprehensive set of guidelines for managing GenAI-based products tailored to specific products or sectors. Bosch, Olsson, and Crnkovic (2018) highlight that AI development is still in its infancy in many of the organizations they have studied, and they foresee a considerable amount of work needed to define systematic and repeatable methods for creating, developing, and maintaining systems using AI solutions. This implies that when introducing GenAI into the process, the organization should have a clear understanding of its goals, which may require a discussion about the organization's maturity in that area.

To address these challenges, continuous monitoring and adaptation of GenAI models are necessary. One potential solution is the implementation and maintenance of the models based on a feedback loop strategy, which helps product managers create less prescriptive product roadmaps and make more data-driven and AI-based decisions (Gurkan and de Véricourt, 2022). Techniques such as LLMOps (Large Language Models Operations) for continuous monitoring and multi-agent approach for ongoing improvement can be helpful in that area.

LLMOps involve the methodologies, strategies, and tools employed for the effective management and maintenance of large language models in production settings. LLMOps is essential for managing the complex lifecycle of LLM development, which includes data ingestion, prompt engineering, model fine-tuning, deployment, and monitoring. It ensures collaboration across teams and maintains operational rigor. LLMOps differ from traditional Machine Learning Operations (MLOps) by addressing the unique needs of managing LLMs. Key considerations include the substantial computational resources required for training and fine-tuning LLMs, often necessitating specialized hardware like GPUs. LLMs typically use transfer learning from foundation models, and human feedback, including reinforcement learning, is crucial for their performance. The development of LLM applications also frequently emphasizes constructing pipelines, created using tools like LangChain or LlamaIndex that integrate multiple calls with external systems, instead of developing new LLMs from scratch (Kulkarni et al., 2023; Shi et al., 2024).

An AI multi-agent system is a decentralized network consisting of multiple intelligent agents capable of sensing, learning, and acting independently to accomplish objectives. Agents utilize their interactions with nearby agents or their environment to learn new contexts and actions. They then apply this acquired knowledge to make decisions and take actions within the environment to accomplish their assigned tasks. Driven by artificial intelligence, these systems exhibit essential features such as flexibility that enables it to effectively address problems across different industries (Dorri et al., 2018; Shamshirband et al., 2013).

3. Knowledge Management Framework for Designing, Monitoring and Optimizing the Business Value of Generative Artificial Intelligence Solutions in Product Management

This chapter builds upon established principles of knowledge management and product management, integrating insights from previous research and best practices to create a comprehensive framework tailored for GenAI in product management.

3.1 Competency Framework

A successful implementation of GenAI solutions in product management necessitates a multidisciplinary team with a diverse set of competencies. Drawing from the competency profiles discussed in (Wodecki, 2023), the framework identifies four key competency groups: business (senior management and/or product managers in that case), data science, experiment design, and information technology. Each role within the project - ranging

from business representatives to data scientists and IT engineers - requires a unique blend of these competencies:

T-shaped Competencies: Business representatives should have deep business knowledge complemented by skills in data science and IT, allowing them to effectively plan business cases, monitor project execution, and manage business value comprehensively.

Pi-shaped Competencies: Data scientists need in-depth skills in data science and a robust understanding of business and software engineering. Experiment design skills are also crucial, forming a second vertical bar in their competency profile.

M-shaped Competencies: Either product or project managers must possess a wide array of horizontal competencies, including product management, project management, change management, and business acumen, along with vertical competencies in data science, IT, and experiment design.

Individuals involved in the project, including business owners, data scientists, IT engineers, and product/project managers, should possess a balanced mix of T-shaped, Pi-shaped, or M-shaped competencies. The success of the project depends on the effective flow of knowledge from these areas, both within the current project scope and by utilizing experiences from similar past endeavors. Imbalances in these skill sets can lead to errors in evaluating the business value of GenAI solution. Our observations reveal that while data science and IT competencies are gradually becoming widespread in mature organizations, expertise in experimental design and implementation remains a challenge for many. Therefore, as part of the knowledge management framework, it is beneficial to consider including external individuals in the team, such as representatives from academia. These individuals can introduce new ideas, methods, and techniques, and provide fresh perspectives on the problem, ultimately enhancing the quality of the solution. Moreover, mature experimental design and implementation methods from the scientific community can help address competency gaps in this area.

3.2 Knowledge Management Processes

The integration of Generative Artificial Intelligence (GenAI) solutions into product management projects involves different aspects of knowledge management, from knowledge creation to sharing and application. GenAI integration projects have distinct characteristics and potential as rich sources of knowledge. Methods for capturing, organizing, storing, and sharing knowledge are explored to provide insights into effective strategies for managing knowledge in this context. The integration of GenAI solutions in product management projects generates valuable knowledge due to their unique nature, addressing diverse business challenges with varied methods and technologies. Knowledge is created throughout the project, often during meetings, milestone summaries, documentation, and experimental results interpretation. Different methods such as automatic tagging, topic modeling or semantic embeddings are employed for knowledge organization. For storing knowledge, advanced methods like prompt retrieval, document embeddings, or pretrained generative model weights are suggested. Efficient knowledge sharing and application depend on accessible interfaces, and the use of conversational interfaces based on generative technologies can address the issue of scattered documents across various locations.

All the aforementioned processes can be evaluated in terms of their maturity, i.e., higher maturity of these processes can facilitate easier integration of GenAI solutions in product management. Different frameworks can be used to assess an organization's maturity in this area. For example, the CLIMB framework (Rossi and Terzi, 2017) is used to evaluate best practices in product management. The model was designed using a combination of theory-driven and practitioner-based approaches. The CLIMB model comprises five maturity levels (Chaos, Low, Intermediate, Mature, Best Practice), selected for their similarity to existing maturity models and assessment tools. The framework categorises 107 product management best practices, across eight areas: activities and flow, decision making, training, roles and collaboration, knowledge management processes, knowledge management techniques, methods, computerisation and software, respectively grouped into four categories: process, people, knowledge management and tools. A questionnaire with a five-point Likert scale can be used to evaluate each of the practices.

3.3 Knowledge Flywheel Framework for GenAI in Product Management

Considering previous discussions on the processes and maturity of knowledge management within organizations, different types of competencies, the involvement of academic representatives in projects requiring experimental design skills, the lack of appropriate methodology, and the use of loop strategies, and

drawing upon (Wodecki, 2023), we propose a knowledge management flywheel framework for GenAI solutions integration in product management utilizing the Business-Engineer-Academy triangle. A strategic flywheel effect is achieved through continuous iterations of knowledge flow among business representatives, engineers, and academic researchers. This iterative process enhances understanding and improves efficiency and maturity of the processes resulting in greater product success.

To determine the accuracy of this framework, it was assessed using semi-structured interviews and open-ended discussions with a mixed group of 12 practitioners. This validation step is based on the evaluation phase of Design Science Research (Peffers et al., 2006) and is a crucial step in the development of many models in the literature. The panel included a balanced mix of individual contributors and those with managerial responsibilities, all of whom had experience working in an AI team (as either product manager or an engineer) within the organization. Their insights on the usefulness, reliability, and effectiveness of the framework were gathered, as they are considered the primary users of this framework.

The triangle works as follows: the business owners identify key performance indicators (KPIs) expected to improve with the implementation of a GenAI solution, the engineering team (comprising data science and IT professionals) executes the technical implementation and the scientists propose and perform experiments, analyze results, validate hypotheses, and present key findings to business stakeholders. With the new insights, the business suggests further experiment iterations and refines success metrics.

A well-structured Knowledge Management (KM) flywheel ensures continuous enhancement of managing the value of GenAI solutions integration in product management, moving beyond just model monitoring and diagnostics. This is achieved through systematic processes for generating, capturing, organizing, storing, and sharing knowledge throughout the project lifecycle (improving knowledge management maturity) and the application of methods such as multi-agent approach to optimize business experiments.

Thus, an exemplary KM flywheel (shown in Figure 1) might operate as follows:

1. New experiments lead to new insights…
2. …facilitating a better understanding of the business and thus…
3. …enhancing:
    a. business efficiency,
    b. internal KM processes and its maturity,
    c. product management process resulting in higher product value and…
4. …motivating the organization to undertake further experiments.

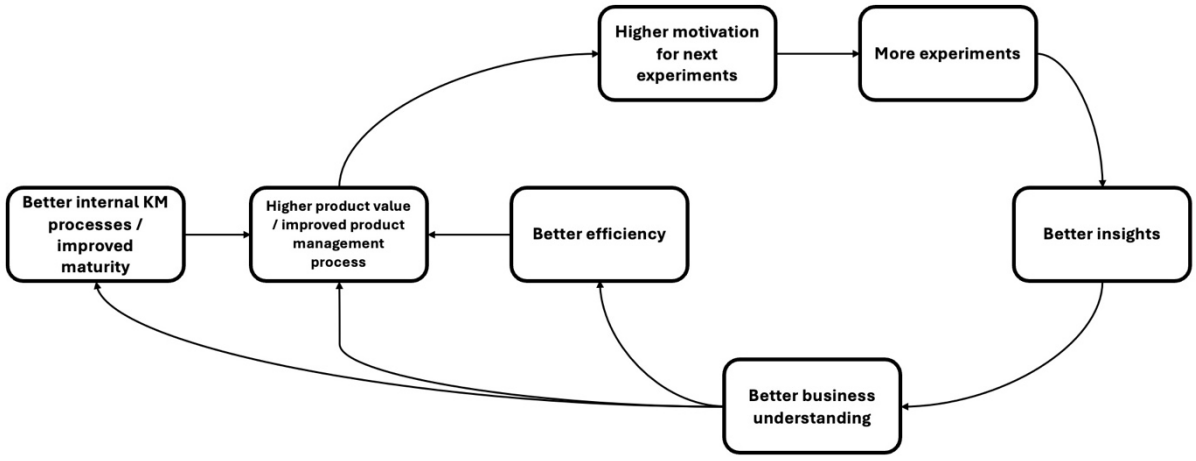

Figure 1: An exemplary Knowledge Management strategic flywheel for GenAI integration in product management process. Source: own elaboration.

4. Case Study

This case study examines the implementation of the proposed knowledge management framework for Generative Artificial Intelligence (GenAI) in product management at XYZ, a leading company in the manufacturing sector, present in all global markets, with locations in more than 30 countries. The study explores

the processes and strategies employed by XYZ to integrate GenAI solutions into their product management practices, highlighting the challenges faced and the adopted path.

XYZ is a globally recognized leader in the production of industrial machinery. The company has a long history of innovation and has consistently invested in advanced technologies to maintain its competitive edge. Recognizing the potential of GenAI, XYZ embarked on a strategic initiative to integrate GenAI solutions into its product management processes.

Product management encompasses both operational tasks (e.g., delivering a product to market) and strategic tasks (e.g., predicting sales for a given product portfolio, creating a product roadmap for the coming years). For certain strategic tasks, such as predicting sales for a product portfolio, "simple" machine learning predictive models can assist by integrating data from different sources (historical sales data, product availability in stock, upcoming major projects).

Interviews conducted within company XYZ identified one primary issue related to strategic tasks, which became the focus of this study. The issue pertains to developing a unified roadmap for multiple diverse product portfolios that utilize the same resources (both engineering and marketing). It was found that many New Product Development (NPD) projects experience significant delays, which continue to escalate. Insufficient engineering resources led, for example, to engineers switching from project to project without having adequate time to fully understand the requirements, resulting in the creation of products with technical issues (failing to pass required tests).

The consideration of hiring additional personnel to increase available human resources proved challenging for several reasons. Firstly, this specific manufacturing sector is quite niche, and finding and onboarding new employees, particularly in engineering roles, is estimated to take 1-2 years, and in extreme cases, up to 3 years before the employee starts making a noticeable impact. Secondly, the high market dynamics result in scenarios where hiring may be feasible in one year, but cost-cutting measures may be necessary the following year, jeopardizing employee retention. Therefore, alternative methods were explored to enhance the efficiency of existing teams in developing roadmaps for various product portfolios, without increasing headcount.

To this end, a collaboration with academia was initiated, not only to alleviate the burden on the current team, already handling multiple projects, but also to approach the problem from a different perspective. This project was spearheaded by the product director (acting as a project manager, overseeing several product managers) and included the academic representative, selected product managers (responsible for different product portfolios), dedicated data scientists, and IT engineers. Each company representative (product managers, engineers) was able to dedicate a few hours weekly to work with the academic representative.

The first challenge encountered was data access. The academic representative had to define the scope of data usage and sign a non-disclosure agreement (NDA). Another challenge was the company's approach to GenAI; the company sought to implement GenAI responsibly. Currently, access to tools such as ChatGPT is blocked on all employee computers to prevent the use of company data in interactions with the chat, as the data processing methods are unknown.

At the design stage, it was decided to experimentally assess the business value of the GenAI solution. Consequently, it was necessary to develop an experiment plan and prepare the appropriate IT architecture. Considering the aforementioned restrictions, the academic representative proposed that, instead of building separate infrastructure within the company, the GenAI model would be hosted on a separate server prepared by the representative, over which the company's IT engineers would have supervision. This proposal was accepted.

The planning of the experiment largely focused on selecting the documents and determining which information the GenAI model should utilize to address the problem. This was done through the analysis of documents available in the organization (various product-related files, previous product roadmaps, and other information) as well as through interviews with stakeholders. Efforts were made to gather as much information as possible, ranging from the team structure to details about the construction of current products from each portfolio.

The selection of an appropriate evaluation method and metric, which would help assess the business value of the model, was also crucial. Choosing between statistical, business, and experimental evaluation methods, the scientist proposed using the experimental evaluation method due to the experimental nature of the implementation. The metric suggested by the scientist was a survey with a net promoter score for the solution proposed by the GenAI model, along with space for additional comments. Specifically, all project participants

(product managers, engineers) would rate the responses of the GenAI model on a scale of zero to ten. The experiment would be repeated, adding new information or incorporating new requirements, until the average score of all ratings exceeds eight. This proposal was accepted.

Collecting information and establishing the metric served as a test of the effectiveness of the internal knowledge management processes. Upon completing the planning stage, the company was assessed using the CLIMB framework by the scientist, who filled out a questionnaire based on interviews with product managers. The company achieved the third maturity level (out of five) overall, as well as the third level in the knowledge management category. According to the scientist, based on the responses and the achieved score (level three corresponds to the Intermediate level), the organization could consider implementing GenAI solutions in the product management process without any noticeable process changes. However, it also helped the organization identify areas needing improvement, particularly in managing knowledge when introducing changes to the process rather than developing a new product. This was evident from the beginning when integrating data from some sources proved challenging.

During the implementation and evaluation phase of the model, the scientist proposed using the LLMOps methodology for effective model management and maintenance, as well as a multi-agent approach to increase efficiency and optimize computational resources. The use of the open-source tool LangChain was suggested due to its extensive capabilities, including support for multi-agent systems. Five agents proposed answers, and an assessor agent, considering the evaluation of each answer along with the given requirements and provided knowledge, presented the final answer. This was then evaluated by project members. A total of three iterations were conducted, and in the third iteration, the average rating exceeded the threshold of eight.

The proposed by the model solution to a problem focused largely on creating technological (both software and hardware) building blocks that could be utilized by products and services from diverse portfolios. Given that these products and services targeted different markets with varying price points, different variants were proposed, ranging from the most feature-rich to the least feature-rich versions. This approach allowed the most complex variant (worst-case scenario from an approval perspective) to be tested during agency approval processes, thereby streamlining subsequent work on the other variants.

This solution enabled engineers to concentrate on building these building blocks by considering the requirements of the other variants, instead of switching between different technological projects. It also enhanced the flow of knowledge, both among engineers and between product managers. It is currently estimated that the Time-To-Market for new products will improve by at least twofold. The use of this solution also encouraged the team to apply it again in later stages of developing the discussed building blocks.

5. Conclusions

This study explores the integration of Generative Artificial Intelligence (GenAI) solutions in product management enhanced by the knowledge management framework. Drawing from the case study from the manufacturing sector, this has highlighted four key insights: 1. The influence of experimental approaches on the processes of assessing the business value of GenAI solutions, 2. The benefit of incorporating external expertise in the integration of advanced AI solutions during the product management process, 3. The impact of external experts on improving internal knowledge management processes and determining the maturity of these processes, and 4. The importance of having team members with diverse competency profiles, including T-shaped, Pi-shaped, and M-shaped skills.

Involving external experts, such as academic representatives, in the integration process of GenAI solutions can bring fresh perspectives and innovative (experimental) methods. This collaboration can enhance and simplify the development of the model and addresses competency gaps within the organization. Also, effective knowledge management is beneficial for the successful integration of GenAI. Practitioners should focus on developing and refining knowledge management processes, employing methods for capturing, organizing, storing, and sharing knowledge. Using frameworks like CLIMB can help assess and improve organizational maturity in this area. Having team members with diverse competency profiles (T-shaped, Pi-shaped, and M-shaped skills) is essential for the successful implementation and management of GenAI solutions. Organizations should invest in developing these competencies across their teams to ensure a well-rounded and effective integration process.

Future research should focus on the long-term impact of GenAI integration in product management, examining how these solutions evolve over time and their sustained effects on business value and process efficiency. Also,

comparative studies across different industries can provide insights into how GenAI solutions can be tailored and optimized for specific sectors, highlighting unique challenges and opportunities.

Collective Transformation: Fostering Peer-Driven Transformational Leadership in Communities of Practice

Xueying Zhang
Ritsumeikan University, Osaka, Japan

ba0747xp@ed.ritsumei.ac.jp

Abstract: While transformational leadership (TL) thrives in uncertain environments through knowledge exploration, research often focuses on the top-down dynamics between managers and employees. This study analyzes peer-driven TL within communities of practice (CoPs). Effective TL involves personal changes that trigger similar transformations in others. With their emphasis on knowledge creation and innovation, CoPs facilitate TL development, community growth, and reliable environments that engender transformative responses among members. Through a comprehensive literature review, detailed analyses, and semi-structured interviews, this study examines the conditions that foster CoPs as facilitators for mutual TL among peers. A novel perspective on TL within CoPs is revealed, shifting focus from unidirectional manager–employee dynamics to peer-to-peer leadership emergence. By nurturing the conditions of role equality and shared narratives, organizations can pursue collective growth, empower employees, and propel organizational transformation through a network of decentralized leadership.

Keywords: Communities of Practice, Transformational Leader, Transformational Leadership, Role Equality

1. Introduction

Transformational leadership (TL) inspires individuals and communities to reach new heights through a shared sense of mission, stimulating learning and provoking new thinking (Hater and Bass, 1988). Traditionally, studies have focused on managers' driving employee performance through TL (Dung and Hai, 2020). However, leadership can emerge organically within communities, with shared goals and collective learning fostering change (Ospina and Sorenson, 2006), suggesting TL potential is for managers and employees. Although TL's effectiveness in response to uncertainty is known (Donate and Sánchez de Pablo, 2015), research often relies on follower evaluations and neglects the leader's perspective (Stock et al, 2023). This study bridges this gap by exploring how communities of practice (CoPs)—collaborative knowledge hubs—can nurture environment-dependent TL. CoPs facilitate innovation, cooperation, and trust, which are vital for TL (Gui, Lei and Le, 2024; Nguyen, Shen and Le, 2022; Scuotto et al, 2022). Studies have shown CoPs' effectiveness in developing leaders (Smith et al, 2018) and promoting informal learning (Zia et al, 2022), aligning well with TL's emphasis on growth and adaptability. Therefore, this study examines the specific elements CoPs can offer to cultivate TL among members. Through a comprehensive literature review, detailed analyses, and semi-structured interviews, it investigates how CoPs can empower individuals to become transformational leaders and drive positive changes within and beyond their communities.

2. Literature Review

2.1 Transformational leadership

Recent research on TL focuses on (1) manager (supervisor) and employee interaction (improving performance and empowerment (Jensen, Potočnik and Chaudhry, 2020), organizational culture (Nguyen et al, 2023), and organizational change (Faupel and Süß, 2019); (2) impact on individual employees self-efficacy (Gao, Murphy and Anderson, 2020), increased creativity (Nguyen et al, 2023), reduced negative emotions (Karatepe and Türkmen, 2023), and identity building (Mulla and Krishnan, 2022); and (3) promoting innovation through the application of knowledge in the organization (organizational learning; Mahmud, 2022), knowledge management (KM) (Gui, Lei and Le 2024), and knowledge sharing (Kim and Park, 2020).

2.1.1 TL: Beyond Manager-Employee Dynamics

TL involves inspiring individuals and communities to reach new heights through a shared vision, learning, and innovation. While extant research focuses on manager-employee interactions (Nugroho et al, 2020), TL's potential extends beyond this dyad. Organizational culture plays a crucial role in this process. TL fosters innovation-supportive (Jung et al, 2003) and HRD cultures, driving positive performance (Nguyen et al, 2023). Asbari (2020) describes TL as a "radar" for organizational realities and a "moral compass" guiding ethical choices. This visionary nature equips organizations for change amidst uncertainty (Faupel and Süß, 2019; Pesut, 2019).

However, several research gaps remain in this field. Understanding how individuals develop into transformational leaders is crucial. Although development needs have been recognized (Pesut, 2019), methods are often underexplored. Siganga (2019) emphasizes the importance of meeting higher human needs, such as self-esteem and actualization, for successful TL. Thus, clarifying the path to self-realization can help nurture effective, authentic transformational leaders.

2.1.2 Transformational Leadership's Impact on Individual Employees

Beyond manager-employee dynamics, TL directly benefits individual employees. Studies show that TL boosts self-efficacy (Gao, Murphy and Anderson, 2020) and creativity (Nguyen et al, 2023), mitigate negative emotions, reduces stress (Karatepe and Türkmen, 2023), prevent turnover and loneliness (Kloutsiniotis et al, 2022), and positively affects overall well-being (Schmitz et al, 2023).Recent research has investigated follower identity and its connection with TL. Mulla and Krishnan (2022) find that supervisors' TL increases recruits' self-transcendent values and reduces their self-enhancing values, fostering value congruence. Similarly, Bakker et al (2023) show that TL promotes follower strength and initiative, improving work engagement and performance. Djourova et al (2020) highlight the link between TL and well-being, demonstrating that inspirational motivation and individual attention directly affect self-efficacy, creating a pathway from leadership style to well-being through self-efficacy and resilience. These studies demonstrate managers' TL's positive impact on their employees. However, research on the effects of TL exhibited by employees, both on themselves and their surroundings, is lacking. Le and Lei (2018) explore the impact of TL and trust on knowledge sharing among members, hinting at the potential of employee-driven TL. Similarly, Alvesson (2020) emphasizes that leadership roles are not always neatly defined, and "followers" can also exhibit leadership qualities.

Therefore, future research should explore employee-driven TL and investigate its impact on individuals, teams, and organizational cultures. By recognizing the potential of leadership beyond traditional hierarchies, we can realize a broader spectrum of talent and create more empowered, thriving workplaces.

2.1.3 Transformational Leadership and Intra-Organizational Knowledge: Fostering Innovation and Learning

TL plays a crucial role in promoting innovation by applying internal knowledge. Research highlights its impact on learning, knowledge creation and practice, and organizational co-optation. Mahmud (2022) emphasizes the mediating effect of TL between learning culture and knowledge application, demonstrating its ability to bridge the gap between knowledge and practical use. Donate and Sánchez de Pablo (2015) propose a "knowledge-oriented leadership" that combines elements of both transformational and transactional styles, emphasizing the need for effective communication and motivation alongside KM practices. This suggests TL can handle KM's creation and communication, while transactional leadership can cater to storage and application.

Studies have explored the specific conditions under which TL fosters innovation. Gui, Lei, and Le (2024) show that while TL enhances innovation capability through knowledge management competence (KMC), its effectiveness depends on the organization's existing innovative climate. Similarly, Nguyen et al (2022) find that KMC and collaborative culture influence the impact of TL on different aspects of innovation capability. Le and Le (2023) demonstrate that TL's effect on exploratory innovation (seeking new ideas) is stronger than that on exploitative innovation (refining existing ideas).

Beyond innovation, TL also influences knowledge sharing, a crucial element of KM. Kim and Park (2020) assert that knowledge sharing mediates the relationship between TL and organizational learning, highlighting TL's ability to encourage knowledge exchange and collaborative learning. Shahzad et al (2022) further show that knowledge sharing strengthens the positive impact of TL on corporate performance, demonstrating its multifaceted contribution to organizational success.

However, TL's effectiveness depends on certain environmental factors. Trust between leadership, members, and among members is crucial (Le and Lei, 2018; Scuotto et al, 2022). Additionally, Gui, Lei and Le (2024) and Nguyen et al (2022) highlight the importance of fostering an innovative and collaborative culture to optimize TL's impact.

While the evidence is clear on TL's potential to enhance knowledge utilization and innovation, a gap exists in defining the specific environments and conditions in which it thrives. Future research must analyze this question, identifying the optimal contexts for utilizing TL's full potential to drive knowledge-based success within organizations.

2.2 Community of Practice

A CoP is a space where people with shared interests, problems, and enthusiasm for a subject come together to enhance their knowledge and skills through ongoing interaction (Wenger, 1998, p. 32). Learning in CoPs is structured into four elements: community, practice, meaning, and identity, which are "deeply interrelated and mutually defining" (p. 5) (Wenger, 1998).

In CoPs, it is "a means for the evolution of practice and the inclusion of newcomers, as well as for identity development and transformation" (Wenger, 1998; p. 13). Consequently, relevant research on CoP is mainly divided into (i) how it leads to identity development and transformation (e.g., knowledge sharing and creation) and (ii) what kind of identity development and transformation it has achieved (e.g., expertise and self-efficacy).

2.2.1 Connecting Communities of Practice to Identity Development and Transformation

CoPs are valuable tools for knowledge sharing and professional development within organizations. Their core role lies in facilitating informal learning and collaborating on shared interests. Jeon, Kim and Koh (2011) highlight the interplay of extrinsic and intrinsic motivations in driving knowledge sharing within CoPs. Budrytė and Vainauskienė (2023) further demonstrate the potential of virtual CoPs in promoting international knowledge exchange and remote collaboration. Furthermore, CoPs play a crucial role in shaping individual and community identities. Aljuwaiber (2016) emphasizes how CoPs foster informal professional learning, create shared identities, and give meaning to professional practice. This is particularly relevant for tacit knowledge, which thrives on dialogue and the informal learning processes often nurtured within CoPs.

Recent research has shifted focus toward the members, recognizing them as the driving force behind continuous knowledge creation and CoP evolution. Choi et al (2020) highlight the significance of CoPs in organizational innovation and improvement. They view CoP members as valuable assets and key players in KM, emphasizing their role in developing knowledge activities, enhancing competitiveness, and strengthening organizational culture. Similarly, Haas et al. (2021) investigated the factors influencing participation in virtual CoPs and found a positive correlation with work engagement. Bolisani et al (2021) explore how CoPs can act as agile responders to crises by fostering deeper connections, a sense of belonging, and community empowerment.

Overall, CoPs research is moving toward a more nuanced understanding of member interactions and their impact on individual and organizational development. Although studies have explored knowledge sharing and collaboration within CoPs, further research is required to examine the intricate dynamics of internal interactions among employees within these communities. Examining how CoPs influence individual identity development and transformation, particularly concerning professional identity, can offer valuable insights into maximizing the potential of these dynamic learning ecosystems.

2.2.2 Identity Development and Transformation in Communities of Practice

While research on CoPs in management often focuses on knowledge-sharing and collaboration, educational studies emphasize their impact on member identities. CoPs provide an ideal environment for building integrated knowledge and pedagogical expertise. This environment fosters critical thinking to prevent groupthink (Li et al, 2009), democratic cooperation (DePalma and Teague, 2008), and trust, which allows for failure and growth (Fitzgerald et al, 2023). Sadiq (2021) emphasizes the sense of unity and security CoPs offer in uncertain environments. McLaughlan (2021) identifies four key facilitators of CoP development for International Graduate Teaching Assistants: social connectedness, confident English teaching, pedagogical support, and self-efficacy in teaching.

Numerous studies demonstrate the positive impact of CoPs on member identities. Lee and Shaari (2012) highlight increased professionalism and autonomy, whereas Goodwin (2019) underscores the development of self-efficacy and career optimism. The post-pandemic context and challenges of building diverse societies have further highlighted the evolving role of CoPs. Ruzycki (2021) demonstrates how cross-disciplinary faculty CoPs foster resilience, adaptability, and an emergent learning framework. Similarly, Johnson (2023) demonstrates the effectiveness of CoPs in developing knowledge and resources for sustainable LGBTQ+ inclusivity.

In addition to individual growth, CoPs contribute to broader educational settings. Retna and Ng (2011) emphasize how mutual involvement facilitates acquiring new knowledge and transferable solutions beyond specific situations. Abedini, Abedin and Zowghi (2021) probe online CoPs for adult learners and find them independent, experience-centered, and self-motivated individuals seeking lifelong learning and professional outcomes.

2.3 Communities of Practice as Incubators for Transformational Leadership in Organizations

By reviewing the defining characteristics of transformational leaders (visionaries, facilitators of learning, and agents of change), we can observe how CoPs may develop transformational leaders.

First, they foster the qualities expected of transformational leaders. Schultze and Stabell (2004) emphasize that CoPs value internal learning, knowledge circulation, and action-oriented knowledge application. This aligns perfectly with the TL's focus on empowering individuals to tap into their inner potential and translate knowledge into meaningful actions. Second, CoPs offer an ideal environment for honing TL skills. Mulla and Krishnan (2022) highlight the importance of training for effective TL, whereas Pesut (2019) views it as a skill that requires development. Smith et al (2018) demonstrate that CoPs can serve as effective leadership development programs. Abedini, Abedin and Zowghi (2021) assert that online CoPs contribute toward lifelong learning and knowledge formation through shared experiences. Third, CoPs nurture essential traits of transformational leaders. Pesut (2019) and Djourova et al (2020) emphasize the need for leaders to cultivate foresight, resilience, and the ability to navigate change. Wenger (2000) defines CoPs as "a way for communities to contemplate their repertoire, identify hidden possibilities, and reveal the power to move forward." This introspective and future-oriented environment aligns perfectly with developing crucial leadership qualities. Finally, CoPs offer a unique space for peer-to-peer interaction, which Siganga (2019) identifies as a critical but understudied aspect of TL development. Unlike traditional hierarchical relationships, CoPs promote horizontal knowledge exchange and mutual learning, fostering employees' self-actualization of leadership potential.

3. Methodology

Descriptive and interpretive narrative approaches were used for data collection and analysis through a semi-structured interview survey. The narrative approach focuses on dialogue, revealing the discontinuity between the subject's story and experience (Sandelowski, 1991).

The suitability of this study for the growth of individuals in CoPs is evidenced in previous studies (Baran and Cagiltay, 2010; Fitzgerald et al, 2023). Moreover, they indicate an over-reliance on questionnaires as a shortfall in TL-related research progress identified by Stock et al. (2023), who state what behaviors produce the desired results to train leaders to be transformational. They emphasize the importance of TL research and mention that most research has merely been followers' evaluations of leaders through questionnaires. Hence, they suggest biases may exist in objective behavioral measures and questionnaires, and that coverage from other approaches is also needed to reduce bias. Thus, this qualitative study of the behavior of transformational leaders can be covered by other approaches.

3.1 Sampling

Regarding the sampling criteria, the study selected four individuals with transformational leader characteristics from four CoPs: painters, badminton, nail design, and IT gadgets. The CoPs were chosen based on the definition of CoP by Wenger (1998), with the criteria of coming together around a common interest or theme, ongoing activities to promote the development of that theme for at least two years, and a minimum of 10 participants. The selection of transformational leaders in the CoPs was then made through interviews with members of each CoP. In each CoP, random members were asked to describe transformational leader behavior (TLB) (Stock et al, 2023) and to "name someone who fits that characteristic." TLB is defined as teaching life lessons, introducing developmental opportunities, providing different perspectives, seeking perspectives, questioning critical assumptions, and speaking affirmatively (Stock et al, 2023). The interviews identified those who fit the TLB as painters (2), badminton (2), nail designers (1), and IT gadgets (1), of which one from each CoP was interviewed.

3.2 Data Collection

This study comprises several one-on-one semi-structured interviews with four transformation applicants from November to January 2023. Each interview lasted 1 hour and was conducted face-to-face or via an online call. The interviews were primarily reflective and used the interviewees' work and community events as guides. Each interview was audio recorded and transcribed verbatim, and the individual confirmed the content.

3.3 Data analysis

The interview data were analyzed using Steps for Coding and Theorization (SCAT) (Otani, 2011, author's translation). Additionally, in studies in education (Villeneuve and Hutchinson, 2013) and social work (Takahashi,

2016), data collection using the narrative approach and data analysis using SCAT allows the subject's theoretical descriptions. SCAT systematizes theories by extracting their commonalities and characteristics from the "theory descriptions" (Otani, 2008). The SCAT steps ensured each interview response was coded, relationships between codes were identified, and two common categories were derived. For validation, the results of the SCAT analysis were shared with the interviewees, and their views were sought. The results confirmed that no new categories were derived, and data were saturated.

3.4 Ethical Considerations

During the survey, the purpose and content of the study were explained to the participants, and their consent was obtained before the interviews. Personally identifiable information was anonymized and carefully collected to protect the participants' privacy, while audio and transcription data obtained from the survey were stored securely. After the data storage period, a specialized company properly disposed of the data.

4. Findings

4.1 Role-Based Equality

Unlike traditional organizations with predefined structures and assigned leadership roles, CoPs present a fascinating alternative. Interviews in this study reveal a key difference: in CoPs, members come first, and leadership emerges organically. While frameworks may exist, they serve as guidelines, not dictates, for the dynamic interplay of individuals. This "role-based equality" challenges the notion of leadership as a singular position. Knowledge creation and application in CoPs stem from egalitarian interactions in which all members contribute and share ownership. As expressed by interviewees, leadership "is not given, but shared," often surprising individuals chosen by their peers. These leaders do not view themselves as superior but as temporary facilitators fulfilling a specific need. They operate out of a sense of reciprocity and community spirit, recognizing the equal value of each member's role. One interviewee stated, "I organize events not out of responsibility but to give back what I get from the CoP." This mutual trust and respect foster a dynamic environment where leadership roles shift based on context and expertise. Members learn from and complement each other, continuously expanding their horizons while recognizing their limitations. Specifically, CoPs nurture a collective leadership model in which knowledge creation and transformation emanate from shared experiences and contributions.

4.2 Shared Narrative of Transformation

While Wenger's (1998) theory of CoPs emphasizes strengthening identity through professional development, this study offers a deeper insight: CoPs serve as mirrors for self-discovery. This quest is fueled by shared narratives of transformation. Members do not simply exchange information; they share personal stories of growth. These stories become anchors of "positive identity-shaping," demonstrating individual capabilities and impacting personal lives. In these narratives within CoPs, each member plays a crucial role in enriching the collective story through interactions, which include answering community questions, enhancing communication skills, and strengthening the overall narrative. The impact of individual stories extends beyond personal growth. They inspire others to form powerful mutual support systems. High-impact stories can elevate owners to temporary leadership roles, showcasing the dynamic nature of leadership in Cops. Ultimately, weaving individual transformation stories fuels CoP's growth and evolution. This egalitarian sharing of experiences ensures knowledge creation and fosters a supportive environment where everyone feels empowered to contribute to and discover their potential. This study highlights the transformative power of CoPs beyond professional development. By providing platforms for sharing stories about individual journeys, CoPs have become catalysts for self-discovery, mutual inspiration, and collective growth.

5. Conclusion

This study examined creating a CoP environment that promotes TL among employees. The findings suggest that role-based equality and a shared narrative of transformation enable employees to practice TL, deepen self-understanding, and experience personal growth. This can lead to deeper employee connections, collective transformation, and a mutually trusting, evolving organization, benefiting CoPs, TL, and transformational learning.

The study also highlights the role of leadership in collaborative projects within CoPs, fostering self-discovery and

leadership roles not imposed by programs but through authentic CoP engagement. Additionally, the research reveals that TL and transactional leadership are crucial for knowledge creation and exchange, with individuals collectively demonstrating the power of collaboration. Further investigation into leveraging TL principles within CoPs is needed.

Abstract: Hong Kong S.A.R., China is one of the most economically prosperous areas in the world, with numerous multinational companies (MNCs) operating here. It is of vital importance for MNCs to leverage their knowledge across the entire organization, including both the head office and overseas branches. However, many MNCs struggle with knowledge transfer across borders due to the differences in national cultural and institutional factors. Therefore, this research seeks to explore these factors affecting knowledge transfer in MNCs in the Hong Kong S.A.R., China. Six semi-structured interviews with professional practitioners were carried out. Knowledge is transferred in MNCs mainly by three processes, namely, on-the-job training, knowledge-sharing sessions, and knowledge retention of leaving employees. Cultural differences including language differences, geography differences and power distance, technical factors, and institutional differences, including organizational structure differences, senior management support, and employee motivation do affect knowledge transfer of MNCs. This study adds new insights into knowledge transfer issues across the boundaries of MNCs in Hong Kong. It provides significant managerial implications that are helpful to these multinational organizations to achieve effective knowledge management in the global context to overcome cultural and institutional obstacles.

Keywords: Knowledge Transfer, Knowledge Management, Multinational Companies (Mncs), National Culture, Institutional Differences

1. Introduction

Knowledge management (KM) can be defined as a process involving a variety of activities, such as knowledge transfer, knowledge sharing, knowledge creation, knowledge retention, etc. (Alavi & Leidner, 2001). Such activities can generate value from an organization's knowledge assets (Mahalakshmi & Ally Sornam, 2012). Innovation in knowledge-intensive industries has an expected positive impact on job creation, the digital economy, and environmental protection (Grigorescu et al., 2020). By actively implementing KM, the quality of services can be improved, new methods can be created, and unnecessary costs can be reduced (World Bank, 2018). The knowledge transfer involves mobilization, assimilation, and exploitation of knowledge resources (Maurer et al., 2011) and encompasses a wide range of actions between individuals and groups; within, between, and among groups, and from groups to organizations to share the "know-how" of the best experts in a given domain (Paulin & Suneson, 2012). Transferring knowledge among employees benefits organizations and individuals by enhancing their capabilities (Sharifuddin & Rowland, 2004). However, KM becomes similar to a “bottleneck” as the managers do not have enough cognitive understanding of KM (Subanidja & Hadiwidjojo, 2017).

Knowledge transfer is one of the important processes of KM (Alavi & Leidner, 2001) that attracts much attention from scholars and practitioners, especially regarding knowledge transfer across borders. For example, Pérez-Nordtvedt et al (2008) examined 102 US organizations and found that the quality of the relationship between the source and the recipient has a strong positive impact on both the efficiency and effectiveness of cross-border knowledge transfer. Dinur et al (2009) revealed that contextual dissimilarity was an obstacle to best-practice transfers, such contextual factors including differences in culture, strategy, decision-making, environment, and technology. Sapuarachchi (2021) conducted an exploratory study by interviewing 15 employees in a US headquarter and its Sri Lankan subsidiary of the MNC. He showed that organizational knowledge transfer was influenced by cultural distance. By examining China-based MNC subsidiaries in the IT industry, Qin et al (2017) showed that cultural distance moderates the relationship between knowledge transfer and subsidiary performance. While other scholars examined the impacts of knowledge characteristics on knowledge transfer across borders. For instance, Argote and Ingram (2000) argue that the knowledge-embedded in people, tasks, and tools is the most difficult to transfer as such knowledge is least likely to fit the new context. In addition, some studies have focused on the key factors that affect knowledge transfer. Organizational culture, structure, knowledge recipients, types of knowledge play an important role in effective knowledge transfer. Social capital dimensions, such as network ties, network configuration, work stability, shared goals, shared culture, and trust

influence the effectiveness (Inkpen & Tsang, 2005) and speed Chen & Lovvorn, 2011) of knowledge transfer. Argote (2024) claims that some factors, including opportunities, knowledge characteristics, knowledge transfer mechanisms and motivation, and the depth of knowledge will affect the success of knowledge transfer.

Despite widespread recognition of the importance of knowledge flows in international organizations, it is necessary to examine the factors influencing knowledge transfer in different cultural and institutional contexts. In addition, Hong Kong S.A.R., China, serving as a financial center in South Asia attracts thousands of MNCs to open up their subsidiaries there, however, limited attention has been paid to examine the factors affecting knowledge transfer in these organizations in Hong Kong S.A.R., China. On the other hand, Hong Kong is recognized as a modern city where Western and Eastern cultures are well merged. Therefore, it is necessary to examine potential factors that could affect knowledge transfer of MNCs in Hong Kong to offer new insights into KM literature. This study aims to investigate:

- How do MNCs transfer their knowledge?
- What are the factors that affect knowledge transfer in MNCs?

2. Methodology

The qualitative data analysis was adopted since this method is appropriate as it provides an “up-close grounded” perspective (Shaw & Luiz, 2018). This involved in-depth interviews with practitioners who have extensive relevant experience and knowledge to obtain primary data. The researchers developed a semi-structured interview guide to capture a range of personal experiences, including open-ended questions asking about various aspects of KM practices. Six qualified interviewees were selected from international companies in Hong Kong, China. Each of them has extensive working experience in MNCs, with an average of over 15 years in the practice. All interviews were carried out in English by face-to-face interviews or online meetings and audiotaped.

The data collected was analyzed using content analysis following Mayring (2000). The interviews' audio tapes were verbatim transcribed. After transcription, the data was coded. Each statement of transcriptions was broken down into smaller textual units for analysis and coded each interview line by line based on the knowledge offered by the reviewers. Different colors were used for the coding items to identify key similarities across the interviews. Similar codes were merged and combined together to form higher-level categories to create themes. The research team met regularly to demonstrate the coding process, discuss coding discrepancies, and clarify any ambiguities in the coding process to ensure reliability and validity.

3. Findings

3.1 Knowledge Transfer Process in MNCs

Knowledge is transferred mainly by three processes, namely, on-the-job training, knowledge-sharing sessions, and knowledge retention of leaving employees.

On-the-job training. On-the-job training typically occurs when new employees or management trainees enter the company on a rotational basis. These training initiatives transfer knowledge to employees focusing on skill development, and compliance requirements through a blend of online modules, face-to-face sessions, and e-learning platforms. By providing training programs, organizations empower staff to enhance their capabilities and adapt to changing roles. According to participant D from a nationalized commercial bank:

> Normally if a staff member joins our company or bank, intensive training would be [D-01-KTM-OTB].

Knowledge sharing session. MNCs hold knowledge-sharing sessions from time to time for knowledge transfer and sharing activities. Different MNCs have different formats for knowledge-sharing sessions, including seminars, workshops, labs, and coffee sessions. Knowledge-sharing sessions play a role in sharing expertise, discussing industry trends, and fostering cross-functional collaboration. These sessions promote a culture of knowledge transfer, encourage collaboration, and nurture a learning community within the organization. Participant A from a major commercial bank, who is the initiator of the internal knowledge-sharing session in his MNC, explained this:

> … organize some team meetings… we…share about what they do of the week. It's like a PC lab meeting [A-01-KTM-KS].

knowledge retention of leaving employees. Knowledge and information are passed from departing employees—

due to retirement, resignation, or relocation—to their successors within MNCs. It helps in capturing tacit knowledge, experiences, and insights of leaving staff before they leave the organization. Organizations prioritize this transition of knowledge, job-related insights, and key contacts to mitigate the impact of staff turnover on business operations. Although multinational organizations have a knowledge retention mechanism for leaving employees, they still lack standardized procedures to transfer knowledge. According to participants E and D:

> They usually try their best to arrange a transition period for the departing staff, transition over to the new staff, to hand over important account matters or any Excel models [E-01-KTM-DKT].

3.2 Influence Factors to Knowledge Transfer in MNCs

Three groups of factors that affect knowledge transfer in MNCs are identified, namely, culture differences factors, technical and process factors, and institutional factors.

3.2.1 Cultural Differences

Cultural differences impact knowledge transfer in MNCs by three factors, first, l*anguage differences and geography differences.* Language significantly impacts communication and cooperation within teams. Language differences result in communication not being smooth and teamwork being hindered, creating communication barriers and thus hindering knowledge transfer across boundaries in organizations. This is particularly evident in MNCs. Participant B expressed as:

> … consultants from Morocco speak French. In this way, communication and knowledge transfer were hindered [B-02-C-LG].

Second, geographical differences also impact knowledge transfer, partly due to the disconnection in teamwork interactions caused by time zone differences. According to participant A:

> It's like, it's my morning, you must take my calls. But that's my night…[A-02-C-G].

Third, power distance in MNCs can hinder the knowledge transfer process. Hierarchical structures and cultural norms, for example, the UK and Hong Kong subsidiaries may lead to a sense of self-limitation among employees and hinder close interaction with the team. This may manifest itself in communication patterns such as lengthy explanations in emails, reflecting the need to justify their behavior due to a perceived power differential, thus the efficacy of knowledge transfer within the organization. Participant A exemplified it as follows:

> UK still sends the air of hierarchy right to Hong Kong……there's also going to be power distance in the cultural aspects as well…... people have a sense of self-limiting, that's a sort of a power distance between people and perception……for example, if you work with India team sometimes they write long emails explaining things and explaining why not and all that stuff [A-02-C-PW].

3.2.2 Technical Factor

The lack of specialized platforms and standardized tools is a significant barrier for MNCs to transfer their knowledge. Platforms such as Microsoft 365 and Zoom are commonly used for communication and collaboration within companies. Existing platforms are mainly used for training and documentation rather than as comprehensive knowledge databases to facilitate organizational knowledge sharing and transfer. According to participants B and E:

> We don't have any specialized IT platforms for knowledge sharing, just simply use Microsoft 365 [B-02-SP-P].

> The platforms are designed and only used for training…there is no platform or knowledge database where you can look up easily for information and knowledge [E-02-SP-P].

In terms of tools, MNCs face challenges in centralizing the use of the same tool for all staff across national boundaries, due to the varying needs of different teams and the market challenges associated with replacing systems. There are differences in the level of understanding of analytics and use of tools, as well as varying levels of capacity and sophistication in different locations.

3.2.3 Institutional Differences

Institutional differences are reflected by organizational structure differences, senior management support, and

employee motivation.

There are clear structural differences within Hong Kong multinational organizations, particularly in terms of communication and knowledge transfer between the headquarters and the branch office. The staff of headquarters work independently and have limited interaction with branch staff. The lack of formal reporting and communication channels between the head office and branches has resulted in knowledge and information transfer being compromised due to the organizational design. Despite being part of the same organization, regulatory differences between nations create barriers to effective knowledge exchange. According to participant D:

> There is no official exchange for cross-border branches, we have less chance to the head office to learn from them……it is in two borders, the regulations and regulators are different, for many reasons or situations, it is not easy to exchange or transfer for knowledge……that means the knowledge there (headquarter) and the knowledge here (branch) it's not quite overlap [D-02-I-OS].

In addition, we found a lack of specialized KM teams in large multinational organizations, resulting in insufficient leadership support for KM practices. Senior management prioritizes profitability over KM. Senior management support for knowledge transfer appears to be driven more by profitability considerations than by clear delegation of authority, causing delays in workflow and impeding the effective implementation of knowledge transfer. According to participant B:

> There's no defined knowledge management team, there's no knowledge manager per se for this team…They (Senior managers) are more concerned about if the Commission is making profits. They're not much concerned about knowledge management [B-02-I-SMS].

Employees' motivation to learn new knowledge and share knowledge can affect knowledge transfer in multinational organizations. As employees of MNCs, they may be reluctant to learn new knowledge on their own but rather expect the company to provide training. Many bank employees prefer to wait for formal training rather than actively seek knowledge. Some employees may not be interested in learning about new systems or technologies. Employees may feel hesitant or unwilling to share knowledge unless prompted or in line with the team culture. These employee motivations hinder knowledge transfer in the organization. Participant F mentioned:

> If you don't ask and I (volunteer to) share it (knowledge) with you, I think I'm a little bit weird about that. I won't take the initiative to say [F-02-I-EM].

The factors that influence knowledge transfer in MNCs are shown in Figure 1.

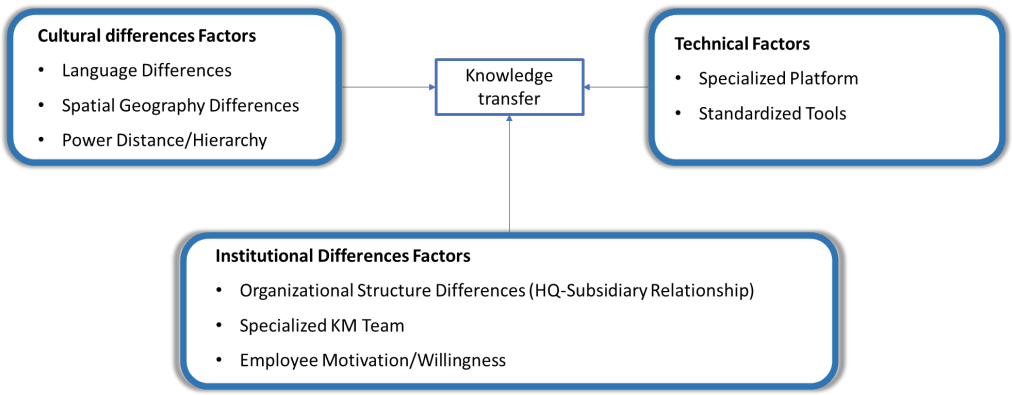

Figure 1: Factors affecting knowledge transfer in MNCs

4. Discussion

Knowledge transfer across boundaries is of vital importance to MNCs (Sharma & Phookan, 2022). However, many multinational organizations are not actively practicing knowledge transfer. Our findings show that MNCs primarily transfer knowledge through on-the-job training, and knowledge-sharing sessions and try to arrange a transition period for departing staff members. These limited approaches to knowledge transfer may impede the organization's ability to effectively transfer and retain critical knowledge assets (Liu, Farzad, et al., 2022; Sumbal et al., 2023). To enhance knowledge transfer within MNCs, organizations need to develop more comprehensive

strategies and mechanisms for transferring knowledge across borders and institutional areas.

The results suggest factors affecting knowledge transfer within MNCs, as well as across borders, including a range of challenges. In line with Gaur et al. (2019), at country level, cultural differences and linguistic barriers, such as differences in communication styles and fluency issues; geographic differences and time zone communication barriers; power distances affecting hierarchies and communication norms; formal and informal institution; structural deficiencies in standardized processes and knowledge transfer mechanisms; these factors largely hinder knowledge transfer across boundaries (Cuervo-Cazurra & Rui, 2017; Liu, Tsui, et al., 2022b). In response to these findings, existing research mentioned that organizations need the formalization and standardization of processes to provide support for their effectiveness as facilitators of consistent knowledge transfer (Zeng et al., 2018). Addressing power distance issues through cultural sensitivity training, fostering open channels of communication can help MNCs transfer and share knowledge more effectively. Besides, MNCs have difficulties in standardizing tools and platforms across locations, limited specialized knowledge platforms lead to differences in capacity and access to resources. A KM system should be developed (Liu, Kianto, et al., 2022) and emerging technologies, such as generative artificial intelligence (Nazeer et al., 2023) can be applied to transfer knowledge in MNCs. Therefore, organizations need to pay more attention to these standardized tools and platforms to create better conditions for effective knowledge transfer and improve organizational performance (Liu, Farzad, et al., 2022; Liu, Kianto, et al., 2022a).

Institutional differences impede cross-border knowledge transfer. MNCs have institutional borders within the organizations, for instance, knowledge transfer from the headquarter to subsidiaries as well as between subsidiaries across borders prevents knowledge exchanges between branches and headquarters (Zeng et al., 2018). Thus, knowledge transfer necessitates a culture of cooperation and collaboration between sources and recipients (Martins, 2016). On the other hand, lack of a specialized KM team and senior management support, and reluctance to learn independently cannot be ignored. Therefore, organizations need to focus on building a knowledge-friendly culture to provide environmental support for knowledge transfer (Liu et al., 2021).

5. Conclusion

This research revealed the issues of knowledge transfer in MNCs under the cross-border and cross-cultural contexts in Hong Kong. It reveals the impact of cultural differences such as power distance, language and geographical disparities on knowledge transfer in MNCs. This study also emphasizes the importance of establishing regulated knowledge transfer mechanisms, formalizing knowledge management processes, and utilizing formal knowledge management platforms and tools across institutions. This study contributes to KM literature by offering a framework that identifies factors that influence knowledge transfer in MNCs, especially in Hong Kong S.A.R., China. Managers can take actions to mitigate the impacts of these factors to achieve effective knowledge transfer in their organizations, for example, building a KM team, developing a knowledge-friendly organizational culture, and initiating KM systems.

There are also several limitations in this research. First, only a small number of employees of major MNCs in the Hong Kong S.A.R., mainly in the financial sector were interviewed, which affects the generalizability of our findings. Within the financial sector, further classification of financial institutions based on their company size, geographical location, and service provision can help to have a better comprehensive understanding of knowledge transfer processes. Research should also be conducted in other regions with a large number of multinationals to understand the relevance of different cultural and institutional differences in knowledge transfer in different regions. The use of different research methods and personnel, e.g. surveying departed employees involved in knowledge transfer transitions, are also recommended.

Knowledge Management and Resilience in SMEs Sector

Krzysztof Zieba
Gdansk University of Technology, Gdansk, Poland

kzieba@zie.pg.gda.pl

Abstract: Purpose: The aim of this paper is to investigate the role of resilience in surviving major disruptions, such as pandemic or war. This problem is especially vital for small and medium-sized enterprises (SMEs), as they often lack both resources needed for survival during prolonged economic hardship and knowledge management (KM) practices which are useful for developing the necessary business resilience. Methodology: The paper uses literature review approach to investigate the current knowledge on resilience and its dimensions as well as the links between KM, resilience and operational efficiency. Systems Thinking approach is proposed to be used to show the complexity of mechanisms behind those phenomena and the impact they have on business competitiveness in the SMEs sector. Findings: Because of their nature, SMEs were particularly severely hit by the COVID-19 crisis. SMEs now have to adjust to the new reality of the post-crisis phase by developing their business resilience. KM practices prove to offer high potential in resilience creation and resilience maintenance. Specific features of SMEs, if combined with operational agility and resilience, may allow them to successfully face challenges of their turbulent environment. Research limitations: This paper is of a preliminary, conceptual nature. Its further development includes investigation of various aspects of KM relevant to strengthening business resilience in SMEs. More data is still needed to develop and test full Systems Thinking model based on the framework proposed here. Practical implications: SMEs owners and managers may benefit from this paper, as they may use it as a guidance in the process of developing business resilience in their organisations. The insights provided in this paper may be useful for decision makers and also for businesses offering knowledge-based services, offering them a deeper understanding of the presented phenomena and relations between them. Originality/value: The paper is focused on SMEs, which are rarely investigated when it comes resilience creation and benefits it offers. The framework presented here provides important insights, which can be useful to numerous stakeholders.

Keywords: Knowledge Management, Resilience, Smes, COVID-19 Pandemic

1. Introduction

COVID-19 pandemic remains a major global disruption of the XXI century. Its scale was unprecedented (Fernandes, 2020) and its characteristics proved to be very complex (Donthu and Gustafsson, 2020).The pandemic significantly influenced and transformed several aspects of everyday life, education, business operations – to name just a few (van Bavel *et al.*, 2020). It is considered to be an intense example of a black swan event, which had a profound impact on virtually all sectors of economy. Most of them were adversely affected (e.g. healthcare, education, tourism and hospitality) with a few exceptions (e.g. telecommunications) (Ahmad, Kutan and Gupta, 2021). Although the impact of COVID-19 currently fades away, there are still numerous threats to global stability: the war in Ukraine, the instability in the Near East, including the intervention in Gaza zone and the tension between Israel and Iran, as well as the problematic situation between China and Taiwan.

In these turbulent times, the concept of resilience appears to be a critical issue for survival and development of business organisations. The original meaning of this concept, which is over 50 years old, comes from ecology and refers to the ability of an ecosystem to respond to unexpected environmental changes and swiftly return to the original state (Holling, 1973). Resilience became a multi-faceted concept used in a range of scientific disciplines. In the so-called VUCA (Volatility, Uncertainty, Complexity, Ambiguity) world the significance of resilience for all organisations is growing, although there is no one single commonly accepted definition of business resilience nor a universal scale to measure it (Kantur, 2015). Additionally, although small and medium-sized enterprises (SMEs) are often referred to as the backbone of contemporary economies (Cowling *et al.*, 2014), the topic of SMEs resilience is greatly under-researched (Alberti, Ferrario and Pizzurno, 2018).

This papers addresses the following research questions: 1. What is the contribution of resilience to SMEs efficiency? 2. How knowledge management (KM) may be used in SMEs for building their resilience? This paper will aim at answering this question by the application of Systems Thinking theory approach and the usage of Vensim PLE tool. The paper develops as follow. First, the concept of resilience is discussed, particularly in the context of turbulent environment, and SMEs characteristics. Second, the System Thinking approach is discussed and its applicability to analysing complex relationships is justified. Then, the proposed framework of SMEs resilience is presented and explained. In the concluding part of the paper, the role of KM in resilience creation is discussed. The paper is then summarised, theoretical and practical contributions are presented, paper limitations are listed, and avenues for the future research are shown.

2. Knowledge Management and Resilience of SMEs

KM is not so often researched in the context of SMEs. This claim made by Hutchinson and Quintas (2008) remains quite true even today. In the earlier days, SMes were not expected to possess awareness, abilities and resources to manage knowledge, despite of potential benefits they could gain. Hutchinson and Quintas proved however that SMEs not only manage knowledge in the informal way (without use of the language and concpets of KM and formal KM structures), but some of them also engage in formal KM, although more occassionally. KM in SMEs remains limited and the major focus is on KM implementation, KM perception, and knowledge transfer rather than knowledge identification, knowledge storage/retention, and knowledge utilisation (Durst and Edvardsson, 2012). Those three last issues seem to be particularly applicable when it comes to SMEs resilience.

The concept of resilience is rooted in ecology and for a few decades it remained absent in social sciences. At the beginning of the XXI century first papers on a more general application of resilience were published (Hamel and Välikangas, 2003), including those related to supply chain management. Considering resilience in the context of supply chain management was a response to September 11, 2001 events, which crippled many American companies dependent on their just-in-time discipline. Subsequent events, such as the train bombings in Madrid (March 11, 2004) and the London's transportation system bombings on July 2005 just added more to this picture (Sheffi and Rice, 2005). The real trigger for analysing resilience in a broader economic context, exceeding just supply chain problems, was the financial crisis of 2008/2009. From that time on, resilience research focuses on such research streams, as organisational responses to external threats, organisational reliability, employee strengths, adaptability of business models and designing principles that may reduce supply chain vulnerability and impact of disruptions (Linnenluecke, 2017). It also became evident that contextualisation of the resilience concept must take into account also SMEs. (Dahles and Susilowati, 2015). They are more vulnerable than their bigger counterparts, as they have less resources to tackle the encountered problems. SMEs face recurrent and multifaceted problems ranging from natural disasters and economic crises to market access challenges, political turmoil and institutional failures (Littlewood and Holt, 2018). It is evident that the majority of publications on resilience are focused on event-driven disruptions (like the above-mentioned ones or the latest COVID-19 pandemic) and most of the studies evaluate such event-driven disruptions in the attempt to propose improvements to business resilience (Kantur, 2015). We still lack a more general understanding of the resilience concept that would emerge from those single disruptions (Littlewood and Holt, 2018).

This general understanding of resilience is difficult to achieve for a number of reasons. Firstly, the concept of resilience would differ across various disciplines. In engineering or physical science the feature of resilience is based on the ability of the system to return to the previous, original state after having experienced a disruption (Dahlberg and Guay, 2015). This original state is the equilibrium of the system and in this approach the system has just one equilibrium state. In other sciences, however, resilience is often focused more on adaption. In psychology, resilience is about the ability to achieve positive performance during unfolding disruption, suggesting that multiple equilibria are possible (Linnenluecke, 2017). This "single equilibrium" approach does not seem appropriate for analysing resilience of SMEs, as it is limited to a "machine view" of organisations with oversimplified cause-and-effect dynamics (Tognazzo, Gubitta and Favaron, 2016). The resilience of SMEs should differ from "engineering resilience" (Conz, Denicolai and Zucchella, 2017), as it incorporates adaptability and ability to keep positive performance a mid of continuing disruptions and challenges and does not cling on to the same state of the business, external relations, internal processes, etc. Additionally, the resilience of SMEs may be substantially different from the resilience of large enterprises. It is a common mistake to assume that conceptual frameworks and organisational theories developed by researching large enterprises may be successfully used for SMEs (Ates and Bititci, 2011; Sullivan-Taylor and Branicki, 2011). Small businesses are not "little big businesses" and apart from obvious quantitative differences they also differ in qualitative way from large organisations. For the need of this paper, the SMEs resilience concept is defined as "not just the one about minimising and managing the impact of the disaster, but also about creating the agility needed to adapt to unexpected challenges and the ability to seize opportunity from adversity" (Alberti, Ferrario and Pizzurno, 2018). Both SMEs resilience and also their competitiveness are shaped by three groups of factors: internal – organisational behaviour, managerial characteristics and overall quality; external – globalisation, and enabling – use of technology, generation of capital, location and marketing, and supply chain integration (Gunasekaran, Rai and Griffin, 2011). In particular, creating resilient SMEs requires knowledge retention through a flexible workforce, proper strategic managerial thinking, but also personal relationship, networking ability, organisational structure and people management (Alberti, Ferrario and Pizzurno, 2018).

3. Systems Thinking Approach to Resilience Research

Systems Thinking is a term having a few meanings (Cabrera, Colosi and Lobdell, 2008). It can be treated as a perspective, a language or as a set of tools, which include causal loop diagrams. Systems Thinking is defined as opposite to linear thinking and offers holistic approach to the analysed phenomena. Its possible applications span across various fields and disciplines (Monat and Gannon, 2015). Systems Thinking is particularly useful when dealing with complexity, as it involves uncertainty, perceiving things form various perspectives, lack of a singular "right answer". Complexity also defies linear logic, leading to various possible outcomes (Kay, 2008).

Systems Thinking approach has already been quite widely used with application to ecology, which is characterised by high level of complexity and interrelations within ecological systems and between them (Hogan and Weathers, 2006; Davis and Stroink, 2016). This wide use of Systems Thinking for investigating ecological issues contributed to gradual adoption of this approach to other scientific areas, such as sustainability and sustainability management (Williams *et al.*, 2017) and broad socio-technical problems (Davis *et al.*, 2014).

Papers that utilise Systems Thinking approach to investigate resilience are relatively scarce. Some of them are of rather general nature, triggered by the COVID-19 pandemic (Hynes *et al.*, 2020; Saulnier *et al.*, 2021). There are also streams of papers focused on community resilience (Mavhura, 2017; Helfgott, 2018), on urban resilience (Connolly, 2018; Robbins, 2022) and supply chain management (Tsolakis, Zissis and Tjahjono, 2023; Wieland *et al.*, 2023). The most promising paper on business resilience research using Systems Thinking draws viewpoints from ecology, physics, sociology, psychology and disaster management to develop a research framework for enterprise resilience (Wright *et al.*, 2012), although it does not adopt the perspective of SMEs.

To sum up, the fundamental systems-thinking perspectives and approaches include: attention to how new knowledge is gained, managed, exchanged, interpreted, integrated, and disseminated, a network-centric approach based on building relations among and between individuals and organizations, the development of models and projections, using a variety of analytic approaches (Leischow *et al.*, 2008). Systems thinking is also perceived as a valuable methodology, particularly suitable for Knowledge Management-related considerations (Rubenstein-Montano *et al.*, 2001; Cavaleri, 2005), offering new ways of thinking and a useful toolbox on different levels and phases of Knowledge Management for practical knowledge users (Gao, li and Nakamori, 2002). The current economic situation is multifactorial, dynamic and nonlinear, hence compartmental knowledge originating from scientific silos is likely to obstruct understanding of the inter-relations among all the significant variables (Leischow *et al.*, 2008). Therefore, the Systems Thinking approach can be considered as the one offering adequate tools for analysing business operations with respect to resilience, efficiency and the role of KM in shaping their relations.

4. SMEs Resilience in Turbulent Times of Globalisation

Globalisation made business world much more turbulent than ever before. Disruptions resulting from natural and man-made disasters are no longer of local or regional scale, as they are transmitted globally through the system of world economy. Increased complexity in the supply chains result in unexpected problems in production and sales. Those risks cannot be avoided, but they can be mitigated or even successfully for improving business performance used through resilience-building in companies (Yu *et al.*, 2019; Wong *et al.*, 2020). Trying to do so became a top priority for business executives in large organisations and SMEs should follow that path.

As can be seen in Figure 1., the impact of disruption on operational efficiency of businesses depends on how severe disruptions are and how often businesses are hit by disruptions. The frequency of disruptions is growing because organizations live and compete in a world that is increasingly interconnected both socially and technologically, making them prone to the so-called "butterfly effect" which is likely to appear in wide interconnected networks of companies. Disruptions are likely to cripple operational efficiency of businesses, leading to lower competitiveness, losing market shares and even business discontinuation. Positive role of resilience in increasing operational efficiency is not obvious, especially in the short run (Gölgeci, Yildiz and Andersson, 2020). On way of creating resilience is building redundancies in the company. Redundancies would operate as a buffer during a disruption (Disruption Absorption), but building and maintaining them is costly. Those additional costs are likely to lower operational efficiency of a business, leading to loosing competitiveness. Another dimension of operational resilience is recoverability. It may be partly based on redundancies representing cost increase, but also – to a greater extent – on flexibility. Unlike redundancies, flexibility yields a number of additional, day-today benefits (Sheffi and Rice, 2005).

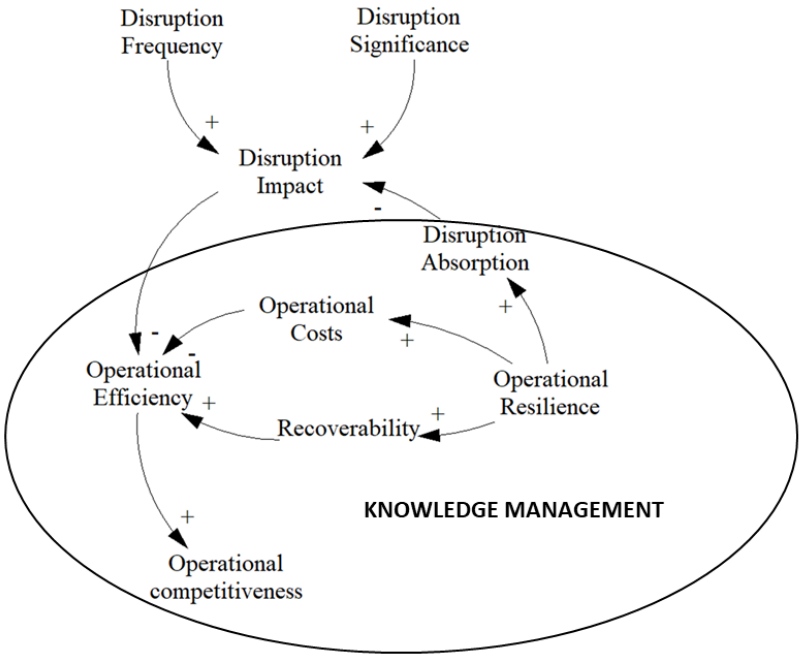

Figure 1: The role of resilience in surviving in turbulent environment (own elaboration using Vensim PLE).

Studies show that both disruption absorption and recoverability have positive, yet unique effects on operational efficiency under varying disruption conditions (Essuman, Boso and Annan, 2020). Although SMEs are more vulnerable to disruptions because of more limited resources, they also have some advantages regarding building resilience. Due to their characteristics they can benefit from less formal procedures and bureaucracy, short decision chains resulting in rapid decision-making, natural flexibility of small and more informal organisation and capacity of fast learning, if only they aspire to operate as a learning organisation (Alberti, Ferrario and Pizzurno, 2018).

5. KM in Resilience Creation

Knowledge is acknowledged as a vital aspect for improving resilience capabilities (FardH and Fani, 2015). As a consequence, Knowledge Management seems to be a very useful tool to build and enhance resilience. In the educational context, Knowledge Management Process, Knowledge Management System Infrastructure, and Knowledge System Quality proved to be effective, resilient strategies that allowed to convert challenges into opportunities during COVID-19 pandemic. In particular, Knowledge Management Process was positively and significantly associated employee commitment and performance, while knowledge sharing, accessibility and application further contributed to increased resilience (Sivagnanam *et al.*, 2023) Higher education institutions are knowledge intensive; their employees – faculty – can be considered as knowledge workers (Bratianu, 2014; Cegarra-Navarro, Garcia-Perez and Bedford, 2020). Therefore, KM practices may be easier to conduct in such a environment. The use of KM practices in SMEs is probably more challenging, but the applicability of the model developed by Sivagnanam (2023) in the context of SMEs is very likely.

In the context of healthcare systems and their response to the COVID-19 pandemic, research suggests that Knowledge Management serves as a significant predictor of organisational resilience and agility. Acquiring, sharing and applying new knowledge results in increased proactivity, adaptivity, agility and resilience (Ibrahim Ismael, Mamdouh El-kholy and Saeed Ahmed Abd-Elrhaman, 2021). Those findings corroborate with earlier results obtained in business context, namely in the banking sector. Knowledge creation process proved to enhance resilience capabilities, contributing to improvement in business performance. Knowledge creation and knowledge sharing activities also develop organisational agility and innovativeness (Alharthy, Sohaib and Hawryszkiewycz, 2018).

One of the possible ways that KM may positively influence business resilience is its link to social capital improvement. Recent research suggests that social capital can be a critical resource of both resilience in the times of crises and disruptions (when it is really needed) and also of efficiency under calmer conditions, when resilience is less useful (Sözbilir, 2018; Gölgeci and Kuivalainen, 2020). Being an element of social capital, social

networks also offer avenues for increased mobilization and transfer of knowledge, dissemination of innovative activities, which in turn increase the resilience of companies (Demmer, Vickery and Calantone, 2011).

The resilience of SMEs is constrained by their behavioural and organisational characteristics, accompanied also by limited access to resources. In order to develop the resilience of SMEs, they should place emphasis on soft aspects of change management (including people, organisational and cultural aspects), planning, preparation and embedding phases of the change process, driving the change internally and adopting proactive rather than reactive attitude (Ates and Bititci, 2011). Knowledge management practices may prove to be an invaluable tool for achieving most of those issues.

6. Conclusions

Research on resilience in business context is still rather fragmented. The concept of resilience lacks clear and common definition, measurement scale and theoretical framework. Yet, resilience becomes more and important for contemporary businesses in their struggle to survive and develop in their increasingly competitive and unstable environment. Although SMEs may be perceived as more vulnerable in this respect, they have also their advantages over bigger counterparts, such as less bureaucracy, the possibility of rapid decision-making and rapid communication, as well as shorter processes.

The potential of Knowledge Management in the area of resilience creation and maintenance is high and still not fully researched, especially with regard to SMEs. The aim of this paper is to shed some light on the possible role of Knowledge Management in making SMEs more resilient. The major limitation of the paper is that at this stage of development, the whole model of KM role in SMEs resilience creation is just preliminarily sketched. It will be further developed and completed using causal loop diagrams. Once completed, it will offer food-for-thought for various stakeholders, including SMEs owners and managers, institutions that support small business development and policy makers.

Abstract: In the past few years, in the current organisational context, the impact of Knowledge Management (KM) on Corporate Social Responsibility (CSR) has become increasingly important for companies in all sectors, as many of them are acting on a larger scale to be competitive in the global marketplace. In fact, KM helps generate sustainable innovation through inclusive CSR implementation practices (Shih, 2024). Companies are required to have a correct approach to Sustainable Knowledge Management (SKM) in order to practice the CSR model. SKM practices promote responsible and ethical knowledge sharing between different stakeholders (Alghamdi et al, 2023) and include several benefits. Promoting innovation and facilitating continuous learning, they ensure the effective and efficient use of KM. That is why this trend focuses on the development and application of innovative technologies. Based on that, this study aims to understand how KM influences CSR considering the role of Technology. The methodological approach is based on a systematic literature review (Tranfield et al, 2003). Particularly, this research was conducted in the three international and multidisciplinary databases – Google Scholar, Scopus and Web of Science – using query strings given by combinations of the keywords: "Knowledge Management", "Corporate Social Responsibility," "CSR," and "Tech*". Subsequently, the resulting scientific documents were selected following the PRISMA guidelines (Moher et al, 2015; Xiao and Watson, 2019), and the data were examined using inductive content analysis. In this article, the authors draw on current literature to identify plausible gaps and discuss future implications of a new perspective. Although the topic is relevant, the findings suggest that academics have many opportunities to examine it.

Keywords: Knowledge Management, Corporate Social Responsibility, CSR, Tech*

1. Introduction

In the past few years, in the current organisational context, the impact of Knowledge Management (KM) on Corporate Social Responsibility (CSR) has become increasingly important for companies in all sectors. Many of them are acting on a larger scale to be competitive in the global marketplace and are including the principles of sustainable development in their business strategies.

In fact, KM helps generate sustainable innovation through inclusive CSR implementation practices (Shih, 2024).

Following the most relevant studies on KM, it is possible to describe it as the process through which an organisation generates, shares, and utilizes knowledge to achieve its objective (Nonaka and Takeuchi, 1995).

The importance of this essential classification underscores the dynamic and interactive nature of KM, highlighting the ongoing process of knowledge creation and application in an organizational context.

More specifically, it is also possible to theorize that KM involves the creation, storage, transfer and application of knowledge within organisations (Alavi and Leidner, 2001). This approach captures the entire spectrum of KM activities, from the initial knowledge generation to its eventual use in decision-making and innovation process. A more comprehensive view identifies KM as a systematic practice of acquiring, organising, and communicating employee knowledge to make it available, actionable, and useful (Davenport and Prusak, 1998). This outlook outlines the structured and methodical approach required for effective KM practices, assuring that valuable insights are available within the organization.

On the contrary, defining CSR is more complex because CSR concept has evolved over the decades, changing its defining boundaries (Carroll, 1999). Using a modernized formulation, it could be defined as the summation of "organizational actions and policies that consider several types of stakeholders and the triple bottom line of economic, social, and environmental performance" (Aguinis, 2011). Simplifying, as a management orientation integrating an organisation's desire to eliminate or reduce the negative effects of its activities on the environment and society through ethically sound strategic visions.

According to these theoretical premises, companies are required to have a correct approach to Sustainable Knowledge Management (SKM) in order to practice the CSR model. SKM practices promote responsible and

ethical knowledge sharing between different stakeholders (Alghamdi et al, 2023) and include several benefits. They ensure that KM is being used efficiently and effectively, promoting innovation and facilitating continuous learning. That is why this trend focuses on developing and applying new technologies.

Understood in this way, Technology includes practical applications of scientific knowledge to improve organisational and operational processes (Daft and Armstrong, 2021). This definition includes a wide range of technological tools and systems that can optimize efficiency and effectiveness in different organizational areas. As described by Drucker (1999), Technology is seen as the set of tools, machinery and procedures used to solve specific problems and improve operational efficiency.

Additionally, it is possible to reveal the transformative potential of digital technology in business models and innovation: digital advancements are not only enhancing existing processes but also creating new opportunities for business growth and competitive advantage through innovative applications. Therefore, Technology, especially digital technology, is essential for transforming business models and driving innovation (Porter and Heppelmann, 2014).

Nowadays, “global economic development based on sustainability is only possible through broadly understood knowledge” (Krawczyk, 2022) and understanding how KM practices are more relevant to CSR is a new critical challenge. The challenges faced by current organisations have changed significantly compared to the past due to global processes, new environmental and ethical issues, and the advent of new technologies in organisational functioning. Therefore, the public interest that governmental and institutional pressures promote leads organisations to adopt a sustainable economic development model that can satisfy the needs of current stakeholders without compromising the needs of future generations.

Combined with the concept of innovation, sustainability is part of a binomial supporting corporate competitive advantages. In fact, companies adopting a CSR model with the goal of creating sustainable value cannot ignore technological innovation processes: to pursue a sustainable competitive advantage, increasing both productivity and environmental protection, enterprises continuously apply new technologies and their ability to transform knowledge into new technologies is relevant (Krawczyk and Kokot-Stępień, 2023).

Related to this, KM is crucial because it is capable of encouraging the development of innovation and facilitates continuous learning. Its relevance for organisational success is widely recognized in literature (Drucker, 1993; Grant, 1991; Nonaka and Takeuchi, 1995).

Despite the acknowledged intensity of the connection between KM and CSR, recent studies have argued that "there is a paucity of management programmes on CSR, which creates a knowledge gap in the implementation of CSR by modern organisations" (Krawczyk, 2022).

Moving from these considerations and considering this gap, this research aims to understand KM's influence on CSR and discover the role of Technology in this relationship.

After this brief introduction and the identification of the research purpose (1), the authors develop the remainder of this study into the following paragraphs: “Methodological design” sets out the theoretical backgrounds and the methodological steps followed in the systematic literature review and data collection process (2); "Findings and discussions” presents the most relevant results obtained during research activity (3); “Stimuli and implications, limitations and future research directions” discusses the results, main limitations and implications for future research (4).

2. Methodological Design

This study offers a theoretical framework on the topic above, applying a methodological approach based on a systematic literature review (Tranfield et al, 2003).

Specifically, the main methodological goal of this article is to review and systemize available academic information to answer the following questions:

1. What Is The Impact Of KM On CSR?
2. What Is The Role Of Technology In The KM-CSR Relationship?

A frame of reference to the theoretical background used for the systematic literature review is helpful in achieving this specific objective. Of the various types of literature reviews that could be referred to for the methodological design of this study, the systematic review was preferred to the other typologies as it is more suitable for its compliance with defined methodological criteria (Xiao and Watson, 2019) and it is coherent with

the need to understand the progress of studies on this topic. Indeed, it outlines possible new directions for further research, which could lead to a broader understanding of the phenomenon and an innovative framework.

Moreover, it is a very businesslike methodology for academics and researchers, managers, business professionals and entrepreneurs. In fact, according to Tranfield et al (2003), "a good systematic review should make it easier for the practitioner to understand the research by synthesizing extensive primary research papers from which it was derived" and also “systematic review can be argued to lie at the heart of a pragmatic management research, which aims to serve both academic and practitioner communities”.

Against this background, the following two sub-sections illustrate the systematic approach used to outline the collected academic contributions, which proves a reliable and repeatable process.

2.1 Methodological Steps

Before investigating the state of the literature on the defined research questions and evaluating the studies included in the selection, the authors developed an inclusive review protocol of the criteria and strategies for searching, evaluating and synthesizing the data. During this phase, they identified keywords based on the search questions and they chose reference databases; subsequently, they designated selection criteria.

The research was conducted in the three international and multidisciplinary databases: Google Scholar (GS), Scopus, and Web of Science (WoS), using query strings given by combinations of the following keywords: "Knowledge Management", "Corporate Social Responsibility", "CSR", and "Tech*".

In particular, the choice of the databases GS, Scopus and WoS depended on several factors: 1) they are the databases widely used by academic scholars; 2) they are international and multidisciplinary sources of data and knowledge (in particular, the multidisciplinary allows the researcher to easily search outside of his discipline); 3) neither database is inclusive but each complements the other (Burnham J., 2006). Particularly, the specific choice to also use the GS database was due to its more extensive numerical availability of contributions on the topic researched. In fact, according to Walters (2007), “GS might be expected to provide especially good coverage of the literature due to its size and interdisciplinary scope”, despite its lack of possibility to filter results with regard to subject area.

Instead, in relation to the choice of keywords, the authors preferred to filter the keyword "Knowledge Management" instead of other knowledge management classifications in order to include all KM practices in the search. With the aim of amplifying the results relating to the Corporate Social Responsibility, the expression was considered both in its extension "Corporate Social Responsibility" and in its acronym "CSR". In addition, the keyword “Tech*” was chosen as the root of the term “Technology” with the intention of including all declinations of the term without altering its meaning.

Scientific documents were extracted in April 2024 and a subsequent follow-up update was carried out in July 2024 in order not to exclude additional contributions and new evidence that could have influenced the research results.

Specific inclusion and exclusion criteria were incorporated in each database. More particularly, in the WoS database (www.webofknowledge.com), the scientific documents were selected for the first time using the following string: "Knowledge Management" (Topic) AND "CSR" (All Fields) AND "Tech*" while, afterward, using a combination of the keywords: "Knowledge Management" (Topic) AND "Corporate Social Responsibility" (All Fields) AND "Tech*"(All Fields). In both cases, the Web of Science categories – “Management”, “Business”, “Economics”, and “Social Science Interdisciplinary” – were filtered out, and only articles written in English were considered. The first research generated 21 results, while 38 papers emerged from the second research, for a total of 59 papers.

In the Scopus database (www.scopus.com), the same two strings were repeated: 1. (TITLE-ABS KEY ("knowledge management") AND TITLE-ABS-KEY ("CSR") AND TITLE-ABS-KEY ("Tech*")) and 2. (TITLE-ABS-KEY ("knowledge management") AND TITLE-ABS-KEY ("corporate social responsibility") AND TITLE-ABS-KEY ("tech*")). Also, for the investigation of the study through this second database, filters were also applied, and these were defined according to the subject areas “Business, Management and Accounting”, “Social Sciences” and “Economic, Econometrics and Finance” and limited to “article” type articles written in English. In total, 18 papers were collected: 7 articles with the first search string and 11 papers using the second keyword combination.

Lastly, also in the GS database (https://scholar.google.com/), the strings given by the combination of keywords – "Knowledge Management" and "CSR" and "Tech*" – and by the combination of keywords – "Knowledge Management" and "Corporate Social Responsibility" and "Tech*" – were included. As in previous research, the criteria selected have included scientific documents written in English. Both search strings generated significantly higher results than the other two databases: while 589 articles were derived from the first search string, 807 articles were derived from the second combination, for a total of 1396 articles.

Overall, 1473 results were obtained. All data were saved in CSV format and all records were extracted, exported, and coded into Microsoft Excel documents, combining the two strings for each database, sorting the titles alphabetically, and eliminating 451 duplicate items both, at first, within each database and, subsequently, among the three databases.

Therefore, 1022 articles were screened. After this step, the titles and abstracts of the articles found were reviewed and those that were not pertinent to the research questions were also excluded. From the total number of studies admitted for retrieval, 106 of them were admitted to the eligibility phase. They were all read to examine the coherence with the objective of this research and 37 studies were considered in the final survey and included in the systematic review.

2.2 Data Collection Process

Throughout the data collection process, the resulting scientific documents were selected following PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) Guidelines (Moher et al, 2015; Xiao and Watson, 2019) and the data were examined using inductive content analysis.

The authors opted to use the PRISMA checklist because it guarantees the survey's transparency and replicability. In fact, they could aggregate all data from the obtained findings and select them through three phases: 1) identification, 2) screening & eligibility and 3) included. The methodological steps described in the previous paragraph have been included in each phase.

Figure 1 shows the PRISMA flow diagram used during the systematic literature review process.

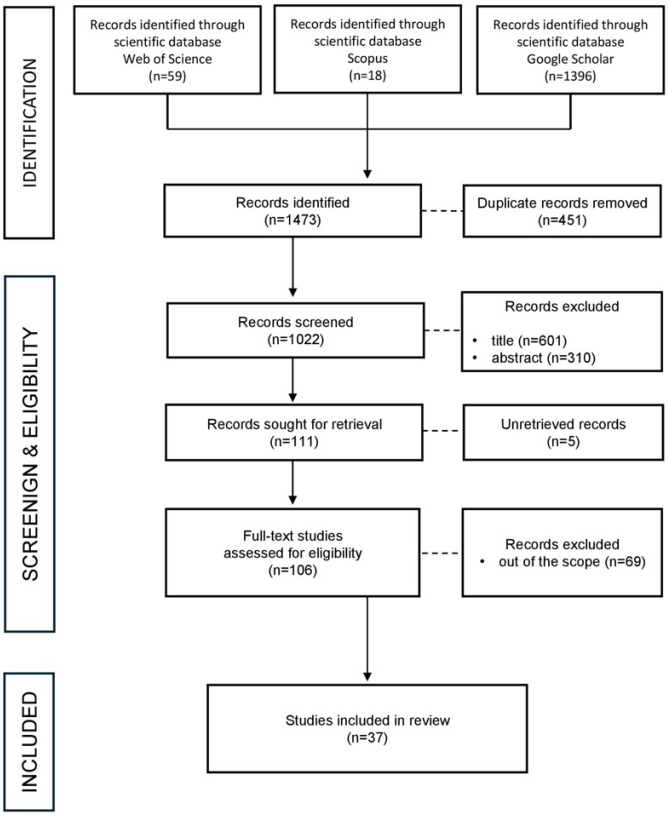

Figure 1: Systematic literature review process adopting PRISMA Guidelines

The studies included in the synthesis discovered different study variables, revealing the presence of various currents of thought in the existing literature.

3. Findings and Discussions

This section highlights the most relevant research findings and spaces for discussion on the topic. On the one hand, it confirms that the CSR-KM relationship is relevant and that technology plays a decisive role in it. On the other hand, it emphasizes a gap in the literature on the topic, resulting in the need for further investigation.

Concerning the CSR-KM relationship, KM practices can enhance the innovation and sustainability variables underlying CSR (Guadamillas-Gómez and Donate-Manzanares 2011) and KM can be a moderator of the influence of CSR on organisational performance (Ling, Y.H., 2019). For example, knowledge improvement inspires employees' sense of responsibility for corporate ESG goals (Solaimani, 2024). The ability of an organisation to implement sustainable innovation, closely related to its CSR and green entrepreneurial orientation, is influenced by KM practices, Technology, and Innovation (Acevedo et al, 2024, Tuncer and Korchagina, 2024, Martínez-Falcó et al 2023; Newaz 2022).

KM practices, in particular knowledge creation (Batista et al, 2017) and knowledge sharing (Areed et al, 2020), have an effect on CSR orientations because of their sustainable competitive advantage (Mahdi et al, 2011) and related studies have confirmed that benefits can be derived from this (Mayarni et al, 2023).

However, integrating the survey with the role of technology and considering the integration of sustainable business models with the prospects of digital technology (Brenner, 2018), it is necessary to consider that technology can improve knowledge management processes (De Bernardi et al, 2020) and that an intelligent organisation with a correct ethical approach, maximising continuous learning processes, use technology to pursue competitive advantage (Godlewska-Majkowska, 2019; Direction, 2011). Technological evolution has made knowledge a key determinant of innovation, contemplating new production and consumption systems that are environmentally friendly, economically sustainable, and socially responsible among the long-term goals (Buchmeister, 2013).

Integrating KM strategies with CSR improves corporate innovation capacity, especially in the renewable energy sector, where technological innovation is particularly important (Gonzáles-Ramos et al, 2023). Some studies have shown that in other sectors technology and knowledge are also important in terms of sustainability. For example, in the agribusiness sector, which is technologically dynamic (Morea, D. et al, 2023), CSR is recognized as a catalyst for the development of the circular economy (Depetris et al, 2023) and also in the health-hospital sector both KM practices and the application of new technologies have been considered relevant to sustainable policies (Borges de Oliveira and De Oliveira, 2022).

Another important result concerns the technological implications on corporate sustainability following the Covid-19 pandemic as the need for digital transformation has emerged (Su et al, 2022), given also the importance of technologies in meeting the demand for sustainable products (Cegarra-Navarro et al, 2021) and its ability to shape human action during a pandemic crisis (Hysa et al, 2024). Both technology and a proper approach to CSR policies can help organisations to deal with complex situations, such as an epidemic, by facilitating knowledge exchanges (Jain et al, 2022).

In addition, Industry 4.0, characterized by artificial intelligence (Panu, 2021) and inclusive of major technological changes, could also support corporate sustainability. In order to achieve greater levels of eco-sustainability, organizations are also resorting to digital platforms (Nemilentseva et al, 2024), as well as the adoption of blockchain technology (Sun et al, 2022). However, few studies deal with sustainable Industry 4.0. These include the study by Anshari et al. (2022), which states that its impact has yet to relate to KM practices.

Affecting CSR orientation positively on technological innovation performance (Anzola-Román, 2024), technology plays a decisive role in sustainable innovation, dominated by KM practices. Presently, managers' perceptions of rapidly changing factors such as technology induce companies to increase their investments in CSR (González-Ramos et al., 2023) while investments in ICT and the recruitment of specialized employees in its use contribute to greater innovation in organisations (Ayestarán Echeberría et al, 2023). Finally, SMEs, which compose most of the industrial fabric of developed and developing countries, can benefit from technology transfer in innovation processes (Scanlan, 2017).

Therefore, new research spaces are configured in the CSR-technological innovation relationship (Yang et al, 2024) and it is clear that there is a need to explore this issue further, better defining the SDGs Research Gap Technology, Innovation and Knowledge (Castro et al, 2021).

4. Stimuli and Implications, Limitations and Future Research Directions

This systematic literature review does not aim to complete the gaps in the state of the art on the investigated subject but its goal is to define them to allow researchers to explore them more thoroughly in the future and discuss new perspectives. In fact, it offers new stimuli for academics and researchers in the sector and similarly raises relevant implications for managers, practitioners, entrepreneurs, and policymakers engaged in developing new business directions and strategies.

The topic is relevant and there might be more opportunities to examine it. Actually, the results of this study open up different lines of multidisciplinary research as they outline possible new directions for further research, which in turn could lead to a broader understanding of the phenomenon and an innovative framework.

In terms of practice, both implicitly and explicitly with reference to the KM and ecodesign relationship (Lima et al, 2024), it has emerged that technology plays a decisive role in the relationship KM-CSR and, consequently, that it would be appropriate to explore it in depth.

Regarding its limitations, our article mentions several constraining factors. Firstly, it is based on the analysis of articles contained only in three scientific databases and in specific sub-areas. On the other hand, the choice of keywords and the inclusion and exclusion criteria defined ex-ante in the search strings may have also influenced the results. Therefore, additional studies should be conducted using other databases, sub-areas and inclusion or exclusion criteria or expanding the keywords and their combinations.

Consequently, the authors believe that this research does not exhaust the investigated topic but could serve as a starting point for future research development, whose directions could be oriented towards the interception of further relevant contributions in the literature concerning the impact of KM on CSR and the role of Technology in the relationship between these two concepts. The specificity of the two research questions and the dependency of the second from the first have conditioned the transition from the "eligibility" to the "included" phases, determining a substantial number of studies excluded as unrelated to the research aim.

In conclusion, on the assumption that literature review knowledge is an essential feature of academic research and knowledge advancement must be built on prior existing work (Xiao and Watson, 2019), future research should investigate the topic, extending the state of the art regarding the challenges approached in this study and exploring which KM practices and the further technological advancements could have the greatest impact on organisational sustainability processes.

Knowledge Management in Social Organizations During a Humanitarian Crisis

Zbigniew Zontek and Ewa Lipianin-Zontek
University of Bielsko-Biala, Faculty of Management and Transport, Department of Management, Bielsko-Biala, Poland

zzontek@ubb.edu.pl
elipianin@ubb.edu.pl

Abstract: This paper presents an overview of issues related to the role of knowledge management in social organizations. Chosen aspects of knowledge management theory in voluntary not-for-profit groups, operating during a humanitarian crisis, are here addressed. The paper aims to demonstrate the determinants of knowledge management, using as an example, events at the Poland/Ukraine border - in the period 2022-2023. The additional aim is to show how to identify common processes underlying knowledge management, and how it was acquired, managed and transferred, in disparate organizations. The authors of this paper took part in the humanitarian action in the first few weeks of the conflict - both independently and in co-operation with non-governmental organizations. This allowed for the collection of extensive material during the first stage of the research, and creation of a database of NGO's, used for the second stage of the research. During preparations for the survey a hypothesis was established: When sudden emergencies arise, a variety of information and knowledge is collected, dispersed, widely shared, and belongs to many different organizations. Therefore, a coherent information system is needed for the dissemination and sharing of knowledge for effective assistance to people affected by the crisis. The methodology of participatory observation and surveys was used for the research. It was found that knowledge was transferred in and out of the organizations, and expertise from earlier experiences was also applied and transferred, thus becoming explicit. Managerial skills and methods were applied in new organizational contexts. Knowledge acquisition, transfer and sharing were clearly identifiable across in a wide spectrum of research, as was organizational learning and the subsequent usage of it. Knowledge management in a crisis situation encompasses all activities aimed at improving preparatory and executive actions. One of the key elements of knowledge management, which determines its success, is effective acquisition, information handling and delivery to the relevant organizations involved. This is essential for the response of individual organisations, whether at the level of local government or national non-profit organizations.

Keywords: Knowledge Management, Humanitarian Crisis, NGO Organizations

1. Introduction

Effective Knowledge Management (KM) serves as a vital instrument for organizations, enabling them to preserve, cultivate, structure, and utilize accumulated knowledge efficiently. Scholars and practitioners alike recognize the potential and significance of knowledge management for organizational success, as underscored by Karamat (2018). Essentially within the dynamic landscape of social organizations in Poland, which boasts substantial knowledge reservoirs, it is imperative that good knowledge management becomes even more essential. Various strategies must exist for the formal recording, transfer, and utilization of knowledge within social organizations.

Non-governmental organizations (NGOs) assume a significant role in ameliorating the adverse ramifications of humanitarian crises. By operating in close proximity to affected populations and directly engaging with the environment, NGOs are adept at accurately identifying emergent issues. Moreover, they often possess more suitable means and methodologies to address the challenges at hand-compared to other entities. Based on independent decisions, NGOs exhibit a heightened awareness of crisis situations, enabling them to operate swiftly and effectively, to reach affected individuals. This results in a more efficient mitigation of the crisis's detrimental effects on individual stakeholders and enhances societal protection.

Non-governmental organizations exhibit a varied approach to crisis situations, potentially fostering mutual trust and nurturing interpersonal relationships during challenging times (Egger and Schopper, 2022).

Haaland and Wallevik (2019) underscore the crucial role of citizens in executing aid activities, asserting that in extensive humanitarian crises involving a substantial number of individuals in distress, the efforts of governmental and non-governmental organizations alone may prove insufficient. Rabiei et al. (2023) similarly highlight the significance of "spontaneous volunteers" in crisis situations, identifying the primary challenge as the effective allocation of volunteers during disasters. Taouktsis and Zikopoulos (2024) emphasize the organizational aspect of knowledge management in crisis situations, proposing enhancements in humanitarian logistics. Mena and Hilhorst (2022) isolate a critical facet of crisis management, noting the shift from development and disaster reduction to humanitarian aid.

Despite an extensive body of literature on knowledge management during crises in developed nations, there remains a notable dearth of research on KM implementation amid humanitarian crises, especially within the Polish context. In the wake of the humanitarian crisis on the Polish-Ukrainian border, Poland found itself in the nascent stages of crafting a knowledge management strategy, encountering numerous challenges, barriers, and deficiencies in the implementation process. This study aims to identify and analyse the factors influencing the efficacy of knowledge management, as well as the obstacles and gaps hindering its successful implementation.

2. The Role of Social Organizations in Managing Humanitarian Crises

As per the Organization for Economic Co-operation and Development (OECD) definition, social organizations are institutions dedicated to activities benefiting the community or public interest, with their primary aim being to foster social or public welfare rather than private financial gain (Lettieri et al., 2004). These entities can manifest in various forms, including non-profit organizations, non-governmental organizations (NGOs), foundations, associations, and other entities dedicated to social good. This sector is characterized by its diversity, encompassing a broad spectrum of endeavours ranging from charitable works to social and educational initiatives. Moreover, social organizations frequently engage in humanitarian efforts, addressing crises and needs within both local and global communities.

In academic literature, the term "Non-Governmental Organization" (NGO) is commonly used internationally as a synonym for social organizations. Additionally, terms such as "non-profit organizations" or "public service organizations" are employed interchangeably to describe these entities. These varying designations underscore the overarching principle that the endeavours of social organizations should be oriented towards addressing diverse social needs at a public level, transcending the individual interests of founders, board members, or organization constituents themselves (Supra-Markowska, 2015).

Within the realm of humanitarian crises, social organizations play a pivotal role in extending aid to affected populations, safeguarding civilian well-being, orchestrating relief efforts, conducting educational initiatives, and bolstering local communities. Additionally, they undertake measures to address the root causes of crises (OECD, 2024). Through their active involvement, the alleviation of suffering among crisis-affected individuals becomes feasible, facilitating their rehabilitation and recovery in the aftermath of disasters or other humanitarian emergencies (Singh, 2023).

As per the OECD's (2019) delineation, humanitarian organizations are entities dedicated to providing assistance in crisis scenarios, encompassing natural calamities, armed conflicts, poverty, and other exceptional circumstances posing threats to individual or community life, health, or safety. These organizations are committed to both pre-emptive measures and crisis response. A cornerstone of their endeavours lies in advocating for human rights, humanitarian principles, and universal values.

Humanitarian organizations operate across a spectrum of scales, ranging from the international level (e.g., the Red Cross, Red Crescent, UNICEF) to the local, regional, and national levels. Within Poland, prominent humanitarian entities include the Polish Red Cross (PCK), Caritas Poland, Polish Humanitarian Action (PAH), The “Ocalenie” Foundation, and similar organizations. These entities frequently collaborate among themselves and with governmental bodies, UN agencies, and local communities to deliver impactful humanitarian aid to those facing the most acute vulnerabilities. Such collaborative efforts not only enhance the efficacy of assistance but also foster the development of innovative solutions (Williams, 2012, pp. 550-560).

3. The Contribution of Polish Social Organizations in Delivering Aid Amidst the Humanitarian Crisis on the Polish-Ukrainian Border

Polish humanitarian organizations have played a crucial role in providing aid during various crises along the Polish-Ukrainian border (Stępień-Załucka & Uliasz, 2023). The armed conflict in Ukraine, initiated in February 2014, stemmed from preceding events, including the Maidan Revolution in Kiev in November 2013 and the ousting of President Viktor Yanukovych in February 2014. The direct catalyst for the conflict was Russia's annexation of Crimea in March 2014 and escalating tensions in eastern Ukraine, particularly in the Donetsk and Luhansk oblasts, where separatist movements emerged, advocating for independence from Kiev. This conflict evolved into an open armed confrontation between Ukrainian forces and pro-Russian separatists, backed by Russia. Subsequently, ongoing hostilities in eastern Ukraine have resulted in tragic consequences for civilians and have contributed to regional destabilization (United Nations, 2022; Freedman, 2023).

Throughout the Ukrainian crises, Poland emerged as a pivotal contributor to humanitarian assistance, driven by several key factors. Firstly, its geographical situation next to Ukraine, positions Poland as a natural ally in extending humanitarian aid during crisis scenarios. Proximity facilitates the logistical organization and transportation of aid to affected regions. Secondly, Poland boasts considerable expertise in humanitarian endeavours, both domestically and internationally. Leveraging this expertise, Polish humanitarian organizations and the governmental Agency for Technical and Programmatic Assistance (Polish Aid, 2024) possess the requisite knowledge and resources to orchestrate humanitarian initiatives effectively. Thirdly, Poland and Ukraine share a profound historical bond, marked by intertwined destinies and enduring relations. Despite historical challenges, a profound sense of solidarity prevails between the two nations, with Poland exhibiting particular empathy and support towards Ukraine during crises and hardships. Provision of humanitarian aid serves as a tangible manifestation of this solidarity and compassion. Lastly, Poland actively champions Ukraine's political, economic, and social transformation efforts. Humanitarian aid stands as a vital component of this multifaceted collaboration, aimed at bolstering democracy, rule of law, and stability within Ukraine (Stępień-Załucka & Uliasz, 2023).

According to Office of the United Nations High Commissioner for Human Rights (OHCHR), Poland assumes a pivotal role in delivering humanitarian aid, offering crucial support to the Ukrainian populace during times of adversity and aiding in alleviating the repercussions of humanitarian crises in the region (OHCHR, 2022). Below are excerpts from sources discussing initiatives undertaken by Polish humanitarian organizations.

Following Russia's annexation of Crimea in 2014, numerous individuals from Crimea were compelled to flee their homes and seek refuge in Poland. In response to this exigency, humanitarian organizations extended material aid, psychological counselling, and assistance in job placement and acclimatization to new living conditions (Patel and Erickson, 2022). During the period of 2014-2015, amid the armed conflict in Eastern Ukraine, thousands sought sanctuary in Poland. Polish humanitarian entities provided vital support to refugees, furnishing them with shelter, sustenance, clothing, medical attention, and psychological counselling (Asmussen, 2014).

Since the onset of 2022 and the escalation of the armed conflict, Polish humanitarian organizations have consistently offered aid to migrants and individuals in distress along the Polish-Ukrainian border. This aid again includes provision of sustenance, clothing, hygiene essentials, medical care, and psychological assistance to individuals navigating challenging circumstances while crossing the border. Additionally, aid includes facilitating transportation to accommodation sites and furnishing comprehensive support in the refugees' newfound places of residence (Patel & Erickson, 2022).

4. Knowledge Management Practices Within Social Organizations

Knowledge serves as vital intellectual capital, underpinning the growth of both individuals and organizations. It plays a structural role, providing a cohesive framework for data and information processing (Zins, 2007), thereby facilitating the derivation of meaning and deeper comprehension. Furthermore, knowledge transcends mere factual contexts, evolving into a wellspring of wisdom through synthesis and reflection upon accumulated content.

In terms of fundamental classification, knowledge can be delineated into two primary categories: explicit and tacit (Smith, 2001; Collins, 2019). Explicit knowledge, being overt and tangible, is readily articulated through defined concepts, figures, or facts. However, it represents only the visible portion of the knowledge reservoir, akin to the tip of an iceberg. Conversely, tacit knowledge, constituting the majority of our knowledge base, proves elusive to capture and express. As observed by Michael Polanyi, we may possess knowledge that eludes clear articulation (Polanyi, 2009).

Another important categorization of knowledge extends to include implicit knowledge (Ahmed et al., 2002). While tacit and implicit knowledge are often used interchangeably, it's important to distinguish that tacit knowledge refers to the type of knowledge an individual may possess without realizing it. This knowledge is typically acquired through experience and practice and may not always be consciously expressed (Chmielewska-Banaszak, 2010). Alternatively, a slightly different perspective on tacit knowledge (Sternberg et al., 2000.) defines it as knowledge that is not directly expressed and is acquired through individual human experience. Tacit knowledge exhibits three distinct characteristics: 1) It is autonomously acquired by the individual; 2) It is primarily procedural in nature, based on skills and methods of conduct; 3) It is directly applicable in practice, meaning it is relevant to specific operational contexts.

This approach underscores the specialized nature of tacit knowledge, which is intricately linked to specific contexts, encompassing effective action methods within particular situations. The context for such knowledge may encompass both an individual's personal experiences and the professional environment in which they operate. Moreover, rich tacit knowledge serves as a springboard for various combinations of established procedures, facilitating its flexible adaptation to new circumstances. This entails the creative utilization of developed patterns and procedures acquired during the knowledge acquisition process, alongside integration of new information (Wąsowska, 2018).

In social organizations, knowledge management endeavours are geared towards fostering continuous learning, enhancing human resource development, and cultivating intellectual capital, to effectively carry out community-oriented initiatives and fulfil organizational missions (Siawsh et al., 2023). As outlined by the Organization for Economic Co-operation and Development (OECD, 2019), knowledge management in social organizations encompasses processes, strategies, and practices aimed at adeptly gathering, utilizing, and disseminating knowledge to advance organizational objectives and cater to the needs of members and stakeholders. This entails the identification, creation, collection, storage, analysis, sharing, and application of knowledge to enhance decision-making, foster innovation, streamline processes, and attain organizational excellence.

The cornerstone of successful knowledge management lies in the seamless collaboration among three sectors: public organizations, non-governmental organizations, and businesses. This management approach hinges on the harnessing of intangible assets, primarily knowledge and human capital (Hislop et al., 2018), complemented by modern information technologies (Karamitri et al., 2020). Possessing human intellectual capital and knowledge spanning not only organizational management but also the latest advancements in technology and contemporary science, is pivotal component of effective knowledge management. Da Silva Avanzi, et al. (2017) propose Disaster Response Management System, supporting aspects of knowledge management such as: knowledge acquisition, organisation and assessment.

Thus, as outlined above, in humanitarian organizations, effective knowledge management serves as a linchpin for enhancing operational efficacy, facilitating information exchange (McGill et al., 2023), mitigating redundancies, and fostering continual improvement. Consequently, this enables more adept crisis response and the provision of efficient humanitarian assistance.

5. Selected Aspects of Knowledge Management During Humanitarian Crises: Insights From Research

The study focused on representatives of charitable organizations engaged in aiding refugees during the humanitarian crisis on the PL/UA border, specifically during the initial weeks of the armed conflict in Ukraine and immediately thereafter. Two distinct phases of the crisis were identified for research purposes: the initial phase, characterized by assistance provision at border reception sites for individual refugees, and the subsequent phase involving aid delivery to refugees at their places of residence in Poland.

As previously mentioned, the hypothesis posited that during sudden emergencies, a plethora of information and knowledge is amassed, disseminated, widely shared, and owned by numerous organizations. Hence, the necessity for a cohesive information system to effectively disseminate and share knowledge in order to aid those affected by the crisis.

As already indicated, the authors of the paper actively participated in a humanitarian operation during the initial weeks of the crisis, both independently and in collaboration with non-governmental organizations, occurring in February and March 2022. Subsequently, during this timeframe and immediately thereafter, phase 1 of the research was conducted. The research employed a methodology encompassing participant observation and a diagnostic survey administered through a questionnaire.

The aim of the study was to explore the potential for establishing knowledge management standards during humanitarian crises. The research utilized a survey questionnaire administered directly in locations where humanitarian operations were underway. A purposive sampling method was employed, with volunteers from organizations actively engaged in assisting on the Polish-Ukrainian border invited to participate in the study. A total of 123 correctly completed questionnaires were collected during the initial phase of the crisis. Subsequently, in 2023, the research was replicated with the same methodological framework. Following the second phase of the crisis, 217 correctly completed questionnaires were obtained.

This paper presents the results of research on the need to use an information system in the dissemination and sharing of knowledge (results from two phases of the research are presented). Another analysed issue is the assessment of aspects of knowledge management in a crisis situation. This question was asked in the second round of research because it was considered that a time distance would be necessary to make the first assessments.

Table 1: Valuing the need to use an information system in the dissemination and sharing of knowledge (2022, n=123)

No.	Specification	0	1	2	3
1.	It is necessary to use an IT system to manage knowledge.	0%	3.3%	14.6%	82.1%
2.	The introduction and use of an information system increases the effectiveness of assistance.	0%	12.2%	13.0%	74.8%
3.	It is necessary to introduce a database of good practices.	0%	0.8%	16.3%	82.9%
4.	A coherent system of recording current activities of charitable organizations is needed.	34.2%	35.7%	17.1%	13.0%
5.	A coherent information system for the exchange of experiences (forums and discussion groups) is needed.	0%	47.2%	47.9%	4.8%
6.	A coherent information exchange system for the group of experts is needed.	24.4%	55.3%	18.7%	1.6%
7.	A coherent nationwide portal is needed where refugees from Ukraine can find various forms of support.	0%	1.6%	14.7%	83.7%
8.	A coherent nationwide portal is needed where helpers (volunteers and charities) can find a variety of information.	0%	8.2%	3.3%	88.6%

Where: 0 - disagree 1 - slightly agree 2 - moderately agree 3 - strongly agree

Source: Own elaboration based on a survey

Tables 1 and 2 depict the findings from the research regarding the significance of individual aspects of the information system in disseminating and sharing knowledge during crisis situations. The results indicate that the passage of time between both phases of the study influenced certain outcomes.

Across both studies, the consensus regarding the necessity of employing a cohesive IT system for knowledge management during crisis situations remained steadfast, with over 80% of respondents strongly agreeing with this proposition. Moreover, support for the notion that such a system would enhance aid effectiveness saw a marginal increase, with the percentage of those strongly in agreement rising from 74.8% to 79.3%. Conversely, backing for the implementation of a database of good practices experienced a decline, decreasing from 82.9% to 71.9% respectively.

Table 2: Valuing the need to use the information system in the dissemination and sharing of knowledge (2023, n=217)

No.	Specification	0	1	2	3
1.	It is necessary to use an IT system to manage knowledge.	0.0%	1.4%	12.9%	85.7%
2.	The introduction and use of an information system increases the effectiveness of assistance.	0.0%	5.5%	15.2%	79.3%
3.	It is necessary to introduce a database of good practices.	3.2%	6.9%	18.0%	71.9%
4.	A coherent system of recording current activities of charitable organizations is needed.	18.9%	28.6%	35.0%	17.5%
5.	A coherent information system for the exchange of experiences (forums and discussion groups) is needed.	10.1%	18.9%	30.0%	41.0%
6.	A coherent information exchange system for the group of experts is needed.	14.7%	29.0%	40.1%	16.1%
7.	A coherent nationwide portal is needed where refugees from Ukraine can find various forms of support.	0.0%	1.8%	14.7%	83.4%
8.	A coherent nationwide portal is needed where helpers (volunteers and charities) can find a variety of information.	3.2%	18.0%	28.1%	50.7%

Where: 0 - disagree 1 - slightly agree 2 - moderately agree 3 - strongly agree

Source: Own elaboration based on a survey

Over time, as aid organizations coordinated their efforts, there was a notable increase in support for a cohesive system to document the ongoing activities of charitable organizations, with the combined indications for moderate and strong agreement rising from 30.1% to 52.5%. This increase was even more pronounced for specific facets of the information system: 1) The percentage of respondents indicating moderate and strong endorsement for a unified system to document the current activities of charitable organizations increased by

approximately 17.5%; 2) There was an 18.3% increase in support for the notion of establishing a platform for exchanging experiences, encompassing forums and discussion groups.

While the percentage of respondents fully supporting a nationwide portal for individuals in need remained steady, slightly above 80%, there was a notable decrease in support for a comparable system designed for aid institutions. In 2022, 88.6% strongly agreed with this concept, but by 2023, this figure dropped to 50.7%. This trend indicates that over time, aid organizations established their own methods for coordination and collaboration.

Table 3 illustrates the findings from the assessment of individual aspects of knowledge management during a crisis situation, conducted during the second phase of the research. Analysis of the results reveals a significant improvement in the rating of access to up-to-date information during the post-crisis phase. Specifically, 44.7% of respondents indicated a rating of 4, while 26.3% indicated a rating of 5. In contrast, during the crisis situation, only 8.8% and 6% of respondents provided ratings of 4 and 5, respectively. However, access to central knowledge databases was rated low during the crisis, with the most frequently selected rating being 2 (40.1% of responses). Similarly, the presence of up-to-date information in these databases received low ratings, with 2 being the most frequently selected rating (35.9% of responses).

Table 3: Assessment of knowledge management aspects in a crisis situation (2023, n=217)

No.	Specification	1	2	3	4	5
1	Availability of up-to-date information during the crisis	11.1%	21.7%	52.5%	8.8%	6.0%
2	Availability of up-to-date information in the post-crisis phase	3.7%	5.5%	19.8%	44.7%	26.3%
3	Access to the central knowledge base during a crisis	16.6%	40.1%	20.7%	16.1%	6.5%
4	Up-to-date information available in the knowledge base	19.8%	35.9%	30.9%	7.8%	5.5%
5	The speed of response of public authorities to a suddenly emerging problem	14.7%	20.7%	41.0%	12.4%	11.1%
6	The speed of the organization's adaptation to a dynamically changing situation	0.9%	14.3%	14.7%	24.9%	45.2%
7	Effectiveness of communication between NGOs	4.1%	8.3%	33.6%	29.0%	24.9%
8	Effectiveness of communication between NGOs and public services	9.7%	22.1%	41.0%	11.1%	16.1%
9	Cooperation and coordination of aid activities	12.4%	18.0%	36.4%	24.9%	8.3%
10	The usefulness of the external knowledge sources	3.7%	15.7%	31.3%	26.7%	22.6%
11	Long-term learning from the experience of the first phase of the crisis	6.5%	11.1%	33.2%	20.3%	29.0%

Where: 1- the lowest mark; 5-the highest mark

Source: Own elaboration based on a survey

The response speed of public authorities to the sudden emergence of a problem received an average rating, with 3 being the most frequently indicated rating (41%). Conversely, the response speed of non-governmental organizations (NGOs) garnered higher ratings, with the majority of respondents selecting the highest rating (45.2%). The effectiveness of communication among NGOs was rated positively, with 53.9% of respondents indicating ratings of 4 and 5, compared to the effectiveness of communication between NGOs and public organizations, where only 27.2% of respondents rated it as 4 or 5.

Assessment of the cooperation and coordination of aid activities and the usefulness of external sources of information yielded average ratings, with 36.4% and 31.3% of respondents respectively indicating a rating of 3.

A crucial criterion for evaluating effectiveness is the ability to engage in long-term learning based on experiences from the initial phase of the crisis. Half of the respondents evaluated this aspect positively, with 20.3% selecting a rating of 4 and 29% selecting a rating of 5. This distribution of responses suggests that NGOs are better equipped to handle potential future crises.

The findings from participant observation aligned with the aforementioned results, revealing that during the initial phase of the crisis, the effectiveness of knowledge acquisition from institutions and organizations was relatively constrained. Given the dynamic nature of the situation on the Polish-Ukrainian border at that time, information was not consistently available on internet information websites. Nonetheless, participants engaged in aid activities expressed a strong desire to acquire such knowledge.

These findings also underscored the significance of informal groups as a means of managing knowledge and facilitating its transfer. Informally provided information often proved to be the sole available knowledge source,

offering real-time updates, reliability, and alignment with recipients' needs. Overall, a notable willingness among volunteers and other stakeholders to share knowledge during the crisis was observed. However, the implementation of a unified knowledge management system during that period could have significantly enhanced aid activity coordination.

6. Conclusions

Several compelling reasons underscore the importance of knowledge management in humanitarian organizations. Firstly, operational effectiveness: Humanitarian organizations frequently operate in crisis environments where rapid decision-making is imperative for saving lives and mitigating suffering. Efficient knowledge management facilitates the optimal utilization of resources, identification of effective strategies, and swift adaptation to evolving conditions. In contemporary contexts, the efficacy of knowledge management is often enhanced through the integration of artificial intelligence and modern information technologies (Al Mansoori et al., 2020).

Secondly, information exchange: Humanitarian organizations employ people with different specializations and experiences, often from different countries and cultures. Knowledge management facilitates effective exchange of information between various departments of the organization, which promotes better understanding of the situation and taking appropriate actions (Golba, 2015).

Thirdly, avoiding repetitions: In crisis situations, time is precious, so it is important to avoid repetitions and use existing knowledge and experiences. Effective knowledge management allows for the collection and sharing of information about previous interventions and best practices (Hall & Andriani, 2003).

Lastly, skill development and activity enhancement: Analysing activities conducted across diverse humanitarian missions yields invaluable insights into their effectiveness and areas necessitating improvement. Knowledge management facilitates the collection of these insights, enabling their utilization to enhance processes and train organization employees.

The results initially supported the hypothesis, demonstrating that knowledge during the analysed humanitarian crisis was widely dispersed among various organizations. The evident need for an efficient knowledge management system underscored the importance of swiftly identifying knowledge gaps while continuously assessing information requirements. However, the presented research results have certain limitations concerning the selection of studied issues. Therefore, to fully verify the assumed hypothesis, further extended research is necessary. Converting accumulated tacit knowledge into accessible and comprehensible information for all individuals involved in the assistance efforts is crucial, and future research should illustrate methods to achieve this.

Internet Treatment is a Blessing or a Curse: Health Knowledge Management

Justyna Żywiołek
Faculty of Management, Czestochowa University of Technology, Czestochowa, Poland

justyna.zywiolek@wz.pcz.pl

Abstract: The social distancing, isolation and shortage of health workers, as well as the COVID-19 pandemic, as well as the ageing of the society requiring healthcare, influenced the fast pace of digital innovation and the implementation of new technologies and even digital services in healthcare health. Is this transformation a blessing or a curse for healthcare? To answer this question, we conducted a literature review on new technologies, innovations in medicine and e-health. A research survey was also carried out in three countries and the Servqual analysis made it possible to estimate the trust in modern technologies for e-health and the trust of surveyors in these methods.

keywords: E-Health, Online Telecommunication Knowledge, Health Knowledge Management

1. Introduction

The growing number of health and social problems worsens the health of our society and thus threatens the existence of future generations. The period of the Covid-19 pandemic showed how dependent we are on healthcare (Akrich and Méadel 2009; Brown et al. 2014), often squander resources by purchasing internet products that are labeled as "healthy" or "cost-saving," despite the fact that they are neither pharmaceuticals nor supplements (Bessant 2019). Most consumers ignore the dangers resulting from the deteriorating health situation and rarely visit doctors' offices or undergo check-ups (Chretien et al. 2015). It is also very difficult for Europeans to admit the need for psychological or psychiatric treatment (El Morr and Eftychiou 2017; Doxey 2021), which was also greatly influenced by the pandemic, home office and social isolation. The shame caused by diseases related to the human psyche and mental problems causes unfortunately the abandonment of treatment or looking for home remedies, advice from people with similar diseases on forums, chat rooms or more and more often online advice from unverified "specialists" (Engel et al. 2020; Hays 2021b).

The terms "innovation" and "innovative" are buzz words that are used widely in many different fields, including healthcare (Bessant 2019). So far, however, there is no comprehensive and generally accepted definition of innovation (Wald et al. 2007), and different sciences (Simon 2016)(e.g. economics, public health, geography, sociology) use slightly different concepts (Thoër et al. 2017; van Leijen-Zeelenberg 2015). Schumpeter was one of the first economists to recognise the importance of innovation in any economic system, from a single business unit to entire economies and the world economy (Żywiołek and Schiavone 2021).

He described innovation as any change in the method of production, the production of new products, company structures or entry into a new market, and as "creative destruction" that is the basis of all advances in a capitalist market regime (Żywiołek et al. 2021).

In the health sector, improvements in quality come from service and quality of life innovations (Żywiołek and Schiavone 2021; van Leijen-Zeelenberg 2015), but they are also a constant challenge for existing healthcare providers and systems (Broom 2005). Advances in medicine require new technologies (Slametiningsih et al. 2020)(e.g. drugs, implants and devices), procedures (e.g. new surgical techniques) or forms of organisation (e.g. palliative medicine as an innovative form of care) (Simon 2016; U et al. 2022).

The aim of the literature review was to search for scientific publications that would: present model patient behaviours from the perspective of multiple ailments and access to the Internet (Beck et al. 2014; Boer et al. 2007). The authors conducted extensive literary studies based, among others, on publications on innovation, digitization and digitization of healthcare, e-health development in a very careful way over the past 10 years. The literature review shows that the main focus of the management science issue is the characteristics and behaviour of patients who are consumers at the same time (Chen et al. 2021). Doctors are experts in the field of health (Brown et al. 2014), while patients / consumers are responsible for managing their time (Archambault et al. 2013), health, access to health information and knowledge (Żywiołek et al. 2021). The authors of this paper found that the solutions provided to patients and the typical consumer behaviour of patients were of particular interest.

The National Institute of Health and Care Excellence in the United Kingdom classifies digital medical technologies according to features such as system services (e.g., electronic prescription systems) (Barker and Barker 2022),

active monitoring applications that connect to sensors (Haar and Ernst 2016), and wearable devices that are designed to enable remote monitoring of patients by healthcare professionals, and advanced artificial intelligence programs that use data to guide diagnostic decisions (J. Zywiołek et al. 2021; J. Żywiołek et al. 2021).

There is so much choice today that healthcare organisations must be able to (J. Żywiołek and F. Schiavone 2021; Krishna and Thompson 2021; Moore et al. 2021):ensure that the digital technologies they implement are functional, safe and effective. Websites have been set up across Europe to focus on a comprehensive, innovation-driven approach to this with the overarching goal of increasing the health life expectancy of European Union (EU) citizens by two years by 2020. It is still unclear whether this goal has been achieved. achieved but efforts are ongoing (Smit et al. 2021).

Regarding the WHO, universal health insurance cannot be achieved without the support of e-health because digitization enables the delivery of scalable solutions to many people, even remotely (Chen et al. 2021; Chretien and Kind 2013). The rapid development of new digital technologies in healthcare, the current COVID19 pandemic, and the heavy burden on healthcare systems around the world are fuelling the digitization of healthcare. How does digitization affect diagnostics, pharmacotherapy, psychotherapy, the doctor-patient relationship, and administrative tasks in psychiatry? Is digitization? blessing or glue?

However, the proposed solutions are either too general or incomplete. Here are some examples of such findings.

The considerations show the following about the patient / consumer (Chen et al. 2021):

- want to be served at the highest level,
- are focused on the future,
- health is more important to them than service time,
- seek to control the impact of their health efforts,
- try to minimise the negative impact of access to technology and knowledge on their health.

The following hypotheses were developed as a result of the specified goal, together with literature study and practical observations connected to online treatment awareness and knowledge:

Hypothesis (H1). The amount of understanding of online treatments boosts trust in these treatments and therapies.

Hypothesis (H2). Modern e-health technologies have increased accessibility to online therapy and treatment.

The text illustrates the intricate interplay between social health challenges and innovation in healthcare. It highlights society's dependence on healthcare systems, especially evident during crises like the COVID-19 pandemic, emphasizing the need for innovative solutions to address existing issues and adapt to changing circumstances. Consumer behaviour, influenced by factors such as stigma surrounding mental health treatment and the desire for convenience, shapes the demand for innovative healthcare solutions. These innovations, ranging from digital technologies to new care models, aim to improve healthcare quality, service delivery, and patient outcomes while addressing complex health challenges. Overall, the rapid digitization of healthcare presents opportunities and challenges, with efforts focused on achieving specific goals such as increasing life expectancy and expanding access to care.

2. Materials and Methods

The researchers in this study implemented the following research methodology: creating a model customer/consumer profile and delineating its behaviours and traits, specifically those pertaining to e-health. The profile of the patient or consumer is presented in the second section of the article. The authors built it based on their own unique concept. The second phase of the study process necessitated empirical investigation. The objective of the study was to ascertain the perspectives and sentiments of patients and consumers who utilise internet solutions for health and treatment. In order to accomplish the established study objective, we have devised a research strategy, executed the investigation, synthesised the findings, scrutinised them, and subsequently derived conclusions. We conducted the study in the latter half of 2021. The study involved patients reporting the utilisation of contemporary technologies in the realm of healthcare and therapy. The individuals ranged in age from 18 to 70 and were from Poland, UK, and Sweden. As a result of the ongoing COVID-19 outbreak, we have discontinued in-person interactions with managers. Alternatively, we employed the survey methodology. We employed a questionnaire as the study instrument. In order to get patient feedback, we employed an online survey and examined a total of 13,6157 individuals residing in these specific nations. The

authors of the publication determined that the use of the research method and research tool in the form of a survey should use a 5-point Likert scale (Sayili et al. 2024), which will allow obtaining reliable research results. The majority of respondents, at 34%, fell between the age range of 40 and 49.

The study questionnaire had twenty-three inquiries sent to patients with the aim of resolving the research quandary. A point scale indicated the answers to each question. The research is centred around studying individuals' preferences and their anticipated actions in the future, as well as the acquisition of knowledge and the establishment of trust. The study centred on individuals' preferences and behaviours and was carried out using representative methodology. The sample fulfils the condition of being representative, although the absence of a breakdown of the data by particular countries is due to their similar geographic location and the comparable level of social awareness regarding the availability of e-health, which is present in 33% of the population across all countries. They have common objectives, strategies, and presumptions in relation to this matter. Encouraging proper conduct within their communities and providing individuals with education result in favourable societal reactions. European inhabitants share comparable levels of economic development and cultural characteristics. The ability to freely migrate between European Union or Schengen zone countries allows for the sharing of knowledge, perspectives, and ideas on problem-solving. The second phase of the investigation involved nine specific inquiries utilising the Servqual approach. To demonstrate the similarities in the behaviour and organisation of national health systems across different countries, the authors have compiled an overview. Although countries vary in size, a notable shared characteristic is the level of knowledge, forces, and resources that each country dedicates. Table 1 displays the parameters that were evaluated to determine the similarities in prevalence as well as the proportion of nation involvement and the utilisation of society.

Table 1: The similarities in the use of e-health methods and the percentage of use by society. (data from 2021)

Health factors	Poland		UK		Sweden	
	Average Value					
Source of e-Health financing - public funds		77%		77%		77%
eHealth capacity building:						
Health sciences students		50-75%		<25%		25-50%
Health professionals		25-50%		25-50%		<25%
	know	use	know	use	know	use
Applications, national programs	84%	79%	89%	84%	91%	82%
Social media and health	86%	83%	93%	83%	93%	90%
Big data and health	78%	63%	82%	76%	89%	88%
Electronic Health Records (EHRs) (year of creation)		2009		1978		1996

Source: Own study based on WHO data from 2021 (; ;).

Table 1 shows the structure of the country's involvement in e-health activities. Knowledge and use of these new forms of access to "health" are manifestations of service consumerism and public awareness. The huge interest in accessing health services and advice also raises problems, as shown in Figure 1.

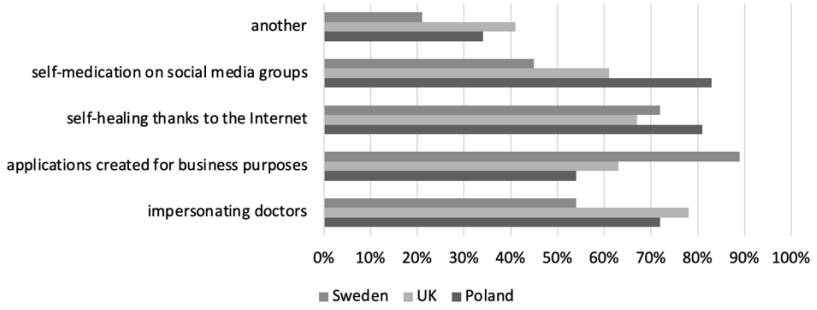

Figure 1: E-health problems in selected countries.

3. Results

The identification of barriers and problems made it possible to define the method of proceeding to solve the problem. The scope and effectiveness of self-treatment with the use of the Internet, online treatment, support methods, and applications supporting the treatment are presented in Table 1. The descriptive statistics for all analysed constructs in the article are related to each other in terms of the effectiveness of the activities carried out on the management of remote treatment methods. Based on the results in Table 2, we can see the moderate mean value for the construction of knowledge and information in the field of treatment (3.53). The mean values for the remaining four constructs that measure the range of remote treatment management methods are low to moderate at best. Average values are: responsibility for treatment (2.83), implementation of solutions (2.90), availability of information and creation of knowledge (2.87), treatment support, and modern methods (2.89). Our part of the research focused on taking action for e-health.

Table 2: Mean values and Cronbach's α coefficient.

Variable	Average value	Cronbach's α
Online treatment knowledge	3,53	0,82
Responsibility for management	2,83	0,87
Implementation of solutions	2,90	0,76
Availability of information creating knowledge	2,87	0,81
Treatment support, modern methods	2,89	0,85
Improved communication	4,43	0,69
High awareness among patients	5,53	0,79
Strengthened cooperation in the field of applied treatments	3,59	0,71

The initial phase of the study was establishing the presence and magnitude of the relationship. In the initial stage of the Servqual study, we calculated the discrepancies between the levels of energy management perception and consumer awareness and the expected levels for the five dimensions. Table 3 presents the outcomes.

Table 3: Differences in perceptual levels were studied using Servqual.

	Features	P	E	Servqual Results "SS" Is the Level of Satisfaction SS = E − P
Online treatment knowledge				
Average Servqual: 0,81				
1	Patient involvement in treatment	9	9,24	0,31
2	Constant monitoring of the health level and disease progression	8	8,16	0,22
3	Knowledge of online treatment options	9	8,52	-0,21
4	Patient involvement in changing attitudes	9	9,49	0,63
Responsibility for e-health management				
Average Servqual: 2,68				
5	Access to information and knowledge	7	6,77	-0,11
6	Usefulness and ease of interpretation of information and knowledge	9	9,38	0,39
7	Patient's level of knowledge	7	8,36	1,24
8	Possibility of combining different treatments	7	8,51	1,38
Availability of information creating knowledge, improved communication				
Average Servqual: 0,21				
9	Alternative ways of communication	8	7,78	-0,39
10	Information systems enabling the search for help	7	5,98	-0,41
11	Organizational activities to disseminate information and knowledge	6	5,56	-0,72

	Features	P	E	Servqual Results "SS" Is the Level of Satisfaction SS = E − P
12	Online treatment culture	9	9,51	0,62
13	Managing medications and supplements	7	7,59	0,81
High awareness among patients				
Average Servqual: 0,52				
14	A high level of self-healing confidence	7	7,89	0,67
15	Trust in online therapy / treatment	9	9,73	0,75
16	Patient information campaigns	8	7,39	-0,41
17	Monitoring applications	6	5,22	-0,43
Strengthened cooperation in the field of applied treatments				
Average Servqual: 0,37				
18	Errors in reasoning and application of solutions	6	6,26	0,32
19	Lack of trust	8	6,27	-1,59
20	Use of medications and therapy based on similar symptoms of friends / family	8	8,46	0,58
21	Ignorance / fear of alternative treatments	6	6,16	0,43
22	Online search for symptoms and self-treatment	6	6,19	0,26
23	Fear of a serious disease	7	6,48	-0,52
24	No treatment	7	7,06	0,13

A graph was produced based on the Table 3 data, which included the results of the Servqual method of perception and expectancies analysis. Figure 3 depicts the graphical representation of the Servqual method's outcomes.

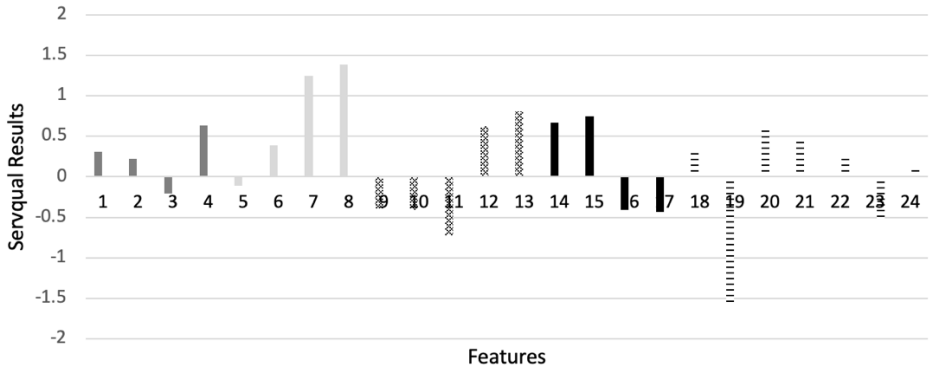

Figure 3: Results of the Servqual analysis.

The results show that 15 of the 24 feasible scenarios achieved satisfaction, whereas the other cases showed no level of satisfaction with the actions associated with information systems aimed at patient assistance. For knowledge dissemination organisations, health monitoring applications, loss of trust in treatments and doctors, and fear of disease, dissatisfaction is critical. However, as you can see, the sources of discontent were lack of understanding, anxiety, and maybe a terrible treatment experience. As a result, it's safe to infer that they're a good area to run social marketing and gain patients' confidence and knowledge. Taking action on your own, such as taking drugs or supplements like people who have similar symptoms, is a very risky phenomenon. It's just as risky to try to heal yourself by typing your symptoms into a search engine. The findings of the study allowed for the identification of the factors that influence the determination of what constitutes online treatment.

4. Discussion and Conclusions

The study showed that a change in approach is necessary, and knowledge in this area has increased awareness of caring for one's health. Older people constitute an increasingly important and growing part of the general population. Digital health and wellness programmes offer the potential to strengthen and facilitate support and

healthy prevention strategies (J. Żywiołek and F. Schiavone 2021). Using a digital health platform that includes integrated functions for both health recommendations and accountability (e.g., by a behavioural trainer) can be a unique feature to encourage patients to be motivated and accountable (Żywiołek 2018; Matsushita 2021; Mann et al. 2020). Future work should build on the concept of a "user-centric" approach, using both qualitative data (e.g., focus groups and surveys) and other data-driven approaches to identify key aspects of eHealth.

It was vital to make adjustments in the medical services industry at a time when societies are ageing at an alarming rate and hospitals and public institutions are unable to absorb patients (Shaheen 2004; Zywiolek et al. 2021). Modern health technology has been employed to take effective measures leading to patient care and access to a specialist. The purpose of the modern approach to raising patient awareness and providing new chances to support the battle against sickness and self-healing via the Internet is to integrate these elements.

The findings are negative, revealing widespread illiteracy, a lack of information, and a fear of taking drugs without contacting a doctor. Future research on this topic should focus on the following areas:

- the adaptation of e-health management methods for different age groups, knowledge and social campaigns to help patients acquire skills,
- activities to better prepare the younger generation to use e-health services,
- the inclusion of sustainable development in educational programs.

The results of qualitative and quantitative research on treatment and therapy in terms of distance and modern instruments utilized in the investigated nations are presented in this article. The employment of specific approaches was linked to the fact that quantitative research allows for the creation of a broad picture of the research topic. Qualitative research, on the other hand, allows you to obtain additional understanding about the identification of components associated with the investigated area and their relationships. The survey's preparation also necessitated the acquisition of specialised knowledge as well as the identification and comprehension of certain components and their relationships (Żywiołek et al. 2021; Simon 2016; Menvielle et al. 2017). This necessitated the application of qualitative research methods. Quantitative research allows for generalisations, but qualitative research based on the principle of ethnographic study allows for a greater grasp of the intricacies of non-human phenomena. The application of research is inextricably linked to the emergence of unique issues and limits. The inability to compare the data to another research period was a weakness of this study. The authors decided that this is a viable research topic for the future and plan to perform a comparison study within the next 2–3 years.

Knowledge-Driven Sustainability: Leveraging Technology for Resource Management in Household Operations

Justyna Żywiołek
Faculty of Management, Czestochowa University of Technology, Czestochowa, Poland

justyna.zywiolek@wz.pcz.pl

Abstract: Conserving energy is a worldwide dilemma for nations as well as individual households. Data indicates that European nations face a significant issue in this regard. Energy conservation is a global issue that both nations and individual households must address. Statistics reveal that European nations face a significant issue in this regard. The literature study revealed that several studies primarily focus on energy conservation, whereas there is a dearth of research examining social consciousness and user proficiency. A report outlines the study findings, aiming to ascertain the level of awareness across various generations about the resources, information, and expertise required for energy management. The objective of the paper was to examine the use of the Internet of Things as a technological instrument for residential energy management in Poland, Portugal, and Italy. We administered an online survey to a total of 18,683 customers from February 2022 to February 2023. The survey used a kind of sampling known as convenience sampling. The research used a survey that included 26 inquiries about customers' awareness and behaviour in the field of energy conservation. Research indicates that the elderly population struggles with vocabulary and often lacks comprehension of instruments. This suggests that they are unable to effectively control the energy use in their households, resulting in inefficient measures. Additionally, future research endeavours were established to explore knowledge acquisition, solution utilisation, and proficient utilisation of technologies for conserving and controlling energy within residential settings.

Keywords: Energy Saving, Sustainable Household, Household Resources, Knowledge Management

1. Introduction

Today's technology development, including the Internet of Things (IoT) and related technologies, finds further applications for this solution, including primarily in enterprises and organisations (Carpino et al. 2018; Amine Chatti 2012), but also in the immediate environment of an employee, client, or user. This necessitates conducting research on how companies and employees perceive IoT technology and devices, as well as establishing a model that verifies the acceptance factors of IoT in private applications by consumers. The purpose of this article is to try to explain and illustrate the acceptance of IoT technologies by different generations of consumers using constructs relating to consumer confidence in these IoT technologies and devices. Employees of different ages accept new technologies to a different degree (Fawkes 2017), which allows us to recognise the studied phenomenon in different age groups but also determines the size of the company or industry.

2. Literature Review

The IoT is not a new concept, as it was invented and proposed in 1999 (Khan et al. 2022), while it was implemented as a practical solution approx. 7–10 years later, but for 3–4 years it has been gaining applications with an ever wider range and is currently experiencing a period of development, and a dynamic one at that . More broadly, we can conceptualize the IoT as an ecosystem where items equipped with sensors interact with computers, both manually and automatically, primarily through wireless networks (Żywiołek 2019). Taking into account the variety of technologies connecting devices included in the IoT category, the very concept of IoT is defined in various ways. K. Ashton, who described the IoT as a sophisticated system where devices communicate with sensors to gather environmental data, provides the most common definition in scientific research. This communication concerns computers and objects connected by ICT networks, mainly the Internet (Tiwari et al. 2022; Himeur et al. 2020). Internet-connected gadgets with advanced intelligence capabilities form the Internet of Things (IoT) system. These gadgets use integrated sensors, processors, and communication equipment to gather, process, and transmit data. IoT devices transmit sensor data by establishing a connection with an IoT gateway or similar device. Typically, the cloud receives this data for analysis (Sayed et al. 2022; Żywiołek et al. 2022b; Shang et al. 2024). The devices do most of the work without user intervention, although it is possible for people to interact with them (Alsalemi et al. 2022). The specific IoT applications implemented and supported by the Internet largely determine connectivity, network, and communication protocols (Krishnan and Jacob 2022). This article categorizes consumer applications into four main groups: wearables, "connected" home appliances, including "smart" home appliances, and consumer building automation. "Intelligent" personal medical devices (personal health), as well as "connected" cars, remain beyond the author's area of interest due to the different specifics of their application (Razip et al. 2022).

The author, when preparing to conduct the study, set a goal for it and then divide it into a theoretical part illustrating the social acceptance of such a solution for energy saving and a practical goal obtained through a qualitative study, giving a practical picture of the level of awareness with particular attention to the older generation. Conversely, the research aims to foster sustainable societies that utilize resources in a comprehensible and mindful manner.

3. Materials and Methods

For the majority of service providers, determining the quality of their offerings is a difficult task because it substantially differs depending on factors including cultural variations, demographics, and individual circumstances (Rosak-Szyrocka and Żywiołek 2022). The individuals involved, their behaviour, and their understanding of the quality of service can also have an impact on how satisfied a client, patient, or city resident is. In conclusion, a number of variables served as the catalyst for this research investigation. (Żywiołek et al. 2022c). First, few studies have measured the quality of services, but this did not apply to city dwellers or the use of media for the functioning of the household. This study focused on filling the gap in urban service quality research, in particular in households.

The analysis of the literature based on research in the field of the use of IoT solutions using the Servqual methods allowed the author to identify research gaps and indicate actions to fill them, as shown in Figure 1.

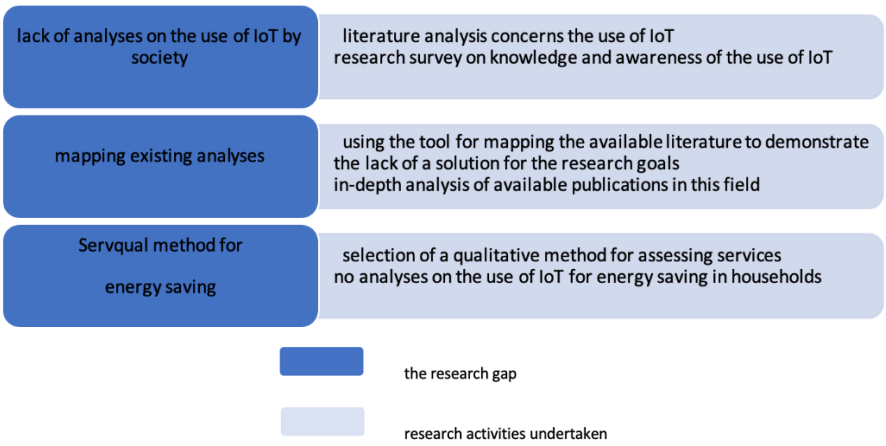

Figure 1: Identifying research gaps and research activities undertaken.

Identification of research gaps and determining what research activities will be undertaken made it easier to conduct them. The sequence of actions was adopted as shown in Figure 1, because it made it possible to achieve individual assumptions, and each subsequent step made it possible to state that the adopted methodology was correct and verified the adopted assumptions. While preparing the literature analysis, the authors made science mappings and found 826 manuscripts concerning the quality of services and the Servqual method. With the use of Vosviewers prop-programming, Figure 2 relating to keywords and Figure 2 relating to the countries in which research is conducted on this subject have been prepared.

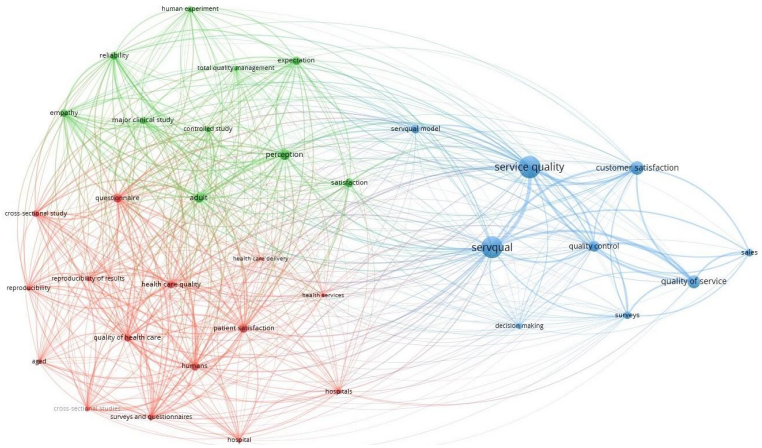

Figure 2: Analysis of keywords that appear in publications in 2019-2022 on quality and the Servqual method.

The completed study in Poland reveals that the quality and Servqual technique are also published. An examination of the publication's keywords suggests that customer satisfaction holds significant importance, and urban residents are also consumers. It is important to focus on those who oversee homes, since they are the ones responsible for determining the effectiveness of energy-saving measures.

The Green Deal for Europe, proposed at the conclusion of 2019, sets the stage for a very ambitious programme aimed at safeguarding the environment. We expect Europe to achieve carbon neutrality by 2050 (Alberg Østergaard et al. 2010). The European Union has implemented a sequence of measures (Żywiołek et al. 2022a; Zografakis et al. 2012). The Green Deal aims to facilitate a sustainable green transition for enterprises and communities in Europe, enabling them to reap its benefits. The ideas, along with a first "roadmap" outlining crucial policies, tackle several concerns, such as reducing emissions, financing cutting-edge research and development, and protecting Europe's ecology (Żywiołek et al. 2021; Valerio-Ureña and Rogers 2019). Implementing the "Green Deal for Europe" initiative would enable EU countries to achieve energy self-sufficiency, potentially leading to significant effects on the energy market and their regional policies. Furthermore, it is expected that achieving climate neutrality in the economy would improve its competitiveness and facilitate its vigorous expansion.

The introduction of the aforementioned legislation in EU states fuelled an increase in the adoption of renewable energy across the entire community. In 1990, renewable sources accounted for 3.8% of the EU-28's overall energy consumption. This figure increased to 5.1% in 2000 and further rose to 10.2% in 2019. The household sector's use of renewable energy sources (RES) accounted for 8.5% of total home final energy consumption in 1990, increased to 10.8% in 2004, and further rose to 7.4% after 16 years. This indicates that the household sector plays a significant role in the utilisation of RES. The construction industry in Europe has a carbon dioxide (CO2) emission rate that is 36% higher and consumes 40% more energy compared to other sectors. The European Union's framework for decreasing energy consumption in buildings encompasses various policy initiatives, such as the Energy Performance of Construction Directive (EPBD), the Energy Efficiency in Buildings Directive (EED), the Sustainable Design Directive, Energy Labelling Compliance, and the aforementioned Renewable Energy Directive (RED) (Di Foggia 2018; Żywiołek and Schiavone 2021; Tezde et al. 2019).

Ultimately, the policies implemented in European Union countries have progressively increased the importance and role of renewable energy sources (RES) in the energy sector's organisation since the 1990s. The National Energy Efficiency Action Plan 2020 (Varlamis et al. 2022) encompasses all the strategies and initiatives devised to achieve the predicted targets.

The approach to achieving national renewable energy objectives varies across countries and is formulated at various levels, which influences the utilisation of renewable energy sources in residential settings. Energy resources have consistently played a vital role in the survival and development of humanity. Energy resources have a significant influence on both social and economic progress. The advancement of technology, utilisation of energy, and growth in the global population are interconnected to some extent. Ensuring an adequate supply of energy resources for entities such as residential dwellings is vital to meeting fundamental societal requirements. Energy use accounts for a significant portion of household consumer expenditure.

With the rise in environmental consciousness, income levels, the number of children, and solar radiation intensity, there is a greater likelihood that individuals may contemplate investing in renewable energy sources (RES). Compared to the elderly, males and those with higher levels of education had a greater likelihood of engaging in RES initiatives. Age, education, gender, income, and the type of building occupied all affect how socially acceptable renewable energy is. The demographic categories most accepting of RES installation were men, those aged 30-49, those with a secondary technical degree, those with low incomes, and those residing in single-family homes. The justification for RES installation was the anticipated long-term savings, but the biggest barrier was a lack of funding (Appel-Meulenbroek et al. 2018; Yi 2009).

The literature frequently discusses sustainable development, which is crucial for energy management. Most of the current publications contain research on technological solutions or describe in detail a solution promoting a given technology. The table contains the research topic, a specific research gap, or a lack thereof. Table 2 presents the latest research and indicates the gap because none of the research shows the social part, the knowledge of people managing households.

In order to identify the research problem, the data available in the reports of the European Union was thoroughly analysed (Yeo and Marquardt 2015). The data analysis covered the five previous years. In order to define the research problem, technical and statistical reports, as well as available research results, were analysed. Defining

a research problem that represents the opportunities and barriers that the use of the IoT brings for home users A survey was conducted among household representatives in Poland, Italy, and Portugal to determine whether consumer behaviour in terms of electricity consumption supports the assumptions of using IoT. The decision on the selection of countries for the study resulted from statistical reports; in the countries mentioned, the highest user involvement in the use of IoT tools for renewable energy sources has been recorded in the last 5 years (Perumal and Sreekumaran Nair 2021; Di Foggia 2018). Only EU countries were taken into account, and the utilisation rate ranged from 27% to 0%. The most frequently reported share in the use of IoT for energy savings is 0%. The survey was conducted among 18,683 consumers in the period using an online survey. The data for the study were collected during the COVID-19 pandemic; however, the method of collecting data via an online form and the subject of households indicate that the pandemic had no impact on the collection of data or the result of the study. The respondents were guaranteed anonymity and voluntary participation in the study. The respondents were selected to participate in the study using a convenient sampling technique. The survey questionnaire used in the study consisted of 26 questions concerning the knowledge and behaviour of consumers related to energy saving. For the purposes of this study, questions related to electricity consumption in households were used. The research group is described in Table 1.

Table 1: Description of the research group

	Description of the Research Group				
1	Sex	Man 67%		Woman 33%	
2	Age	18-29 years	21%	18-29 years	11%
		30-39 years	28%	30-39 years	38%
		40-49 years	34%	40-49 years	32%
		Over 50 years	17%	Over 50 years	19%
3	Education	high school 42%		higher education 58%	
4	Using any source of renewable energy	Yes 100%		No 0%	
5	The level of knowledge about technologies for energy saving	Low 3%	Middle 31%	Higher 38%	Expert 28%

Male respondents account for as much as 67% of those surveyed, but this does not result from EU social statistics; it results from statistics on the gender of the person managing the household in the field of bills and savings. EU statistical results in the years 2020–2023 say that this result is from 65% to 70%, where men manage households in the selection of heating, energy bills, and saving (MALINOWSKI 2012; Du et al. 2022; Carpino et al. 2018).

After doing the study, the results were gathered, analysed, and conclusions made. The poll was divided into many sections, and participants were required to score their opinions on a 7-point scale, where 1 represents full disagreement and 7 represents entire agreement. The first section of the survey focused on consumers' familiarity with renewable energy sources for residential use and aimed to assess their understanding of such sources. The second section of the questionnaire verified which individual in the family is responsible for energy management and energy use. The subsequent section included inquiries on investments in farm-centric solutions that provide advantageous outcomes. This segment also encompassed inquiries about information technology solutions, such as apps. The poll also focused on the accessibility of IoT-related solutions, collaboration between users and producers via assistance, and the adoption of these solutions in homes. People's preferences and future behaviour were evaluated using a 7-point Likert scale. The implementation of this scale enabled the classification of respondents into three categories: low, medium, or high levels of pro-ecological and pro-social attitudes. This classification served as the basis for identifying possibilities and obstacles for various groups of individuals with varied levels of awareness. This division facilitated the development of inferences about their future conduct and the potential for further utilisation of IoT. The research focused on the decisions and future behaviour of future generations. The study included individuals

between the ages of 26 and 50, with 54% being male and 46% being female. The sample was deemed to be typical of the population.

Given the following parameters: significance level = 0.01, maximum estimate error d = 1% (u = 3.1426), and assuming that the probability of success p is unknown, European Union member nations, known for their cohesive approach to energy management and conservation, conducted the research. This is evident in their apparent collaboration and comparable level of planning and assumptions.

Utilising diverse question types and the seven-point Likert scale enables the evaluation of citizens' and residents' awareness, facilitating the identification of both challenges and prospects. The writers express their professional aspirations and expectations about the energy economy, primarily emphasising the avoidance of financial losses. Hence, the authors directed their attention towards examining the accessibility of consumer information and their inclination to develop not just tangible abilities but also intangible ones that are embedded inside their knowledge. The research further included an evaluation of client satisfaction with the implemented solutions using the Servqual methodology. We examined the data gathered in a Google spreadsheet using Microsoft Excel, Statistica, and SmartPLS3 for analysis. The authors choose to use qualitative techniques, namely the Servqual approach, together with statistical methods like the student's t-test and SmartPLS3 software, to analyse the data.

4. Empirical Results

These constructs are interrelated in terms of the success of actions taken for managing energy resources and consumer awareness, including According to the findings in Table 2, the average value of increasing consumer knowledge in the area of energy management is moderate (4.11). The other four structures that gauge how well energy is managed have mean values that are, at best, low to moderate. Average values include being responsible for managing energy (2.83), putting solutions into practice (2.37), having access to information and producing knowledge (3.05), and using the Internet of Things (3.12). Our contribution to the study focused on the utilisation of IoT, conducting analyses across a range of age groups, and the effectiveness of energy management while assuming varied levels of awareness. Participants in energy management initiatives are required to disclose their involvement in the survey.

This could potentially influence the perception that current energy management efforts, particularly those that emphasize the use of IoT, are effective. However, we found a range of values for the measured performance constructs. The average values are as follows: adept energy management, high social awareness, improved use-related cooperation, and use of IoT-related solutions. The values demonstrate that varying levels of activity are required to use the IoT for energy management. In reality, the actions of the analysed group of firms demonstrate a modest level of efficacy. Table 2 displays the findings of the complete international survey.

Table 2: Mean values and Cronbach's α coefficient

Variable	Average value	Cronbach's α
Consumer awareness	4,11	0,88
Responsibility for energy management	2,83	0,89
Implementation of solutions bringing economic benefits	3,05	0,81
Availability of information using the Internet of Things	2,87	0,93
Availability of energy management application solutions	2,97	0,89
Improved communication	4,53	0,80
Use of renewable energies	5,79	0,95
Strengthened cooperation on the measures used	3,71	0,86
Better learning	3,69	0,71

The Internet of Things has made it feasible for customers to be more involved and knowledgeable in household energy management, which helps to increase elder consumers' awareness and expertise while simultaneously

making it easier for younger consumers to understand how applications and systems work. The Internet of Things is extremely important in this regard because of the expanding accessibility of contemporary systems and the development of a culture of energy conservation. Using the qualitative analyses and the research that has been done, SEM structural equations were also prepared, which determine the relationships between the tested factors (Fig. 3). The main study's findings underwent analysis. First, we determined the total number of ratings for each statement. We used these data to conduct a study on the associations between individual summaries, taking into account the ratings provided (Table 3). The next stage was calculating the standardised Cronbach's alpha using the determined correlations.

Table 3: Relationships between factors.

I3	Continuous learning in the field of energy management of your household	H3	Consumer involvement in changes in the way energy is managed	C3	Errors in reasoning and using the application	M3	Safety culture	G3	Incorrect reading or interpretation of measurements
						M4	Lack of trust in IT systems		

5. Conclusions

Given that the precision of energy-saving and energy-saving management solutions reflects a favourable stance towards the sustainable operation of society, we can infer from our research that there are statistically significant correlations between energy-saving behaviour and methods of conserving energy, as well as energy-saving management and attitudes towards fostering a sustainable household. These findings align with previous research findings documented in the existing body of literature.

The energy-saving behaviour shown by individuals is a clear demonstration of the environmentally conscious mindset prevalent in this age. Naturally, the prominence of these fundamentals varies to some extent depending on the generation. The findings of our research validate the inclination of young individuals to allocate more

funds towards consumption and exhibit superior proficiency in saving. According to the research review, older individuals tend to engage less in these activities owing to variables such as reduced social awareness, limited interest in technical advancements, and a lack of understanding about saving possibilities. While all the energy-saving behaviours we examined had a substantial influence on their adoption of energy-efficient home management systems, it is worth noting the conspicuous omission of considering the user's technical skills. This research aims to address this gap. The findings align with research suggesting that the degree of knowledge among young individuals on the need to conserve energy is substantial. (Bogers 2011; Himeur et al. 2021). The results of our study show that although the percentage of users declaring pro-ecological behaviour in all surveys is still growing, there is a lack of education in this area and low social awareness.

PhD Research Papers

Conceptual Model of Knowledge Management Implementation in the Heavy Equipment Industry to Enhance Innovation and Productivity

Ahmad Anwari and Amalia Suzianti
University of Indonesia, Depok, Indonesia

ahmad.anwari@ui.ac.id
suzianti@eng.ui.ac.id

Abstract: Productivity and innovation are two components that are very important for the progress of a company. Business competition, rapidly changing situations and the increasingly short life cycle of a product require companies to be able to carry out exploration and exploitation in order to achieve high performance and at the same time maintain business continuity. Knowledge plays an important role in improving exploration and exploitation capabilities, so every company needs to pay special attention to how to manage knowledge so that it can be utilized optimally. Therefore, the role of knowledge management becomes very important. From the research of previous researchers, the implementation of knowledge management in various knowledge-intensive industries has been widely carried out. The heavy equipment industry, which has its own character and uniqueness, also requires a knowledge management model. This research is aimed at developing a conceptual model of knowledge management in the heavy equipment industry based on knowledge management models that have been introduced by previous researchers. It is hoped that the results of this research can help companies operating in the heavy equipment industry to implement knowledge management so that they can increase their innovation capabilities and productivity

Keywords: Conceptual Model, Heavy Equipment Industry, Knowledge Management System, Productivity and Innovation.

1. Introduction

Productivity and innovation are two components that are very important for the sustainability of a company. Innovation is the introduction of a new product, process, solution, or idea that can change the way a business operates or meets customer needs. Innovation allows businesses to stay relevant and competitive in an ever-changing market. Meanwhile, productivity is a term that refers to the way an organization manages its resources, including labor, equipment, and processes, to increase operational efficiency and produce more output with the same or fewer resources.

Increasingly fierce competition, a rapidly changing and disruptive environment, and increasingly short product life cycles are several factors that require companies to be able to carry out exploration and exploitation in order to survive and achieve successful performance (Filippini et al., 2012). Ambidexterity has become an important strategy for companies to solve the dilemma between exploration and exploitation that exists in a highly competitive environment. When a combination of exploitation and exploration occurs in a company, it is called organizational ambidexterity (OA) (Fernández-Pérez De La Lastra et al., 2022). The concept of ambidexterity is applied to organizations that are able to simultaneously engage in competitive strategies, both in knowledge exploration and knowledge exploitation. (Simeoni et al., 2020)

Knowledge is a fundamental basis in Organizational Ambidexterity (Nahapiet and Ghoshal, n.d.). Knowledge plays an important role in improving exploration and exploitation capabilities, so every company needs to pay special attention to how to manage knowledge so that it can be utilized optimally. Therefore, the role of knowledge management becomes very important.

From research by previous researchers, the implementation of knowledge management in various knowledge-intensive industries has been widely carried out (Arling and Chun, 2011; Calitz and Cullen, 2017; Hossain et al., 2022; Hsieh et al., 2020; Masa'deh et al. , 2019; Samuel and Justina, 2023; Yu et al., 2017). This emphasizes the importance of implementing knowledge management in knowledge-intensive industries.

The research question developed in this study is what is the ideal knowledge management model for the heavy equipment industry to increase innovation capabilities and productivity?

The Knowledge Management Model (KMM) is important in responding to the challenges faced by the heavy equipment industry. KMM offers a systematic approach to measuring how effectively knowledge assets are managed within a company. By understanding the level of KM maturity, a heavy equipment industry company can identify areas that need improvement and develop strategies to achieve these goals.

2. Literature Review

2.1 Heavy Equipment

Heavy equipment or heavy machinery is large mechanical equipment designed to carry out construction functions such as earthworks, road construction, building construction, agriculture and mining (Jaya et al., 2022). Various types of heavy equipment used for industrial activities are categorized based on their function and role, and all heavy equipment has the same purpose as operational support (Jaya et al., 2022). In large-scale construction projects, heavy equipment plays a crucial role. The use of heavy equipment makes tasks easier and more efficient, resulting in faster project results (Mandira and Damayanti, 2023). Industries involving heavy equipment play an important role in the economic development of many countries in the world. The mining industry contributes significantly to GDP and offers employment to millions of people (Hamilton et al., 2022).

Maintaining high-performance heavy equipment is essential due to demands for higher product quality, faster production times, and increased operating efficiency in an environment of ever-changing consumer demands (Saputra et al., 2023). The importance of maintaining machine performance cannot be ignored. High product quality, fast production times and increased operational efficiency are key demands in today's competitive business environment. Without effective knowledge management, achieving the expected level of performance becomes difficult (Saputra et al., 2023). By implementing KM concepts, heavy equipment industry companies can ensure that knowledge of best practices, latest technology and operational efficiency strategies is available to everyone in the organization. This allows them to continuously improve their performance and remain competitive in an ever-changing market (Bougoulia and Glykas, 2023).

On the other hand, because heavy equipment usually operates in environments that have never been inhabited by humans, the heavy equipment industry is faced with several specific challenges such as extreme work site conditions, both in terms of land contours and weather. Construction and mining activities generally take place in harsh environments, ranging from remote deserts to remote mountains. In these situations, machines must continue to operate effectively, even when exposed to extreme heat, dust and even other extreme weather conditions. These conditions will directly put significant pressure on heavy equipment performance. Therefore, the need for proper knowledge in operating, maintaining and repairing equipment in difficult conditions like these is very important so that the equipment can operate with optimal performance.

The next challenge is the problem of limited human resources both in quantity and quality. Workers in the field often face complex situations that require precise knowledge to overcome the problems that arise. However, with a limited number of qualified technicians and operators, ensuring that any problems are handled quickly and efficiently becomes a challenge. By applying the KM concept, heavy equipment industry companies can build a centralized knowledge base that can be accessed by all employees, enabling them to obtain the information they need quickly and effectively, even if they do not have direct experience with the problems they face.

Another challenge is the issue of fuel efficiency. According to the International Council on Mining and Metals (ICMM), fuel costs account for 32% of total energy costs in mining. This implies that for large-scale mining operations, diesel fuel costs can be an important factor in overall company profitability (Figueiredo et al., 2023). Knowledge Management can assist in identifying, storing, and disseminating this knowledge throughout the organization, allowing each unit to manage their equipment efficiently.

2.2 Knowledge Management (KM)

Knowledge has emerged as a company's most strategically significant asset (Grant, 1996). Organizations continue to look for innovative ways to exploit the benefits of their knowledge assets (Lyu et al., 2016) where the essence of the analysis of competitive advantage and sustainability lies in the issue of the ability to imitate knowledge (Spender and Grant, 1996).

Knowledge Management is the planned and sustainable management of tools, processes, systems, structures, and culture to improve the creation, sharing, and use of knowledge that is important for decision making and competitiveness. Knowledge Management is a valuable strategic tool, because it can be a key resource in decision making, especially for the formulation of alternative strategies to achieve a series of capabilities to increase competitiveness (Carneiro, 2000). Two goals of Knowledge Management (Wiig, 1997): (1) Make the organization act as intelligently as possible to ensure its survival and overall success; (2) To realize the best value from its knowledge assets.

Knowledge plays an important role by facilitating better decision making, improving the quality of work, and driving innovation. The application of knowledge management produces significant benefits, including increased efficiency, improved decision quality, stimulation of innovation, and enrichment of employee knowledge (Astarika, 2022).

A knowledge management model serves as a structured framework used to operationalize knowledge management initiatives, providing comprehensive guidance and structure while assisting organizations in selecting appropriate tools and techniques. The Knowledge Management Model helps determine the right starting point, implementation steps, and resource requirements to drive long-term company development (Hsieh et al., 2009).

2.3 Knowledge Management, Innovation and Productivity

In their research, Chen et al. says that Knowledge Management is responsible for a company's efficiency, effectiveness and innovation (Chen and Yan, 2022). In the innovation literature, knowledge is considered a key component in the recombination process that drives innovation (Galunic and Rodan, 1998). In emerging distributed organizations, success is closely related to effective knowledge sharing between individuals, teams, and units (Alavi and Leidner, 2001). Knowledge exchange is considered to play an important role in growing organizational capabilities, such as innovation, which is fundamental to driving company performance (Kogut and Zander, 1996). Organizations' interest in Knowledge Management (KM) is motivated by the potential for further benefits such as increased creativity and innovation in products and services (Darroch, 2005) Knowledge plays an important role in fostering creative thinking and encouraging innovation. This explains why innovation is considered the most significant area of impact resulting from KM initiatives (Majchrzak et al., 2004). Knowledge creation, knowledge integration, and knowledge application facilitate innovation and performance (Mardani et al., 2018)

Effective Knowledge Management has a positive impact on productivity and makes workers more innovative and makes a meaningful contribution in strengthening the company's competitive advantage and growth (Torabi and El-Den, 2017). Therefore, Knowledge Management is an important factor to ensure sustainability and increase productivity in organizations..

3. Conceptual Model

Heavy equipment companies with unique operational characteristics and challenges require the implementation of an appropriate knowledge management system to support various operational activities and assist management decision making. The implementation of a knowledge management system in heavy equipment companies is expected to increase operational efficiency. In addition, this system can encourage collaboration between teams and departments, speeding up the innovation process through a more structured exchange of ideas. Therefore, optimal implementation of a knowledge management system that suits the specific characteristics and needs of companies operating in the heavy equipment industry is very necessary.

Knowledge management has a maturity level that is used to measure how far an organization has developed and adopted knowledge management practices. This maturity level is measured through practice-related activities that directly or indirectly support the application of knowledge management.

Corporate culture is a convention of values that influences interactions between workers in a company as well as interactions between management and workers (Nguyen et al., 2019). The similarities in values and habits between workers that occur over time will naturally form organizational culture. Culture is the most important factor in increasing company productivity. Several studies have also concluded that there is a positive and significant relationship between corporate culture and knowledge management. When a company has a constructive work culture (a culture that emphasizes values related to encouragement, affiliation, achievement, and self-actualization), they tend to achieve greater success in Knowledge Management (KM) (Leidner et al., 2006) . Culture can support teamwork and collaboration, which can increase productivity levels. Additionally, culture can stimulate new ideas to encourage innovation.

In addition, a clear organizational structure can facilitate the flow of information, making decision making easier. Flexible organizations that support new ideas can drive corporate innovation. As organizational structures become more decentralized, KM will increase. High centralization inhibits interaction between organizational members and hinders creative solutions to problems (Mahmoudsalehi et al., 2012). The more complex the organizational structure, the greater the increase in KM. Higher complexity implies greater functional differences

in terms of goals, task orientation, and autonomy. Knowledge management has a positive effect on organizational performance; the better the knowledge management, the higher the organizational performance.

From several studies it was also found that ethical leadership behavior is related to the creation and development of knowledge, codification and storage of knowledge, as well as the use and utilization of knowledge (Çelik and Sağsan, 2022). Visionary leadership will be able to transform the ambitions and preferences of their followers into a cohesive whole. Leadership is a person's capacity to persuade others to do or not do something to achieve predetermined goals. This skill is useful for motivating and influencing subordinates, building enthusiasm for work, increasing the spirit of collaboration, and having a disciplined attitude to achieve certain goals systematically.

Another factor that is no less important is Social Capital. In various studies, many academics are increasingly considering the importance of social capital factors where social capital acts as a binding force that keeps institutions in place (Agyapong et al., 2017). In an organization, social capital is critical because it contributes to organizational knowledge and provides opportunities to understand its network structure, both of which are important for a company's success. The level of trust is a key indicator of social capital. Agyapong et al. 2017, in his research stated that social capital has a positive effect on innovation and innovation has a positive relationship with performance (Agyapong et al., 2017)

With respect to effective management practices, technology plays an important role in increasing the level of knowledge management maturity in companies by providing decision support tools and human-machine interfaces to measure company performance during digital transformation. Additionally, technology plays an important role in supporting these efforts. In realizing innovative ideas and increasing human productivity, technology can facilitate goals more efficiently. For example, technology can automate processes, improve communications, and meet customer needs during periods of high demand and over time. Technology can reduce the possibility of errors occurring in work processes and eliminate the possibility of product defects. Hosseini revealed that processes and technology have a significant influence on Knowledge Management (Hosseini et al., 2014)

From the results of a review of relevant literature, the study proposes a conceptual knowledge management model to answer research problems related to the implementation of knowledge management for the heavy equipment industry (Fig. 1). The conceptual model consists of five variables, namely Culture, Organization, Leadership, Social Capital and Technology. These variables are based on theories from previous research and adapted to the characteristics of the heavy equipment industry so that these variables are believed to be the main success factors in implementing KM in the heavy equipment industry to increase productivity and innovation capabilities.

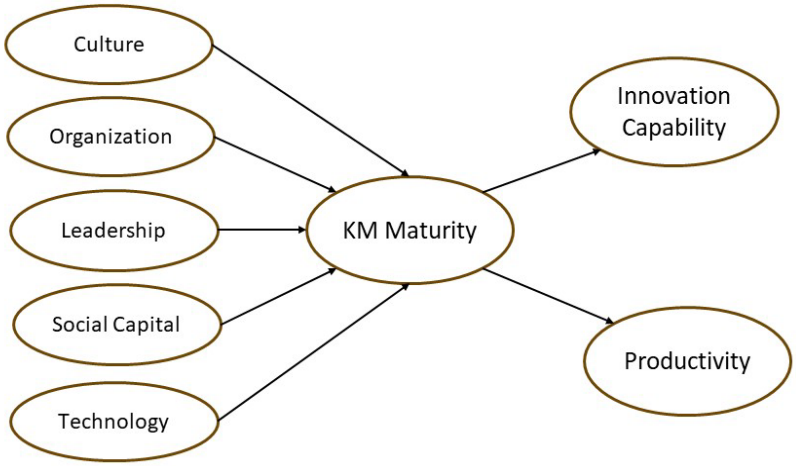

Figure 1: Conceptual Model Framework

Effective KM practices play an important role in increasing a company's productivity and driving innovation by ensuring that knowledge is systematically collected, organized and stored in a way that facilitates its future utilization.

4. Conclusion

With a better understanding of how to manage knowledge effectively, companies can optimize the utilization of their resources, improve product quality, and increase their competitiveness in global markets. Therefore, the application of KM concepts is not only important but also urgent for the long-term success of the heavy equipment industry.

Each industry has its own characteristics so that the variables that influence the effectiveness of knowledge management implementation are also different. Heavy equipment which mostly operates in isolated locations, faces extreme environments and demands for minimal breakdown levels requires a specific approach to knowledge management variables. Based on relevant literature studies, Culture, Organization, Leadership, Social Capital and Technology are variables that need more serious attention to increase the effectiveness of KM implementation in the heavy equipment industry or other industries that have similar characteristics.

Culture will support teamwork and collaboration, which can increase productivity levels. Additionally, culture can stimulate new ideas to encourage innovation. The formal organizational structure in a company influences interactions between employees which directly or indirectly will influence knowledge management within the company. A flexible organizational structure will encourage interaction between employees. Leadership style also influences the implementation of knowledge management in the company. Leaders who frequently recognize their employees' contributions to the company's success will improve performance through the knowledge management process. In an organization, social capital is very important because it contributes to organizational knowledge and provides opportunities to understand its network structure. Apart from that, technology plays an important role in supporting the implementation of knowledge management. In realizing innovative ideas and increasing human productivity, technology can facilitate goals more efficiently.

5. Limitation and Direction for Future Research

Research related to the implementation of knowledge management in various knowledge-intensive industries has been widely carried out. This research was conducted with a focus on several variables that influence knowledge management and which are in accordance with the characteristics of the heavy equipment industry and heavy equipment applications in general. Therefore, future research can be carried out for more specific heavy equipment application industries such as mining, forestry, agroindustry and construction. This research may be applied to other industries that have similar characteristics.

The Effect of Knowledge Sharing on Innovative Behavior in the Moroccan Pharmaceutical Industry

Houssam Baakir and Hanane Ellioua
LAMSAD research laboratory, Systems Analysis and Modeling Laboratory and Decision Support
National school of applied sciences BERRECHID, Hassan 1st University, Morocco

h.baakir@uhp.ac.ma
Hanane.ellioua@gmail.com

Abstract: In the dynamic landscape of contemporary global industries, the imperative to foster innovation has been recognized as an indispensable key to corporate growth. Nowhere is this more pronounced than in the pharmaceutical sector, where the pursuit of groundbreaking advancements in research and development is deemed indispensable. Understanding the factors that influence innovative behavior (IB) among employees is of utmost importance, and this paper seeks to study the influence of knowledge sharing (KS) within the pharmaceutical sector in Morocco, specifically focusing on two essential dimensions: knowledge donating (KD) and knowledge collecting (KC). The study aims to collect and analyze data from a diverse sample of 100 engineers in the Moroccan pharmaceutical industry. We used quantitative methodology by employing correlation and multiple regression methodologies, the research endeavors to unravel the intricate association linking knowledge sharing and pharmaceutical engineers' Innovative behavior. Preliminary findings reveal a positive influence of the dimensions of knowledge sharing on workers' innovative behavior. This suggests that a climate of knowledge exchange and actively seeking knowledge plays a crucial role in driving innovation within the pharmaceutical workplace. Notably, the study places a nuanced emphasis on the efficacy of knowledge donating, underscoring its pivotal role in fostering a dynamic and innovative environment. These findings contribute valuable insights to the broader discourse on organizational innovation. By highlighting the positive correlation between KS and IB, the investigation provides actionable information for practitioners in the pharmaceutical firms. Grasping the effect of KD and KC can empower firms to sustain a culture that encourages collaboration, continuous learning, and ultimately, groundbreaking innovations. As industries continue to evolve, this exploration serves as a timely contribution to the ongoing dialogue on organizational innovation, offering practical implications for both industry professionals and scholars alike.

Keywords: Knowledge Sharing, Moroccan Context, Pharmaceutical Industry, Quantitative Study, Innovative Behavior.

1. Introduction

The pharmaceutical sector in Morocco is experiencing rapid and dynamic growth, representing a strategic field focused on the research, development, and distribution of sophisticated medical products Berrado, A. (2018). At the heart of this transformation process, knowledge sharing has become a crucial aspect, playing a vital role in shaping the innovative behavior (IB) of workers in this evolving environment Chatterjee, D. (2020). This investigation aims to examine in detail the underlying mechanisms, obstacles, and advantages that define the dynamic connection between knowledge sharing (KS) and the development of innovation in the Moroccan pharmaceutical sector.

The current environment necessitates an extensive analysis of the factors that boost innovation, not only to maintain a competitive position in the global marketplace but also to satisfy the rising requirements of the healthcare sector (Liu, 2021). Innovation in the pharmaceutical sector is a major factor in developing more efficacious, secure, and accessible medicines, thereby boosting public health globally. It encourages individualized approaches to therapy, tailored to the specific circumstances of each patient. Additionally, it plays a vital role in improving healthcare accessibility by offering more affordable medicines and innovative retail techniques (van Muijlwijk-Koezen, 2020).

Innovation supports regulatory alignment and strengthens drug quality and safety (PAHI, 2020). The sharing of knowledge among staff makes a tremendous difference in the performance of pharmaceutical firms (Christofi, 2021). By supporting innovation and R&D, it accelerates the drug development cycle. Knowledge sharing further encourages ongoing training, allowing staff to maintain up-to-date awareness of new developments in the field (Sajjad, 2021). In summary, knowledge sharing is a vital foundation for the development of competitiveness and sustainable growth of pharmaceutical corporations.

Thus, the aim of our examination is to explore the association between knowledge sharing (KS) processes and innovative behavior (IB) in pharmaceutical corporations. Consequently, the purpose of this investigation is to examine how knowledge donating (KD) and knowledge collecting (KC) impact innovative behavior in the pharmaceutical industry in Morocco. To address this issue and achieve our objectives, we have chosen to conduct a quantitative study using a questionnaire. In this section, we will provide a literature synthesis of the

main constructs and the theoretical framework used to evaluate the effect of KD and KC on IB. The outcome of this section will be the research model.

2. Conceptual Framework: Innovative Behavior and Knowledge Sharing

2.1 Innovative Work Behavior

Organizational innovation results from individual innovativeness (Kalisz, D. E. 2021). Hence, there is considerable interest in IWB as a key to organizational efficiency (Janssen, 2000). Van Gyes (2012) describes innovative behavior (IB) as «The planned implementation, adoption, and application of new thoughts, procedures, policies, and products by individuals in their work role, group, or organization». Innovation is indeed a dynamic and complex social process (Avellar, 2013), comprising an interactional framework driven by a collection of interconnected human interactions (Purwanto, 2022). The human dimension occupies a central position in this process, as it is at the heart of generating, promoting, and implementing creative thoughts (Ali, 2019). The understanding of the role of IWB is reinforced by De Jong and Hartog (2010), who emphasize that individuals extend beyond the formal routine duties of a group or company to explore actual innovations, suggest alternative approaches to meeting targets, engage with existing methods of operation, and secure the necessary resources to implement their creative ideas. Innovative work behavior entails a model of high-level thinking, the identification of current and future challenges, the pursuit of opportunities, and the evaluation of performance gaps, as well as the exploration of contemporary approaches to addressing these gaps and challenges (Afsar, 2016).

Innovative behavior (IB) is a richer concept than creativity; it encompasses various stages with significant theoretical and practical implications (Ali, 2019). The innovation process consists of a specific set of steps (Ali, 2019): (1) Discovery of new ideas leading to opportunities for innovation or identification of weaknesses; (2) Idea generation involves exploring alternative approaches to solving problems and improving the current situation; (3) Idea promotion is defined as actively disseminating new ideas, building alliances to garner support and acceptance from stakeholders; (4) Implementation involves turning the idea into reality, experimenting with the innovation, adapting it, and integrating it into work practices. Employees who embrace innovative work behavior can readily and effectively identify new work circumstances and generate novel approaches to enhancing services and products (Prikshat, V. 2023). The prevalence of effective knowledge sharing serves as one of the drivers of IWB in companies (Prikshat, V. 2023). Therefore, it is crucial to investigate the type of knowledge sharing that stimulates IWB.

2.2 Knowledge Sharing Behaviors

The construct of knowledge sharing is largely debated in the management studies literature. It constitutes one of the important elements of KM, leading up to knowledge utilization. Knowledge sharing is a behavior whereby people reciprocally exchange their knowledge (Islam, T., & Asad, M. (2024). In the corporate context, knowledge sharing among workers fosters the creation of valuable tacit knowledge, contributes to the generation of new knowledge, enhances organizational knowledge, and provides advantages for the business. It is crucial to differentiate between behaviors and attitudes regarding knowledge sharing. Behaviors can be conceived as tangible actions that stem from attitudes. As observed by de Smékalová, L. (2023), KS behavior is influenced by an employee's attitude, namely their desire to exchange knowledge. Understanding the drivers, processes, and barriers related to knowledge sharing is crucial for developing appropriate approaches to foster a knowledge-sharing mindset and optimize the asset value of an enterprise's intellectual wealth. Knowledge sharing is an indispensable activity in corporations aimed at promoting the circulation and reciprocal transfer of know-how, competencies, and qualifications among employees (Anugrah, 2017). This practice supports innovation, organizational learning, and successful decision-making (Vanhaverbeke, 2019). Knowledge sharing involves two distinct active processes: knowledge collecting and knowledge donating. KC entails soliciting intellectual capital from others to discover what they know, while knowledge donating (also referred to as diffusion or contribution) involves sharing one's personal intellectual capital with colleagues (Nguyen, M. 2023).

The first process, knowledge donating, encompasses effectively sharing information, qualifications, or know-how with other workers. This can be achieved through various means such as teaching, training, mentoring, participating in conferences, and more. Knowledge donating is rooted in the principle of making a valuable contribution to the progress and advancement of others by offering what we have learned (Guo, 2021). On the other hand, knowledge collecting involves the process of investigating, gathering, and acquiring knowledge from

diverse sources. It entails collecting relevant and valuable knowledge and then applying it to solve problems, generate new insights, and foster innovation. Knowledge collecting methods can include documentary research, data analysis, observation, and investigation (Fatimah, 2024). Both processes enrich knowledge and promote advancement across various spheres of life, regardless of the professional or academic context (Wibowo, 2020).

3. Theoretical Framework and Hypothesis Development:

Many investigations on knowledge management have reinforced the notion that knowledge sharing results in better business outcome, including innovation (Du Plessis, 2007). Innovation is defined as "a process by which economic or social utility is derived from knowledge through the generation, dissemination, and conversion of knowledge to create novel or materially advanced products or services that benefit the community" (Kahn, 2018).

Today's corporations are striving to maintain their dominant market positions by enhancing their competent and creative workforce. Numerous investigations have underscored the importance of human capital and skilled human resources in addressing corporate sustainability and innovation issues (Rasli, 2014). Several investigations have highlighted the critical effect of KM in enhancing corporate effectiveness (Kim, 2012). As knowledge represents the greatest corporate asset, it enables the acquisition of new business outputs, including innovation (Shaalan, 2020). Knowledge sharing not only fosters problem-solving potential but also enhances workplace productivity (Mehrbani, 2021). Knowledge serves as the foundational element of the innovation cycle. Despite the limited investigations on knowledge sharing and innovative behavior, earlier studies have been constrained in exploring the drivers that encourage workers to embrace innovative behavior (Hussain, 2020).

According to Tran (2021), a corporation that encourages its staff to share their knowledge is expected to generate novel thoughts and foster new opportunities for the enterprise, thereby facilitating better innovation initiatives. Many researchers have observed that knowledge sharing has a positive impact on IWB; it enables staff to transfer their know-how to other team members and provides others with the opportunity to acquire valuable knowledge.

Sajjad (2021) examined the role of knowledge sharing (KS) on innovation and identified a favorable effect on innovation. Additionally, the research community has emphasized the necessity for more detailed studies on innovation and expertise (Rasli, 2014). This investigation analyses the significant aspects of knowledge sharing in conjunction with innovative behavior (IB), which have traditionally received less attention in the academic world. Innovation is the outcome of knowledge exchange among workers. Knowledge sharing generates valuable insights that subsequently facilitate and anticipate organizational innovation (Cuellar, 2020). Therefore, it can be hypothesized that the sharing and gathering of knowledge have a positive effect on the IB of workers within the company. Consequently, our research proposes the hypothesis that knowledge is crucial for innovation, and therefore, knowledge sharing exerts a beneficial influence on the development of IB among staff within the company.

Building on the preceding discussions and the analysis of earlier papers, the following hypotheses are proposed.

H1: knowledge donating influences pharmaceutical engineers' IB positively and significantly.

H2: Knowledge collecting influences pharmaceutical engineers' IB positively and significantly.

4. Field of Investigation

The pharmaceutical industry in Morocco is a rapidly evolving and expanding sector, making significant contributions to public healthcare and the economy. The industry is experiencing robust growth, fueled by increasing domestic demand for medications and high levels of exports. Morocco boasts a strong legal framework for the pharmaceutical business, with internationally recognized standards for quality and safety. While the country manufactures a portion of its drugs domestically, it also relies on imports to meet local needs. The government actively promotes domestic manufacturing through various measures and programs aimed at strengthening the country's pharmaceutical sector.

The Moroccan pharmaceutical industry is dedicated to investing in the research and development (R&D) of new products, although this investment is still relatively limited compared to other regions worldwide. However, there is a growing interest in producing generic drugs. The Moroccan government is committed to ensuring affordable access to medication for all Moroccans by implementing public health programs aimed at enhancing the availability and quality of essential medications. Despite its rapid growth, the Moroccan pharmaceutical industry

faces several challenges, including competition from international rivals and the proliferation of counterfeit medications. Nonetheless, there are numerous opportunities for expansion, particularly through increased exports to other African countries and by fostering innovation and R&D activities.

5. Sampling Technique, Sampler Size and Questionnaire

The selected respondents were primarily sourced from LinkedIn, utilizing a convenience sampling approach. This method was chosen as accessing workers directly was not a straightforward option for the investigators. Data content analysis yielded the following results: 50 respondents were women, compared to 170 men. The participants' ages ranged between 26 and 45.

Pharmaceutical engineers were contacted via direct email and invited to participate in a self-administered study. Initially, 500 surveys were distributed, but only 230 were returned fully completed and deemed suitable for analysis.

To quantify the underlying sub-dimensions of knowledge sharing, our research adopted the scale utilized by Lin (2007). For assessing innovative behavior, we utilized the 9-item scale developed by Janssen (2000), which comprises three components: generation, championing, and implementation of innovative ideas. Pharmaceutical engineers were asked to provide their responses using a Likert scale with four points: 1= strongly disagree, 2= disagree, 3= agree, and 4= strongly agree.

6. Results and Analyses

6.1 Overview of Descriptive Statistics

Table 1 shows that the variables "Knowledge Donating", "Knowledge Collecting" and "Innovative Behavior" are measured on a scale of 1 to 4. The mean of "Knowledge Donating" is 3.78 with a standard deviation of 0.713, showing a particularly high degree of knowledge sharing. For “Knowledge Collecting”, the mean is 3.69 with a standard deviation of 0.828, also showing a high degree of knowledge collecting. As for "Innovative Behavior", the average is 3.67 with a standard deviation of 0.551, also demonstrating a strong degree of "Innovative Behavior".

Table 1: Descriptive statistics

Variables	Minimum	Maximum	Mean	Std. Deviation
KD	1	5	3.78	.713
KC	1	5	3.69	.828
IB	1	5	3.67	.551

6.2 Exploratory Factor Analysis

To investigate the convergent and discriminant validity of the measurement scales for "Knowledge Donating," "Knowledge Collecting," and "Innovative Work Behavior," we conducted a factorial analysis using principal component analysis (PCA) (Table 2). To determine the appropriateness of our data for PCA (Hair et al., 2014), we performed the Kaiser-Meyer-Olkin (KMO) measure of sampling adequacy and Bartlett's test of sphericity (Hair et al., 2014). The results of the KMO test and Bartlett's test indicate that the data meet the fundamental requirements for factor analysis and exhibit sufficient correlations.

The KMO coefficient is 0.83, and Bartlett's test is significant ($p < 0.001$). We then applied principal component analysis (PCA) with Varimax rotation to group all variables into principal components. The number of factors extracted was determined using the Kaiser criterion, which retains only principal components with eigenvalues greater than 1. Factors with eigenvalues less than 1 were considered non-significant and excluded. The factor analysis yielded a three-factor solution with a satisfactory total cumulative variance percentage of 77.11%.

Principal component analysis also revealed that items intended to measure the same construct loaded strongly on the same principal component, with a minimum loading of 0.61, indicating shared common variance and thus demonstrating convergent validity. Additionally, items measuring different constructs primarily loaded on distinct components, indicating good discriminant validity.

Table 2: Component matrix

Items	F1	F2	F3
Kd1	0.67		
Kd2	0.87		
Kd3	0.61		
Kc1		0.63	
Kc2		0.90	
Kc3		0.71	
Iwb1			0.63
Iwb2			0.73
Iwb3			0.81
Iwb4			0.97
Iwb5			0.75
Iwb6			0.69
Iwb7			0.79
Iwb8			0.68
Iwb9			0.71

F1 : Knowledge donating (Kd) ; F2: Knowledge Collecting (Kc); F3: Innovative Work Behavior (Iwb)

6.3 Reliability Assessment through Cronbach's Alpha:

Before beginning the correlation analyzes and testing our hypotheses, we will study the reliability of the measurement scales studied with the help of Cronbach's Alpha. The findings of the reliability analyze of the constructs demonstrate that "Knowledge donating" with three items obtained a Cronbach's alpha coefficient of .781, denoting excellent reliability. Similarly, the "Knowledge Collecting" variable showed an alpha coefficient of .832 with four items, suggesting satisfactory reliability. The "Knowledge Sharing" variable combining the two previous variables presented satisfactory reliability with an alpha of around .804. Finally, the variable "Innovative Behavior" presented the highest alpha coefficient, at .898, with nine items. These results support the reliability of the variables studied in this research.

6.4 Analysis of Correlations

The correlation matrix (Table 3) presents the relationships between the variables of "Knowledge donating", "Knowledge Collecting" and "Innovative Work Behavior". The correlation coefficients are significant at the 0.05 level. We observe a significant positive correlation between "Knowledge donating" and "Knowledge Collecting" ($r = .24$, $p < 0.05$) as well as between "Knowledge donating" and "Innovative Work Behavior" ($r = .40$, $p < 0.05$). In addition, a significant positive correlation is also observed between "Knowledge Collecting" and "Innovative Work Behavior" ($r = .44$, $p < 0.05$).

Table 3 : Matrice de corrélation de Pearson

Variables	Knowledge donating	Knowledge Collecting	Innovative Work Behavior
Knowledge donating	1	.24*	.40*
Knowledge Collecting		1	.44*
Innovative Work Behavior			1

**. Correlation is significant at the 0.05 level (2 tailed).

6.5 Hypotheses Testing by Multiple Regression Analysis

The findings of the regression analysis are illustrated in Table below indicate a significant influence of the variables "Knowledge donating" and "Knowledge collecting" on "innovative behavior", with respective

standardized coefficients of 0.220 and 0.127. This means that each one-unit increase in "Knowledge donating" is associated is to an augmentation of 0.220 in "innovative behavior", while each one-unit increase in "Knowledge collecting" is associated with an increase of 0.127 in “innovative behavior”. These coefficients are statistically significant, with t-Student values of 2.708 and 2.910 accordingly, and p-values of 0.008 and 0.004, both below the significance level of 0.05.

Furthermore, the regression model appears to be overall significant, with a coefficient of determination R2 of 0.71, which means that 71% of the variance in "Innovative Behavior" is explained by the variables included in the model. The Fisher test also shows a significant F statistic, with a value of 30.351 for a degree of freedom of 2 and 228, confirming the overall relevance of the model.

Regarding collinearity, the values of VIF (Variance Inflation Factor) are both less than 10, with values of 2.903 for "Knowledge donating" and 1.760 for "Knowledge collecting", which demonstrates the absence of major problems of multicollinearity between the predictors and reinforces the validity of our model.

Table 4: Results of multiple linear regression

	B	B	t	p	S.E	Collinearity Statistics	
Constant		.084	.617	.538	.135	Tolerance	VIF
KD	.220	.245	2.708	.008	.091	.344	2.903
KC	.127	.117	2.910	.004	.040	.568	1.760

R^2=.71

Fisher (2,228) = 30.351

7. Discussion and Interpretation of Results

The purpose of our investigation is to study the effect of KS on the innovative behavior of pharmaceutical engineers in Morocco. The research findings corroborate the formulated hypotheses. Following a comprehensive review of existing academic literature, two hypotheses are proposed.

Hypothesis H1 posits that KD has a positive and significant impact on the IB of pharmaceutical engineers. The findings of this investigation strongly support this hypothesis, indicating that KD indeed exerts a significant and positive effect on the IB of pharmaceutical engineers. This outcome suggests that pharmaceutical engineers who engage in knowledge donating within the workplace demonstrate a greater sense of commitment to the company's success. This aligns with Roman Kmieciak's research (2020), which finds a strong correlation between the KD and innovative work behavior within a major Polish capital group.

Furthermore, the second hypothesis posits that KC exerts a significant and positive impact on the IB of pharmaceutical engineers. The findings presented in the table substantiate this claim, thus providing support for the second hypothesis. This suggests that employees who demonstrate a greater inclination towards acquiring new knowledge within the organization are also more likely to exhibit a heightened commitment to the company's success. This underscores the relevance of fostering an organizational culture that promotes continuous learning.

This corresponds with Guo's (2021) findings, which indicate a positive correlation between knowledge collecting and IWB in Chinese software companies. Knowledge collecting enables workers to increase their personal knowledge reserves, enrich the knowledge necessary for innovation, and improve their capabilities, which significantly impacts innovative work behavior (Smith, 2006).

The result of our study aligns with previous research conducted by Du Plessis, M. (2007), who identified that employee knowledge sharing (KS) enhances a company's innovativeness. However, the specific impact of knowledge donating (KD) and collecting (KC) on innovative behavior (IB) has not been thoroughly investigated until now. Additionally, Carneiro, A. (2000), in their research note, proposed that KS contributes positively to employees' innovative behavior, a notion supported by the findings of this current study. Similarly, Migdadi, M. M. (2020), among the latest researchers, have also identified the beneficial impact of KS on IB.

Furthermore, the findings of this study reveal insightful aspects: both KD and KC significantly influence

employees' IB. Specifically, employees demonstrate higher levels of IB when they engage in knowledge collecting rather than knowledge donating. To put it differently, employees exhibit greater IB when they have the opportunity to gather information rather than simply disseminating it. As noted by Newell, S. (2000), during knowledge exchange, employees not only share information but also coordinate, develop, and transform it into meaningful and useful forms. Moreover, when employees acquire knowledge from their colleagues, they enhance their capacity to innovate (Tarhini, A., 2016). The underlying rationale behind employees' willingness to donate and collect knowledge is quite apparent. In essence, sharing knowledge represents a powerful expression of an employee's personal character, enabling them to recognize their own intrinsic value.

Moreover, it allows them to satisfy their urge for self-expression (Tarhini, A., 2016). However, this study suggests that individuals exhibit greater IB when they are empowered to expand their knowledge. Our findings reinforce the positive and significant impact of both KD and KC on the IB of pharmaceutical engineers. These findings underscore the importance of promoting knowledge-sharing and knowledge-donating practices within organizations, not only to foster the professional development of employees but also to enhance their commitment to the overall well-being and performance of the enterprise.

8. Conclusion

The conclusion of this examination underscores the critical value of knowledge sharing (KS) in the Moroccan pharmaceutical industry, both from a managerial and theoretical perspective. By investing in policies, technologies, and management practices that facilitate knowledge sharing, companies can not only foster innovation and enhance performance but also bolster their competitive position in the global marketplace. The positive and significant results obtained for hypotheses H1 and H2 underscore the critical value of fostering an organizational culture that promotes KS among pharmaceutical engineers. Managers and senior executives should take proactive measures to cultivate this culture by implementing incentives, sharing platforms, and policies that incentivize and recognize knowledge donating and collecting. Additionally, pharmaceutical companies should invest in knowledge management systems and technological platforms that streamline and facilitate knowledge sharing and collection processes. These tools can not only enhance operational efficiency but also stimulate innovation by enabling employees to readily access pertinent knowledge and share it with their colleagues. Executives have to grasp the significance of knowledge sharing (KS) for innovation and should receive training to promote and facilitate this practice within their teams. Training and awareness programs can be instituted to acquaint employees with the advantages of knowledge sharing and to enhance their communication and collaboration abilities. Companies can promote the establishment of informal collaboration networks where employees can exchange ideas, collaborate on problem-solving, and share experiences. These networks cultivate an environment conducive to innovation by enabling individuals from various functional backgrounds and different levels of expertise to collaborate and learn from one another.

Although our findings offer some precious indications on the influence of knowledge sharing (KS) on IWB within the Moroccan pharmaceutical industry, several research avenues are emerging to further enrich our understanding of this pivotal domain. Conducting an in-depth analysis of the cultural and organizational factors that shape individuals' willingness to share knowledge would be beneficial. This could encompass examining cultural values, organizational norms, leadership styles, reward systems, and trust climates, and how these components interplay to shape knowledge sharing behaviors. Gaining a deeper understanding of the underlying mechanisms by which knowledge sharing (KS) influences innovative behaviors in the workplace would be invaluable. This may entail identifying intermediary variables that elucidate the connection between KS and innovation, as well as moderating variables that influence the strength of this relationship in various contexts. Comparing knowledge sharing (KS) and innovative behavior (IWB) between the Moroccan pharmaceutical industry and other industries or countries would illuminate local specificities as well as international best practices. Such comparisons could facilitate the identification of learning opportunities and areas requiring strategic interventions to enhance competitiveness.

By addressing these research questions and fostering interdisciplinary collaboration across the domains of knowledge management, innovation, organizational psychology, and sociology, we can further enhance our comprehension of the underlying mechanisms that facilitate knowledge sharing (KS) and innovative behavior (IWB) within pharmaceutical firms. This, in turn, will enable us to develop managerial practices and policies that foster progress and sustainability in this critical sector.

Beyond Rational: Understanding of Fake News in the Post-Truth Era

Anastasiia Iufereva and Elisabetta Risi
IULM University, Milan, Italy

anastasiia.iufereva@studenti.iulm.it
elisabetta.risi@iulm.it

Abstract: The paper focuses on fake news as one of the most serious threats and distinguishing features of the post-truth period, which is defined by the following aspects: the rise of diverse sources of information on the Internet, the devaluation of facts, and the proliferation of fake news. These conditions necessitate a revision of the algorithm, the verification and presentation of information, as well as tactics and techniques for dealing with fake news. The purpose of this research is to describe the distinct characteristics of fake news. The authors have specifically extracted research from the Web of Science, Scopus, and Google Scholar search databases; the sample includes 120 scientific articles with titles related to fake news that were published after 2016 when the term "fake news" gained legitimacy after being named word of the year by Collins (usage of the term increased by 365% since 2016). The analysis focused on key definitions of fake news suggested in each selected research and its permanent and non-permanent characteristics.

Keywords: Fake News, Misinformation, Disinformation, Journalism, Social Media, Post-Truth Era.

1. Introduction

The proliferation of the Internet and popular social practices online have resulted in significant shifts in the mass media sector during the last decade. Post-truth era has emerged, characterized by the intersection of sometimes opposing ideas, perceptions, and techniques. Under these conditions the fake news is spreading, which destroy public discourse in the media environment and exacerbate political and social differences. As a result, the primary goal of this research is to describe characteristics of fake news and determine which parts comprise the nature of this phenomena.

2. Sample Description

For this research scientific papers have been extracted from the database Web of Science, Scopus, and Google Scholar search. The sample consists of 120 scientific publications with titles that mention "fake news". The selected papers were published after 2016, when a term “fake news” was acquired a certain legitimacy after being named word of the year by Collins (since 2016 usage of the term had increased by 365%). The analysis focused on two crucial issues: (1) how each of the studies defined and operationalized the term of “fake news” and (2) what are the permanent and non-permanent characteristics of this phenomenon.

3. Results of Analysis

3.1 Fake News: Approaches to the Definition

Fake news is crucial phenomenon since it contributes to the formation of our "real" world through the constant consumption of media products that present their interpretation of reality. Even though fake news is widespread, it is defined differently. As a result, the definition of fake news remains ambiguous, causing semantic uncertainty.

Fake news is "a catch-all term with multiple definitions" (Lilleker, 2017, p. 1), resulting in various approaches to identifying fake news. In the academic literature, research focuses on two critical components in defining fake news: how fake news is communicated and circulated in today's information ecosystem, and the kind of fake news content that is created and shared. According to the first approach, scholars define communication technologies (e.g., websites, social media, etc.) as tools utilized solely for the creation and dissemination of fake news in today's information environment. This perspective is consistent with the technological determinism approach since it asserts that the emergence and subsequent development of social media platforms has exacerbated the problem of widespread fake news. The media is viewed as an essential component of fake news, and the role of the internet environment in the propagation of such messages is underlined. As for the second approach, the study focuses on the content of fake news, namely the format of such messages and degree of inaccuracy. Scholars describe the format in which fake news is provided, the features of it, and the degree to which they may be real or false. Therefore, the following part of the current research will outline in more detail two approaches frequently found in definitions of fake news: (1) the role of the medium as an

integral component of fake news and as the basis for the circulation of fake news; (2) the news format (false information masquerading as news), and the degree of falsity.

(1) According to the first approach which is in line with the technological determinism approach, fake news is "produced and published by mass communication vehicles such as social media, dominating traditional and social platforms, becoming increasingly part of many people's daily lives" (Rocha et al., 2021). Sutu (2019), for instance, states that "fake news is authentic material used in the wrong context, news products disseminated on websites that specialize in fake news and use layouts similar to those of real media sites <…>" (p. 83). According to Bakir & McStay (2017), a key element of contemporary fake news is that "it is widely circulated online" (p. 1). Thus, it leads to information overload and the dissemination of fake news. Fake news multiply rapidly and act as narratives that omit or add information to facts. Other studies highlighted the methods by which fake news spreads, emphasizing the crucial role that technology plays in communication (Aldwairi & Alwahedi, 2018). One such example of a technological communication tool is social media. Fake news can also be propagated through email chains, posters on streetlights, and other means (Rini, 2017). However, there is a substantial correlation—especially during the 2016 election—between social media and fake news (Rini, 2017, p. 45). Social media has completely changed the composition, scope, and intricacy of news in the last few years (Berkowitz & Schwartz, 2016; Copeland, 2007). Social media is widely regarded as an essential channel for disseminating news and user-generated material, among other types of information. According to Nielsen (2016) and Vosoughi et al. (2018), Facebook, Instagram, and Twitter are the main platforms used for information dissemination. These platforms publish a large number of postings each day. Social media serves as a platform for social engagement, communication, and entertainment in addition to information sharing (Hwang et al., 2011; Kuem et al., 2017). People can share diverse opinions and values if they have unrestricted access to a wealth of knowledge (George et al., 2018; Kim et al., 2019; Rubin, 2019). It is simple to become disoriented in this information flow and stop telling authentic news from fake news on social media (Stein-Smith, 2017, Kumar et al., 2018). According to Machete & Turpin (2020), "search engines and social media platforms contribute to people's tendency to believe the information they come across on these platforms without verifying its veracity, even though they do not encourage people to believe the information being circulated." Hence, fake news has become a major part of social media, raising doubts about information credibility, quality, and verification (Olan et al., 2022).

(2) A further area of investigation is the idea that fake news is an intrinsic feature of the Internet's information space. Proposed definitions ignore the media as a tool for the production and dissemination of fake news in favor of focusing on the characteristics of fake news, methods of content presentation, and the effects of dissemination on the general population. Definitions of "fake news" will be determined by interpreting two factors: (a) the way fake news is presented; and (b) the way facts and the degree of trustworthiness of the information are presented.

(a) The existing definitions are preoccupied with the format of fake news. There are numerous ways to propagate inaccurate or misleading information online, and this news format is just one of them. However, the definitions of recent research have consistently included the news format, as seen here: messages disguising themselves as news and disseminated via the Internet or other media are known as fake news. They are typically produced as jokes or to sway political opinions (Cambridge Dictionary, 2018). False information about the world is presented in fake news in a style and with material that mimics that of reliable news sources (Levy, 2017). "Fake news is made-up news, manipulated to look like credible journalistic reports that are designed to deceive us," according to Brennen (2017, p. 180). One of the goals of fake news is to mimic real-world events and situations. It often mimics the conventions of traditional media news and its key characteristics, which are verifiability, accuracy, balance, and truthfulness (Kim & Dennis, 2019; Jaster & Lanius, 2018, Lazer et al., 2018). For this reason, fake news may seem to be true news. According to these definitions, fake news frequently appears in the news format, which is a respectable method of reporting on current affairs in the real world. Furthermore, it should be mentioned that "this conceptualization of fake news emphasizes, on the one hand, that this information formally imitates media content and, on the other hand, that it has not been produced following the same processes or with the same intention as news produced by the media" (Miró-Llinares & Aguerri, 2021, p. 5).

The next definition of fake news is defined as news items that are purposefully and demonstrably incorrect and have the potential to mislead readers (Allcott & Gentzkow, 2017). According to Klein & Wueller (2017), "the online publication" of incorrect statements of truth might be interpreted as "fake news" (p. 6). "Altered truths" are the definition of fake news, demonstrating the validity of the media's agenda (Shrivastava et al., 2020). False information bundled to trick the public into believing it was created by experts who respect the truth, according to Fiedler (Rimer 2017). "Information that is knowingly false, erroneous, or deceptive and that is intended to

hurt the public or be profitable" (HLEG, 2018). These definitions have two essential components: intent and authenticity. Firstly, information that can be independently verified as false is included in fake news. This time, the notion of falsity is included in the definition and the attribution of falsehood is made at the narrative level. Second, the purposeful fabrication of fake news is to deceive readers. Numerous recent studies have embraced this definition (Mustafaraj & Metaxas, 2017; Conroy et al. (2015), Allcott & Gentzkow, 2017). The motivation behind fake news writers is described in certain scholarly studies, and it may be boiled down to two things: subverting social norms and shifting power dynamics. Therefore, we contend that a more comprehensive definition of fake news should be adopted, one that encompasses the phenomena of information flow between an actor and an action that primarily aims to refute widely held beliefs about reality to challenge established power structures (Weiss et al., 2021).

(b) Some research indicates that fake news has a certain degree of credibility. Manipulation of facts results in two sorts of fake news, each with varying dependability. It is worth noting that the fluidity and ambiguity of truth are also important characteristics of post-truth, which is distinguished by the absence of rigid structures, elasticity and plasticity, idea substitution, and the presence of multiple points of view, each of which can claim the truth. Under these conditions, a fact in fake news may be made up and have nothing to do with reality. According to Gelfert (2018), "fake news has little to do with real-world events." Fake news is defined as articles "invented entirely from thin air," completely contrived, transmitting "new content [that] is 100% false," and having "no factual basis" (p. 96). Other studies have defined fake news in similar ways, with a focus on facticity. For example, Pennycook et al. (2018) define fake news as "entirely fabricated and often partisan content that is presented as factual" (p. 1865). Another type of fake news is when a factual truth is altered or presented wrongly. In this scenario, we're dealing with partially produced fake news: "fake news" is defined as "complete or partly false information, (often) appearing as news, and typically expressed as textual, visual, or graphical content with the intention to mislead or confuse users."

Therefore, according to our view, fake news is a piece of information that might be completely or partially fictitious and deal with real events and situations. Fake news is purposely generated to mislead and/or manipulate a certain audience. To establish credibility, the news format is used to simulate a popular journalistic genre (actual news) with a structure (title, image, content) designed to capture readers' attention, inspire confidence, and, as a result, mislead them. "Once the reader suspends credulity and accepts the legitimacy of the source, they are more likely to trust the item and not seek verification" (Kalsnes, 2018). To identify the distinct characteristics of fake news, it is vital to highlight both continuous and non-constant traits.

3.2 Characteristics of Fake News

This section of this research deals with a discussion of the key characteristics of fake news. To determine the features of this type of disinformation, it is necessary to distinguish between constant and non-constant characteristics. Thus, the author suggests a certain type of typology that encompasses features of fake news. It can not only organize and systematize the existing knowledge regarding fake news, but also it can facilitate the recognition of this type of information.

3.2.1 Constant Characteristics of Fake News

A lack of evidence base. Fake news lacks a systematic, cohesive, and well-structured evidentiary base for the claimed issue. The evidence base is a collection of reputable sources of information that includes references to official documents, critical data, statistics, scientific papers, and so on. The news story, which includes recent events or words made by an actor (for example, a politician), is frequently at the heart of fake news. The news story is developed and condensed around this information occasion, and appealing to an evidence foundation is beyond the producers' attention span.

Suspicious and unverified primary sources. The source of fake news is difficult to detect. It can take the shape of a post on a news feed (on Facebook) or a tweet (on Twitter), just as true news is posted on these social media platforms (headline). Title, image, and signature/source. However, not all sources are equal in authority. "From this perspective, those who distribute fake news are completely identifiable: some pages take the names of famous newspapers by changing one or two letters to deceive; others create real websites, blogs, pages, Facebook or Telegram groups that often evoke conspiracy theories; sometimes, they are personal accounts of natural persons - often fake - who gain users' trust by touting important knowledge or by declaring their freedom from "the system" (Guerra e fake news, 2022). There is also the news without a link to the source: users spread this message making it popularized without knowing of origin of this news.

Imitation of news format. Many studies argue that fake news follows the format of a news narrative, resulting in increased attention and trustworthiness (Baptista & Gradim, 2020; Allcott and Gentzkow, 2017; Lazer, 2018; Rochlin, 2017; Kalsnes, 2018). Fake news is usually associated with freshly emerging, time-critical events, or hot topics in order to attract the attention of internet users, and this content may not have been thoroughly vetted by existing knowledge bases due to a lack of confirming evidence or assertions (Shu et al., 2017, Zhang & Ghorbani, 2020).

The importance of the topic for a certain segment of the society. The prevalence of fake news may be substantially determined by the publication's relevance/importance to the public (Salgado and Bobba, 2019; Galeotti 2019; Trilling et al. 2016). This importance is subjective, as this disinformation may appeal to certain readers but not others. Rini (2017) included this component in the definition of fake news, claiming that bogus information is produced to confuse a section of the audience, despite the fact that one of the primary purposes of fake news is to achieve popularity. To the degree that fake news is relevant, its popularity can be linked to the coverage features of a certain event or the topic covered or studied (Vosoughi et al. 2018; Bright 2016).

The velocity of fake news. Fake news and its creators are typically short-lived (Allcott & Gentzkow, 2017). Fake news, viral or not, has a limited duration. If the news spreads and sparks a public debate, competent journalists and fact-checkers may be able to quickly expose it. For example, several active fake news websites during the US presidential election of 2016 no longer exist following the campaign (Zhang & Ghorbani, 2020).

Intense emotional connotation of the message. Newsmakers frequently communicate their thoughts, emotions, attitudes, and sentiments through fake news. Zhang & Ghorbani (2020) present the concept of "non-physical content" as the core kernel of fake news, stating that it encompasses all of the significant ideas, sentiments, and perspectives that the authors wish to convey to the readers. Sentiment polarity is another significant aspect of non-physical material in fake news. To make their news more persuasive, authors frequently express strong positive or negative emotions in the text body (Devitt & Ahmad, 2007). In particular, stories that elicit powerful emotions become more appealing and widely disseminated. Aside from multiple categories and sentiment polarity, fake news can target certain domains and subjects. Some research (e.g., Galil & Soffer 2011) have found that fake news about crises, conflicts, catastrophes, money laundering, crimes, sexual offenses, or fraud, etc.) receives more public attention. Furthermore, the appealing theme is a political one. Vosoughi et al. (2018) reveal that incorrect content concerning politics was not only widely circulated, but also reached a larger number of people than other subjects.

Simplified language and style of the fake news. It has been recorded that the vocabulary employed by fake news is more formal and simpler in terms of details and production techniques, not just in article headlines but also throughout the content (Horne & Adali 2017). Fake news producers regard certain aspects, such as straightforward and stunning messages, appealing headlines that appeal to the audience's emotions, and clickbait, as important for multiple disclosures. In contrast to traditional media, the most commonly used words in discovered fake news, such as "sex", "death", "corruption", "illegal", "alien", or "lies", refer to dramatic or scandalous content (Budak 2019). Another feature of fake news is message repetition, which enhances its credibility: "Just one prior exposure to fake news headlines is enough to significantly increase subsequent awareness about their accuracy" (Pennycook et al., 2018, p. 1876). This repeating effect is exploited by web bots who are involved in fake news. Flooding the internet with social media bots and fake news sites that post and share the same fake news can make a bogus article appear credible (Tandoc, 2019). For example, a user may stumble across a bogus news report online and decide to search Google to confirm it. If that person sees similar fake news posted elsewhere, they may be misled into believing the post is genuine (Tandoc et al. 2018). As a result, repetition effects imply that repeated exposure to the same information—even if the repeat message comes from the same source and is thus rationally redundant—makes that information more convincing (Gelfert, 2019).

Conscious intent to deceive or mislead. The intentions of content creators are malicious. These intentions amount to the conscious intention of the authors to deceive or mislead the audience. For this reason, fake news is different from journalistic errors (a type of misinformation) and other types of journalistic genres (e.g., satire and parody). For instance, journalistic errors occur inevitably in the process of reporting on often intricate matters (Jaster & Lanius, 2018), and the main aim of satire and parody is to entertain the public, there is an implicit understanding between the author and the reader that the item is false (Tandoc, 2017).

Variability of the authenticity of the news. One distinguishing element of fake news is the manipulation of content validity. However, the credibility of such information varies. Most authors argue that fake news does not need to be completely false or fabricated. Fake news is completely or partially untrue (Tandoc et al. 2018;

Gelfert 2018; Rini 2017; Allcott & Gentzkow 2017; Jaster & Lanius, 2018), adheres to the media agenda, and attempts to describe actual occurrences while distorting and twisting the truth (Rini, 2017). Regarding the identification of sources of information, this can be indicated as a link to primary sources (e.g., reports, statistics, video, images, etc.). However, even if there is a factual basis, the data presented may be erroneous. "Many fake news stories are not completely false, but rather combine purposeful falsehoods with well-known realities to obfuscate. Almost all fake news claims to be about genuine people and entities, which contributes to its initial legitimacy. After all, bogus news claims to be news, not fiction" (Gelfert, 2018, p. 100). Many fake news stories are not entirely fictitious, but rather combine purposeful falsehoods with well-known facts to obfuscate the truth. The latter, purposely misleading one's audience, might be accomplished simply by selectively presenting partial truths. This implies that there is no value "to overstate the degree of disconnect that exists between fake news and reality, or, in any case, that it should not be built into the definition" (Gelfert, 2018).

3.2.2 Non-Mandatory Characteristics of Fake News

Fake news tends to be viral. The fundamental purpose of fake news is to become viral (Rini 2017) and generate a large number of reactions, including views, likes, reposts, and debates. However, this feature is not always present in fake news, as not all items may become popular and gain widespread attention. In the age of digital cacophony, most news, including fake news, goes ignored by users. The following factors can influence virality: topic relevance, high value of the news (for example, content with photos and video material makes the news more appealing), correctly selected format for presenting the news, and platform (fake media website, social networks, instant messengers, etc.). It is crucial to note that the success of falsified things is dependent on pre-existing social conflict (Tandoc, 2017). An equally significant component is the competent selection of the target audience, because, as previously stated, fake news is directed at a specific part of society, thus the content must relate to the values and attitudes of that target group in order to be noticed.

Mobilizing cognitive bias. Since fake news is directed at a specific demographic, it may involve manipulation of our bias. Gelfert (2018) even used the term "confirmation bias" to stress that the goal of fake news is to exploit consumers' pre-existing cognitive biases. "The most striking example is confirmation bias, the universal tendency to want new evidence that confirms our beliefs and theories" (Gelfert, 2018, p. 1). Far from being a side consequence of fake news, the systemic ways in which it mobilizes our cognitive biases and alters our thinking processes, are integral to its purpose. Confirmation bias contributes to many informal fallacies that stifle critical thinking, as well as systematic issues in the architecture of the sources and channels via which fake news travels, creating barriers to critical thinking and active investigation. Much fake news employs representational strategies that actively alter customers' cognitive biases, to deceive consumers into propagating (e.g., through online "sharing") the very statements that misled them in the first place (Gelfert, 2018).

Presence of photos, videos, and other multimedia materials in fake news. Fake news has also been defined as the alteration of real photographs or videos to create a misleading narrative. Visual clues are a significant but optional feature of fake news because not every fake news contains visual or graphical content (Kalsnes, 2018). As previously demonstrated, fake news exploits individual vulnerabilities, frequently relying on exaggerated or inaccurate visuals to elicit wrath or other emotional responses in customers (Shu et al., 2017). Visual characteristics are collected from visual materials (such as photographs and videos) to capture the many aspects of fake news. Image modification has grown in popularity as a result of digital photography, strong image alteration software, and expertise (Tandoc 2017). Effects might range from simple to complex. Simple modifications can include expanding the space. Effects might range from simple to complex. Simple modifications can include adding more space and deleting little items. More extreme modifications could include removing or putting people into the photograph. Another type of manipulation is when fake news appears in photo manipulations and uses images from one context in another (for example, fake news uses photographs that depict a completely different event and are unrelated to the situation being described, which is especially common for natural disasters, military operations, and so on) (Kalsnes, 2018).

Presence of sensational headline of fake news. Typically, fake news headlines are false and outrageous, having exaggeration, sensationalism, and even violence in common. However, this characteristic is not mandatory. Given the tendency of fake news to imitate real news, headlines can be neutral in tone, avoiding exaggeration and attempts to immediately shock readers.

Table 1: Characteristics of fake news

Constant characteristics of the content of fake news	
The lack of evidence base	Fake news lacks a systematic, cohesive, and well-structured evidentiary base for the claimed issue. The evidence base is a collection of reputable sources of information that includes references to official documents, critical data, statistics, scientific papers, and so on.
Suspicious and unverified primary sources	The origin of fake news is difficult to determine since it can spread on the Internet, particularly on social media, without attribution to the source. Internet users can propagate bogus news. Fake news can also surface on questionable news websites or on sites that resemble legitimate, authoritative media but are not.
Imitation of news format	Fake news takes the form of true news and refers to freshly developing, time-critical events or hot topics in order to attract the audience's attention.
The importance of the topic for a certain segment of the society	The chosen topic addresses the interests and values of a specific segment of the audience to produce a viral impact on the message.
The velocity of fake news	Fake news, viral or not, has a short lifespan.
Intense emotional connotation of the message and emotional response of the audience	News makers often communicate their thoughts, emotions, attitudes, and sentiments through fake news, making it more shareable and popular.
Simplified language and style of the fake news	The material is written in easy language. The presenting manner for the event is informal. The story's title is engaging and appropriately describes its content. Persuasion strategies may include several repetitions.
Conscious intent to deceive or mislead the audience	Fake news is manufactured and circulated for selfish reasons, since the author seeks to fool the audience.
Variability of the authenticity of the news	All fake news has one thing in common: the content is false, which varies depending on the author's aims. They typically showcase wholly or partially created content based on true facts (there is a reference to an event or famous persons).
Non-mandatory characteristics of the content of fake news	
Fake news tends to be viral	The primary purpose of any fake news is to become viral and generate a lot of reactions (views, likes, reposts, etc.). However, this feature is not always present in fake news, as not all items may become popular and gain widespread attention.
Mobilizing cognitive bias	Fake news may exploit customers' innate cognitive biases. It leads to several informal beliefs that stymie critical thinking, as well as systematic aspects in the architecture of the sources and channels via which fake news travels, creating hurdles to critical thinking and active inquiry.
Presence of photos, videos, and other multimedia materials in fake news	Fake news has also been defined as the alteration of real photographs or videos to create a misleading narrative.
Presence of sensational headline of fake news	Fake news headlines are typically inaccurate and outrageous, with exaggeration, sensationalism, and even violence as prevalent themes. However, this feature is not required because headlines can have a neutral tone.

4. Conclusions

The problem of fake news remains relevant and continues to spark discussions about its definition, features, and characteristics. The authors of this research have attempted to contribute to the analysis of fake news. We have identified the crucial characteristics of fake news, which might be beneficial for media experts and professional journalists. It is vital for them to be capable of identifying fake news, as legacy media still act as gatekeepers in the current media space by making decisions about which stories are featured or published. Moreover, understanding fake news in a more profound way is important for comprehending the consequences and effects of the post-truth era. In this context, the position of fact is changing, as subjective information that aligns with personal beliefs plays a more critical role. This shift leads to increased polarization of opinions and fragmentation of the mass media landscape, which, in turn, facilitates the spread of fake news.

Mapping University Knowledge Management: A Bibliometric Analysis

Kitti Lekszikov
University of Pannonia, Faculty of Business and Economics, Department Management, Veszprem, Hungary

lekszikov.kitti@gtk.uni-pannon.hu

Abstract: Knowledge management is becoming an increasingly important and popular research topic. Overall, higher education institutions do not have a dedicated knowledge management system, but in recent years there has been an increasing focus on knowledge management in higher education, as higher education institutions need to manage knowledge effectively to meet current educational challenges and needs. Knowledge management in higher education is a set of processes and tools that collect, structure, capture, store and share knowledge in higher education institutions so that it can be used by learners, teachers and managers. The research aims to undertake a comprehensive survey and review of the literature in the field of knowledge management in higher education. It also aims to map and analyse in detail the thematic scope of related research. In doing so, the research will provide an extensive insight into the context of knowledge management in higher education and current research directions. In my analysis, I chose the framework provided by the PRISMA method, as it guides the process from the first step of data collection to the last step of data processing. Using the PRISMA method, a systematic literature review is conducted, the relevant literature on the topic is listed, summarised and analysed. The analysis is based on the search rules predefined by the author, and the Web of Science database was used as a bibliometric data source for sampling the research, to examine publication trends in higher education knowledge management research. The research sample (N = 967) consisted of publications with the terms 'university' and 'knowledge management' in their titles, and after selection, analyses were performed on a sample of 100 items. VOSviewer software was used to support the analysis process and visualize the results. The literature review results in a comprehensive information table summarising and grouping knowledge management research in higher education according to a rule defined by the author. The results of this research provide a starting point for researchers interested in the field, identify research gaps and identify possible further research directions.

Keywords: Higher Education, Knowledge Management, Bibliometric Analysis

1. Introduction

Knowledge management is the process of managing and using knowledge effectively. The management and sharing of knowledge is increasingly seen as a key factor in higher education as it has become essential for its growth (Areekkuzhiyil, 2016). Knowledge management is particularly important in higher education institutions, as research and education are core activities. Knowledge is created through a variety of human activities (Dhamdhere, 2015; Ranjan and Khalil, 2007), which can take different forms (facts, opinions, experiences, models, etc.) (Adhikari, 2010).

Given the knowledge-intensive nature of higher education institutions, the development, existence and proper functioning of a higher education knowledge management system is essential.

During her research, the author surveyed the literature on knowledge management in higher education, aiming to analyse the publications in a quantitative way.

This article sought to shed light on the field of knowledge management in higher education by answering three research questions:

1. What are the prominent research themes in the field of higher education knowledge management?
2. Which countries are at the forefront of publishing articles on higher education knowledge management?
3. Which aspects of the knowledge management process are prominent in terms of publications in higher education?

The author considers this research to be incomplete, as none of the articles we have examined have addressed these three research questions together.

2. Literature Review

In practice, the implementation of knowledge management cannot be successful unless it has the support of all relevant stakeholders in higher education institutions, as well as government regulators. The stakeholders in

higher education institutions - faculty, administrative staff and students - are a community and must play a joint role in the implementation of knowledge management (Kanwal et al, 2019; Hawkins, 2000)

From the perspective of higher education institutions, knowledge management can be explained as a set of practices that help an institution to improve its teaching, research and administrative roles and encourage stakeholders to use and share data and information in decision making (Petrides & Nodine, 2003).

Rivera et al. (2016) proposed a six-factor process that facilitates knowledge creation, storage, transfer and application. Their model consists of: leadership, culture, structure, human resources, information technology and measurement. Furthermore, their study showed that cultural, human and structural aspects play an important role in university knowledge management models.

One of the most important facilitating factors for knowledge management in higher education is leadership behaviour, as leaders have a significant influence on the direction and effectiveness of knowledge management in their organisations (Nam Nguyen & Mohamed, 2011). Leaders can provide conditions that enable participants to implement and develop their transformational skills in order to enrich their own knowledge and access relevant knowledge shared by others (Crawford, Gould & Scott, 2003); and leadership behaviour can nurture knowledge production and validation (Von Krogh, Nonaka & Rechsteiner, 2012).

Fullwood and Rowley (2017) found in their study that knowledge management policies implemented by higher education institutions are either inadequate or unpredictable. However, there has been a recognition of the importance of knowledge management in higher education institutions (Veer-Ramjeawon & Rowley 2020), followed by initiatives to promote and opt for knowledge management in most cases (Iqbal et al. 2018).

3. Methodology of the Literature Research Process

The author has carried out a systematic literature review to explore the literature, which reduces the risk of relevant publications being omitted from the literature analysed.

Petticrew and Roberts (2008) argue that a systematic literature review is a way of generating meaning from significant amounts of information, and a tool that helps to clarify questions about what is and is not being obtained.

Arksey and O'Malley (2005) state that the rapid growth in the field of literature reviews has resulted in a diversity of terminology that shares characteristic bases across different denominations. The authors stress that these approaches, although given different names, agree on certain basic characteristics. These include the collection, evaluation and presentation of research evidence. According to Arksey and O'Malley, despite the diversity of names in the rapidly evolving field of literature reviews, the basic principles of methodology are similar and are linked to the systematic collection and evaluation of available research data.

Based on the structure used by Massaro et al. (2015), Dumay et al. (2015), Ayodele et al. (2018), who have already published a systematic literature review on knowledge management, the author has created his own rules. The approach they use comprises five interrelated stages, these are:

1. Formulation Of The Research Questions
2. Writing The Research Protocol
3. Identifying The Articles To Be Included In The Literature Search
4. Grouping And Coding The Articles
5. Analysis And Discussion Of The Results

The author used a hybrid approach in the literature search, combining the structure used by Massaro et al. (2015), Dumay et al. (2015), Ayodele et al. (2018) with the PRISMA method.

3.1 Formulating the Research Questions

For the purposes of this article, the research questions I formulated in the introduction will guide me. This article is not intended to answer the research questions that follow, but merely to provide a basis for collecting literature and writing the forthcoming publication. These questions are intended to ensure that this literary analysis is accurate and relevant to all aspects of the subject.

The following research questions were formulated for a comprehensive literature review:

Q1: Does a complex knowledge management system tailored to higher education institutions exist today?

Q1a: If so, what are the factors that influence the process of knowledge management in higher education?

Q2: Do higher education institutions have a knowledge management system in place and, if so, what is the nature of the system? If not, what are the reasons for this?

Q3: What are the factors that influence the process of knowledge management in higher education and the construction of the system?

Q4: What factors help and what obstacles hinder the effectiveness of knowledge management in higher education institutions?

3.2 Writing the Research Protocol

Systematic review of the procedure and methods used in a pre-defined, well-defined protocol is essential (Petticrew and Roberts, 2008; Dumay et al., 2015; Ayodele et al., 2018).

For the analysis, the framework provided by the PRISMA method proposed by Moher et al. (2010) was chosen as it guides the process from the first step of data collection to the last step of data processing. PRISMA provides a comprehensive and transparent process, can be applied to any research field and strongly supports the reproducibility of the review (Vu-Ngoc et al., 2018). The methodology used for systematic literature review consists of four basic steps, these are: identification, screening, eligibility and inclusion.

3.3 Identifying the Articles to be Included in the Literature Search

In the previous section, the method I use in my analysis was presented, thus completing the structure (Petticrew and Roberts, 2008; Dumay et al., 2015; Ayodele et al., 2018). This third stage, defined by them, is fully mapped to the PRISMA method process. The figure below shows the data collection and pre-processing steps used. The number of excluded articles is also highlighted at each step.

Figure 1: PRISMA flowchart

Source: own edit

The first step in the PRISMA analysis method is identification. The analysis was based on a database provided by Web of Science, where a keyword search was used to identify all relevant literature on the topic. The author searched several databases of scientific articles in order to find a platform for data collection, the Web of Science database was chosen because it is a comprehensive database containing hundreds of thousands of records. The

database was downloaded without any time-frame restriction, so it contains articles from 1995 to the date of download (3 April 2023), which represents a total of 967 scientific publications with content related to knowledge management in higher education. This article does not aim to compare periods and, as it does not include a longitudinal study, it does not have the problem of analysing all the articles published up to the date of download. In order to preserve more information, the database contains data up to the date of extraction, which is why the 2023 truncation year publications are also analysed. With the filters and search rule specified, nearly 1,000 hits were obtained: university* AND "knowledge management".

The next step in the analysis is screening. The analysis was based on a single database, so there was no need to remove duplicate records. The present step of the method can be divided into three stages. In the first stage, the hits were narrowed down to the subject area, discipline classification, selecting those that belonged to the discipline. Thus the following topics were selected: Management; Education & Educational Research; Knowledge Engineering & Representation; Economics; Operations Research & Management Science. This section excluded 377 hits from the analysis. In the second stage, the type of document was identified, and the choice was made for the articles, as the later part of the analysis will require the processing of the relevant literature that follows from the reading of the abstract. With this narrowing down, a further 26 articles were excluded. Finally, in the third stage, the refinement ended on the language aspect of the publications. Only the articles published in English were retained in order to avoid problems in the later stages of the analysis when comparing the results. At this stage, a few articles in French, Russian and German were excluded from the screening and later from the analysis. At the end of the second phase of the PRISMA method, 494 articles remained.

In the next, third stage, a manual reading was carried out to determine eligibility, during which all articles (494) in the downloaded database were read and literature relevant to the research was isolated. In this step, a further 394 studies were excluded because they were not relevant for the following reasons: (1) they mentioned knowledge management but did not examine it from the perspective of higher education institutions, (2) they mentioned knowledge management but the content was not knowledge management specific.

The manual reading is followed by the inclusion step, which consists of keeping the scientific publications that remain in the database after the above steps have been carried out and identifying different sets. The database consists of 100 relevant scientific publications.

After establishing relevance, a fourth stage of the structure (Petticrew-Roberts, 2008; Dumay et al., 2015; Ayodele et al., 2018) follows.

3.4 Grouping and Coding the Articles

The fourth step is to group the different articles received for the structured review. The main purpose of the grouping of articles is to facilitate the effective application of the systematic methodology, thus helping to produce a structured review. This grouping will make it easier to extract relevant information from the literature reviewed. The structured grouping allows a systematic overview and comparison of the literature, allowing it to be analysed from different perspectives. All this will help to define the research framework for future research and to formulate research questions and hypotheses.

Dumay et al. (2015) and Ayodele et al. (2018) use the same grouping and coding principles, however the groupings are developed according to the author's own preferences in order to best serve the structured processing of the literature. The relevant literature has been organised according to the grouping principle presented in the figure below.

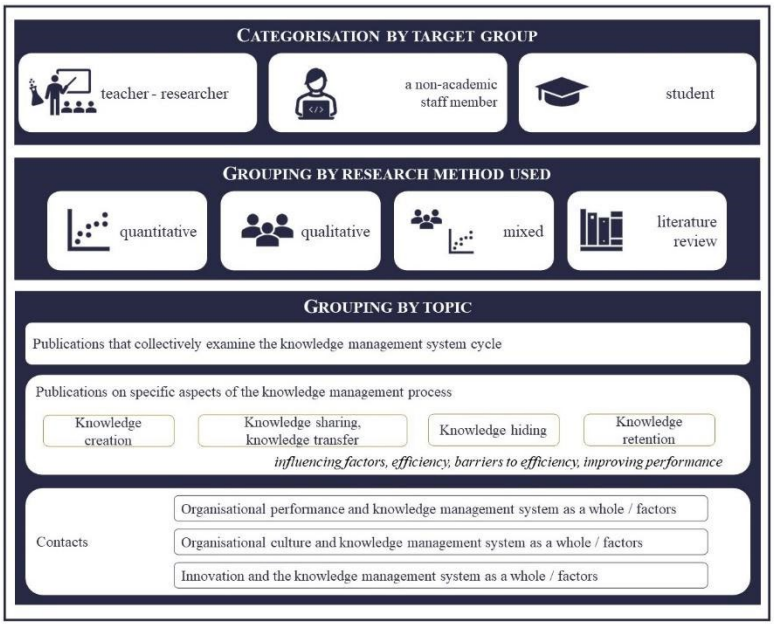

Figure 2: Grouping of reviewed articles

Source: own edit

In the literature review, the articles can be divided into teaching/research, non-academic staff and students according to the target group of the research. I choose this grouping for my research. The group of academics/researchers includes all employees who are closely involved in the teaching of students or who are involved in research activities that contribute to the development and innovation of their field. The next unit in the grouping I have defined is the non-academic staff, who do not carry out teaching and research activities but who provide and promote the University's activities. Finally, the third group is made up of full-time, part-time, undergraduate, masters and doctoral students.

In terms of the methodology used by the authors in their scientific publications, a distinction can be made between literature review, qualitative, quantitative, qualitative and quantitative research and data analysis methods. When grouped by topic, a distinction can be made between research that examines the entire knowledge management cycle as a whole, research that examines individual aspects of the cycle separately, and research that relates individual elements of the knowledge management system to other research areas.

4. Literature Research Results

During the literature search described above - prior to the manual reading - and after the final selection, I also carried out a quantitative analysis of the available data set. VOSviewer software supported the analysis process and visualization of the results. The analysis focused on 494 scientific publications before the manual reading and 100 scientific publications afterwards.

First, I examined the keywords indicated by the abstract of the publications. For a total of 494 items, the top 10 most frequently indicated keywords are "knowledge management" (n=286), followed by "innovation" (n=99), "performance" (n=92), "impact" (n=73), "universities" (n=57), "knowledge sharing" (n=52), "management" (n=55), "model" (n=47), "university" (n=42), "systems" (n=38). The figure below illustrates the keywords by network visualization with the exception of the keyword "knowlegde management" (its appearance distorted the network, suppressing the other keywords due to the size of the element count).

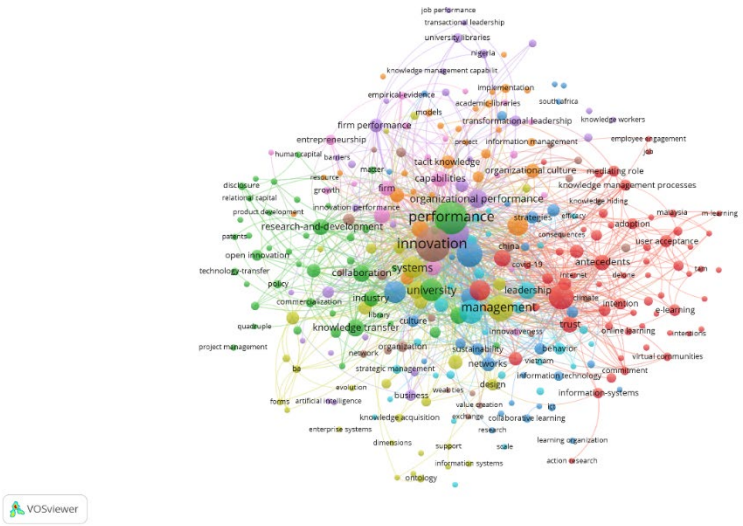

Figure 3: Cooccurrence of keywords in publications on knowledge management in higher education

Source: based on downloaded database, own editing

The keywords that were most frequently mentioned after manual reading were "knowledge management" (n=52), "knowledge sharing" (n=22), "innovation" (n=22), "performance" (n=21), "model" (n=15), "impact" (n=18), "management" (n=15), "antecedents" (n=12), "trust" (n=10), "universities" (n=18). The figure below illustrates the occurrence of keywords in the database filtered by network visualisation after manual reading. The keyword "knowlegde management" was excluded from the visualisation to avoid bias.

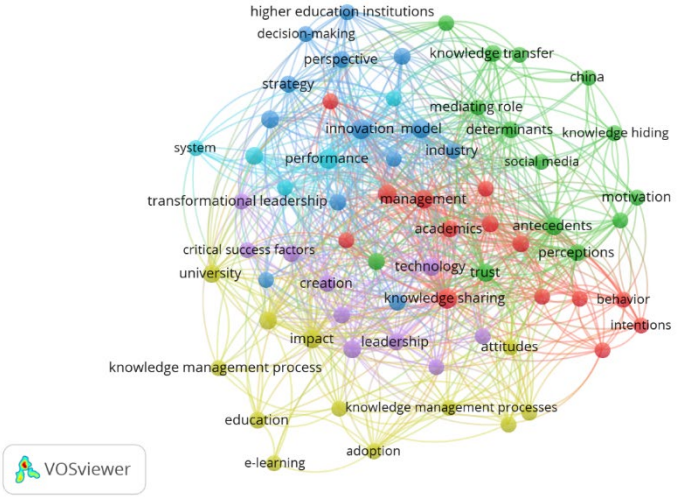

Figure 4: Cooccurrence of keywords in selected publications on knowledge management in higher education

Source: based on downloaded database, own editing

The network shows peaks in different colours. The colours represent the cluster classifications, so that vertices with the same colour belong to a cluster, connected by edges with the same colour. There is a high co-occurrence rate between keywords belonging to the same cluster. The size of the vertices represents the number of co-occurrences, while the thickness of the edges connecting the two vertices represents the frequency of co-occurrences.

From the two visualisations, it can be seen that the number of keywords has been reduced after the manual reading, with "innovation" and "performance" retaining their magnitude, but "knowledge sharing" being promoted. Knowledge hiding" (n=3), "knowledge transfer" (n=5), "knowledge creation" (n=8) and "trust" (n=10) were added to the map.

Quantitative literature analysis shows that knowledge creation, knowledge sharing, knowledge transfer and knowledge hiding are areas that have been researched in academic publications on knowledge management in higher education, but which have further research potential.

Quantitative approaches are also interesting for countries researching this topic. In the visualisation, countries where at least 3 publications have been published are indicated.

The following figures, first before and then after the manual reading, show a grid of countries contributing to knowledge management in higher education (peaks represent countries, edges represent the number of citations), with a reference focus. The figures below follow a gravity arrangement, i.e. whichever country has the most referral links is central in the middle, while those with few (or no) links are on the periphery. The following graph does not show isolated peaks, i.e. countries that are not connected to other countries.

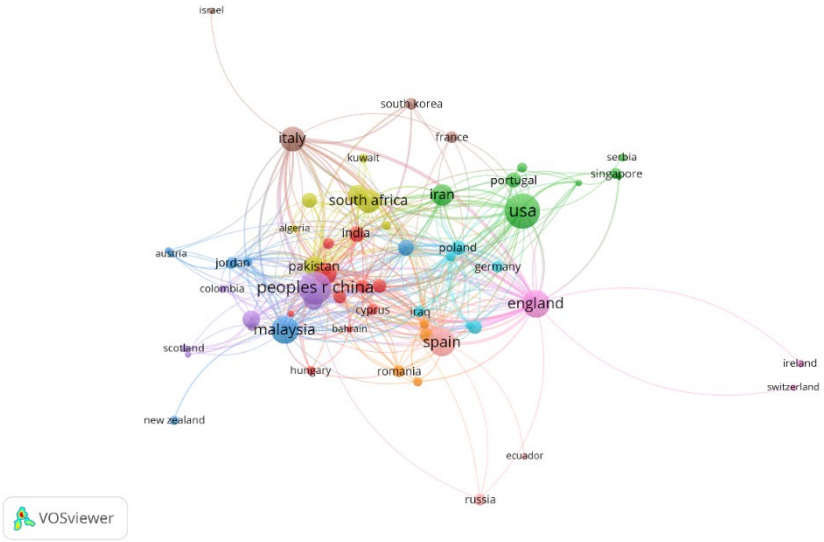

Figure 5: Network of countries publishing on knowledge management in higher education

Source: based on downloaded database, own editing

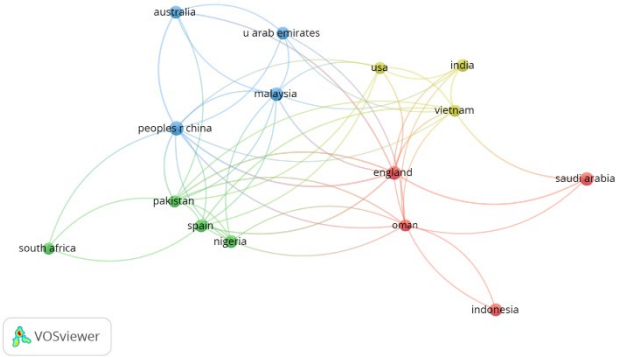

Figure 6: Network of countries publishing on knowledge management in higher education - after selection

Source: based on downloaded database, own editing

After manual reading, it can be said that, apart from China and England, knowledge management in higher education is the most researched area among researchers from Asian and African countries. It is important to note that among the European countries, only Spain is on the map. From the above, it can be concluded that, apart from Spain, there is no international literature on European institutions. It is important to note, however, that this indicates the country under which the researcher is publishing and not the country of higher education system studied.

Based on international publications, it can be concluded that, as a less researched area in our region, there is a great research potential for research on knowledge management systems in Hungarian higher education institutions.

5. Discussion

Knowledge management in higher education is increasingly coming under the spotlight as universities and research institutions recognise the importance of managing and sharing knowledge effectively. The results of

my research have led to several interesting and relevant conclusions that contribute to the academic discourse in this area.

5.1 Prominent Research Topics

Based on the analysis, the most prominent research topics in the field of knowledge management in higher education include general knowledge management, innovation, performance, knowledge sharing, and trust and knowledge hiding. The dominance of the keyword "knowledge management" in the publications is understandable, as it is the most general term, encompassing the whole cycle. At the same time, the prominence of innovation and performance suggests that researchers have a strong interest in investigating the effectiveness and efficiency of knowledge management systems.

Particularly noteworthy is the role of knowledge sharing and knowledge capture, which directly influence knowledge flows in institutions. And trust, as an increasingly prominent factor, also plays a key role in effective knowledge management processes. These findings suggest that future research should explore these factors in more depth, with a particular focus on their interactions and effects.

5.2 Leading Countries in Knowledge Management Research

The spatial distribution of publications also yielded interesting observations. The dominance of China and the UK alongside Asian and African countries suggests that there is a strong research activity in these regions in the field of higher education knowledge management. The presence of Spain as the only European country among the publications examined indicates that the European research community is less active in this field or less present in the international publication space.

This observation may have important implications for higher education institutions in Hungary. The data show that there is significant research potential in the study of knowledge management systems in Hungarian universities, which could contribute to the international academic discourse and increase the academic visibility of the region.

5.3 Outstanding Factors in the Knowledge Management System Process

Knowledge sharing, knowledge creation, knowledge hiding and trust play a key role in the study of knowledge management system processes. These factors have a significant impact on the effective flow and use of knowledge in educational institutions. The research results clearly show that these processes are closely interrelated and that the effectiveness of knowledge sharing is highly dependent on the level of trust within the organisation.

These factors may be of particular relevance for higher education institutions in Hungary, where the development of knowledge management systems can contribute to improving the effectiveness of teaching and research. The frequent occurrence of the keywords innovation and performance suggests that the development of knowledge management systems can directly contribute to the competitiveness and innovative capacity of institutions.

6. Conclusion

In conclusion, the results of the research highlight that knowledge management in higher education is a dynamically developing field of research, which offers many opportunities for future research. Innovation, performance, knowledge sharing and trust are key elements to be further explored in order to improve knowledge management systems. In particular in Hungary and the region, there is great research potential in this area, which can contribute to the development and international visibility of universities and research institutions.

7. Further Research Opportunities

The findings of this research have identified a number of further research directions and opportunities in the field of knowledge management in higher education. In what follows, I highlight two potential research topics that I believe hold great potential for future research. Firstly, I will highlight the motivations and consequences of knowledge hiding as a further research direction, which aims to assess why knowledge is hidden by lecturers, researchers and students and what impact this has on organisational performance. A further research option is

to investigate the effectiveness of knowledge sharing strategies, with the aim of examining the effectiveness of different knowledge sharing strategies in higher education institutions.

8. Research Limits

The present research has fundamental limitations, as only article-type documents were included in the database. Conference papers excluded by the rule would be relevant and relevant because their results appear faster than the publication process of journal articles. However, this study focused only on high-ranking scientific publications.

Enhancing Knowledge Legacy: Strategies for Employees with Long Scientific Seniority in Construction Academia

Katarzyna H. Tomiczak
Faculty of Management, Warsaw University of Technology, Warsaw, Poland

katarzyna.tomiczak.dokt@pw.edu.pl

Abstract: This paper presents the results of a pilot survey conducted as part of a doctoral research project on the management of tacit knowledge of employees with long scientific seniority (LSS), defined as 25+ years post-doctorate, focusing on knowledge transfer in the academic environment related to construction. This planned research aims to identify the best methods to support the dissemination of tacit knowledge of LSS employees among employees of other generations. The primary goal was to create a model that supports the transfer of LSS tacit knowledge to other employees. The research question is: How should the tacit knowledge of LSSs be managed to preserve and pass their legacy on to younger generations? A pilot online survey was conducted with three groups of respondents: LSSs, their leaders (L-LSS), and co-workers(C-LSS). The anonymous survey included 72 statements in five areas: 1. awareness of tacit knowledge, 2. personal motivation to share tacit knowledge; 3. the traditional approach versus the innovative approach; and 4. organisational support for knowledge sharing; 5. management of generational diversity. The first two areas contained different questions for each of the three groups, whereas areas 3–5 contained identical survey questions. Responses were recorded on a five-point Likert scale. The pilot study involved research institute employees who volunteered to participate. The study sample consisted of 22 participants. The group of respondents comprised four generations. The lowest mean (below 3.0) concerned statements in Areas 2 and 4. Similarly, a median (equal to 3) was obtained for these areas. The remaining areas had a mean of 3.1 or above, with a median of 4. The standard deviation ranged from 0.93 (Area 3) to 1.25 (Area 2), which indicates that Area 2 (personal motivation to share tacit knowledge) and Area 4 (organisational support in sharing knowledge) are important areas for further analysis. The next step (February 2024) will be to conduct an online survey of two technical universities and two research institutes in Poland, followed by in-depth interviews (spring/summer 2024). The same procedure will be used for all the four European institutions (2024). The value of this study lies in determining the best practices for generational tacit knowledge sharing.

Keywords: Tacit Knowledge Management; Long Scientific Seniority (LSS); Knowledge Transfer; Generational Diversity; Construction Academia; Tacit Knowledge Dissemination.

1. Introduction

1.1 Background

Knowledge management and tacit knowledge are well-known among researchers. From works of Polanyi (1958) and Drucker (1959), Nonaka et al. (1994), and Prusak et al. (1998) to more recent works like Dalkir (2017), to name a few. There are also articles discussing possible futures in this field, including collaboration with artificial intelligence, presented by Bencsik (2021). It is also a topic presented on ECKM by Zabeda et al. (2023) and Kucharska et al. (2022). With technological progress reshaping industries, effectively managing tacit knowledge has become essential for organisational competitiveness, especially in heavy research sectors. The challenge intensifies in academic construction environments where experienced researchers possess significant yet often unarticulated knowledge. Recognising and utilising this expertise is crucial for sustaining innovation and guiding the sector's evolution. This paper investigates approaches to managing the tacit knowledge of long-term scientific seniority personnel, aiming to encourage practical discussions and collaborative research efforts within this specific context.

The subject was derived from the author's professional trajectory, stemming from her involvement at the Building Research Institute (ITB) since 2016. Two opposing mechanisms of tacit knowledge management have recently been identified within the ITB. The first pertains to the challenges of transferring knowledge from senior researchers, as impending retirement could precipitate a significant loss of experiential knowledge. The second, in contrast, illustrates the successful acquisition of tacit knowledge through interactive observation, a process the author has experienced first-hand during her collaboration with ITB's scientific secretary, Professor Lech Czarnecki, an outstanding specialist in the field of building materials engineering who has accumulated unique experience and skills during his over forty-year scientific career.

1.2 Key Definitions

The definitions of the key terms used in this study are described in detail. The management method "is a proven, recognised, logically structured way of solving specific organisational problems" (Morawski and Prudzienica, 2011). Tacit knowledge "is inextricably linked with a person, not easy to transfer and codify, it is a unique compilation of know-how, professional qualifications based on knowledge obtained in the process of formal education, skills (...), experiences, substantive observations, developed methods of conduct (...)." (Morawski 2017). An employee with long scientific seniority (LSS) obtained a PhD degree at least 25 years ago (approximately 1999 and earlier). Construction is characterised by a rather conservative and formal approach, which results from the obligations involved in designing and erecting buildings. This attitude can hinder knowledge diffusion. In addition, tacit knowledge can be an essential resource for further development of construction science..

1.3 Literature Review

1.3.1 Knowledge Management, Generations and Academia

A preliminary literature review was conducted to establish this research context. Sanei et al. (2013) delineated the process of knowledge transfer between generations T, BB, X, and Y in construction and engineering organisations headquartered in the United States. Brčić and Mihelič (2015) reported the results of research conducted in Slovakia on employees from the BB, X, and Y generations. This study examined how selected individual factors, including willingness, motivation, communication, and cooperation, influence the sharing of knowledge with colleagues. Virta's (2011) doctoral thesis analysed the transfer of knowledge between retiring employees and their successors in a medium-sized Finnish company that designs and produces electrical devices and systems for the global market.

In Poland, an article published in 2018 (Chomątowska, Żarczyńska-Dobiesz, 2018) explored the characteristics of the BB generation and presented the results of a study on the barriers to knowledge sharing among BB generation representatives. Responses were provided by representatives of both the organisation and the BB generation. Sidor-Rządkowska (2018) discussed the challenges of managing generational diversity in contemporary organisations and the benefits of implementing mentoring programs.

Dziadek (2019) presented a different perspective, which examined the problems and challenges associated with intergenerational knowledge transfer in modern enterprises across four generations: BB, X, Y, and Z. This study focused primarily on determining whether knowledge transfer systems were implemented in selected organisations and the ways in which these systems function, as well as understanding the intergenerational knowledge transfer model in businesses. Research conducted by Morawski (2017) appears to be closest to the doctoral student's area of interest, as it relates to the ability of key employees of the company to share knowledge (diffusion) and how employees with long scientific experience can be defined.

In recent publications, a study conducted by Chinese researchers (Rui and Ju, 2022) examined the application of relationship management theory in the transfer of knowledge between generations among younger employees aged 40 or less from various industries in China. Another article (Wang et al., 2023) discussed the relationship between workplace ostracism and knowledge-sharing behaviour in academia in China.

From the literature, four main research interests related to LSS have emerged:

- the diffusion/transfer of tacit knowledge of LSS employees,
- the way of managing this tacit knowledge,
- the management of generational diversity,
- identifying and overcoming barriers to knowledge sharing.

Together, these areas shape the research context on the tacit knowledge of LSS employees (Fig. 1).

Figure 1: Four main areas of the research context, [own elaboration]

1.3.2 Tacit Knowledge in Construction

Publications related to the construction field primarily focus on enhancing the productivity of organisations in the construction industry. It is essential to acknowledge that tacit knowledge plays a crucial role in the construction industry, as highlighted by Pathirage et al. (2007). In a subsequent article by the same authors (Pathirage et al., 2008), tacit knowledge in construction was defined as "understanding, abilities, skills, and experience of the person concerned, often expressed in action as thoughts, viewpoints, evaluations, and advice; produced and acquired by past experiences [...]". Research conducted on construction contractors in Hong Kong confirmed the more significant strategic role of tacit knowledge, as described by Chen and Sherif (2009). Khuzaimah and Hassan (2012) addressed the role of CoPs in knowledge management related to construction projects. Among more recent publications, Zhou et al. (2022) emphasised the process of externalisation of tacit knowledge in construction projects.

2. The Phd Thesis Framework

2.1 Scientific Gap

The noticed scientific gap refers to the primary process of sharing tacit knowledge (and more broadly, other processes) by LSS employees, that is, employees with long scientific seniority (min). 25 years after their doctorate, thanks to their unique life, professional, and scientific experience, they probably have unique tacit knowledge, which translates into their high scientific and research potential. The determinant here is not the employee's age, but his or her scientific experience counted from the year of obtaining a doctoral degree. Construction is a field that requires strict compliance with standards and rules and careful introduction of innovations and is characterised by formality and conservativeness. This is because the constructed structures must ensure the safety and durability of use. In this context, the tacit knowledge of construction scientists–a combination of experience, skills, and engineering intuition–is an important resource that can influence further development of scientific knowledge in the field of construction. The aforementioned formalism and caution may pose additional challenges to the diffusion of such important tacit knowledge.

2.2 Research Problem Definition

The primary aim of this study was to verify and develop methods to support the management of tacit knowledge of LSSs in construction institutions. Unlike tacit knowledge, explicit knowledge can be easily shared through scientific publications, databases, manuals, training materials, policies, and procedures, or the Internet and social media. Tacit knowledge, in the form of intuition, experience, skills, or reasoning, is not easy to capture, but is essential for retaining knowledge (in the context of staff turnover), strengthening cooperation between employees, improving efficiency and productivity, and fostering innovation. The main research question of this study is: “How should the tacit knowledge of LSSs be managed to preserve and pass their legacy onto younger generations?”

2.3 Research Methodology:

2.3.1 Research Methods

The doctoral project will utilise the following methods.

- Review and critiquing the literature
- Analysing documents (if applicable)
- Diagnostic surveys: Online questionnaires and in-depth interviews
- Expert Panel Discussion
- Heuristic techniques, such as brainstorming (if applicable, based on research outcomes and changes in the situation).

The expert panel offers valuable insights that are not accessible using other methods. Combining all these methods aims to provide a thorough, multi-sided view of the research topic, which will help develop a more customised method to encourage the spread of tacit knowledge among LSS employees.

2.3.2 Sample Selection

This research will be conducted across eight scientific institutions, split evenly between Poland and Europe. In Poland, the investigation will involve two research institutes and two construction faculties of polytechnics/universities. The same arrangement will apply to Europe-based institutions as well.

A purposive non-random sampling strategy ensures the most representative research results. The sample will include three study groups.

- LSS employees,
- Leaders of LSS employees,
- Individuals working with LSS employees (both academic and administrative staff).

Preliminary studies will be carried out at one Polish research institute, while other studies will be conducted across all eight institutions. The choice to concentrate on European countries rather than on Asian or American ones stems from their common cultural and historical contexts, which could affect tacit knowledge transfer methods.

2.3.3 Research Plan

In the first year, preparations for the research were conducted, including a literature review. Research assumptions in the academic environment of management sciences and construction were presented (participation in national and international conferences). The second year focuses on research, conducting a pilot and main survey as well as in-depth interviews, analysing all collected data, and developing a method to promote the spread of LSS employees' tacit knowledge. The third year is set aside for implementation, testing, and validation of the method. In the fourth year, the last year, it is planned to prepare conclusions and recommendations for academic institutions in the field of construction that employ LSS workers.

2.4 Expected New Contribution of the PhD Study

2.4.1 Theoretical Contribution

It is assumed that as a result of doctoral research, the following contributions will be made to the existing theoretical knowledge:

- Development of tacit knowledge management methods for different generations,
- Defining a group of LSS people, i.e. with long scientific experience, whose tacit knowledge is important for the development of construction,
- Identifying key challenges and barriers in managing tacit knowledge in construction due to significant generational differences,
- Identifying potential benefits from consciously managing the tacit knowledge of LSS employees.

2.4.2 Practical Contribution

The expected practical contributions to the research include the following:

- Developing a set of best practices and strategies for managing tacit knowledge, encouraging cooperation and knowledge sharing among different generations of researchers,
- Developing recommendations for changes in organisational structures, processes, and internal policies to better manage tacit knowledge in construction.

Subsequently, the insights obtained from this study could be applied and investigated further in diverse geographical contexts, including Asian, African, and American countries. Similarly, the methods and tools developed in this study could extend beyond construction to other disciplines and industries. Future research could explore how tacit knowledge is managed in various fields, such as the sciences, humanities, and social sciences, and how companies across different sectors manage and promote the diffusion of tacit knowledge across generations.

3. Methods

3.1 Methodology

3.1.1 Basic Information

This pilot study was the first element of a doctoral research programme. It was an online survey (three different forms) whose purpose was, among other things, to verify research tools and data collection methods. The main goals were to check how research workers in the field of construction would cope with a survey related to the tacit knowledge of employees with long scientific seniority (whether the questions are understandable and the scale of answers is appropriate, plus feedback and comments on the study), testing the research tool (MS Forms) in terms of providing answers, as well as their analysis and preliminary identification of survey areas requiring changes. MS Forms was used to conduct the survey was MS Forms and Microsoft Excel was used for the analysis. The choice of these tools is dictated by their availability and ease of use.

3.1.2 Sample

The pilot study was conducted at a Polish research institute specialising in construction; 22 individuals from all three groups took part. Participants were selected based on voluntary registration, meaning that those who met the conditions and expressed their willingness to participate after being informed about the purpose and scope of the study were invited.

3.1.3 Questionnaire

The study included 72 statements in five areas, with a space for comments after each area, and at the end, the so-called metrics for each group. These areas are:

I. Statements regarding awareness of tacit knowledge (15 statements);
II. Statements regarding personal motivation to share (or not) tacit knowledge (28 statements);
III. Statements regarding traditional vs. approach innovative (12 statements);
IV. Statements regarding organizational support for knowledge sharing (11 statements);
V. Statements on managing generational diversity (six statements).

A separate MS form was prepared for each treatment group. The respondents were asked to rate the statements on a Likert scale (1-5), where 1 means "I strongly disagree" and 5 means "I strongly agree ".

3.1.4 Data Analysis

Statistical analysis was conducted using MS Excel, which is the most easily available software. Mean values, medians, and standard deviations were calculated for each statement area across the entire sample group. Subsequently, the mean values for each area were computed for the three specific participant groups and compared to the overall results. This approach helped identify areas that required more attention in the main study. Additionally, technical changes were introduced into the structure of the main survey, and it was decided to change the tool for the main survey.

3.1.5 Influence on the Main Survey

As a result of the pilot survey, the following changes were made to the survey questionnaire:

- Context and more detailed descriptions of the statements were added to make it easier for respondents to answer.
- The number of statements increased to 94, especially in Areas II (+9), IV (+5), and I (+4).
- In the description of the rating scale, the value "3", previously described as "I have no opinion", was defined as "I have no opinion/both yes and no/I don't know", which gave greater freedom to express uncertainty.
- The part regarding the so-called “metrics” has been rearranged and unified to make it identical for all three survey forms.

In the main survey, to allow more time for responses and to allow them to be carefully considered, the questionnaires were sent as PDF files via e-mail before sending the survey link.

The response collection tool was changed to allow participants to save the survey while completing it, and to facilitate data analysis. The change was also dictated by an increase in the total number of questions in the questionnaire to over 100 (including the “metrics”), which exceeded the limit available for free in the MS Forms.

3.1.6 Limitations

Because the survey was conducted in one research institution, attention should be paid to the limitations of this study.

- limited representativeness of the research sample,
- the influence of the institutional context,
- limited objectivity of respondents.

The actual research group includes eight institutions, four from Poland and four from Europe, which will translate into a greater diversity of respondents and more reliable results.

3.2 Study Description

The preparations were performed prior to the pilot survey. On 23 November 2023, a meeting with the institute's employees was held, during which the concept of the doctoral dissertation was presented, key definitions and expected results were explained, and further steps regarding the research were taken. The assumptions of the survey, its objectives, and a discussion of the questionnaires, divided into areas, were presented and discussed. After the meeting, questions were sent to the participants who provided feedback. On this basis, some changes were made to the questionnaire.

The pilot study allowed for testing the survey questionnaire under practical conditions, with the participation of individuals representing the studied population. This enabled the collection of valuable feedback on the clarity and comprehensibility of the questions, as well as the overall structure of the research tool, contributing to the optimisation of the methodology before proceeding to the main stage of the study.

Links to the surveys were sent by e-mail and posted on the intranet, along with a cover letter and a short introduction to the topic. The survey form was active from 8 December 2023 to 3 January 2024. There were no restrictions on the time required to complete the survey, and anonymity was ensured using the appropriate MS Forms function. A total of 22 complete surveys were conducted. The groups were broken down as follows.

- Three LSS individuals
- Four individuals serving as LSS leaders, L-LSS
- 15 individuals cooperating with LSS, C-LSS

The main research will cover eight research institutions and will include:

- at least eight LSS individuals
- at least eight individuals serving as LSS leaders
- at least 16 individuals cooperating with LSS.

This means that the pilot sample constituted of (assuming minimums):

- LSS individuals: 37.5%
- LSS leaders: 50%
- Individuals cooperating: 94%

for the group planned for the main research.

4. Results

4.1 Research Sample Characteristics

The following is a summary of the data characterising the research sample. Given that respondents volunteered to participate, the distribution was

Table 1: Division by gender

Gender	Number	Share
Women	11	50%
Men	11	50%

Table 2: Division by generation, according to Sidor-Rządkowska, 2018

Generation	Number	Share
Generation T	2	9%
Generation BB	2	9%
Generation X	11	50%
Generation Y	7	32%

Table 3: Division according to the type of work performed

Type of work	Number	Share
Academic Staff	11	50%
Administrative Staff	11	50%

Table 4: Degree/title of academic staff

Degree/Title of Academic Staff	Number	Share
Professor	2	18%
Doctor with habilitation	2	18%
PhD	7	64%

Table 5: Education level of administrative staff

Level of Education	Number	Share
PhD	2	18%
Eng/Bachelors	2	18%
Masters	7	64%

Using a 5-point Likert scale in the study enabled the determination of the respondent's level of agreement with the presented statements. A low level occurs when the average value (the arithmetic mean calculated from all responses) is equal to or less than 2.99, moderate when the average falls in the range of 3–3.99, and high when the average is equal to 4 or greater than 4 (Sekaran & Bougie, 2016, as cited in Piwowar-Sulej, 2022).

Upon examining the average values for the five statement areas presented in Table 6, it is noted that only two statements registered averages below 2.99, signifying a low level of concordance among respondents. The remaining three statement areas exhibited average values that fell within the range of 3 to 3.99, reflecting a moderate degree of agreement. Table 7 shows the average response scores for each group relative to the overall mean. This delineation distinctly reveals a high level of agreement in the first area between LSS individuals and their coworkers. Conversely, the second and fourth areas showed low agreement between the LSS and C-LSS groups. The third area maintains a moderate level of statement agreement, whereas the fifth area shows high concordance among leaders and moderate agreement within the cohorts of the LSS and their co-workers.

Table 6: Statistical data for five survey areas, results for the entire research sample

Area	Average	Median	Standard Deviation
I. Statements regarding the awareness of tacit knowledge	3.9	4	1.04
II. Statements regarding personal motivation to share (or not) tacit knowledge	2.96	3	1.25
III. Statements regarding traditional vs. innovative approach	3.67	4	0.93
IV. Statements regarding organizational support for knowledge sharing	2.94	3	1.12
V. Statements regarding the management of generational diversity	3.6	4	1.08

Table 7: Statistical data – average – for five survey areas, results for each group

Area	Average LSS	Average L-LSS	Average C-LSS	Average
I. Statements regarding the awareness of tacit knowledge	4.16	3.35	4.0	3.9
II. Statements regarding personal motivation to share (or not) tacit knowledge	2.87	3.14	2.93	2.96
III. Statements regarding traditional vs. innovative approach	3.78	3.31	3.74	3.67
IV. Statements regarding organizational support for knowledge sharing	2.91	3.05	2.92	2.94
V. Statements regarding the management of generational diversity	3.50	4.04	3.50	3.6

To further explore the statements showing the most significant discrepancy, the following is an analysis of all five areas, detailing the responses from each group. In the first area, respondents agreed that the experience of LSS is valuable and unique. There is some disagreement between the L-LSS and other groups regarding the support offered by the LSS. However, the most significant discrepancy occurs in the statement regarding statement 9: "The knowledge of an LSS person is too specific to be transferred in a simple way, so the ability to observe and imitate his actions is important." People with LSS disagree with this opinion, while the other two groups agree.

Within the second statement area, consensus was evident across all groups for the nine statements. Notable divergence was observed between the L-LSS and the other two groups on the nine statements. A similar pattern of low agreement was noted between C-LSS and the other groups for two statements and across all groups for five statements.

In the third area, relating to the application of innovations and traditions in construction, respondents also agreed highly with seven statements. Some discrepancies appeared in tradition-related statements (three). However, the most significant disagreement concerns two statements. Both LSS and C-LSS agree that new trends in science are often overrated (L-LSS disagrees on this matter). Regarding the statement about "sticking to traditional approaches in construction because they have been tested by time", this area has the most significant disagreement. LSS individuals agree on this matter, L-LSSs disagree, and C-LSSs do not have clear opinions.

In the fourth area, all groups consistently agreed on three statements. Lower levels of agreement were found between the L-LSS and the others on two statements and between the C-LSS and the others on two statements. Finally, four statements demonstrated low agreement among all the groups.

In the fifth area (Fig. 5), there is general agreement on the three statements. In the case of the two statements, LSS and L-LSS agree, and C-LSSs do not have a common opinion. As for one statement, only the L-LSSs agree; the remaining groups do not have a clear opinion.

5. Discussion

5.1 Summary of Main Findings

This pilot survey yielded several important conclusions regarding the management of tacit knowledge among employees with long scientific seniority (LSS) at a construction institution. This study identified key areas in which tacit knowledge sharing is both robust and insufficient. In particular, the areas of personal motivation to share tacit knowledge and organisational support for knowledge sharing showed the lowest means and medians, indicating the need for further study. The results of the pilot survey suggest significant divergence in perceptions and motivations among LSS employees, their leaders, and co-workers. Notably, LSS employees appear to

undervalue the specificity and importance of their tacit knowledge, which may hinder effective knowledge transfer. This will be further examined in the main study.

5.2 Addressing Goals of the Pilot Study

The pilot study aimed to verify the research tools and data collection methods with specific goals:

- Assess understandability and appropriateness of questions: The pilot study successfully identified areas where the questions were unclear, or the scale of answers was inappropriate. This feedback led to adjustments in the survey design, improved clarity and ensured that the questions accurately captured the intended information.
- Test the research tool (MS Forms): The use of MS Forms was evaluated for its effectiveness in collecting and analysing data. While the tool was generally user-friendly, the pilot study revealed the need for a more sophisticated platform for the main survey, prompting a switch to a tool that allows saving progress and facilitates easier data analysis.
- Identify survey areas requiring changes: Preliminary analysis of the pilot data highlights specific areas requiring modification. For instance, an additional context was added to statements, the number of questions was increased to cover gaps identified during the pilot, and the rating scale was refined to better capture respondents' opinions.

By addressing these goals, the pilot study provided valuable insights that informed the refinement of the research methodology, ensuring that the main survey was more robust and capable of capturing comprehensive data on the management of tacit knowledge among LSS employees.

6. Conclusions

Here, represents the sum of the main conclusions.

- LSS employees do not realise that their knowledge and experience are unique and sufficiently specific to require appropriate diffusion methods.
- There is a need for greater support for organisations to share knowledge in material and organizational areas (including organizational culture).
- The role of a mentor should be formally embedded in the organisation, especially in the case of LSS people with high authority.
- Supporting interdepartmental and team initiatives with a diverse generational profile may result in greater efficiency in such teams' work and strengthen relationships and understanding between different groups of employees.

The pilot survey results shed light on LSS people's motivations for sharing tacit knowledge. In several cases, there were apparent differences between the perceptions of LSS individuals and the reception of these people by their leaders and colleagues. There are differences in the perception of the role and value of tacit knowledge among LSS, L-LSS, and C-LSS, especially in terms of effectiveness, motivation, and organizational support. All groups agreed on the need to balance tradition and innovation and the importance of mentoring and collaboration for scientific development. The development of organizational tools and strategies to support the diffusion of tacit knowledge is necessary. This indicates the need to better understand and implement modern communication tools and knowledge management methods to respond to different generational needs. Increasing awareness and appreciation of tacit knowledge at all organizational levels is necessary to maximise its potential for innovation and institutional development.

These results will be verified by an actual survey in which representatives of 16 scientific units from Poland and Europe will participate.

Integration of Conversational AI Capabilities in Knowledge Management Processes for Higher Education

Joanne Chi-hang Tsoi and Fred Strønen
Oslo Business School, Oslo Metropolitan University, Oslo, Norway

joanne.ch.tsoi@oslomet.no
fredst@oslomet.no

Abstract: This paper explores the application of knowledge management (KM) in higher education institutions (HEIs), focusing on the potential of artificial intelligence (AI) technologies, especially Conversational AI to transform knowledge processes. By examining conversational AI systems, this paper investigates how such technology can enhance knowledge creation, sharing, and application within educational contexts. The illustrative example of Georgia State University's "Pounce" chatbot show practical benefits of AI in administrative and educational support. The paper suggests that integrating AI into KM practices can address the evolving needs of HEIs, supporting their mission to provide high-quality education to society. The paper underscores the importance of adopting advanced technologies to augment institution's competitive advantage. Through a real-life example of Con-AI application in KM, this paper contributes to the understanding of how HEIs can leverage technology to enhance their core functions and sustain their competitive edge.

Keywords: Artificial Intelligence, Knowledge Management, Alavi's Typology, Conversational Agent, Chatbots

1. Introduction

Higher education institutions (HEIs) offer different knowledge to individuals through mental, physical, and ideological training so that they can contribute to society (Deem, Mok and Lucas, 2008). Phusavat et al. (2011) also believes these types of well-educated individuals can increase the overall performance of organizations, regions or even countries. There seems to be a linkage between "knowledge" and "competitive advantage" in organizations and a significant body of research also shows that knowledge management (KM) factors contribute (Cepeda-Carrión and Vera, 2007; Haas and Hansen, 2004; Hart and Rodgers, 2023). HEIs play a vital role in society (Blass and Hayward, 2014) by providing opportunities for advanced learning, carrying out research, and advancing the development of knowledge and skills. They have the mission of providing high-quality instruction, encouraging creativity, and preparing students for professions in a variety of fields (Blass and Hayward, 2014). To survive and be competitive is also crucial for any HEI. In terms of competitiveness there is a need to fight for better reputation and international and local rankings for the institutions (Edwards, 2007). Like other businesses, HEIs also face a multitude of changes and challenges, such as the disruption of innovation and new technology (Blass and Hayward, 2014) in terms of artificial intelligence (AI)

There has been a noticeable increase in scholarly papers about AI since 2019, with a growth rate that is higher than 50% when compared to 2018 as noted by Lee et al. (2023). This trend indicates a visible increase in scholarly attention to AI, resulting in a significant rise in similar publications by the year 2023. Despite the substantial volume of research on AI-related topics, Duan, Edwards, and Dwivedi (2019) identified a significant gap in existing literature. They noted a lack of a comprehensive theoretical framework aimed at systematically understanding the utilization of AI-based tools and their impact on organizations, especially for HEIs.

There are only a few Conversational artificial intelligence (Con-AI) review studies in the context of HEIs. Dempere et al. (2023) did a literature review to explore the usages and effects of ChatGPT within HEIs and concluded that there are notable benefits in research support, automated grading, and enhanced human-computer interaction. They also highlight the potential advantages of the usage of ChatGPT, such as streamlined enrollment, improved student services, teaching enhancements, research aid, and increased student retention. However, this study focused more on the predictive and generative nature instead of the benefits of being conversational and interactive of ChatGPT. Pereira et al. (2023) did a scoping review of chatbots in HEIs to investigate the purpose of chatbots usage, the feasibility of chatbots and to figure out the quality of different chatbots within HEIs. In the context of HEIs, there seems to be very limited research on Con-AI, competitive advantage and KM. Thus, this paper will try to build up the relationship between the three mentioned components based on the study of Alavi and Leidner (2001) about how technology and system can enhance KM processes (including knowledge creation, knowledge sharing, and knowledge application).

2. Literature Review

2.1 The Knowledge-Based View and Knowledge Management Processes

The "knowledge-based view" (KBV) emphasizes the value of knowledge as a strategic asset for organizations. It proposes that knowledge, in its various forms, such as explicit and tacit knowledge, plays an important role in creating competitive advantage and driving organizational performance (Grant, 1996). Some other studies of KBV also considers a firm as a system that creates, integrates, and disseminates knowledge through the activities of its workforce, generating value for the firm (Kianto, Sáenz and Aramburu, 2017; Felin and Hesterly, 2007). In essence, the KBV emphasizes the importance of effectively managing and utilizing knowledge to achieve long-term success in today's dynamic environment. In the past, there were different studies about how KM should be considered as processes (Davenport, Järvenpää and Beers, 1996; Teece, 1998; Alavi and Leidner, 2001). While all these studies had the perspective of confirming KM as processes, Alavi and Leidner (2001) concluded that there are four major KM processes which can be enhanced by technology and systems. The study defines KM as a systematic and organizationally specified process for acquiring, organizing, and communicating both tacit and explicit knowledge. It also suggested that technology can be used to manage organizational knowledge by supporting the creation, sharing, and application of knowledge in organizations.

2.1.1 Knowledge Creation

Knowledge creation is often the reconfiguration and recombination of pre-existing background knowledge, but also includes building up concepts and creating solutions from scratch. As a result, organizations can adjust to changing circumstances and environments (Bhatt, 2001). Furthermore, knowledge acquisition from outside sources is also a way in creating one's own knowledge (Alavi and Leidner, 2001). Consequently, obtaining knowledge through information sourcing or search may be a form of knowledge creation (Alavi and Leidner, 2001; Jarrahi et al., 2023). Besides, Nonaka (1994) identifies four modes of knowledge creation: socialization, externalization, internalization, and combination. Socialization is the process of converting tacit knowledge into new tacit knowledge via social interactions and shared experiences among organizational members, such as engaging in discussion and team projects. Combination is the process of creating new explicit knowledge by merging, categorizing, reclassifying, and synthesizing current explicit knowledge, such as through literature surveys. Externalization is the transformation of tacit knowledge into new explicit knowledge, such as articulating best practices or lessons learned. Internalization is the process of developing new tacit knowledge from explicit knowledge, such as through reading or discussion. Knowledge creation within academic settings is crucial for preserving valuable insights, documenting local knowledge, and fostering academic excellence.

2.1.2 Knowledge Sharing

Knowledge sharing is the intentional exchange, dissemination, and transfer of knowledge among individuals, groups, or organizations to promote learning, innovation, and problem solving. It is the process of identifying valuable knowledge assets, capturing them in usable formats, and disseminating them to others via various communication channels. Knowledge sharing promotes collaboration, improves organizational performance, and helps with collective learning and decision-making (Bock et al., 2005; Alavi and Leidner, 2001; Van Den Hooff et al., 2003). Within HEIs, knowledge sharing is essential for promoting teamwork, creativity, and academic success.

2.1.3 Knowledge Application

After sharing of knowledge, the next step will be to put knowledge into practice, and this is termed as “knowledge application”. It can involve the repackaging of best practices or other available knowledge resources into useful and suitable solutions within an organization (Bhatt, 2001). To apply knowledge, it also requires careful and skillful selection, analysis, and assimilation of the relevant external knowledge in order to satisfy the needs of the organization at a suitable timing (Jarrahi et al., 2023). In the context of HEIs, knowledge application can refer to academic teaching, research and expertise in practical ways that benefit society.

2.2 Competitive Advantages and Knowledge Management Processes of HEIs

As per Hart and Rodgers (2023), the concepts of “competitiveness” and “competitive advantages” are distinct. In their study, it stated that “competitiveness” of a HEIs is “the ability to engage in educational exports, withstand competition, attract resources, provide employment, and foster a knowledge-based culture” and “the

institution's capacity to combine resources and competencies in unique ways" (Hart and Rodgers, 2023). It focused more on the external environment. While for "competitive advantages" of a HEI, it is the major abilities of an institution to have better performance over industry's competitors by using its valuable, scarce, inimitable and irreplaceable resources (Lo and Tian, 2019).

Previous research found that KM processes and systems, that support the working of employees can enable the operation of institution to function efficiently and effectively, thus increasing the competitive advantage of HEIs Alavi and Leidner (2001). Istikhoroh and Ardhiani (2022) did a correlational study to examine the relationship between KM processes and competitive advantage in the context of HEIs by using a quantitative approach, and they found the competitive advantage of an institution can be better through KM processes. Mohammed, Abdul and Gururajan (2018) investigates knowledge management processes in Australian higher education, highlighting its role in competitive advantage, university rankings, and profits. Using brainstorming with six ICT managers at a Queensland Regional University, the study figured out that the KM processes of knowledge creation, knowledge sharing, and knowledge transfer are some of the key themes.

2.3 AI and Technologies

According to Alavi and Leidner (2001), KM processes can be augmented by technology which enhance communication, facilitate collaboration, improve access to information, and enable routine tasks automation. Thus, technology is a critical enabler for successful KM in an organization, leading to improved decision-making and competitive advantage. In the past decades, AI has been one of the groundbreaking technologies. AI is still evolving speedily and thus its definition is also changing with new extensions. For instance, Russell and Norvig (1995) believe AI can be defined as machines or systems that mimic human's cognitive function to learn, to solve problems and to interpreting and generating languages. In addition, the Institute of Electrical and Electronics Engineers (IEEE) Corporate Advisory Group refers to AI as "the combination of cognitive automation, machine learning (ML), reasoning, hypothesis generation and analysis, natural language processing (NLP) and intentional algorithm mutation producing insights and analytics at or above human capability". In the past decade, due to the advancement in technologies (such as deep learning and NLP), augmentation of computer power, as well as the explosion of available data for algorithms training, AI has accelerated its momentum with new application possibilities (Bornet, Barkin and Wirtz, 2021). For instance, some online interactive platforms or tools might extend the definition of AI which can interpret and give replies to users' queries or prompts and create an interactive communication experience that mimics humans in the form of text, voice, or both in a way (Dwivedi et al., 2023).

2.4 The Relationship Between AI and KM Processes

In the past two decades, with the advancement of technology and the launches of different systems, the interaction between technology and KM processes is essential (Alavi and Leidner, 2001). By heavily facilitating the generation, sharing/transfer, and using of knowledge inside organizations, technology is bettering competitive advantage of an organization through these KM processes (Singh and Singh, 2019). Almeshref and Khwanda's (2022) study emphasizes the role of information systems in enabling KM processes, indicating that technology can have a significant impact on knowledge sharing, acquisition, and application. In terms of KM in HEIs, universities use a multifaceted approach that includes structured processes as well as digital tools (Al-Kurdi, El-Haddadeh and Eldabi, 2018). It includes creating and maintaining document databases, using platforms for collaborations, and integrating learning management systems to efficiently organize and disseminate knowledge resources. Furthermore, since promoting a culture of knowledge sharing among faculty and students, facilitating work collaboration, and encouraging the creation and dissemination of scholarly work are often regarded as important for HEIs (Brewer and Brewer, 2010), thus any technologies or systems which can help with these aspects will be very useful. Those KM-relevant technologies, which can encourage experience sharing to help transform tacit knowledge into explicit knowledge, contribute to achieving KM success (Nonaka and Von Krogh, 2009).

This synergy between AI and KM can lead to more efficient knowledge sharing, learning, and innovation within the organization (Sundaresan and Zhang, 2021; Jarrahi et al., 2022). Therefore, AI serves as a catalyst that contributes to the development of competitive advantage through the enhancement of KM processes within organizations. Hence, the interplay between AI and KM processes is symbiotic, with each element reinforcing and complementing the others to propel competitive advantage of an organization in the face of rapid technological advancements and market changes.

2.5 Conversational AI in HEIs

Amongst different kinds of AI, Con-AI has aroused the interest of academic research in recent years, due to the advancement in NLP since 2010, with the launch of Siri by Apple which is the first and most widely accepted virtual assistant (Campbell, 2020). Con-AI is a type of communicative AI, and it can perform designated tasks as a communicator which mimics humans (Guzman and Lewis, 2020). Through computational algorithms of NLP, Con-AI learns to automatize communicative functions and thus can "talk" to humans in natural language (Ng, 2022). Some well-known examples are Google Assistant, Apple Siri and Amazon Alexa which can respond to human requests by text or by voice. People can communicate with these unsupervised human-like "virtual assistants" and this is trending because of the navigation of Con-AI in daily life (Guzman, 2019). Some of the Con-AI will even make use of "large language models'' (LLM), such as ChatGPT, and it can help its users in a broad range of tasks thus offering convenience and personalization to the users (Gieselmann and Sassenberg, 2022). While other Con-AI systems can also discuss different topics and reply to a large number of questions from users (Smutny and Schrei-berova, 2020). Moreover, study from Sahab, Haqbeen and Ito (2024) also found that Con-AI, usually incorporates with ML and deep learning, can take the role as a facilitator during online communication and discussions. The study concluded that with the help of Con-AI, participants' engagement and collaborative problem-solving can be enhanced.

Con-AI tools are becoming more common in HEIs, benefiting teaching and administration. With these online chatbots, students can have 24/7 access to information and knowledge and can get immediate feedback from a human-like mean. By storing all the previous conversations of students, chatbots can give personalized assistance. KM processes can then be facilitated by using these Con-AI tools while students are interacting with them (Al-Sharafi et al. (2022). In the literature review of Chen, Chen and Lin (2020), they stated that the web-based and online intelligent education systems working together with humanoid robots and online chatbots can improve the efficiency of the educator's works, e.g. reviewing and assessing assignments from students. This can free up their time for improving teaching quality. In addition, curriculum can also be personalized according to students' progress due to ML capabilities of the AI-supported interactive educational system, which would in turn improving drop-out rate by improving overall learning experience of the students (Chen, Chen and Lin, 2020). Hannan and Liu (2021) also gave examples of how AI applications help HEIs to improve their competitive advantage. For instance, the paper figured out that online chatbots, such as IBM's Jill Watson, can be used as teaching assistants to avoid disconnection between students and their study. Besides, Microsoft's Azure can support students in their native languages when they interact with this on-campus chatbot which consists of ML algorithms to assist in speech transcription and text translation. The AI-chatbot "Pounce" for the Georgia State University also help to increase the enrollment rates of students into courses (Hannan and Liu, 2021).

As mentioned previously, technology like Con-AI which can help with KM processes will be valuable to the HEIs and their competitive advantage., Most of the literature about Con-AI are from the commercial sector with limited of them within the context of HEIs (Al-Sharafi et al., 2022). For research relevant to KM processes and Con-AI, Al-Sharafi et al. (2022) makes use of a hybrid SEM-artificial neural network (SEM-ANN) approach and develops a theoretical model based on extracting constructs from the expectation confirmation model, combined with the KM processes (knowledge sharing, knowledge acquisition, and knowledge application) to understand the sustainable use of chatbots (as a kind of Con-AI) for educational purposes. This study has found that if a Con-AI system can facilitate the processes of knowledge creation, knowledge sharing and knowledge application, it will benefit students to learn and acquire new knowledge. In addition, Sumbal and Amber (2024) did qualitative research by interviewing researchers and faculty members who have teaching and researching responsibilities from a university in Hong Kong, and they figured out that Chatbot powered by LLM and with a large knowledge base can facilitate Nonaka's 4 modes of knowledge creation.

3. Illustrative Example: "Pounce" AI Chatbot at Georgia State University

Background: At the beginning, "Pounce" AI chatbot acted as an institutional tool to help new students to get familiar with knowledge and information about registration, finances etc., to get around the new campus life. Later, the chatbot started to integrate into course content in 2021. Since then, besides daily interactions with students, Pounce will also push direct reminder about assignments and exams to students, giving them a chance to text them questions through "PolsPounce" to their instructors. These reminders are personalized according to the study progress of students and Pounce will also give students short quizzes before exam. Students can also have interactive practices with Pounce and can get immediate feedback. Pounce will also direct students to

internal discussion forums or study groups where they can collaborate and share their understanding about course content (Mdavis, 2022).

Knowledge Creation: When students ask Pounce questions, it is just like sharing their difficulties and challenges with the chatbot. This can create a vast amount of data and the Con-AI system can later analyze them and sort out common issues amongst students. For instance, tactic knowledge, such as areas which students may need more support or gaps in curriculum, can be transformed to read-to-use explicit knowledge after analysis of student's conversations with the chatbot. In addition, the ability for Pounce to collect real time feedback from students after each class can better curriculum development, thus more targeted and effective learning materials can be formed earlier. These will further encourage ongoing learning and participation in inventions within HEIs, and ultimately contribute to sustained organizational competitive advantage (Yang, 2007).

Knowledge Sharing: Pounce can provide quick and real-time answers to students' questions, e.g. information about course content, assignments deadlines and university services. This makes it possible for the sharing of knowledge efficiently 24/7 from Pounce's knowledge base to students. Pounce can facilitate peer-to-peer knowledge sharing by diverting students to different online forums or study groups for collaboration and sharing their understanding about course content. This will can foster a learners' community that actively share knowledge thus enhancing the overall learning environment

Knowledge Application: Based on individual profiles and past conversations with students, Pounce can provide personalized questions, prompts, advice and reminders to help students in applying knowledge they have gained in a practical way. Besides, with a knowledge base being built up from different systems and resources, Pounce can also suggest study materials and tutoring services in a timely and accurate manner. Students can then have better informed decisions about their academic activities which also benefits the effectiveness of application of knowledge and skills.

Results of using Pounce: Pounce AI chatbot at Georgia State University is a powerful tool that enhances KM processes by providing efficient, personalized, and continuous support to students. Its ability to facilitate knowledge creation, sharing, and application. By engaging students proactively, there was an obvious jump in students' performance in the institution. Besides, for the benefit of the educators, Pounce also freed up their time and resources in assisting their students as the Con-AI learned about from students' questions and experiences and augmented their knowledge base for frequently asked questions. Pounce also facilitated communication between students and educators by directing students who needed help from a human on a timely basis. This could help to detect in-risk students and prevent drop-out from course (Mdavis, 2022).

4. Concluding Discussion

This paper aimed at figuring out how Con-AI tools can improve the major KM processes as proposed by Alavi and Leidner (2001) in HEIs and thus augmenting the competitive advantage. The KM processes of knowledge creation, knowledge sharing, and knowledge application as facilitated by AI-supported chatbots can increase efficiency for teaching and administrative tasks within HEIs. This will in turn reduce certain costs and improve the work quality of students, faculty members and staff in the institution. By using an illustrative example, KM processes of a particular HEI has been improved after deploying Pounce AI chatbot and thus the competitive advantage of the institution. As a result, a theoretical framework has been developed as per below:

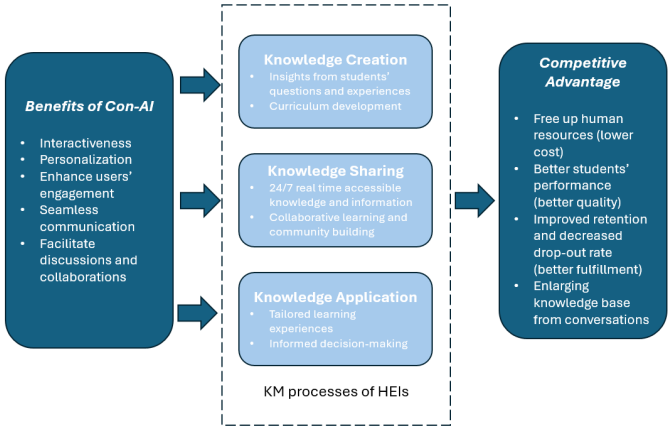

Figure 1: Con-AI enhanced KM processes and thus competitive advantage and competitiveness of HEIs

The KBV highlights knowledge, which is a strategic asset, is critical for organizational competitive advantage. By creating, integrating and disseminating knowledge, value can be generated by firms or organizations as a system. Besides, knowledge creation, sharing and application are effective KM processes which can be supported and enhanced by technology like AI. On the one hand, knowledge creation reconfigures existing knowledge, while knowledge sharing is more for collaboration and information dissemination. On the other hand, knowledge application means using knowledge to create practical solutions. All these 3 KM processes drive academic success and societal benefits.

Competitive advantage is about how an institution can have better performance over competitors by using its internal resources which are valuable, scare, inimitable and irreplaceable. In the context of HEIs, KM processes as supported by chatbots, such as Pounce, can be one of those unique resources. For Con-AI chatbots which are having advantages of allowing immediate access of knowledge for the users, as well as being communicative, conversational, and interactive, they can support students and enhance the operations and knowledge / information flow within different internal stakeholders of the institution. Communication and collaboration within the institution can also be better thus ultimately leading to better decision-making and augmented efficiency. For instance, studies confirmed Con-AI can enlarge the knowledge base and benefit the knowledge creation process. Both Nonaka and Krogh (2009) and Chen, Le and Florence (2021) stated that the ability for Con-AI to learn from past interactions from users and be equipped with relevant knowledge to answer different questions automatically, will enhance knowledge's connection and acquisition. Pounce functions similarly by acquiring tactic knowledge from different students when they interact with the chatbot. It can get insights to enrich the knowledge base for future enquiries and better curriculum development by transforming tactic to explicit knowledge. For knowledge sharing, Pounce can provide immediate access to information, answer enquiries from students and thus facilitating seamless communication across internal stakeholders of HEIs. Pounce can also help supporting individuals to apply and utilize knowledge possessed by others without learning or acquiring such knowledge, due to the knowledge base of Con-AI system is usually improved continuously with data from users' conversations. In addition, for knowledge application, Pounce can base on the students' profile and the past conversations and interactions to tailor-made quizzes to students. This can help students to apply their knowledge by facilitating brainstorming with also real-time feedback. Overall, AI chatbot Pounce have demonstrated tangible improvements in educational engagement and administrative efficiency for Georgia State University, providing the augmentation of the institution's competitive advantage.

In conclusion, HEI can largely improve their operational efficiency, educational outcomes and overall institutional performance with the support of Con-AI to optimize KM processes. The role of Con-AI and other AI technologies will continue to evolve and expand in KM processes which will probably transform the landscape of higher education.

5. Contribution and Future Research Opportunities

As AI tools are increasingly adopted in every industry in the past few decades, this paper contributes by bringing light to an under researched aspect of KM in the context of HEIs. It enriches the existing knowledge on the role Con-AI can play in HEIs in different means. First, this paper focuses on the communicative, interactive and conversational aspects of AI chatbot and discusses its role to strengthen the three major KM processes in HEIs. As an evolving technology, research on Con-AI by using the lenses of KM is not abundant, especially within the context of HEIs (Jarrahi et al., 2023). Second, by using an illustrative real-life example of Pounce at the Georgia State University, this paper explores the potential of how Con-AI can enhance the competitive advantage of HEIs through making sense of KM processes. It can help researchers to start diving deeper into the phenomenon of how Con-AI can help institutions in the future. This paper also gives valuable insight into how management of HEIs can make use of AI chatbot to better KM processes especially in teaching and administration thus augmenting institutional performance over industry's competitors. The benefits associated with Con-AI should encourage adoption by more HEIs and thus the need for resources allocation. This paper calls for future research to study the relationships between Con-AI, KM processes and competitive advantage of an institution within HEIs by using empirical research to have a more thoughtful understanding about the current happenings and future challenges. A suggestion for future research could be to conduct a multiple case study with data from stakeholders in different levels within different HEIs, such as private and public universities, HEIs in different regions, to understanding how Con-AI facilitate KM processes and the respective impact on the institution's performance. This can provide evidence-based practical insights which validate previous theories and contribute to a comprehensive understanding of such complex phenomena as Con-AI.

Exploring Knowledge Management Dynamics in International Film Productions: Insights from the Maltese Film Industry

Tomasz Zontek
Warsaw University of Life Sciences, Faculty of Economics, Department of Management, Warsaw, Poland

tomasz.zontek@sggw.edu.pl

Abstract: This paper discusses an empirical analysis of the knowledge management in international film productions. It presents the findings of exploratory data research taking place during the research trip to Malta. The research took place between 2023 and 2024 during two film productions undertaken in this country. The main study aim is to indicate which forms of tacit and explicit knowledge management are used in international film productions. To achieve the aim of this study, several research questions were formulated: What is the nature of knowledge sharing in the Maltese Film Industry? Is it tacit or explicit knowledge that is shared? What is the difference between collaboration and knowledge sharing? What factors influence effective knowledge management within an international film crew, particularly in the context of the Maltese film industry? The study established a research hypothesis: The management skills of the film producer and the heads of departments, as well as efficient management of explicit and tacit knowledge, are essential factors in the success of film production. The multicultural differences of the film crew members are noticeable, but they are not considered as a disadvantage or a barrier. The methodology of this paper is based on qualitative research. A survey was used as the research method and the interview questionnaire was chosen as the research instrument. Interviews were carried out between 2023 and 2024. The study identified best practices for knowledge management during international film productions. Preliminary research results have identified factors influencing the effectiveness of knowledge management, as well as barriers related to the initiatives undertaken. Finally, the results obtained highlight the importance of compromise, mentoring and trust. Film production processes require effective knowledge management and efficient, talented film production managers. These individuals should be familiar with the principles of knowledge management and also be open to the cultural diversity of their employees.

Keywords: Knowledge Sharing, Film Production, Collaboration, Trust

1. Introduction

In contemporary academic discourse, knowledge management has emerged as a prominent area of scholarly inquiry. Scholars have noted a heightened appreciation for knowledge in present times, as evidenced by the proliferation of literature dedicated to this subject. This corpus encompasses theoretical treatises elucidating the phenomenon's intricacies, alongside empirical investigations shedding light on its practical manifestations. Hence, a consensus may be reached that, at a broad level, knowledge management has been sufficiently comprehended and explicated within academic circles (Miroński, 2010).

The intricacies of data, information, and knowledge are subjects of perpetual exploration and debate, especially within the contexts of knowledge management and information theory (Lei & Yucong, 2021). Despite their ubiquity in everyday language, the precise distinctions among these terms remain elusive, often used interchangeably rather than with precise delineation. Within scholarly discourse, various conceptual frameworks, such as the “pyramid of knowledge” or “knowledge hierarchy”, and the “pyramid of information” or “information hierarchy”, are employed to structure these cognitive entities, with the DIKW (Data, Information, Knowledge, Wisdom) framework standing as a notable exemplar. The article describes differences between those elements. Furthermore it explores the differences between knowledge sharing and collaboration. The article discusses knowledge management in the multicultural film context. It gives a brief description of Maltese film Industry and focuses on what type of knowledge is shared amongst the film crews participating in multicultural film projects. It provides the evidence that both tacit and explicit knowledge is shared during the film production. The conducted interviews allow to analyse the shared knowledge based on the industry professionals’ experience. The methodology based on the literature review provides tools to investigate how to share knowledge amongst film projects multicultural film projects’ participants. The article elaborates on the factors influencing effective knowledge management within an international film crew.

2. Difference Between Data, Information and Knowledge

The terms 'data', 'information' and 'knowledge' are among those that are difficult to define because of their original nature. These terms are often used interchangeably in everyday discourse, reflecting prevailing trends rather than precise distinctions. Their elucidation finds particular significance within the realms of knowledge

management and information theory (Lei & Yucong, 2021; Wolski & Gomolińska, 2020). Consequently, within scholarly discourse, the hierarchical structuring of cognitive entities is alternatively referred to as either the "pyramid of knowledge" or "knowledge hierarchy" or as the "pyramid of information" or "information hierarchy", contingent upon disciplinary orientation. Furthermore, the acronym DIKW, derived from the sequential arrangement of data, information, knowledge, and wisdom, serves as a notable framework within these domains for conceptual organization and analysis. As the final element within the DIKW framework, wisdom pertains predominantly to the philosophical domain, thus its detailed discussion falls beyond the scope of this analysis (Grabowski & Zając, 2009).

A prevailing perspective, echoed with minor deviations, posits that data is raw numerical values and facts, information denotes processed data, and knowledge emerges as authenticated information (Dreske, 1981; Machlup, 1983; Vance, 1997). However, the proposition of a hierarchical progression from data to information to knowledge, with each tier distinguished by various dimensions such as context, utility, or interpretability, seldom withstands rigorous evaluation. If we assume that information is a stream of data to which we assign a certain meaning (relevant to the goals we are achieving), then knowledge is an information resource. However, it is a resource organized in a special way - it corresponds to the intentions of its creators and users. In the case of companies competing for rare resources (e.g., orders, grants, popularity support), these intentions can be reduced to gaining a sustainable advantage on competitive market (Jemielniak & Koźmiński, 2021).

3. Intercultural Knowledge Management

Knowledge management, as a young field of management, encompasses the latest methods and techniques to ensure the most effective use of knowledge resources (Kłak, 2020). The basic dimensions of knowledge management are: acquisition, storage, transfer, development, use and creation (Desmarais et al. 2009, p. 219). In this paper the primary focus is on multi-cultural knowledge management. The primary objective of cross-cultural knowledge management is to facilitate the management of knowledge in other areas (e.g. functional areas: marketing, human resources management, production) in an international setting, and ultimately the management of the entire company (Grosskopf & Barmeyer, 2021; Schewe et al., 2022). Properly applied, intercultural knowledge should allow other knowledge to be used more fully in situations of contact with other cultures. For this to happen, it is necessary to go beyond recognising, understanding and accepting cultural differences. People and organisations should strive to treat cultural differences as sources of inspiration, new knowledge and experience. Previous studies suggest that managers should consider cultural differences in management (Luthans & Doh, 2012) and link intercultural management issues to business needs (Chmielnicki & Sulkowski, 2017, p. 51).

4. Maltese Film Industry

The assertion that "Malta has built a reputation as the mini-Hollywood of the Mediterranean" as articulated by journalist Daniel Rosenthal (Rosenthal, 2002) reflects the pre-existing prominence that the archipelago had attained within the realm of the film industry. It was during the early twentieth century that Malta commenced its role as a host to foreign productions, owing to the proficiency of its craftsmen, adept set builders, and model makers. By the late 1960s, this relatively small and newly independent island emerged as a cost-effective alternative to more established production hubs such as Italy, Spain, and France (Guest, 1968), capitalizing on its remarkable landscape versatility capable of simulating diverse geographical terrains. Nevertheless, for a duration spanning approximately four decades, international production activities remained sporadic, primarily due to the absence of adequate infrastructure and service networks required to attract foreign filmmakers (Xuereb, 2023). It was not until the early 2000s that the archipelago solidified its status as a competitive entity within the global film production domain (Graziano, 2015).

5. Methodology

Based on the literature review three research questions were stated: 1) What is the nature of knowledge sharing in the Maltese Film Industry? Is it tacit or explicit knowledge that is shared? 2) What is the difference between collaboration and knowledge sharing? 3) What factors influence effective knowledge management within an international film crew, particularly in the context of the Maltese film industry?

The methodology of this paper is based on qualitative research. A survey was used as the research method and the interview questionnaire was chosen as the research instrument (table 1). In this study, the perception of the respondents serves as the primary unit of analysis. Moreover, the respondents are not directly prompted to

discuss knowledge management and knowledge sharing; instead, they are guided to elaborate on the mechanisms of collaboration and skill-sharing within the Maltese film industry.

The study established a research hypothesis: The management skills of the film producer and the heads of departments, as well as efficient management of explicit and tacit knowledge, are essential factors in the success of film production. The multicultural differences of the film crew members are noticeable, but they are not considered as a disadvantage or a barrier.

Table 1: Interview protocol

No.	Survey question
1	What qualities should a professional director/production manager/production coordinator have?
2	Did you have a mentor, who would guide you through the intricacies of your film career?
3	What is important during the a) pre-production b) production c) post-production d) distribution (only for the film director) stage of the film?
4	How do you manage an intercultural film crew?
5	What are the differences between the international and national film production?
6	What was the most difficult film that you had to manage?

Source: Research methodology, own research

The present report scrutinizes the data to discern evidence of knowledge sharing and delineate the facilitating and impeding factors as elucidated through the depiction of knowledge sharing occurrences provided by the participants during interviews. Two research interviews were conducted with film industry professionals from November 2023 to February 2024. The list of these interviews is provided in table 2. The selection process for the initial two participants was predicated on recommendations from Maltese film producers. Subsequently, the results of the interviews were enriched by adding and analysing data compiled by Alony, I., Whymark, G., & Jones, M. L. in their work titled "Sharing tacit knowledge: A case study in the Australian film industry" (Alony et al., 2007). The interviews collected by mentioned authors are listed in table 3. It is noteworthy that the interview protocol didn't include specific questions about knowledge management. Due to the fact that the film professionals were confused when asked the question about knowledge management it was decided that other questions leading to this topic will be used.

Table 2: Completed interviews used in this study

Interviewee	Profession	Type	Date of record	Place of record	Pseudonym/ Citation
1	Director	Interview	19.01.2023	Malta	(Alex-Director, 2023)
2	Production Manager	Interview	26.01.2024	Malta	(Karl-Production-Manager, 2024)
3	First Assistant Director	Interview	29.04.2024	Malta (online)	(Ioan-First-Assistant-Director, 2024)
4	Camera Operator	Interview	06.05.2024	Malta (online)	(Michael-Camera-Operator, 2024)

Table 3: Interviews used in previous study completed by other authors

Interviewee	Profession	Type	Date of record	Place of record	Pseudonym/ Citation
1	Producer	Interview	14.10.2004	Australia	(Alice-Producer,2004)
2	Production Manager	Interview	04.03.2004	Australia	(Lyn-Production-Manager, 2005)

Source: Alony, I., Whymark, G., & Jones, M. L. (2007) "Sharing tacit knowledge: A case study in the Australian film industry", *Informing Science Journal*, vol. 10, pp 41-59.

Individuals within specific professions are typically well-positioned to offer comprehensive insights into film management, encompassing associated challenges and procedures, particularly concerning knowledge sharing and collaborative endeavours. The interviews conducted were structured around open-ended questions, facilitating extensive probing and contextualization. A selection of these questions is presented in Table 2, although variations were introduced across interviews based on the trajectory of discussion, information provided, and the interviewee's role. Furthermore, it was envisaged that the questionnaire would evolve over time to align with emerging data categories (Alony et al., 2007).

6. Results

The research results allowed to describe the nature of intercultural knowledge management in film productions based in Malta. It also allowed to describe the explicit and tacit knowledge shared amongst the film crews. Furthermore it shows the difference between knowledge sharing and collaboration. Lastly, it points out the three factors that influence effective knowledge management within an international film crew, particularly in the context of the Maltese film industry.

6.1 Intercultural Knowledge Management

The film director when asked whether he changes the style of management when talking to people from different cultures, replied: “I don't know if I would be aware of it if I am. I think just what typically happens is, you know, a film, you're so pressed for, for time and resources. A lot of these things tend to fall away and just become more instinctive. And it's probably a little bit more about the individual” (Alex-Director, 2023).

The film director, in response to a question regarding potential alterations in management style when interacting with individuals from diverse cultural backgrounds, expressed uncertainty. He suggested that the demands of filmmaking, characterized by time and resource constraints, often lead to such considerations becoming instinctual rather than deliberate. Additionally, he implied that individual differences play a significant role in shaping his approach.

The production manager asked the same question replied: “I don't think the problems come with cultures because we in the industry are totally used to be around people from all over the world” (Karl-Production-Manager, 2024). Karl indicates positive outcomes of intercultural collaboration: “You find that most people from most countries are great people with extensive experience that you can learn from” (Karl-Production-Manager, 2024). Karl highlights the favorable results stemming from intercultural collaboration by emphasizing the inherent value of individuals from various backgrounds. He expresses that individuals from diverse countries typically possess considerable expertise, presenting opportunities for mutual learning and growth.

Alex as a film director tells his experience with directing cast in an intercultural film project: “Because I'm not fluent in Maltese, I had an enormous benefit that I never really had opinions about how my actors are saying their lines exactly. But what I'm more attentive to is what is being communicated non verbally in their performance. What are their eyes doing? What's their body language doing? How are they breathing? Those are the things I'm looking at when I'm watching my monitor. And I think that those things say a lot more about a character's emotional state in a scene than just how they read a line” (Alex-Director, 2023).

The multicultural dimension significantly influences intercultural communication dynamics. As the author underscores, non-verbal communication emerges as a pivotal component within this context. Non-verbal cues, encompassing gestures, facial expressions, body language, and vocal tone, often convey nuances of meaning that transcend linguistic barriers. In intercultural interactions, where verbal language may pose challenges due to differences in language proficiency or cultural nuances, reliance on non-verbal communication becomes particularly important. These non-verbal signals serve as a universal language that bridges cultural divides, facilitating understanding among individuals from diverse cultural backgrounds. Therefore, recognizing and interpreting non-verbal cues accurately is essential for effective intercultural communication, enabling individuals to navigate cultural differences and establish meaningful connections across multicultural contexts.

6.2 Explicit Knowledge

“I like to think that a lot of times the script is going to direct the film. That applies a lot to the actors, but it even applies to the department heads. If you've written something, that has a kind of a gravity, if it has a momentum, if it has a clarity, those are marks of a good writing. But I think it also, It generally kind of leads people along the same thought process” (Alex-Director, 2023).

The director refers to the film script as the most important document during film production. It contains vital information for all film departments. Throughout the film the director can go back to the script and refer his and his colleagues' ideas to the script. In this sense script can be considered as the main database of the film production. Script changes affect most of the film departments, and has to be debated with the heads of departments. Major script changes have impact on film budget, scheduling, casting, location choice etc.

6.3 Tacit Knowledge

The subsequent quotation distinctly delineates the characteristics of tacit knowledge exchange and its magnitude within the MFI. The collaborative dynamics on a film set entail a substantial dependency on the sharing of knowledge among individuals.

"Now with that said there are things you need to be dead clear on. And that's just for every director to decide about what those things are. It's just impossible to say in the abstract what they are on a given film or in a particular scene. Like I said, what I'm hoping is that the script is directing people. I'm hoping it's really dead clear in the script. And sometimes you find that it's not. And you have to take a moment and to say, I know you had a different idea about this, but here's what I need. And to express yourself very clearly, and when you're in production, which is different than when you're in pre-production. On pre-production, you can have a five or ten minute conversation about it" (Alex-Director, 2023).

The aforementioned quotation can be interpreted as either information sharing or knowledge sharing. Nonaka posits that while the message may initially convey factual data or information, its significance extends beyond mere content. When interpreted or internalized within a broader context, this information transcends into knowledge (Nonaka, 1994).

From the quote above it can be concluded that tacit knowledge complements explicit knowledge. People on the film set rely on the script as the most important database of the filmmaking. Unfortunately this database misses some of the details or contains some mistakes, which are critical to the film production process. Exchanging tacit knowledge allows to eliminate those mistakes and make correct decisions.

Another quote from the Alony et al. (2007) studies provides an understanding about the nature of communication on the film set: "a perfect example is probably ah, a costume designer going to a designer, and saying "what colour are you going to paint that wall in the set, because I really want her to wear this dress…" and he'll say "Oh I'm going to paint it orange" and she'll say "this dress is perfect for the sequence, absolute perfect for the sequence, and it won't look good against that orange wall." And that is the sort of collaboration you have to have, I mean these are all incredibly talented, highly volatile, very creative people and um, they've all got a vision but as long as they've all got the same vision then it works" (Alice-Producer, 2004).

The constant changes in film production process and the dynamic film environment require crew members to be open-minded, flexible and communicative. Film is a gathering of multitalented artists, who need to collaborate on many different levels in order to finish the product which is the distributed film. The quote above shows that knowledge sharing and collaboration are the key factors of any film production process.

6.4 Knowledge Sharing

"My friends told me about an amazing fund out of Germany through the public television broadcasters at "xxx"[1]. They have a program, whose name in German, I can't recall now how it's pronounced, but essentially it's a television program that gets some kind of financing under the prerogative to essentially program films from the European community that demonstrate a unique aspect of a European culture" (Alex-Director, 2023).

The film director gives an example of knowledge sharing without collaboration. In this example the knowledge exchanged is information about a fund provided by a German television. During the information transfer the sender of the information is active and the receiver of the information remains passive. The receiver gets the information, and it is then at their discretion whether they choose to utilize it or not.

Another useful example of knowledge sharing is provided by the cinematographer Ioan. On one of the projects due to unforeseen circumstances he needed to change his role from the first assistant director to downloader

[1] The name of the broadcast company is hidden for research purposes

"My boss called me at night and says: you're gonna go download tomorrow. I said to him: I've never done this before. And he's like: you'll be fine. There's someone who's going to teach you everything over the phone" (Ioan-First-Assistant-Director, 2024). This example shows evidence of knowledge sharing in which the receiver is taught over the phone about his new responsibilities on the film set. Later he says: "I ended up showing up the set. I called Nicola, who's the downloader that just left that production and he told me everything, how to do this job. So I picked it up pretty quick. Yeah, I've been doing it since" (Ioan-First-Assistant-Director, 2024). Ioan after this experience became the professional downloader, it proves that a simple conversation in which knowledge sharing occurs can change the direction of someone's professional career.

6.5 Collaboration

"I had met a young producer, we were probably about the same age. When I was trying to sell my first film at co-production markets back in 2017. He just started out a company called "xxx"[2] out of Berlin. He just kind of tracked up, we had a great conversation back then in 2017. Obviously my first went on a big journey between 2017 and 2021 when it came out. But he remembered the project, he saw the film, he loved it, he kept in touch. His company had an amazing track record in those intervening years and they made great co-productions like the film "xxx"[3], which was a big hit at Cannes, a year or two ago. Our film fit with what they were looking for" (Alex-Director, 2023).

In this example it's clearly seen that sometimes the collaboration doesn't start from the beginning. At first the director and the film producer communicated on one of the film markets in 2017. They kept in touch between the four years and it resulted in collaboration. The newest film of the director was coproduced by the company of the mentioned producer, as the result of four years of exchanging information and knowledge.

"You get very close to people who you work with, you form very strong bonds, more than the average people who work in an office environment do because you spend so much time together" (Lyn – Production-Manager 2005). The close relationships built in-between the crew members and the time that they spend together is a great environment for collaboration. Often the strong bonds last after the project, which means that most probably the collaboration will also last longer.

6.6 Compromise

Regarding the information exchange, it's crucial to think about the two sides of collaboration and what is their aim in information sharing. The next example gives an overview on the reasons behind collaboration: "Then essentially the trade is that you're giving them the free to air broadcast rights in Germany for whatever one or two years, I forget what the term is. Essentially it was a pre-sale for public television in Germany, for a Maltese language film, which is amazing and very rare. The amount of money makes a huge difference for us. But in the bigger scope of filmmaking, that's probably a pretty small fund. So for them, I think it's, it's kind of a low risk proposition, but for us it's like game changing" (Alex-Director, 2023). In this example the director of the small-budget Maltese film gets part of the funding of his film from the German broadcaster while the other side of the collaboration gets an exclusive broadcast rights in Germany for two years. The provided example shows that both sides of collaboration need to benefit from it.

You don't need to take all of the notes, but it's a quite rigorous application process and it's competitive and in the particular year that we were applying was more competitive than at other times, so I would take their advice seriously. I mean, just like in anything, you never want to take one hundred percent of people's notes, and you never want to take zero. You see, you're kind of foolish to do either of those things, so, you know, it was that kind of process" (Alex-Director, 2023).

In this excerpt director indicates that acquiring knowledge is a long and complicated process. There is a long way for the receiver to understand the sender's message and then to transfer that into action. The sender needs to be patient and understanding of receiver's beliefs, knowledge and opinions. Especially in art, where the information sent is a lot of the times subjective it's easy for misunderstandings and arguments.

[2] The name of the company is hidden for research purposes
[3] The name of the film is hidden for research purposes

6.7 Mentoring

“Communication is paramount. So being patient and clear is very important. Being able to say what you want to say with a few words, especially if you're talking over radio, you have to be able to condense your idea or to get the message across. And yeah, I think that's important is to be patient with people and to understand that, especially if you're one of the more senior people in a department that you're constantly going to have newer people and you have to be aware that that knowledge trickles in gradually, so they're not going to know all the lingo immediately. You have to be patient to explain things clearly enough, but to also help them like understand what's the specific term that you're using mean and help them learn that so that next time you can just say that one word and they'll know” (Michael-Camera-Operator, 2024).

Michael in his interview underlines the importance of mentoring. Mentor has to be patient and excellent in communicating. It’s really important that he communicates his ideas thoroughly and briefly. Patience is the factor that helps older crew members with communicating with trainees, a lot of the times trainees need more time to process information and to learn the professional language specific for the film set.

6.8 Trust

When asked about what are the biggest limitations of intercultural film production, production manager replied: “Of course you have problems along the way, be it a language barrier, be it cultural differences. Speaking in the position I'm in, I think getting to know the people is extremely important. You have to know the people who built their trust. Once you build trust, no matter where you come from, there's an element of security” (Karl-Production-Manager, 2024).

Karl highlights the importance of trust as the key factor gluing together the intercultural film production. When asked about the primary challenges encountered in intercultural film production, the production manager candidly addressed key limitations. However, speaking from his vantage point within the production realm, he emphasized the paramount importance of establishing genuine connections with the individuals involved. According to him, investing time and effort in understanding the diverse backgrounds and perspectives of the team members is essential. Building trust emerges as a critical factor in fostering a collaborative environment wherein individuals feel valued and supported. Once trust is cultivated, irrespective of cultural origins, a sense of security permeates the production process, enabling smoother coordination and enhanced teamwork.

7. Conclusions

In conclusion, this study has provided valuable insights into the knowledge management practices within the international film productions, particularly focusing on the context of the Maltese film industry.

All the researched questions were answered in the “Results” section. The nature of knowledge sharing in the Maltese Film Industry is based both on tacit and explicit knowledge. The findings indicate that effective knowledge management in international film productions requires a combination of tacit and explicit knowledge sharing. While explicit knowledge, such as that contained in scripts and production documents, provides a framework for the production process, tacit knowledge plays a crucial role in adapting to dynamic situations and making informed decisions. The results from the interviews confirmed the moderate relevance of the factors assumed in the research hypothesis to the effective functioning of the film crew and the success of film projects.

Article answers the question about differences between collaboration and knowledge sharing. Furthermore, the study demonstrated the interconnectedness of collaboration and knowledge sharing in the film industry. Collaborative efforts among filmmakers, producers, and crew members facilitate the exchange of knowledge and expertise, leading to more innovative and successful productions. Through qualitative research methods including interviews, the study explored factors influencing effective knowledge management within an international film crew. The results obtained focus the importance of compromise, mentoring and trust. The multicultural dimension of film crews adds complexity to knowledge management, but it also presents opportunities for learning and collaboration. The study revealed that successful film productions rely on strong interpersonal relationships and effective communication methods to navigate cultural diversity and achieve common goals. This study offers valuable insights for filmmakers, production managers, and industry stakeholders, by identifying best practices and highlighting the importance of cultural competence and collaboration. Moving forward, continued research in this area can further enhance the understanding of effective knowledge management strategies in the evolving landscape of global film production.

Masters Research Papers

The Role of a Facilitator in Multidisciplinary Collaboration and Student's Experienced-Based Learning

Mamoru Miyazawa
Toyo University, Japan

s3f102300089@iniad.org

Abstract: This paper focuses on the necessity of experiential learning models and the importance of facilitators in the implementation of collaborative learning for students who have had no prior experience to such collaboration. It proposes a new role for educators in this. Multidisciplinary collaboration is defined as the process where by individuals with different perspectives recognize each other's expertise. In today's world, a high-tech business cannot succeed with a team specializing in only one field; business experts are required to collaborate with engineering experts to launch new high-tech businesses. Thus, university students must learn how to collaborate with multiple experts. The research adopts a case study of a Japanese university workshop where engineering, business, and design students, jointly create a high-tech business idea, and test their hypothesis. This multi-disciplinary collaboration develops student's ability to work with other specialized students. Past literature emphasizes the importance of experience-based learning: a learner recognizes specialized forms of knowledge through team discussion. For students who don't receive such learning, it's hard to understand how they learn from their experiences. As most Japanese students don't practice collaborating with other specialized people, they don't understand how to learn from their experiences. They are beginners in learning multidisciplinary collaboration, revealed by the fact that university students couldn't hold effective discussions and explain their own learning experiences. Interviews were conducted with students participating in collaborative learning workshop at university. It was found that novices repeatedly engaged in trial and error without effectively learning from experience, and the presence or absence of a facilitator influenced how they thought and derived value from their experiences. This challenge cannot be adequately addressed by students who are complete beginners; thus, intervention by educators or students who are actively engaged in collaboration is crucial. It was concluded that, irrespective of the outcomes of the workshop, the presence of a facilitator is key in promoting collaborative learning. Using Kolb's (2017) learning model, the study clarifies the impediments to a beginner's experience-based learning and how to overcome them. It proposes the role of a facilitator who is expected to promote experience-based learning. This paper could resolve issues related to multidisciplinary collaboration by adding a new facilitator role to intervene in the learning process and the students' experience-based learning.

Keywords: Multidisciplinary Collaboration, Experience-Based Learning, University Education, Facilitator, Multiple Experts

1. Introduction

This study examines how educators should utilize existing experiential learning models and what points they should consider when aiming to improve university students' multidisciplinary collaboration abilities. Furthermore, it highlights the insufficiently discussed role of facilitators, who are essential for learners' experiential learning, proposing new roles for them. There are many existing models of experiential learning suited for adult education (Kolb & Kolb, 2018; Kolb, 1999; Miettinen, 2010; Jarvis, 2005; Fry, 1979). Experiential learning learners draw from past experiences to bridge theory and practice and encourages reflection. By anchoring learning in the learners' experiences, it facilitates effective knowledge acquisition and enhances educational outcomes (Lewis, 1994). Diverse approaches to experiential learning exist, including methods that focus on encouraging learners to reflect on their experiences (Dewey, 2017; Ord, 2012; Lewis, 1994) and those fostering self-awareness through the contemplation of past experiences (Mezirow, 2014; Lewis, 1994).

The skill set required for multidisciplinary collaboration is essential in fields such as healthcare and engineering, and it is being fostered through different learning in universities and corporations (Lary, 2008; Heikkinen, 2015).

The ability to manage conflict and foster mutual understanding among students is a critical aspect of the knowledge base needed to function effectively in an organization and to drive innovation (Remenyi, 2009; Brown, 2008; Sanders, 2008; Allison, 2011; Nonaka, 2015). Universities have established departments focused on multidisciplinary collaboration skills, and ongoing discussions concern the development of various learning methods and the most advantageous ways to introduce them to cultivate these skills (Laura, 2006; Estes, 2004; McKelvey, 2006; Koch, 2017).

Despite the literature introduced and expanded learning opportunities, there is a gap in the discussion concerning the effectiveness of experiential learning for learners (Serda & Alsina, 2018; Kirschner, 2006; Koch, 2017). Educators have concentrated on providing the most affective learning opportunities. Additionally, emphasis has been placed solely on learners' experiences in teams, and the notable absence of facilitator engagement in the experiential learning process is problematic (Lary, 2008; Heikkinen, 2015; Kirschner, 2006;

Cindy, 2015). The presence of a facilitator in experiential learning is pivotal because they facilitate reflection and support the process by which learners acquire necessary knowledge (Boud, 1990; Kolmos, 2008).

Furthermore, future discussions will be required involving many facilitators to propose methods for facilitator development, using examples in businesses and universities, regardless of the field (Ames, 2011; Jones, 2006; Cindy, 2006). Facilitations focusing on business projects and collaborations in enterprises (Beranek, 2014; Den Hengst, 2005; Den Hengst, 2007) and the promotion of learning within communities and individuals to foster innovation in universities have been particularly noted (Yang, 2008; Harvey, 2001). However, this paper focuses on students who are unfamiliar with facilitation and collaborative learning, examining the role of the facilitator in supporting Kolb's experiential learning model. (Kayes, 2005)

Therefore, the present paper discusses methods around multidisciplinary collaboration skills, critically examining and enhancing Kolb's experiential learning cycle. In particular, Kolb's cycle recognizes the role of a facilitator in the experiential learning process, allowing them to engage with learners' experiences and promote learning and knowledge acquisition (Kolb, 2014). This enables a discourse and proposal of facilitator roles that are absent from current methods and those focused on experiential learning in multidisciplinary collaboration skills. Nevertheless, there is a lack of in-depth discussion on adapting Kolb's experiential learning cycle to education centred around multidisciplinary collaboration skills (Sato, 2015; Masuo, 2015; Morris, 2018). This study seizes the opportunity to examine exercises at Japanese universities aimed at students with no prior experience in multidisciplinary collaboration skills, discussing the significance of experiential learning for learners who are new to these competencies, as well as the indispensable role of facilitators in the process.

2. Literature Review

2.1 Experiential Learning

Past literature on experiential learning capitalizes on learners' experiences, engaging them in reflection and introspection to facilitate learning processes. With the proliferation of collegiate learners, the leveraging of student experiences has enhanced diverse educational outcomes (Miettinen, 2010). Among the various approaches and models predicated on experiential learning, John Dewey's paradigm serves as a foundation, focusing on the learner's self-reflection to achieve conceptual understanding and further learning (Dewey, 2017; Miettinen, 2010; Lewis, 1994). Mezirow's transformative learning posits that learning from experiences not only fosters personal growth but also endows individuals with fresh perspectives (Mezirow, 2014; Lewis, 1994). In addition, Jarvis (2006), with his theory of human learning and association with lifelong educational support, has highlighted experiential learning in the context of education, suggesting that learning occurs through the confluence of the inner person with the outside world. Despite the availability of experiential learning models that aid in the acquisition of knowledge and perspectives, prior discussions – such as Kolb's experiential learning cycle (Kolb & Kolb, 2018) – have not explicitly delineated the facilitative roles or the learning processes involved.

2.2 Kolb's Experiential Learning and Facilitators

This paper discusses Kolb's experiential learning cycle, which is comprised of four processes: experiencing, reflecting, thinking, and acting. Learners pass through these stages with facilitator intervention, moving from experience to reflection. According to Kolb (2014), experiential educators in this learning cycle embody roles as facilitators, subject experts, standard setters and evaluators, and coaches. Kolb's model posits that learners, through experience, engage in reflection, which then informs their thinking and subsequent actions (Kolb, 2015). The facilitator's profile – defined as possessing a warm, affirming style and focusing on 'inside-out learning' to motivate and foster self-knowledge – is critical for transitioning through the learning stages and building personal relationships and dialogues (Kolb, 2014). Furthermore, educators must accommodate the nine learning styles and the four dialectics of the learning cycle, tailoring their facilitation to the learners' styles. This paper examines the role of facilitators as defined by Kolb's cycle, especially within the context of learning aimed at interdisciplinary collaboration capabilities. However, Kolb's experiential learning doesn't focus on students who are complete novices. Additionally, it doesn't provide facilitators with examples of how to best utilize collaborative learning. Therefore, this paper discusses which aspects of students' experiences should be intervened to promote collaborative learning among novices.

2.3 2-3 Multidisciplinary Collaboration Skills, Experiential Learning, and Facilitators

Learning that centres on multidisciplinary collaboration skills is becoming increasingly prominent in universities and businesses, with emphasis placed on methods of collaboration and instructional strategies. Project-based learning, as an example of such learning, has been critiqued for lacking facilitator intervention in the learners' experiences (Cindy, 2015). The complementarity of lecture-based knowledge transmission and self-directed learning (as in project-based learning and reflective learning) suggests that combining the knowledge from lectures with self-guided learning can yield the benefits of collaborative and project-based learning education. However, existing methods fall short in providing appropriate reflection and action strategies for student experiences (Bernat-Carles Serda & Ángel Alsina, 2018). According to Kirschner (2006), the education-psychological stance is that experiential-based learning and project-based learning are mostly learner-centred, with educators minimally involved in learners' experiential activities. He advocates for experts and educators to actively engage with learners' experiences. Heikkinen (2015) claims that educators in existing collaborative learning scenarios focus too much on the introduction of learning opportunities while being involved in learners' experiential learning. He argues for educators to facilitate the transition of learners' experiences into practical applications within the context of interdisciplinary team projects.

Laura (2006) suggests that educators' negligence in engaging with student experiences can hinder the acquisition of the desired interdisciplinary collaboration skills; intervention by educators is crucial to maximizing the educational potential of varied experiences within projects. Koch (2017) emphasizes the enhancement of experiential learning through facilitators who engage with learners' motivations at technical universities. The role of facilitators is under-defined despite their necessity for supporting learners and fostering broader perspectives to facilitate learning (Goodyear & Dudley, 2015). Boud (1990) deliberates on how educators can draw from learner's to affect learning experiences, underscoring the critical interaction between students' and facilitators' joint learning endeavours.

(Ames, 2011) states that in higher education programs for university students, the impact of facilitation programs varies depending on students' learning attitudes and participation motivation. Additionally, facilitation in project-based learning at universities involves posing questions, encouraging thinking, and defining problems for learners. This paper concludes that the success of such programs is determined by facilitation. Similarly, (Jones, 2006) discusses the necessity of promoting shared understanding among students when using facilitation in collaborative learning (Cindy, 2006).

However, these studies don't focus on students who have never experienced collaboration or facilitation. In practice, (Hengst, 2005; Hengst, 2007) highlight the challenges facilitators face. Furthermore, (Harvey, 2001) analyses the roles and functions of facilitation in practice and works on conceptualizing facilitation.

Past literature claims that multidisciplinary collaborative capability is recognized as a critical skill that facilitates mutual understanding and conflict acceptance among people within organizations and sparking innovation (Remenyi, 2009; Brown, 2008; Sanders, 2008; Allison, 2011; Nonaka, 2015). This capacity is referenced throughout concepts, models, and philosophies such as design thinking (Brown, 2008) and co-creation (Sanders, 2008), which emphasize the sharing of knowledge and perspectives across diverse fields to conduct business effectively. Allison (2011) has discussed sharing methodologies for the knowledge necessary to generate innovation and train proactive business leaders. Additionally, McKelvey (2006) has argued for the necessity of bridging what students learn in academic education and research with practical applications. Nonaka's 'A Dynamic Theory of Organizational Knowledge Creation' (2015) has been noted as prominent, representing a collaboration method that is different from the workshop collaboration discussed in this paper.

Therefore, while collaborative-themed learning opportunities are considered, the absence of facilitators renders experiential learning inadequate. The specificity of facilitator roles should be examined depending on the field and learning method. This paper discusses the significance of experiential learning and elaborates on the essential role of facilitators in supporting learners' acquisition of interdisciplinary collaboration skills.

3. Case Study

This study discusses the existence and functions of facilitators with an emphasis on multidisciplinary collaboration capabilities through the Kolb's experiential learning cycle. The workshop involves students from technical and business disciplines teaming up to address a given theme – from identifying the problem to proposing solutions – over a one-year period. These students begin with little to no training or perspective on multidisciplinary collaboration, and they are uncertain about how best to leverage their expertise. Especially in

Japan, learning centred on collaboration is developing, and the students exhibit characteristics different from those in other countries. For instance, their passive and reticent attitudes can impede the experiential learning that would enhance their interdisciplinary collaboration skills (Sato, 2015). Additionally, there is a limited presence of educators capable of intervening in student experiences. Japanese universities possess structured learning and education systems where students generally adopt a passive stance. The emphasis tends to lie on credentialism, such as whether an experience contributes to job hunting success, or on sensory experiences like the ability to converse with others rather than on experiential learning that could impart multidisciplinary collaborative abilities. Moreover, concern often centres on whether students can complete a given learning process rather than engaging in effective discussion (Sato, 2015).

In this study, we conducted interviews with five respondents who had experienced workshops at the undergraduate level, focusing on their remarks about collaboration, experiences, and leadership. Each respondent was interviewed individually for 30 minutes. Students A, B, and C participated in workshops as members of team's conscious of facilitators and collaboration. Regardless of their workshop grades, these students reflected on their roles and awareness of collaboration, finding their experiences beneficial for future opportunities such as internships. In contrast, students D and E reported that the workshops weren't useful for their learning and that they had limited experiences. Although their teams had leaders, these students expressed discomfort and frustration with the facilitators and the ultimate team activities, describing their experiences as negative.

It analyses the experiences of learners in an ongoing year-long workshop concerning what they have learned and how they perceive multidisciplinary collaboration. Table 1 summarizes the interview results with students who participated in multidisciplinary collaboration practice, showing how this study aggregates the experiences of participants who were in teams both with and without a student fulfilling the role of a facilitator. Consequently, facilitators are intentionally left undefined, requiring the participating students to undertake a process of self-guided exploration and experimentation to ascertain their roles. Starting with questions regarding the importance of discussion that embraces conflicting viewpoints to bolster collaboration capabilities, the study explores university students' understanding of multidisciplinary collaboration and the experiences throughout the workshop.

Table 1: Interview results with students who participated in multidisciplinary collaboration workshops

	Presence of a facilitator	**Experience-based learning**	**Recognition of multidisciplinary collaboration skills**	**Consciousness of the learning process**
Student A, B, C	Exists	Occurs Through experience, recognizing one's own lacking expertise or elements	Encouraging mutual understanding among students Complementing each other	By having experiences Applying it to one's own field of expertise or practices such as internships
Student D, E	Does not exist	Does not occur Failures and disagreements of opinion Only directional and idea discrepancies	Working independently as individuals Seeking direction from the team leader to avoid friction Conforming unduly to each other's ideas	Experiencing only dissatisfaction through the experience No experiencing of proactive collaboration or active discussions Learning differs in content

4. Findings

The case study examining multidisciplinary collaboration workshops for university students suggests that when they operated within teams with a facilitator, they were capable of converting their experience into learning, gained awareness of collaborative skills, and became cognizant of their learning processes.

From the interviews, it was revealed that the role of the facilitator, along with the experience of the collaborative learning process, is crucial in promoting multidisciplinary collaboration. Students who experienced collaboration had different impressions of the workshop compared to those who didn't. The presence of a facilitator enabled the students who were conscious of collaboration to act more proactively, and even those who were not initially

aware started to think about contributing to the team and making efforts to engage. Moreover, students attempted to bridge the gap between the technical and business domains, striving to excel from their respective perspectives through trial and error. As a result, they were able to apply the experience gained from the workshop to internships and other practical endeavours.

In contrast, without a role that facilitates collaboration, even if students were aware of the importance of collaboration, the workshop became a routine group activity rather than a truly collaborative effort. Particularly, students D and E felt that the absence of an effective leader resulted in a team structure that didn't foster multidisciplinary collaboration. For them, the workshop ended up being an opportunity to experience the failure of collaboration.

The workshop participants responded as follows in the interviews;

Student A, specializing in programming, expressed initial bewilderment concerning multidisciplinary collaborative skills but acknowledged that participation in the workshop provided an opportunity to recognize and experience these capacities. The experience led to active participation in discussions and subsequent actionable behaviours.

Student B, with a design specialization, demonstrated an understanding of multidisciplinary collaborative skills. Compared to learning opportunities with passive students and absent facilitators, the workshops served as first-time experiences and understandings of these skills.

Student C, through their experience, recognized a personal deficiency in perspective regarding multidisciplinary collaboration and has since learned and applied this understanding, utilizing their newfound knowledge for practical action.

Conversely, students who participated in teams without a facilitator lacked experiential learning, recognition of multidisciplinary collaboration skills, and awareness of their learning processes, significantly deviating from the cases and models discussed in this paper.

Student D struggled to understand multidisciplinary collaboration through the workshop and reported an inability to achieve teamwork among peers. Instead of embracing 'frictions and conflicts', a quality typically associated with multidisciplinary collaboration, avoidance was prevalent, resulting in a lack of assertive collaboration. Student misinterpreted multiple disciplines working separately as collaboration. Not knowing about the role of facilitators meant that there was no one to guide the experiential learning process.

Student E had a narrow interpretation of multidisciplinary collaboration, equating it solely with experiencing inconsistencies and misalignments without any mention of embracing conflicts. The awareness of a learning process was absent, with learning equated only to experience and personal sentiment. Individual work, being straightforward, was preferred, signifying a misunderstanding of collaboration.

The interviews revealed that for students being introduced to workshops and the concept of multidisciplinary collaboration for the first time, the presence of a facilitator is crucial. For those without experiential learning perspective, the workshops served as an opportunity for experience, not for learning transformation and action. Facilitators are necessary to guide learners through the experiential learning cycle. Rather than attributing significance to mere experiences, facilitators are required to direct learners towards experiences that can be utilized in experiential learning.

In particular, the interviews elucidated that within the context of Japanese education, where one-sided instruction traditionally prevails, students have mentioned a lack of knowledge about collaborative discussions, experiences, and facilitators when it comes to multidisciplinary collaboration. Thus, when implementing experiential learning for learners with no multidisciplinary collaborative capabilities, facilitators who can guide them through Kolb's experiential learning cycle are essential. Moreover, facilitators who can create experiences that lead to knowledge and skill enhancement are needed.

For instance, Kolmos (2008) defined the role of a facilitator as someone who assists in motivating students and determining their direction, which is crucial at the learning initiation stage. In collaborative education in Norway, the introduction of facilitators has been shown to promote students' experiential learning (Kolmos, 2008). Similarly, Matsuo (2015) critiqued Kolb's experiential learning model and proposed roles for facilitators, suggesting that factors such as seeking challenging tasks, critical reflection, enjoyment of work, learning goal orientation, and a developmental network can foster learning. Moreover, the literature on leadership skills

indicates that educators and learners should discuss and construct the learning process, competency development, and the role of the facilitator (Estes, 2004).

In the present paper, we focus our attention on Kolb's experiential learning cycle (Figure 1). In particular, our discourse revolves around the learning steps of Concrete Experience (CE) and Reflective Observation (RO), contemplating the necessity of facilitators (Figure 2). These facilitators are entrusted with pivotal roles to target completely novice students, make them aware of effective experiences, and provide opportunities. Without the presence of a facilitator, learners may find themselves merely repeating experiences without deriving learning from them.

5. Discussion, Conclusion, and Limitations

This paper has demonstrated the necessity of experiential learning models and the importance of facilitators when implementing collaborative learning for students who have had no prior experience to collaboration. Firstly, the presence of a facilitator enables the promotion of collaborative learning and the intervention in experiential learning, thus leading to transformative changes in students. Specifically, the role of the facilitator as utilized in Kolb's Experiential Learning Cycle is considered instrumental in providing experiential learning opportunities and advancing the learning process for students not accustomed to collaboration.

Past literature has focused on increasing the frequency of experiential learning and collaborative learning sessions, as well as reviewing methods of implementation and ensuring a student-centred learning approach. Therefore, this paper examined a workshop designed to impart multidisciplinary collaboration skills based on experiential learning as a case study, concluding that facilitator intervention is a critical element in the experiential learning of novices. Specifically, grounded in Kolb's learning model, this study proposed the elements of experiential learning that can be utilized for multidisciplinary collaboration learning and the role of facilitators

for novices. Kolb's learning model (2017) employs an experiential learning approach that uses nine cycles to transform learners' experiences into more reliable and effective encounters. The study identifies the obstacles beginners face in experiential learning and the methods to overcome them.

The case study and findings show that facilitators play a crucial role in experiential learning by encouraging learners' experiential learning and guiding them through Kolb's experiential learning cycle. It was especially noted that the Japanese students featured in the case study aren't accustomed to the premise of experiencing, reflecting, and engaging actively. Furthermore, Japan has a scarcity of educators trained to deliver experiential learning (Sato, 2015). Therefore, for learners who have never engaged in experiential learning, facilitators are necessary, and Kolb's experiential learning requires refinement. This paper highlights that the presence of a facilitator is an essential element when providing knowledge of multidisciplinary collaboration skills to novices who have no prior perspective on collaboration. Past arguments have emphasized the absence of facilitator intervention, valuing the mere experience of existing experiential learning. In this context, focusing on the role of facilitators as defined in Kolb's experiential learning, this paper found that the presence of a facilitator is instrumental in guiding novices through the learning cycle and in supporting their learning.

In terms of future directions, several aspects weren't addressed in the main text, such as methods for training facilitators necessary for collaborative learning and how to provide experiential learning tailored to the needs of organizations and communities. Specifically, this paper doesn't analyse how novices should create concrete experiences through Kolb's experiential learning cycle. Kolb's experiential learning doesn't define the specifics of what constitutes a concrete experience. Therefore, it is essential to discuss what types of experiences can accelerate learning for learners. Morris (2018) claims that Kolb's model has a lack of clarity regarding what constitutes a concrete experience, and past literature has debated about the elements a facilitator should have and who should do it. Matsuo (2015) developed a model in which five facilitators (seeking challenging tasks, critical reflection, enjoyment of work, learning goal orientation, and developmental network) directly and indirectly facilitate the performance of the four steps of Kolb's experiential learning process. In coaching, which resembles facilitation, peer coaching has developed among students and within businesses, enhancing mutual learning (Jones, 2019; Parker, 2008) Japan's deficiency in educators able to support learners as facilitators necessitates a discussion on how to cultivate such skills. Thus, future research is expected to clarify the role of facilitators in experiential learning for multidisciplinary collaboration.

Exploring the Impact of Artificial Intelligence on Knowledge Management in Automotive Manufacturing within Different Cultures: China and Germany as Examples

Rui Wang and Yifen Yin*
Faculty of Humanities and Social Sciences, Macao Polytechnic University, Macao

p2313391@mpu.edu.mo
yfyin@mpu.edu.mo

Abstract: This study explores the impact of artificial intelligence (AI) on knowledge management (KM) in the automotive manufacturing industry with a focus on different cultural contexts in China and Germany. The role of cultural factors on the effectiveness of AI in KM practices is explored by comparing automobile manufacturers in China and Germany. This study uses case studies to compare, and contrast leading automotive manufacturers in both countries and combines industry reports, papers journals, and other digital resources on the Internet to explore how the manufacturing industry can use AI technology to improve efficiency in the KM process. In addition, the study explores the impact of culture on organizational structure, decision-making, and employee engagement with new technologies within a company. The preliminary findings suggest differences in the understanding and use of AI and KM between China and Germany due to their different history, culture, and level of economic development. In China, the integration of AI into KM is driven by rapid technological advances and strong government support, focusing on efficiency and scalability. In contrast, German companies show more caution, emphasizing accuracy, reliability, and augmentation of human expertise. These differences reflect broader cultural attitudes toward technology and innovation in both countries. The study contributes to the understanding of the interaction between AI and KM in the context of cultural differences. The findings will have important implications for subsequent AI research and policy development.

Keywords: Artificial Intelligence, Knowledge Management, Automotive Manufacturing Industry

1. Introduction

1.1 Importance of AI in the Automotive Manufacturing Industry

AI plays an increasingly important role in the automotive manufacturing industry, mainly in several key application areas to improve efficiency, increase safety, promote innovation, and enhance customer satisfaction. Different application scenarios and means reflect different importance.

For example, AI can improve automation in automotive production lines, reduce human error, and increase productivity. At the same time, AI can analyze production data, optimize workflow, reduce waste, and improve resource utilization efficiency (Kamran et al. 2022). By using AI vision systems for real-time inspection and quality control of automobiles in production, defects, and non-compliant products are identified and corrected. This ensures product quality and reduces the need for rework and after-sales service. It can also help automakers manage their supply chains more efficiently by optimizing inventory levels through predictive analytics, forecasting demand, reducing surpluses or shortages, lowering costs, and improving supply chain transparency and flexibility (Hofmann et al. 2023; Jarrahi et al. 2023).

In automotive design and engineering, AI can assist in design decisions through simulation and predictive analytics, optimize vehicle performance including fuel efficiency, safety, and durability, play a role in material selection and engineering testing, and increase the speed of innovation (Demlehner and Laumer, 2020). Help automakers offer more personalized vehicle configuration options that optimize vehicle performance based on customer preferences and driving habits. In after-sales service, predictive maintenance can be used to reduce vehicle breakdowns and improve customer satisfaction. Although not directly involved in the manufacturing process, AI plays a central role in the development of autonomous driving technology and has a significant impact on the development of the automotive manufacturing industry enabling vehicles to understand their surroundings and make safe and effective driving decisions (Uludağ et al. 2019).

1.2 The Critical Role of KM in the Automotive Manufacturing Industry

KM plays a critical role in the automotive manufacturing industry, which involves creating, sharing, using, and managing information and knowledge within an organization. In a highly complex and technology-driven industry such as automotive manufacturing, by effectively managing and sharing internal knowledge, automotive manufacturers can accelerate the process of new product development and enhance innovations

ranging from new technologies to new design concepts. This helps companies maintain a competitive edge and respond quickly to market changes and consumer demands. KM systems can help employees quickly access production processes, operating manuals, and best practice guidelines, which can reduce errors and improve efficiency and quality control on the production line (Hofmann et al. 2023; Jarrahi et al. 2023).

The automotive manufacturing industry has a complex supply chain involving numerous suppliers and partners. Effective KM helps to increase supply chain visibility, optimize inventory management, reduce delays, and ensure efficient coordination of all aspects of the supply chain.

KM can provide the necessary data and information to support fact-based decision-making. This includes market trend analysis, consumer behavior research, and evaluation of competitor strategies, thus helping management make more informed strategic decisions. KM systems enable new employees to assimilate more quickly into the company, and by accessing the company's knowledge base, they can learn the company's workflow, culture, and standard operating procedures more quickly (Demlehner et al. 2021). For existing employees, it's also a great resource for continuous learning and career development. Automotive manufacturing involves multiple departments such as design, engineering, production, and sales. KM helps break down barriers between departments and facilitates cross-departmental information sharing and collaboration, which improves the efficiency and effectiveness of the entire organization. KM can also support better customer service.

The relationship between intelligent vehicles and knowledge management can be effectively analyzed through the lens of the DIKW hierarchy theory, which stands for Data, Information, Knowledge, and Wisdom. This theory provides a framework for understanding how raw data is transformed into meaningful knowledge and ultimately wisdom. Data Collection and Management， Intelligent vehicles are equipped with a multitude of sensors that collect vast amounts of data. Effective knowledge management begins with the efficient collection, storage, and processing of this data. This involves Data Aggregation， Data Filtering， and Data Storage. Information Processing. Once data is collected, it needs to be processed to become useful information. For instance, image recognition algorithms can identify pedestrians, vehicles, and road signs from camera data. The next step is to transform information into knowledge. Identifying patterns in data that can inform decision-making. For example, recognizing that a certain intersection tends to have heavy traffic at specific times. Machine learning techniques allow intelligent vehicles to learn from past experiences and improve their decision-making over time. Finally, the application of knowledge to make wise decisions involves. Using knowledge to make real-time driving decisions. For instance, deciding when to change lanes or how to navigate around obstacles. This could involve updating algorithms and models to better handle new driving scenarios.

The integration of DIKW in intelligent vehicles has several practical implications. Improved data processing and knowledge management can lead to safer driving decisions, reducing the likelihood of accidents. Intelligent vehicles can optimize routes and driving behaviors to reduce fuel consumption and travel time. Providing drivers and passengers with relevant information, such as traffic updates and optimal routes, enhances the overall travel experience. The DIKW hierarchy theory provides a valuable framework for understanding the relationship between intelligent vehicles and knowledge management. By effectively managing data, transforming it into useful information, and applying knowledge wisely, intelligent vehicles can make better decisions, enhance safety, and improve efficiency. The ongoing advancement in AI and machine learning technologies will continue to enhance this relationship, leading to even smarter and more autonomous vehicles in the future.

1.3 Impact of Cultural Factors on KM

KM is not only about technology and processes, but is also closely related to people, organizational culture, and social interactions, so the influence of cultural factors in it should be explored in depth. Among them, organizational culture has a significant impact on the creation, sharing, and utilization of knowledge. Some key cultural factors have a critical impact on KM (Ammal et al. 2021).

An open culture encourages communication and collaboration among employees and facilitates the free flow of knowledge. Trust is the cornerstone of knowledge sharing; only when employees trust each other are they more willing to share their knowledge and experience. Fostering a culture of continuous learning and innovation is critical to KM. In such a culture, employees are encouraged to explore new ideas, learn new skills, and see mistakes as opportunities to learn and grow (Zhao et al. 2022; Yan et al. 2023; Kuang et al. 2018).

The culture should support knowledge sharing and creation through rewards and incentives. If the organization rewards employees who contribute knowledge and help others, then this will encourage more knowledge-sharing behaviors. In highly hierarchical organizational cultures, greater power distances may impede the flow

of knowledge. Lower-level employees may be reluctant to share knowledge with their superiors, fearing that their ideas and feedback will not be valued. Both direct and indirect communication styles can influence KM. In cultures that favor direct communication, knowledge sharing may be more direct and frequent. Whereas in cultures that favor indirect communication, people may be more cautious and need to build stronger trusting relationships to share knowledge (Manik et al. 2022).

A culture's tolerance for risk can influence an employee's willingness to try new approaches or come up with innovative ideas (Grum, 2020). In cultures that tolerate failure, employees may be more willing to share their knowledge and experiences, including those attempts that did not succeed. Organizations in collectivist cultures that place more emphasis on teamwork may be more likely to implement KM practices because knowledge is seen as a shared asset of the team. Whereas in an individualistic culture, knowledge may be viewed as an individual's property and employees may be more reluctant to share it (Tubaro and Casilli, 2019).

2. Theoretical Background and Research Methodologies

2.1 Overview of Automotive Manufacturing in China and Germany

Germany is one of the world's most famous automobile manufacturers, has a long history of automobile manufacturing, and is the founding place of many automobile brands, such as BMW, Mercedes-Benz, Audi and Volkswagen.

The German automotive manufacturing industry has long been a leader in automotive technology and innovation, especially in high-performance vehicles, luxury cars, and automotive engineering and design. In addition, influenced by Germany's Industry 4.0, German automotive companies have invested heavily in research and development (R&D), with the German automotive industry totaling €39 billion in R&D worldwide in 2017, twice as much as a decade ago, and averaging about 6 percent of overall sales (Uludağ et al. 2019; Manik et al. 2022).

The German automotive industry accounts for around 35% of the total R&D investment in the German economy. This puts it well ahead of other sectors. In 2018, the Volkswagen Group invested €13.9 billion in R&D for the year, ranking it number one in the global manufacturing industry. Through this fine and mature division of labor in R&D and its continuous optimization, the German automotive industry as a whole continues to show great potential for innovation and rapid efficiency improvements (Tubaro and Casilli, 2019).

China is the world's largest automotive market, ranking first in passenger car sales, and in recent years the demand in the field of electric and new energy vehicles has grown rapidly. It is worth noting that the government has played a driving role in the development of China's automotive industry.

As early as 2015, the Chinese government put forward the "Made in China 2025" strategy, the core of which is to realize the comprehensive intelligence of the manufacturing industry, more and more manufacturing industries have begun to transform in 2015, and started to integrate with AI in depth (Jarrahi et al. 2023).

Since 2015, more and more manufacturing industries have begun to transform and deeply integrate with AI. Especially in the new energy automobile industry, not only has it invested large capital, but the government has also played an active role in promoting the development and popularization of the new energy manufacturing industry through subsidies and special policies, which has led to the rapid modernization of China's automobile manufacturing industry, and the development of many Chinese automobile brands, such as BYD, Geely, the Great Wall, and Hongqi, in both domestic and international markets. Many Chinese car brands such as BYD, Geely, Great Wall, and Hongqi are becoming increasingly popular in both domestic and international markets (Teece, 2019). With increasing cooperation with international companies, including joint ventures and technology sharing, the competitiveness of Chinese automobiles in the global market is also gradually increasing (Zhao et al. 2022; Kuang et al. 2018).

As shown in Figure 1 below, in general, the German automotive industry is known for its innovation and high-quality products, while the Chinese automotive industry is known for its large market size and fast-growing new energy vehicle sector. The automotive industries of both countries are in a constant state of development and change, with far-reaching impacts on the global automotive market and technological development.

Figure 1: Timeline of the development of the automotive industry in China and Germany

2.2 Automotive Manufacturing and AI Applications Analytical Methods

This paper divides the degree of manufacturing AI into four aspects, as shown in Figure 2. That is intelligent manufacturing, automatic driving systems, AI virtual assistants, intelligent networks, and through these four aspects of Sino-German AI technology and automotive industry intelligence analysis. The parameter selection criteria are as follows:

1. Intelligent manufacturing: mainly refers to the automation, intelligence, and networking of the manufacturing process through the Internet of Things, cloud computing, big data, AI, and other intelligent technologies. Intelligent manufacturing indexing is quantitatively analyzed in terms of the amount of funds invested in the automotive manufacturing industry's preliminary R&D, the proportion occupied by the automation of the production process, and the utilization rate of production data (Taherdoost and Madanchian, 2023).
2. Autonomous driving: a rating of the level of automation of a vehicle, with specific classification criteria as shown in Figure 3 (Manik et al. 2022).
3. AI Assistant: It is a specific application of AI technology in the field of life assistance. It uses advanced technologies such as natural language processing, machine learning, and deep learning to provide users with personalized and intelligent services.

If we quantify the evaluation standard of AI, we can measure the professional degree and experience of AI assistants by the accuracy rate of navigation and road conditions, the accuracy rate of safety monitoring data, and the degree of entertainment information service.

4. intelligent network: also known as an Intelligent Transportation System (ITS), refers to the close integration of communication technology, information technology, and transportation technology, in the road traffic information system, life and social facilities system, and automobile system at three levels, to promote the transportation operation of the intelligent network application system. It aims to create an intelligent transportation network that can address social, economic, and environmental challenges, including construction, operation, and maintenance. The information interaction rate,

information transmission rate, and information carrying capacity per bit are analyzed as indicators for evaluating intelligent networking when measuring intelligent networking (Teece, 2019).

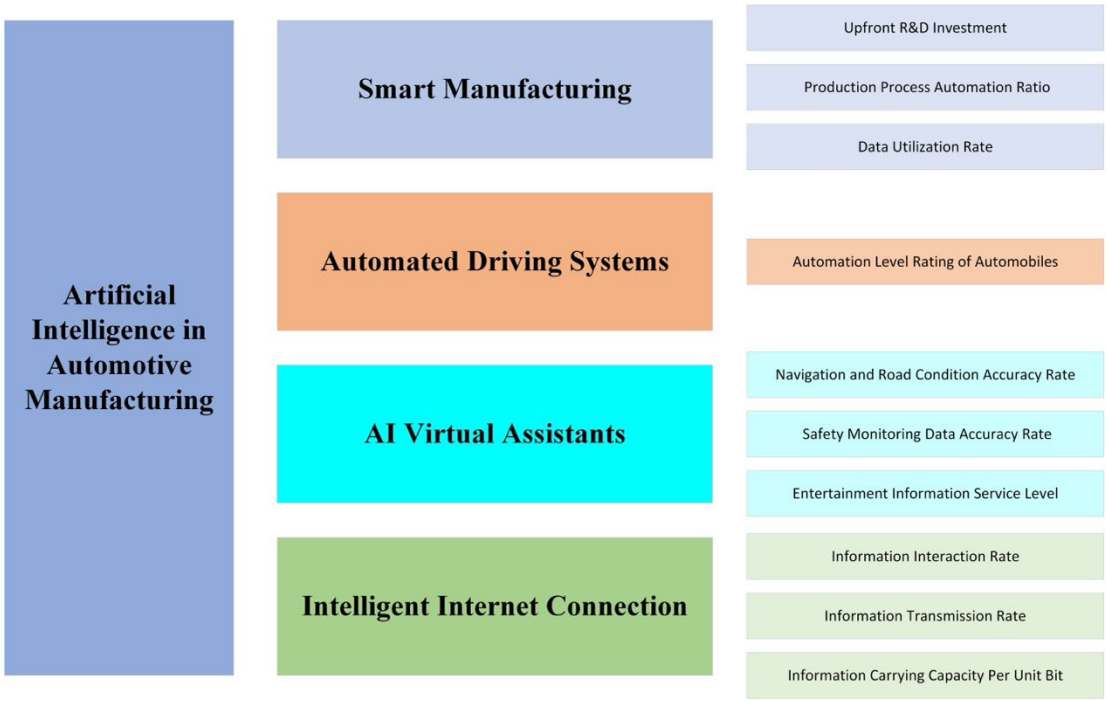

Figure 2: Quantitative criteria for the degree of intelligence in the automotive manufacturing industry

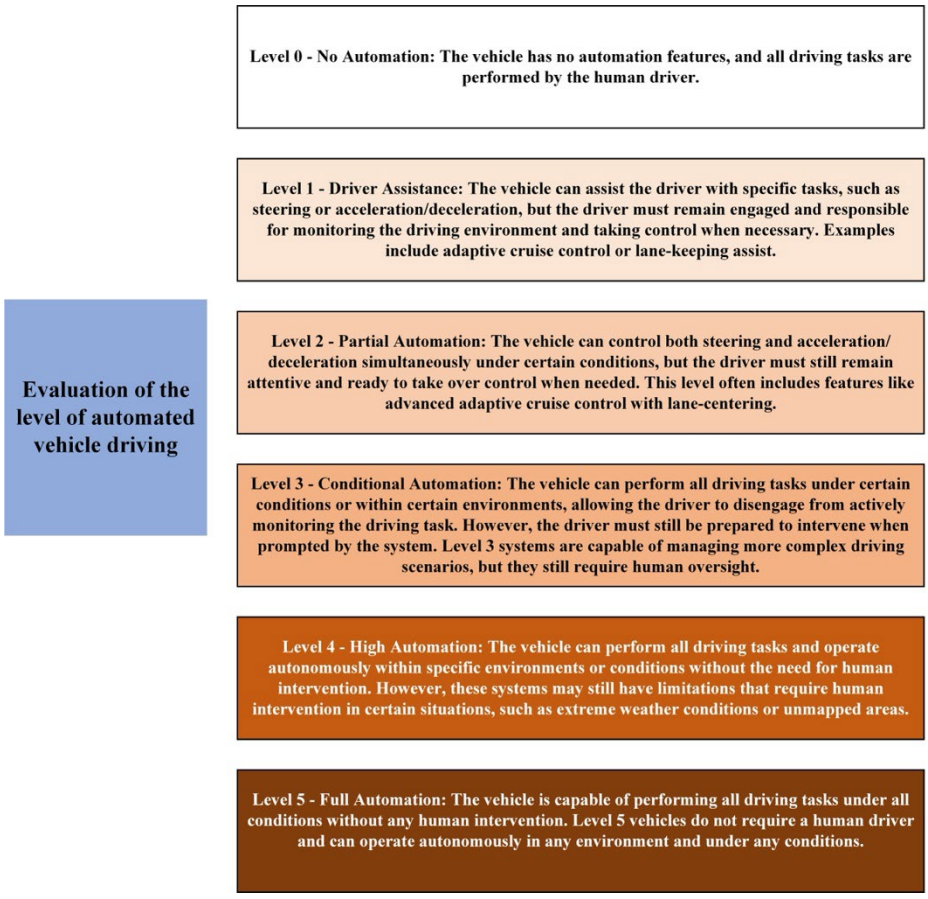

Figure 3: Rating criteria for automotive automation levels in this paper

2.3 Data Analysis

As seen in Figure 4 and Figure 5, the use of AI in China's automotive manufacturing industry is mainly focused on the pre-development of products, accounting for 51 percent of the total use of AI. The main use is reflected in the use of AI technology to automate the production process and improve production efficiency and quality control. By analyzing data from production equipment, AI can predict possible problems and maintenance needs of the equipment, reduce unplanned downtime, and improve productivity. This is the efficiency that China's manufacturing industry cares about the most. In addition to this, China's automotive manufacturing industry cares about user experience, such as the development and updating of AI virtual assistants, which account for 28% of China's manufacturing industry. Data from "China Intelligent Vehicle (Intelligent Connected Vehicle) and World Intelligent Vehicle Industry Speculation and Prospect Forecast Report, 2021-2024" published by China Automotive Industry Research Institute (CAIRI)

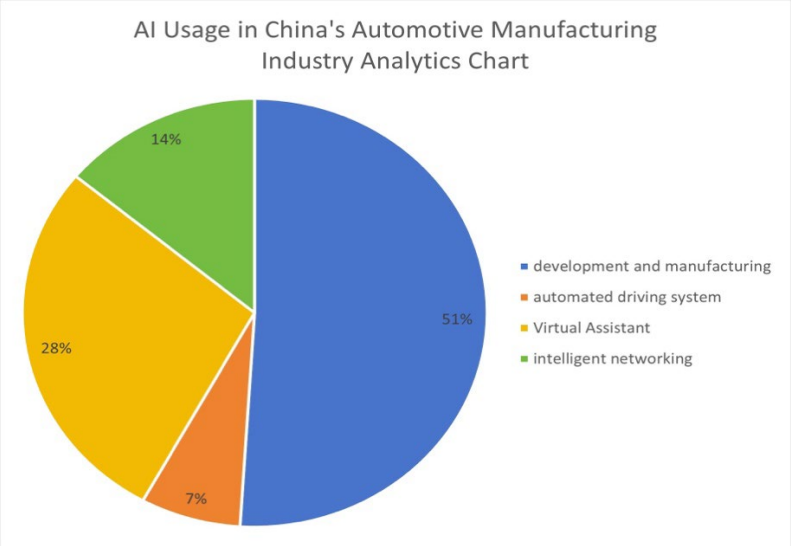

Figure 4: Percentage of intelligence degree of China's automobile manufacturing industry under this paper's standard

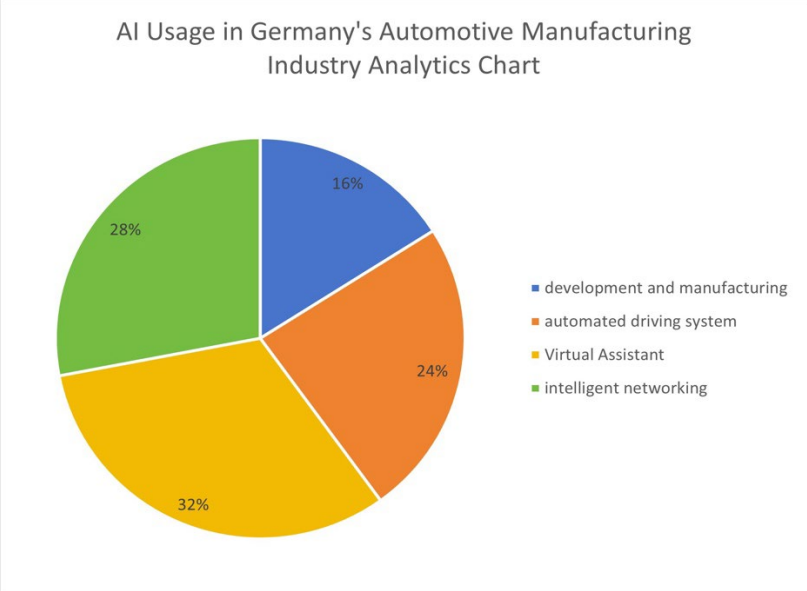

Figure 5: Percentage of intelligence degree of Germany's automobile manufacturing industry under this paper's standard

As seen in Table 1 below, the German automobile manufacturing industry in the use of AI, mainly concentrated on the late use of the product, and in the car's pre-development and design the use of AI accounted for only 16%, which has lot to do with Germany after the industrial revolution for the traditional fuel car obsession, from

the automation of the driving accounted for only 24% can be seen in Germany's new energy vehicle transition slower, in the international economic society Germany is lagging slightly behind in the international economic and social digitalization wave.

Table 1: AI in German Automotive Manufacturing

AI in German and China Automotive Manufacturing				
Areas of Application of AI	Development and manufacturing	Automated driving system	Virtual Assistant	Intelligent networking
AI in German Automotive Manufacturing Percentage	16%	24%	32%	28%
AI in China Automotive Manufacturing Percentage	51%	7%	28%	14%

The current background is that China is a global leader in key technologies and production levels such as batteries, motors, smart cockpits, etc., with an average range of over 460 kilometers for pure electric passenger vehicles, and many new technologies have emerged and taken hold in the country. China continues to make breakthroughs in the technological innovation of new energy vehicles. Battery technology is one of the keys to developing new energy vehicles. In recent years, Chinese enterprises have made remarkable progress in battery technology, such as China's latest generation of lithium iron phosphate batteries, which have an energy density of 180 watt-hours per kilogram and a range of more than 500 kilometers, which not only improves the energy density and range of batteries but also reduces the cost of batteries. AI is practically applied to the automobile manufacturing industry.

In recent years, Germany for using AI in the automotive industry, has also joined the R&D, Mercedes-Benz in the CES demonstrated the new MBUX virtual assistant. Based on large language modeling technology, its voice interaction is as natural as human communication; empowered by 3D graphic technology, its virtual image also has deep feelings and can express different emotions. It can integrate route guidance and driving assistance, presenting road environment information, navigation information, and dynamic information about the car in real-time and seamlessly on the screen. BMW Group also demonstrated a new voice assistant based on a large language model at CES 2024. The use of AI will be shown more fully. So what is the development of the German automotive industry for new energy vehicles? Official data shows that new car sales in Germany in February 2023 improved by 5.4% year-on-year to 217,388 units. However, Germany's progress on electric vehicles remains mixed, with sales of pure electric vehicles down 5% year-on-year, while plug-in hybrid electric vehicles (PHEVs) saw an increase in sales, with PHEV sales of 14,575 units, a 22% year-on-year boost (Uludağ et al. 2019).

With the use of AI, Germany as a result of the Industrial Revolution period ate the dividends of traditional fuel vehicles, coupled with the German automakers for traditional fuel vehicles manufacturing process has been skilled in the heart, want to break the routine there is a certain dilemma, which leads to Germany in the automobile manufacturing industry for the investment in new technology R&D, the transformation of the automated driving system there are ideological difficulties, and therefore companies want to develop new Energy is not enough power. In China, however, the government attaches great importance to environmental protection and has a strong interest in the development and use of new energy sources. In addition, China has maintained a high degree of enthusiasm for the digital economy in recent years. in 2023, China's new energy vehicle production and sales completed 9.587 million and 9.495 million units, respectively, an increase of 35.8% and 37.9% year-on-year, with a market share of 31.6%, and production and sales remained the world's first for nine consecutive years.

3. Comparative Analysis of KM in Chinese and German Automobile Manufacturing Industries

3.1 Differences and Similarities of KM in Chinese and German Automobile Manufacturing Industries

In recent years, Germany's federal education and research department set up a "future investment program" for the field of automotive machinery technology research and innovation to provide financial support. At the same time, Germany encourages German students to actively participate in automotive R&D and experiments for the internationalization of German brand vehicles and adopts various modes of KM to meet the needs and

challenges of the global market, such as centralized and unified intellectual property management, intellectual property management under the responsibility of R&D department, and joint management of intellectual property rights by the legal department and R&D department (Kamran et al. 2022).

China's automobile manufacturing industry has adopted various measures in KM, such as building a KM system, big data intelligence analysis, science and technology innovation knowledge service, and a new energy automobile national big data alliance to improve R&D efficiency, control costs and meet user needs.

Through the previous summary and analysis, we see that both Chinese and German automobile manufacturing industries attach importance to KM as a key factor to enhance competitiveness and innovation, but due to the differences in historical background, cultural characteristics, and market development stage, there are some significant similarities and differences between the two countries in the practice of KM. we will systematically compare and organize the two:

3.1.1 Similarities

Innovation emphasis: the automobile manufacturing industries of both countries attach great importance to innovation and regard KM as an important tool for promoting R&D and technological progress (Yan et al. 2023). This includes investment in new product development, and new technology applications (e.g. electric vehicles and autonomous driving technology).

Technology and digital applications: Both Chinese and German automakers are actively adopting advanced information technologies, such as AI, big data analytics, and cloud computing, to support KM and improve design, production, quality control, and customer service.

Global cooperation: Automakers in both countries recognize the importance of global knowledge sharing and international cooperation, and promote the exchange of knowledge and dissemination of best practices through cooperation with foreign partners, suppliers, and research institutions (Zhao et al. 2022).

3.1.2 Differences

Culture and organizational structure: German corporate culture is often more structured and hierarchical, emphasizing precision and quality control. KM systems tend to be more formal, emphasizing standardization and processes. In contrast, Chinese corporate cultures may be more flexible and dynamic, adaptable, and decision-making processes may rely more on relationships and networks. This may lead to KM practices that focus more on interpersonal communication and informal knowledge-sharing channels.

Knowledge sources and types: German KM tends to focus on internal R&D and the protection and utilization of long-term technology accumulation, valuing deep engineering knowledge and technological innovation.

China's automobile manufacturing industry, in its rapid development stage, is more likely to focus on integrating and absorbing international advanced technology and management knowledge, while at the same time rapidly enhancing its independent R&D capabilities (Demlehner et al. 2021).

Knowledge sharing and cooperation approach: German firms are likely to rely more on formal KM systems and procedures to facilitate knowledge sharing, such as through internal databases, standard operating procedures, and regular training. Chinese firms may rely more on informal networks and personal relationships for knowledge sharing, although formal KM practices are also being gradually established and improved.

Market orientation and customer needs: KM in German automobile manufacturing may focus more on product quality, innovation, and engineering excellence to meet the global market demand for high-end vehicles. China's automobile manufacturing industry may focus more on rapid market response and diversified needs in terms of KM, especially in the field of new energy vehicles and intelligent internet-connected vehicles, to adapt to the rapid changes in domestic and international markets. Based on these similarities and differences, the automotive manufacturing industries of the two countries show different effects on the application of AI.

3.2 Comparison of the Impact of Cultural Factors on KM in Chinese and German Automobile Manufacturing Industries

Through the above combined, it can be seen that the automobile manufacturing industries in China and Germany are affected by their unique cultural factors in KM, and these cultural differences have shaped the different practices of the two countries in knowledge creation, sharing, storage, and application, and we look at

the impacts of the different cultural factors on the automobile manufacturing industries in the two countries respectively:

3.2.1 Cultural Influences on China's Automobile Manufacturing Industry

Relationship orientation (relational): Chinese culture emphasizes interpersonal relationships and networks (i.e., "relationships"), which is reflected in KM by relying on strong personal relationships to facilitate knowledge sharing and transfer. Informal communication channels play an important role in knowledge flow (Demlehner et al. 2021).

Collectivism: Collectivist tendencies lead to a greater tendency for employees to work in teams and share knowledge, but at the same time may lead to individuals being less likely to initiate innovative ideas to avoid conflicting with the team's viewpoints.

Hierarchy: In a more hierarchical corporate culture, knowledge sharing may be hindered because subordinates may be reluctant to communicate information, especially critical or negative feedback, to their superiors.

Rapid Adaptation and Change: Flexibility and the ability to quickly adapt to changes in the market in Chinese corporate cultures help to quickly absorb and apply new knowledge, especially in areas of rapid technological advancement such as electric vehicles and smart internet vehicles (Taherdoost and Madanchian, 2023).

3.2.2 Cultural Influences in German Automotive Manufacturing

Structured and standardized: German corporate culture favors highly structured and standardized processes, which promotes the formalization and standardization of KM and helps to create, store, and share knowledge efficiently.

Quality and Precision: German engineering culture emphasizes quality, precision, and reliability, which is reflected in KM by high requirements for knowledge quality and strict control of knowledge creation and application processes (Ammal et al. 2021).

Risk aversion: The risk aversion tendency in the German culture may lead to more caution in knowledge innovation and trying out new methods, but it also implies more thorough evaluation before adopting and applying new knowledge.

Long-term planning and continuous improvement: The emphasis on long-term planning and continuous improvement in German corporate culture supports the emphasis on long-term knowledge accumulation and continuous learning in KM.

Based on this we integrate and compare the two and can find the different utility of cultural factors in the following three main aspects for KM in the automotive manufacturing industry in the two countries:

1. Knowledge sharing: In Germany, formal structures and processes promote systematic knowledge sharing, while in China, informal interpersonal relationships and networks play a more important role in knowledge sharing (Grum, 2020).
2. Knowledge innovation: The risk-averse tendency of German firms may lead to a cautious attitude towards knowledge innovation, whereas the rapid adaptability and ability to change of Chinese firms help to absorb and apply new knowledge quickly, especially in fast-changing markets and technologies (Uludağ et al. 2019).
3. Organizational structure: The hierarchical structure in the German automotive manufacturing industry may lead to vertical barriers in knowledge flow, while the hierarchical system in China may have an impact on knowledge flow both horizontally and vertically.

4. Conclusion

This study examines the impact of AI on KM in the automotive manufacturing industry in different cultural contexts in China and Germany. A comparative analysis of the Chinese and German automotive manufacturing industries provides new insights into understanding the impact of AI on KM in different cultural contexts and offers suggestions for KM practices in multinational enterprises in the context of globalization. The paper aims to emphasize the importance of adopting and promoting new technologies to understand and consider cultural factors. The study found that AI in both countries facilitated knowledge collection, analysis, and sharing, but the specific practices and ways of application differed. In China, automotive companies have shown a tendency to

adopt new technologies quickly and are very inclusive of new things, which is one of the reasons why Chinese-branded vehicles have gained international recognition in recent years. However, new technologies also bring new challenges, and the protection and management of digital knowledge is urgent. In Germany, automotive companies are adopting AI technologies with a greater focus on systematic and structured processes, reflecting their emphasis on quality and accuracy. This promotes the rigor and reliability of KM in Germany, in addition to the challenges it faces, such as increasingly stringent environmental regulations, the rise of electric vehicles, and global supply chain issues.

Based on the cultural specificities of China and Germany, then, we offer the following advice: For Chinese companies, it is important to focus on IP management and establish a sound legal and policy framework to support continuous innovation and technology development. German companies, on the other hand, can introduce more mechanisms to promote cross-functional cooperation and knowledge sharing to improve the organization's innovation capability and market responsiveness; on the other hand, they can encourage open innovation and external cooperation, pay attention to environmental regulations, and utilize external knowledge resources to strengthen the competitiveness of their enterprises. We believe that both Germany and China will have better development in the automotive industry. But while developing the automotive industry it is important to focus on understanding how different cultural backgrounds understand the use of AI.

Cost Learning as a Knowledge Management Tool in the Process Of Building the Competitiveness of Logistics Enterprises

Sylwia Łęgowik-Świącik and Joanna Kadłubska
Czestochowa University of Technology the Faculty of Management, Poland

s.legowik-swiacik@pcz.pl
joannakadlubska1@interia.pl

Abstract: This article contributes to research on the factors building the competitiveness of enterprises, taking into account knowledge management processes, by deepening the understanding of cost learning processes. The cost learning construct is a knowledge management tool that allows for searching for new areas for building the competitiveness of enterprises. Cost learning processes are particularly important in logistics companies due to the service-oriented nature of their operations. Cost learning in building the competitive advantage of logistics enterprises requires the identification of factors building their competitiveness. Therefore, considering the current state of research and experience in the field of cost learning in building the competitive advantage of enterprises, the objective of this publication has been to understand and explain the relationships between cost learning and the factors building the competitiveness of logistics enterprises. To achieve the assumed objective, the following research methods were used: critical literature analysis, survey questionnaire and Pearson correlation analysis. The empirical research was conducted on a sample of 100 enterprises. The research conclusions suggest that building competitiveness should take into account the selection of strategic factors building the competitiveness of enterprises, identified on the basis of knowledge management processes that take into account cost learning. The issue of cost learning in building the competitive advantage of logistics enterprises is important and up-to-date due to its impact on strategic decision-making in these enterprises.

Keywords: Cost Learning, Knowledge Management, Competitiveness of Enterprises

1. Introduction

The development of enterprises in a competitive environment depends on the selection of strategic goals, design, implementation, and execution of the strategy. Therefore, making the right decisions regarding building competitiveness requires the implementation of knowledge management tools that will allow for the correct diagnosis of the current state of the enterprise and the indication of directions for its further development. Cost learning processes are an important knowledge management tool since they allow for searching for new areas for building the competitiveness of enterprises. Cost learning processes are particularly significant in logistics companies due to the service-oriented nature of their operations. Logistics companies are organizational units specializing in the implementation of activities such as transport, logistics, forwarding, warehousing, as well as additional activities such as reloading, handling, packaging, and labeling (Brah, Ying Lim, 2006). This definition emphasizes the specificity of operations of logistics companies, which means that they must have specific elements of assets and liabilities necessary to conduct business activities by such entities. This means that logistics companies operating in a competitive market are focused on developing strategies to take advantage of market opportunities (Lin, Ho, 2011).

Cost learning is a knowledge management tool in the context of building the competitiveness of logistics companies, as it allows them to identify and analyze key areas in which they can reduce operating costs, without negatively affecting the quality of services. Through cost learning, logistics companies are able to better understand where and how they can introduce innovation to reduce costs and at the same time increase the value of the services they offer. Moreover, cost analysis and learning on its basis helps logistics companies identify potential operational and financial risks and develop strategies to minimize them. Cost knowledge allows logistics companies to make more informed strategic decisions. This means that logistics companies can use cost information to plan long-term development, invest in new markets or technologies, which directly affects their competitive position. However, the adaptability of logistics companies, especially in terms of the geopolitical situation in Eastern Europe, is limited and does not guarantee obtaining a sustainable competitive advantage. Therefore, cost learning processes are becoming more and more important, as they enable flexible adaptation to customer needs. Hence, when considering the current state of research and experience in the field of cost learning in building the competitive advantage of enterprises, the objective of this publication has been to understand and explain the relationships between cost learning and the factors building the competitiveness of logistics enterprises. To achieve the adopted objective, the structure of the article has been divided into two main parts. In the first part of the article, theoretical one, the competitive strategy based on cost leadership is discussed, pointing to cost learning processes in logistics companies in counterpoint. Then, the

factors building the competitive advantage of logistics enterprises in the context of cost learning are identified. The second part of the article is the presentation of the results of the empirical research, including the description of the research methodology applied. The discussion and summary present and discuss the results of the empirical research, including the conclusions with some practical implications.

2. Theoretical Foundations for Cost Management and the Implementation of the Cost Leadership Strategy

Searching for new areas of cost management and the implementation of the cost leadership strategy is the result of permanent changes occurring in the endogenous and exogenous environment of modern enterprises. In the literature on the subject, the cost management process includes making decisions related to planning, identification, analysis, evaluation and control of activities connected with the use of resources in the enterprise's operations (Kaplan, Cooper, 1998). However, the critical analysis of the presented approach to the definition of cost management raises the question whether it is really a process that allows for learning costsin the enterprise? The cost management process implemented in enterprises often results in cost reduction, which allows lower prices, which leads to an increase in sales and profitability of the business conducted (Zengin, Ada, 2010). This means that the driving factor of the cost management process is decisions that reflect the choice of one of the possible courses of action in the given situation (Coeurderoy, Durand, 2004). However, it should be noted that when new competitors appear on the market, companies should modify not only the cost management process. In order to acquire new knowledge about costs, operational activities should be reoriented, which will allow for generating new revenue streams as a result of cost learning (Banker, et al., 2018). Conducting the cost management process aimed at creating value may also prove problematic (Kulmala, et al., 2002). When implementing cost management processes, it should be remembered that customer needs and expectations are changing (McNair, et al., 2001). Therefore, the cost management process should strengthen the current value creation or enable the expansion of the current scope of activity through diversification. The idea of managing company costs is also criticized for the extermination of costs, the construction of a strategy based mainly on financial measures and the issue of detaching managers' remuneration from the increase in the value of the company (Henri, et al., 2016). This type of situation can be improved by striving to increase profitability while controlling costs and optimizing the capital structure in order to reduce the cost of capital.

In this context, the cost leadership strategy is important in the cost management process if it leads to learning how to achieve higher prices, lower costs, and greater sales (Valipour, et al., 2012). This means that the cost leadership strategy should take into account the correct relationships between strategic resources, customers and value creation (Hamel, 2001). The cost leadership strategy should be related to strategic resources through the configuration of unique activities, resources and competencies the task of which is to support the implementation of strategic goals (Baroto, et al., 2012). If the cost leadership strategy remains in compliance with the customer, it provides benefits, thus creating, on the one hand, a combination of customer relationships, and on the other hand, it is a point of connection between the company and the customer (Tanwar, 2013). It is worth noting that the cost leadership strategy, while being related to value creation, determines the efficiency of the business conducted (Nandakumar. et al., 2012), increasing the ability to create profit.

However, it should be emphasized that the literature on cost management and the implementation of the cost leadership strategy in logistics companies, especially in terms of the geopolitical situation in Eastern Europe, is fragmentary and dispersed. The current state of knowledge in the field is characterized by methodological diversity. The lack of in-depth theoretical research in this field results in few attempts to explain the relationships between cost learning and factors building the competitiveness of logistics enterprises. The above arguments led to an attempt at theoretical analysis and empirical research to fill the identified gap by deepening the understanding of the cost learning process and the mechanisms underlying it.

3. Competitive Strategy Based on Cost Leadership and the Process of Cost Learning in Logistics Enterprises

The competitiveness of enterprises is the basic concept characterizing modern economies, it is the sustainable ability to design, produce and sell products the prices of which, as well as quality and other values are more attractive than the corresponding products offered by the competitive environment. The competitiveness of enterprises combines not only specific product features but can also be perceived through the prism of competitiveness in terms of available resources (financial, human, material, intellectual) (Nikolova, et al., 2017). All the above features of competitiveness increase the company's potential and reduce its operating costs

(Stonehouse, Snowdon, 2007), which positively affects product prices and the level of profits achieved by the company. In all theories regarding the competitiveness of enterprises, strategy plays a key role. The most famous concept in the literature is the concept of competitive advantage by M.E. Porter (Porter, 2000). Its basis is the search for sources of competitive advantage in individual economic sectors in which enterprises operate.

The competitive advantage strategies formulated by ME Porter are universal and can also be used by logistics companies. M.E. Porter distinguishes three competitive advantage strategies (cost leadership, differentiation, and focus) (Porter, 2003) but the cost leadership strategy is essential in the context of learning costs by logistics companies. This is due to the fact that placing emphasis on competing based on a leading position in terms of total costs in this strategy allows logistics companies to obtain the status of a leader in the sector of logistics services in relation to the level of generated costs. The cost leadership strategy is a bit of a challenge for logistics companies (Chluska, 2023) since it allows for achieving a relatively high market share, provided that logistics companies are able to maintain a low level of operating costs, otherwise they will be forced to look for alternative types of a competitive advantage (Porter, Magretta, 2014). The benefit of implementing the cost leadership strategy for logistics companies is the ability to generate higher profits. Additionally, logistics companies can benefit from flexibility in terms of services provided and the ability to gain a favorable position in the market, which benefits may result from the implementation of the cost leadership strategy, as presented in Figure 1.

Figure 1: Benefits of the cost leadership strategy in logistics enterprises

Source: Porter, M., Magretta, J. (2014). Strategy and Competition: The Porter Collection (3 Items). Harvard Business Review Press.

The application of the cost leadership strategy must consider cost learning processes. Cost learning can take place by observing the experience curve (Yelle, 1979), which describes the phenomenon of the decrease in unit costs of manufacturing products as the total production volume increases (Li, et al., 2015). The idea of the cost learning process assumes that the more units of a product the enterprise manufactures, the more it learns about the production process, which allows for the optimization and improvement of operations, due to which it is possible to reduce the level of unit costs of products and thus improve performance. Cost learning within the experience curve may consist in cost reduction. In this case, with each doubling of cumulative production, a decline in unit costs can be observed (Gray, et al., 2009). This is the result of increased efficiency, better use of resources, innovation in processes, as well as employee skills and experience (Jaber, et al., 2008) . This means that the greater the cumulative production, the greater the possibility of cost reduction. This effect is noticeable since companies learn how to minimize waste, improve processes, and increase productivity (Yu, et al., 2020). Through cost learning, logistics companies can identify ways to improve processes such as inventory management, transportation, warehousing, and customer service (Zhu, et al., 2021). By using modern technologies and automating processes, logistics enterprises can help reduce operating costs and increase performance. Moreover, as the volume of freight and routes handled increases, logistics companies can reduce operating costs, which contributes to the implementation of the cost leadership strategy.

To sum up, it is worth emphasizing that cost learning is an important knowledge management tool in the implementation of the competitive strategy based on cost leadership. It allows for systematic cost reduction due to greater production and experience gained. Enterprises, especially those in the logistics industry, can use cost learning to optimize their operations and increase competitiveness through the cost strategy. However, it is important not to neglect other key aspects of the business such as quality, innovation, and customer service. This is possible to achieve when the functioning of logistics companies is based on a low-cost position implemented in a strategic segment, or on high differentiation of services, or by applying both solutions.

4. Identification of Factors Building the Competitive Advantage of Logistics Enterprises in the Context of Cost Learning

The understanding of cost learning processes in logistics companies should be determined by a selected set of factors (Figure 2), which should include areas such as (Jaber, Saadany, 2011):

- introducing changes in the company's competitive strategies regarding key resources,
- acquiring knowledge in the company by creating new organizational practices,
- learning in the enterprise by searching for and implementing good practices,
- taking advantage of opportunities and making innovative decisions,
- diversification of activities as a factor determining the market position of the enterprise,
- taking actions to implement positively assessed opportunities.

Figure 2: Factors building the competitive advantage of logistics enterprises in the context of cost learning.

Source: Jaber, M.Y., Saadany, A.M., (2011), An economic production and remanufacturing model with learning effects, Int. J. Prod. Econ. 131 (1).

Introducing changes in competitive strategies in terms of key resources of logistics companies should contribute to distinguishing a given company from competitors (Tomski 2014). Therefore, logistics companies ought to focus their activities, on the one hand, on cost learning by introducing changes in terms of cost rationalization, as well as the selection of key resources, and on the other hand, on searching for new sources of revenue (Ranjith, 2016). The changes should also consider relationships with key customers and the scope of services and products provided (Bumane, 2018).

Acquiring knowledge in the enterprise by creating new organizational practices and learning through searching for and implementing good practices is a manifestation of strategic innovation (Kramer, Porter, 2011). Therefore, strategic innovation is reflected in taking actions aimed at knowledge acquisition and organizational learning. It is worth noting that strategic innovation, through acquiring knowledge and cost learning, contributes to changing the business model and maintaining the adopted level of competitiveness of logistics enterprises (Dyduch, 2019).

Taking advantage of opportunities and making innovative decisions is a sign of strategic entrepreneurship, which, however, requires the implementation of the process of planning and learning costs by logistics companies for the idea to be implemented. Therefore, strategic entrepreneurship should not only enable taking advantage of opportunities and making innovative decisions (Kaplan, Norton, 2006), but also allow for planning new ventures and taking actions to implement positively assessed opportunities in the environment (Lepak, et al., 2007).

The diversification of activities as a factor determining the market position of the enterprise is the factor of the company's position in the market. The factors of positioning a logistics company on the market should consider professionalism and flexible behavior, as they determine the market position of the company (Mangan, 2004). Therefore, the diversification of activities of the logistics company (Skowron-Grabowska, 2023) ought to take into account cost learning processes, since they determine the company's ability to engage in new areas of operation, allowing for acquiring new markets and new skills, abilities and competences (Kim, Mauborgne, 2017).

Taking actions to implement positively assessed opportunities is an important factor determining the company's predispositions to compete in the market. The identification of the company's predispositions to compete on the market of logistics services should take into account: high quality of the services provided, good price-quality ratio of the services provided and low costs (Otola, Grabowska, 2020). This means that taking actions to implement positively assessed opportunities requires the implementation of cost learning processes, carried out by assessing the ability of logistics companies to conduct business and compete in the market, considering internal and external factors resulting from the market environment.

Summarizing the above considerations, it can be noted that the selected set of factors for implementing cost learning processes in logistics enterprises constitutes a conceptual instrument of strategic management, acting as a template for the cost learning process. Its advantage is the primacy of strategic choices, which causes that managers' attention is focused on strategic factors building the competitiveness of logistics enterprises, enabling, on the one hand, cost reduction and, on the other hand, achieving a competitive advantage (Stępień, 2022). The correctly selected set of factors needed to implement cost learning processes constitutes the basis for developing a detailed cost learning plan in logistics companies. This means that logistics companies should choose a set of selected factors to implement cost learning processes that will allow them to specify the most critical management areas while considering the company's strengths and weaknesses against the background of existing and identifiable opportunities and threats.

5. Research Methodology and the Structure of the Research Sample

The empirical research was quantitative in nature. The selection of the research sample was purposeful. The research was carried out using - CATI Computer Assisted Telephone Interview (Hair, et al., 2014). The applied research method has both limitations and advantages. The limitations include difficulties associated with examining areas that are complicated for the respondent and the complexity of the process of conducting research consisting of many questions (Vogel, Koutsombogera, Costello, 2020). The advantages of using the CATI method when achieving the research objective include: systematicity of stages occurring during the research, obtaining high-quality results in a short period, integrated data collection flow (Oláh, et al., 2019) . To accomplish the research objective, a survey questionnaire was used, which was verified in the presence of the interviewer. The questions used a five-point Likert rating scale. The respondents were asked to answer to what extent they agreed or disagreed with each statement. Answer 5 meant "I completely agree", 4 - "I agree", 3 - "I don't know", 2 - "I disagree", and 1 - "I completely disagree". The structure of the research sample is presented in Figure 3.

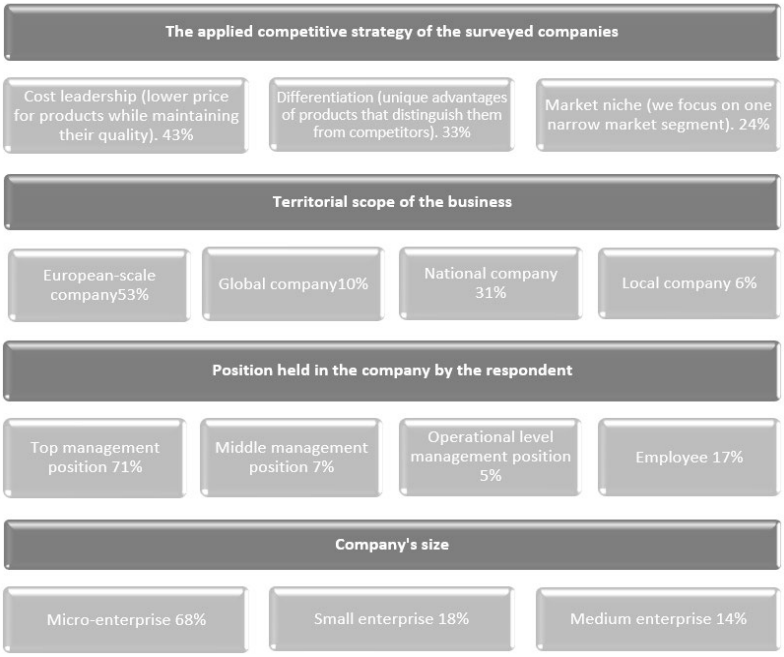

Figure 3: Structure of the research sample

Source: Own study based on the conducted research.

The population of the surveyed enterprises consisted of 100 micro, small and medium-sized logistics enterprises operating in Poland. When analyzing the structure of the research sample, it is noted that most of the research covered enterprises using the cost advantage strategy (43%). Considering the territorial scope of their activities, the vast majority of the surveyed entities were European-scale enterprises (53%). Most of the survey respondents held top management positions (71%). When considering the size of the business conducted and the size of the enterprise, it should be noted that the vast majority of the surveyed entities were micro logistics enterprises (68%).

6. Results of the Conducted Empirical Research

In order to understand and explain the relationships between cost learning and the factors building the competitiveness of logistics enterprises, the Pearson correlation coefficient was used, which takes the values in the range < -1.1 >. The tested relationships were additionally confirmed by a significance test (at the level of $\alpha = 0.05$). Table 1 presents the research results obtained using the Pearson correlation matrix for introducing changes in the company's competitive strategies and the factors determining the company's competitiveness, i.e. low costs.

Table 1: The relationship between introducing changes in the company's competitive strategies (changes in the set of key resources) and the factor determining the company's competitiveness (low costs).

Pearson correlation matrix	Low costs as a factor determining the company's competitiveness
Introducing changes in the company's competitive strategies in terms of key resources	0.75

Source: Own study.

When analyzing the data presented in Table 1, it is noted that there is a strong positive relationship between introducing changes in the company's competitive strategies regarding key resources and the factors determining the company's competitiveness, such as low costs (0.75). Logistics companies are aware that low costs have a positive impact on their competitive position in the market. Additionally, the surveyed companies are changing the set of key resources. As a result, competitors' strategies change, making them more attractive in the market. Table 2 shows the correlation between strategic innovation manifested in acquiring knowledge in the surveyed enterprises and low costs.

Table 2: The relationship between acquiring knowledge in the enterprise by creating new organizational practices and low costs.

Pearson correlation matrix	Low costs as a factor determining the company's competitiveness
Acquiring knowledge in the enterprise by creating new organizational practices	0.75

Source: Own study.

Based on the results presented in Table 2, it can be concluded that in the surveyed enterprises there is a strong positive relationship between strategic innovation in the process of acquiring knowledge by creating new organizational practices and low costs as a factor determining their competitiveness (0.75). Creating new organizational practices can increase the efficiency of enterprises and contribute to the reduction of waste, which may translate into lower operating costs. Table 3 shows the correlation between the input variables of strategic innovation and the factor determining the economic competitiveness of the surveyed enterprises, i.e. low costs.

Table 3: The relationship between learning in the company by searching for and introducing good practices and low costs.

Pearson correlation matrix	Low costs as a factor determining the company's competitiveness
Learning in the company by searching for and introducing good practices	0.71

Source: Own study.

When considering the results presented in Table 3, it can be concluded that there is a strong positive relationship between strategic innovation in the process of searching for and implementing good practices and low costs treated as a factor determining the competitiveness of micro, small and medium-sized logistics enterprises (0.71). The surveyed companies are searching for and implementing good practices and at the same time analyzing the level of decision-making costs. Table 4 shows the correlation between the factors determining the company's competitiveness, such as low costs, and taking advantage of opportunities and making innovative decisions.

Table 4: The relationship between taking advantage of opportunities and making innovative decisions and low costs.

Pearson correlation matrix	Low costs as a factor determining the company's competitiveness
Taking advantage of opportunities and making innovative decisions	0.67

Source: Own study.

When analyzing the research results presented in Table 4, it is noted that in the case of the logistics enterprises studied, there is a strong positive relationship between the factor determining the company's competitiveness, such as low costs, and the ability to seize opportunities and make innovative decisions, which are a manifestation of strategic entrepreneurship (0.67). These enterprises are aware that low costs are an important factor in building the competitiveness of enterprises, and taking advantage of opportunities and making innovative decisions increases the attractiveness of the sector. As a result, companies become much more competitive in the market. Table 5 presents the research results obtained using the Pearson correlation matrix of the input variables for business diversification and low costs.

Table 5: The relationship between the diversification of activities and low costs in the surveyed enterprises.

Pearson correlation matrix	Low costs as a factor determining the company's competitiveness
Diversification of activities as a factor determining the company's market position	0.67

Source: Own study.

The conducted research presented in Table 5 indicates that in the case of the logistics companies surveyed, there is a strong positive relationship between low costs as the competitiveness factor and the diversification of activities treated as a factor determining market position (0.67). Micro, small and medium-sized logistics enterprises are becoming more competitive by maintaining low operating costs, which allows them to offer their products or services to customers at lower prices. However, the diversification of activities allows them to offer a wider catalog of services, which makes them more attractive to their clients. Table 6 shows the correlation between the factors determining the company's competitiveness, manifested in low costs, and strategic entrepreneurship, consisting in positively assessed opportunities resulting in taking actions aimed at their implementation.

Table 6: The relationship between taking actions to implement positively assessed opportunities and low costs.

Pearson correlation matrix	Low costs as a factor determining the company's competitiveness
Taking actions to implement positively assessed opportunities	0.60

Source: Own study.

Based on the correlation research, a strong positive relationship (0.60) is noted between the factor determining the company's competitiveness in the form of low costs and strategic entrepreneurship implemented through positively assessed opportunities resulting in taking actions aimed at their implementation (Table 6). This may indicate that the surveyed enterprises, while implementing a strategy focused on low costs, also take actions aimed at implementing positively assessed opportunities. Each positively assessed opportunity is a motivating factor to act, and aiming at low costs in relation to positively assessed opportunities increases the competitiveness of the surveyed enterprises.

7. Discussion

When considering the results of the obtained research aimed at understanding and explaining the relationships between cost learning and the factors building the competitiveness of logistics enterprises, it is noted that there are strong positive relationships. When analyzing strong positive relationships in relation to cost learning processes through the implementation of the factors such as: introducing changes in competitors' strategies in terms of key resources, or taking advantage of opportunities and making innovative decisions, it can be concluded that the surveyed logistics companies are aware of the potential of their knowledge and use opportunities to build their competitiveness. A similarly strong positive relationship exists between low costs and acquiring knowledge by creating new organizational practices, as well as learning through searching for and implementing good practices, which may translate into a long-term process requiring the management staff to have knowledge about the customer to provide them with services of high quality and acceptable prices. Based on the results obtained, it can be concluded that there is a strong positive relationship between low costs and the diversification of activities, which is a factor determining the market position of the company, as well as taking actions to implement positively assessed opportunities. This may mean that the surveyed logistics companies rationalize their cost structure based on positively assessed opportunities, which will allow these entities to become more competitive by maintaining low operating costs to offer their products or services to customers at lower prices.

Summarizing the results of the research procedure in the field of examining the relationship between the factors building the competitiveness of the surveyed logistics enterprises, it should be noted that the low-cost strategy is characteristic of logistics enterprises which, while conducting their operations, on the one hand, take actions aimed at learning the company's costs, and on the other hand, identify factors building competitiveness, striving to increase sales revenues, which has a positive impact on the economic results of the surveyed enterprises.

8. Conclusions

To sum up the presented considerations, it should be stated that they allow for the following conclusion that, in a situation of environmental variability, the factors that highlight the consistency between the ability to identify factors of competitive advantage and the ability to initiate changes undertaken in the area of conducted business activities are of great importance. The following conclusions emerge from the conducted research:

- the surveyed logistics companies build competitive advantage based on cost learning processes, which constitute a knowledge management tool, understood as a long-term process, requiring the management staff to have knowledge about the product and the customer,
- when assessing the conditions for building the competitiveness of logistics companies, it can be noted that the processes of learning the costs of strategic innovation of the surveyed enterprises are positively influenced by factors building their competitiveness, which may indicate an increase in the awareness of the management staff of logistics industry enterprises regarding the potential associated with having knowledge.

The business environment of logistics companies is dynamic and requires constant adaptation to new conditions. Therefore, cost learning becomes an element of building the competitiveness of logistics companies that allows them to quickly respond to market changes and meet competitive challenges. Moreover, cost learning, which is a knowledge management tool in logistics companies, enables not only cost optimization, but also innovation, strategic decision-making, and flexible response to changes, which is the basis for building competitiveness in the logistics services market. In conclusion, the considerations presented in this study allowed for achieving the intended objective. The issue of understanding and explaining the relationship between cost learning and the factors building the competitiveness of logistics enterprises is important and up-to-date due to its impact on strategic decision-making in these enterprises.

The recommendation for the surveyed logistics companies is to implement cost learning processes to build competitive advantage and improve competitiveness. The accurate identification of factors building competitiveness allows for changes in competitive strategies and should lead to distinguishing the company from its competitors.

Ba in Projects and Programs: Creating the Habitat That Nurtures Knowledge

Tiziano Villa
PMP®, PMI-ACP®, PMI®-DASSM®, The Project Management Lab®, Monza, Italy

tiziano.villa@pmlab.it

Abstract: By their nature, projects and programs are temporary and innovative initiatives, crowded by knowledge workers who are called to interact, discuss, collaborate, in an ad-hoc way of working due the uniqueness of the projectized environment. Because of this, one of the main challenges for project and program managers is "how to address the knowledge dimension". In other word "how to create the habitat that nurtures knowledge, mainly the tacit one". Creating the right *Ba* is the turning point. Of course, during the project/program life cycle, many and different *Ba* must be created and lived. This paper is aimed at discussing in a very practical way a collection of projectized *Ba*. They are: *Ba* for project risks identification according to a predictive approach; *Ba* for project sprint retrospective according to an agile approach; *Ba* for organizational change readiness in a large program; *Ba* for moving from project delivery to business value. Each *Ba* fosters the engagement of knowledge workers in sharing their tacit knowledge towards the common goal of the project/program. Is your project at risk of colliding with the iceberg of knowledge? Does the tacit knowledge remain in the deep layers of the iceberg? Doesn't the register of lessons learned tell the true life of the project? Aren't project key people engaged in sharing knowledge? This paper can help you.

Keywords: ADKAR®, Benefits Management, Knowledge Creation, Knowledge Workers, Organizational Change Management, Portfolio Management, Program Management, Risk Identification Techniques, Sprint Retrospective, Tacit Knowledge, Value Chain.

1. Sketching the Scene

In 1998 Nonaka and Konno published on California Management Review the paper "The concept of *Ba*". *Ba* is defined as "a shared space for emerging relationships" (Nonaka Konno, 1998). "*Ba* provides a platform for advancing individual and/or collective knowledge. Thus, we consider *Ba* to be a shared space that serves as a foundation for knowledge creation." (Ibidem). *Ba* has become a pillar of knowledge management. In September 2023 at the ECKM – European Conference on Knowledge Management in Lisbon, Prof Konno during his keynote speaker presentation (Konno, 2023) highlighted the still current centrality of *Ba* as "the realm of knowledge, a shared dynamic context in which knowledge creation occurred, a place where individuals share knowledge for a soft alliance focused on innovation" (Konno Schillaci, 2021). No doubt, *Ba* is still today and will remain tomorrow the North Star that guides organizations and individuals to navigate the complex and fascinating sea of knowledge, especially when the waves, the sea currents and the winds of projects and programs must be faced. *Ba* may be considered as a social habitat. Habitat is the natural environment of an organism, the type of place where it can best live and grow. Referring to human relationships, we can depict habitat with the term "Cynefin". *"Cynefin, pronounced ku-nev-in, is a Welsh word that signifies the multiple factors in our environment and our experience that influence us in ways we can never understand"* (Snowden Boone, 2007). The projectized habitat is crowded by knowledge workers that might share their tacit knowledge "on condition that…" but "not regardless". Changing the conditions, changing the results. Conditions refer to the organizational and social habitat within which knowledge workers (i.e. project team members) are asked to meet, clash, confront, perform. According to an organizational perspective, some habitat conditions that, for better or for worse, must be taken in consideration are: project vision and goal, team ground rules, project management plan, monitoring & controlling criteria, work-life integration. If these conditions are recognized, discussed, agreed spending the time and effort it takes, the exchange of knowledge flows naturally. If these conditions are ignored, passively accepted, imposed skimping on the time and effort it takes, the exchange of knowledge ends abruptly. Similarly for the social perspective: on the one hand, high levels of trust, respect, openness foster knowledge sharing; on the other hand, low levels of trust, respect, openness hinder knowledge sharing. Because of this, social habitat is *"the place of our multiple belongings"* (Snowden 2011) that should be well addressed. We can sum-up this scene with a simile: *"knowledge workers are like the cats: it depends which way you brush their fur"* (Villa, 2020). If you pet the cat in the right direction, the cat will purr at you. If you pet the cat in the wrong direction the cat will scratch you. The cat is still the same, but the result is quite different! Thus, let's enter in more details in order to understand how to create the right habitat, that's to say the *Ba* that can nurture knowledge. Particularly, the Originating *Ba* to be understood as *"the world where individuals share feelings, emotions, experiences, and mental models. Originating Ba is the primary Ba from which the knowledge-creation process begins and represents the socialization phase (tacit knowledge sharing). Physical, face-to-face experiences are*

the key to conversion and transfer of tacit knowledge" (Nonaka Konno 1998). Of course, different projectized *Ba* should be designed and implemented moving across management approaches (i.e. predictive/waterfall vs. adaptive/agile), ontological levels (i.e. project vs. program vs. portfolio), ways of working (physical proximity vs. remotely).

2. *Ba* n.1 – Project Risk Identification – Predictive Approach – Physical Proximity

PRM - Project Risk Management bases much of its effectiveness on the process. "Identify Risks". The key benefit of this process is *"the discovery and documentation of existing individual risks and the sources of overall process risk"* (PMI, 2021). This way the project team can use details and insights coming from identified risks for prioritizing them and developing appropriate risk responses. The challenge is "how to identify a huge, meaningful and disruptive amount of project risks?", going beyond a partial, trivial and generic list of risks. In other words, moving from the small visible top of the iceberg to the large submerged part of the iceberg. This challenge requires to share tacit knowledge that project team members own about project risks. Therefore, a *Ba* focused on risk identification should be carefully designed and implemented. A risk identification meeting entails a *Ba* with these ten characteristics: 1) Participants: a small group (a maximum of 10 people), project manager and all project team members in case of a small project, project manager and members of PMT – Project Management Team in case of a large project. 2) Duration: two hours. 3) Location: a large room for exclusive use where we can move freely and with a large wall on which we can stick post-it notes, one large table, no chairs, everyone standing and never sitting (of course, special accommodations as needed). 4) Materials: a set of 12 packets of post-it notes in 6 different colours (2 per colour), a set of 10 pencils, a set of 4 different colour markers, laptops and similar are forbidden, no risk checklists. 5) Comfort items: water, soft drinks, candies, snacks for free. 6) Input: poster with the description of the project charter hanging on the wall. 7) Agenda: Opening session (how will we work together in a safe, open, collaborative way?) 10'; Crawford Slip & Affinity Diagramming working session 20' with post-it of colour yellow; Assumption Analysis working session 20' with post-it of colour green; Stakeholder Analysis working session 20' with post-it of colour orange; RBS – Risk Breakdown Structure working session 20' with post-it of colour pink; Risk Syntax final working session 20' with post-it of colour azure; Closing session 10'. 8) Operating rules: during each working session participants discuss and write risks on post-it notes; at the end of the working session participants stick post-it notes on the wall clustering them by categories (each category is written on a post-it of colour red); during final working session participants rewrite risk descriptions according to a formalized risk syntax. 9) Final Result: the portfolio of project risks ordered by categories (i.e. Technology, Customer, Sellers, Organization, Policies, Skills, etc.), written on post-it notes, formalized with a formal syntax, codified by ID, hanging on the wall. A separated category list of risks that need to be better understood. 10) Takeaways and Next Steps: selfie of participants with the wall with risks in the background; let's congratulate ourselves on the quantity and originality of the risks we have identified; lessons learned from the meeting (pros and cons table); action plan for risk analysis (vital few vs. trivial many) and risk responses (focus on priority risks and risk ownership). This type of *Ba* exploits risk identification techniques like the episodes of a knowledge exploration game.

3. *Ba* n.2 – Project Sprint Retrospective – Adaptive Approach – Remotely

Sprint Retrospective is one of the four agile ceremonies formally established by Scrum and generally suggested by other agile methods. *"The purpose of the Sprint Retrospective is to plan ways to increase quality and effectiveness. The Scrum Team inspects how the last Sprint went with regards to individuals, interactions, processes, tools, and their Definition of Done. Assumptions that led them astray are identified and their origins explored. The Scrum Team discusses what went well during the Sprint, what problems it encountered, and how those problems were (or were not) solved. The Scrum Team identifies the most helpful changes to improve its effectiveness"* (Schwaber Sutherland, 2020). Sprint retrospective is based on the twelfth principle of the Agile Manifesto: *"at regular intervals, the team reflects on how to become more effective, then tunes and adjusts its behavior accordingly"* (Authors of agile manifesto, 2001). Sprint retrospective can be performed physically in presence or remotely. In both cases, sprint retrospective requires a live synchronous interaction. Sprint retrospective is a powerful opportunity for sharing knowledge according to a continuous improvement perspective. However, sprint retrospective might prove to be completely unproductive with participants pretending to discuss but not going into things and simply exchanging obvious considerations. In short: "much ado about nothing!". Thus, sprint retrospective requires its own *Ba.* Nowadays, the most part of agile projects is based on virtual teams, geographically distributed. Because of this, the suggested *Ba* should be organized as follows: 1) Video Energy: open the meeting with a 3' music video that brings people into the right mood. 2) Initial

retrospective declaration: “regardless of what we discover in this retrospective, we know and firmly believe that each of us did the best job possible and made available everything we knew, our skills and abilities, the resources available at that moment for the specific project situations addressed"; show this declaration on the first page of the collaboration tool (i.e. Mentimeter). 3) Our ground rules: “Let's try not to interrupt each other; We accept other people's opinions, as they are neither right nor wrong, but they are opinions as such; Everyone speaks for themselves and not in the name and on behalf of others; We pledge to listen to whatever a person has to say, before responding; Let's decide in advance what is important to say to justify the time we will take; There are no set-ups behind and at the expense of someone present in the meeting; Let's feel free to intervene whenever we feel like it, we are not obliged to contribute in every step of the retrospective, to say something at all costs, to carry out all the assigned tasks”. Show these rules on a Mentimeter page. 4) Preliminary safety secret ballots: “In this session, how comfortable are you in being able to openly say what you think needs to be said?”; scale (from 5=safe to 1=unsafe): 5- No problem, I feel like saying everything openly, 4- I feel like saying most things but some things will be difficult to say, 3- I feel like sharing some things, but I will keep others to myself, 2- I intend not to say much. Mostly I'm going to leave room for others, 1- I will smile, I will say that everything is ok, I will agree with whatever comes out of the discussion, but I will in no way allow others to understand what I really think.; use a Mentimeter Scales Page to collect secret ballots. 5) Overall perception: “how do you think this sprint went?”, score from 5 = very well to 1 = very bad, scores do not need to be justified; use a Mentimeter Scales Page to collect scores. 6) Sprint strengths: “what worked or went well and why? do it again!”; everyone writes his/her considerations on a Mentimeter Open Ended Page, then general discussion and insights written on a similar Mentimeter page. 7) Sprint Weaknesses: “what caused problems, failed to work properly or did not go well and why? don’t do it again!”; everyone writes his/her considerations on a Mentimeter Open Ended Page, then general discussion and insights written on a similar Mentimeter page. 8) Sprint Improvements: “what can we done differently in the next sprint to improve our way of working (processes and/or behaviors) and overcome the problems incurring previously? do differently next time!”; everyone writes his/her considerations on a Mentimeter Open Ended Page, then general discussion and insights written on a similar Mentimeter page. 9) Improvement plan: for each improvement action a member of the agile team takes the ownership on voluntary basis; avoid to force ownership; appreciate taking ownership. 10) Warnings: last Mentimeter Open Ended Page collects alerts: “hey guys, let’s pay attention to this …, in order to gain the benefits of our sprint retrospective!”. This type of *Ba* takes the agile team by the hand and accompanies it along its learning adventure.

4. *Ba* n.3 – Organizational Change Readiness – Program Level - Physical Proximity and Remotely

“Benefits through change”. This is the essence of a program. A program consists of *“related projects, subsidiary programs, and program activities managed in a coordinated manner to obtain benefits not available from managing them individually”* (PMI, 2024). Programs must realize benefits. It can happen only implementing organizational change that supports the transition from deliverables to outcomes. For this reason, program management encompasses a specific performance domain called “Change”. The purpose of this domain is *“to manage program change to improve effectiveness and efficiency of benefits realization, delivery, and sustainment during the program life cycle and after its transition to an organization’s operations”* (Ibidem). This domain applies models, methods and techniques coming from the discipline of “Change Management” defined as *“a comprehensive, cyclic and structured approach for transitioning individuals, groups and organizations from a current state to a future state with intended business benefits”* (PMI, 2013). The conclusion is that program management and change management are strictly overlapped disciplines. The starting point of an effective program change is the change readiness assessment of recipients (one or more). This assessment *“measures of the reality of the current organization in relation to the future state from two perspectives: organizational systems and structures that need to be improved or will support the change; and the people and culture that are able to support or may resist the change”* (Ibidem). This assessment should be performed just at the outset of the program, in order to understand whether the desired change is viable and at which cost. Imagine a large, expensive and innovative program that must completely renew the company CRM system. The main recipient consists of a sales force of 500 people distributed in four European countries. The new CRM system will totally overturn the way of working and behaviors of the sales force, one year from now. Thus, the question to try to answer now, and not a year from now, is “which is the current level of change readiness of the sales force?”, and consequently “which are the cost of change management required for achieving the necessary level of readiness?”. Change readiness is not declared, it must be elicited. How? With a specific *Ba.* The purpose of this *Ba* is to explore the current level of change readiness of the recipients and not to sell the future outcome. For this reason, recipient should be actively engaged in exploring its level of change readiness and the underlying

reasons. Experiences, insights, perceptions, beliefs, attitudes of people involved in change should be revealed and shared. Therefore, this *Ba* should be designed around the profile of recipient (job description, organizational structures/legal entities to which people belong, geographical distribution, cultural diversities, number of people involved, etc.). These are some key features of this type of *Ba:* 1) Assessment Target: all people of the recipient if small (<30), a selected sample of the recipient if large; mixed sample with different change attitudes (Leading, Supportive, Neutral, Resistant, Hostile) and different legal entities, countries, languages, cultures, in case of a global recipient. 2) Assessment Plan: depending on the profile of the target, organize the assessment activities in person, remotely, or hybrid. 3) 5W1H Change Statement: a brief summary (big picture) highlighting Why the change? What is the change? Who is interested in the change? When the change is expected? Where the change will happen? How the change might be implemented? communicate the statement to recipient through media that fit best. 4) Change Metaphor: ask the target the question: "this change is as if it were..."; invite to answer using figurative language based on metaphors, similes, hyperboles, images, symbols, oxymorons, idioms, aphorisms, titles of movies/songs, etc.; collect and share the figurative answers without judging them. 5) You and the Change: ask the target the question: "how do you see yourself in this process of change?" according to the ESVP categories (Explorer, Shopper, Vacationer, Prisoner); collect, categorize and share the answers without judging them. 6) Resistance to change: starting from results of previous steps that depict the "as-is readiness" (low – high) explore the underlying causes of resistance; use the ADKAR® model for the diagnosis: Awareness of the need to change ("Have stakeholders really understood why they have to change?" An unaware stakeholder doesn't commit and promote change), Desire to participate and support the change ("Do stakeholders see gains for them deriving from the requested change?" A stakeholder without benefits and/or with disbenefits doesn't commit and promote change), Knowledge on how to change ("Do stakeholders know how to implement the required change?" A stakeholder that doesn't have previous experiences and/or is not organized to put in place the change, doesn't commit and promote change), Ability to implement the change, Reinforcement to keep the change in place ("Do stakeholders have the capacity and capability to implement the change?" A stakeholder without the necessary resources in terms of effort and/or skills, doesn't commit and promote change), Reinforcement to keep the change in place ("Are stakeholders able to maintain in place the implemented change?" A stakeholder that, after the extraordinary effort to implement the change, is unable to maintain the change in place, doesn't commit and promote the change). ADKAR® may be applied through different techniques such as brainstorming, focus groups, guided workshops. 8) Change Tales: ask the target to write 50-word tales about situations of change they have experienced in the past; collect and share the tales without judging them. 9) Everything like before! ask the target "what are the pros and cons of maintaining the status quo?"; collect, categorize and share the answers without judging them. 10) Final Thought: close the assessment asking the target to greet us with a final thought that enhances the work done together during the assessment; show the thoughts. This type of *Ba* enables sharing knowledge about change as a normal condition in organizations.

5. *Ba* n.4 – Value Chain – Portfolio level – Physical Proximity

"Do the project right" not necessarily means *"Do the right project".* A delivery compliant with requirements does not automatically generate business value. Because of this, the world of projects is full of "white elephants". Project managers are too often focused on a limited deliverable-oriented perspective. This is fine as all the project team's efforts are concentrated on carrying out the new solution while respecting time, cost and quality constraints. This can work in simple and stable business conditions but not in complex and dynamic business conditions. Sometimes, for program managers too. The concept of Value Chain can avoid this impasse. The Value Chain is circular. It starts from Strategy and ends into Strategy. For example, the strategy of a city may be "to become a best place to live". Strategy breaks down into high-level goals, called Strategic Objectives. For example, "to improve the local economy of the city". A strategic objective can be accomplished through the execution of a Portfolio of specific initiatives (Programs and Projects). For example, the program "Attraction of new businesses" and the project "Business of the year award". Deliverables are tangible artifacts created by an initiative such as a project. For example, "a new business platform for local job search and offer". Outcome is a new organizational state after the transition of deliverables to final users. For example, "80% of local companies and workers regularly use the new job search and offer platform". Benefit is a gain realized by the organization and beneficiaries through portfolio, program, or project deliverables and resulting outcomes. For example, "the city attracts more talents, companies have improved revenues, jobs increased 15% year over year". Finally, benefits create Value, that's to say the net result between achieved benefits and incurred costs. For example, "our city went from fortieth to twenty-fifth place in the Job opportunities National Ranking". Value is evaluated to understand if the strategy worked, should be refined, must be rethinked. Each link of the chain is knowledge-sensitive, in that to be effective, it requires the availability of a wide and multifaceted mix of skills, gained on

field by many roles at different organizational levels. We can focus on the Portfolio link, upward connected with Strategic Objectives and downward connected with Programs and Projects. A portfolio is *"a collection of projects, programs, subsidiary portfolios, and operations managed as a group to achieve strategic objectives"* (PMI, 2017). *"A portfolio exists to achieve organizational and business unit strategies and goals". (Ibidem).* In jargon they say that portfolio is "the bridge between strategy and execution". Therefore, *"a functioning portfolio should be a representation of an organization's intent, direction, and progress at any given moment"* (Ibidem). Building a portfolio entails its own *Ba.* This *Ba* should support portfolio management that must *"balance conflicting demands among portfolio components, allocates resources (e.g., human, financial, assets, and intellectual) based on organizational priorities and capacity, and integrates management principles and sound practices to deliver business value aligned with the strategic objectives"* (Ibidem). Which are the characteristics of a Portfolio *Ba*? Let's analyse them using an example. Imagine we are the BU – Business Unit Europe of a global engineering company. There are similar BUs for other geographic areas. The company provides ad-hoc projects to private and public organizations. The BU is focuses on the Europe portfolio, and the BU Manager (portfolio manager) is accountable for the business results of this portfolio. Portfolio is divided into two main types of components: customer projects and internal projects. The Europe business has grown strongly in the last year. This trend is good and bad at the same time. Good because the pipeline of customer projects is increasing with higher perspective revenue and profit. Bad in that the BU has a limited capacity of resources that can't be increased in the short term. Furthermore, there are some mandatory internal projects that cannot be deferred with heavy penalties from the regulatory bodies. The challenge is "how to balance customer and internal projects according to the limited capacity?". Roles involved are BU Manager (1), Specialist of PMO – Portfolio Management Office (1), projects manager (2) of internal projects, account managers (5) of customer projects The pipeline consists of 2 internal projects and 13 customer projects, for a total of 15 portfolio components. Portfolio *Ba* could work as follows: 1) Portfolio Statement: share a brief declaration of the profile of Europe portfolio. 2) Sell the portfolio component: each of the 7 component requestors (2 project manager and 5 account manager) runs a short presentation of each candidate component (why to invest on this component? what would happen if the component was not activated? Which are the constraints within which the component must be carried out?). 3) Top-down guidelines: recap the BU strategic objectives. 4) Strategic Objectives / Portfolio Components Matrix: use the matrix to discuss and assess whether and to what extent each component supports the achievement of strategic objectives. The matrix provides answers to these questions: A) Which is the component that provides the lowest contribution to objectives? What does this component have to do with the portfolio? B) Which is the component that provides the highest contribution to objectives. What can we do to find the funds for this component? C) Which is the strategic objective least supported by the portfolio components? What other components can we activate to better support this objective? D) Which is the strategic objective most supported by portfolio components? Are all these components necessary for this objective? 5) Components are not for free: each requestor provides and explains the investment required to complete the component; estimated are compared. 6) BU Capacity: assess the available resources (FTE and skills) of the BU, distributed along time periods, for example quarters. 7) Demand /Supply Matrix: provide a big picture, highlighting the gaps over time between demand and supply for each of portfolio resources (i.e. designer, engineer, technical leader, etc.). 8) Balance the portfolio: select a subset of portfolio components which can start in the next time window, for example in the first half of the year, balancing benefits, costs, resources, risks. 9) Component Ownership: agree the person accountable for each component execution. 10) Communicate the project selection: align interested people regarding the selection made and the expected value for the BU. This type of *Ba* unchains tacit knowledge moving from project delivery to business value.

6. Conclusion

Ba is a powerful concept for knowledge creation in projects, programs, portfolios. Many and different are the projectized situations where a well-designed *Ba* can make the difference. This paper has documented four types of *Ba*, moving across management approaches (i.e. predictive/waterfall vs. adaptive/agile), ontological levels (i.e. project vs. program vs. portfolio), ways of working (physical proximity vs. remotely). For each *Ba* specific criteria and steps have been provided for an effective design and implementation. Sponsors, project manager, program manager, technical leader, PMO specialists should become more familiar with *Ba*, in order to unleash the power of tacit knowledge owned by knowledge workers. Indeed, this is a big challenge to cope with, particularly for large, complex and innovative projectized initiatives. This challenge requires a strong commitment by top management, clear knowledge roles and responsibilities, experiments and feedbacks in order to improve incrementally the design and the implementation of *Ba* within the organization. Otherwise, *Ba* remains a remains a beautiful principle only on paper.

Identification of Benefits and Risks for Enterprises Arising from Consumer Engagement: A Preliminary Discussion

Monika Eisenbardt
University of Economics in Katowice, Poland

monika.eisenbardt@ue.katowice.pl

Abstract: The concept of collaboration between consumers and businesses is the main premise of the study. It is crucial in generating knowledge relevant for both business and consumers. This collaboration, characterized by continuous change, is based on the utilization of new technologies, devoid of formal contractual limitations, and stems from the active involvement of consumers in business activities oriented towards knowledge and consumer ideas. Although this collaboration brings numerous benefits, it also entails risks for businesses. Utilizing the results of previous research, this study employs a systematic literature review to identify the benefits and risks arising from consumer involvement in business activities. The study results are presented as variables and divided into four categories of benefits: product-related, reputational, economic and social, and informational and technological. Additionally, risks have been identified. These variables will be used in further research among businesses, providing valuable insights for companies seeking to effectively leverage consumer knowledge while simultaneously mitigating associated risks.

Keywords: Consumer Engagement, Enterprise Collaboration, Benefits, Risks, Knowledge Creation, Research-in Progress.

1. Introduction and the Research Gap

The primary focus of this ongoing research is the concept of collaboration between consumers and enterprises. This collaboration is fundamental for knowledge creation within enterprises, providing knowledge that is useful for business purposes as well as for consumers. It is characterized by continual variability and dynamism, built upon the utilization of specific knowledge sources and new technologies. This collaboration takes on an informal nature, meaning it is not regulated by any contracts or documents. It often stems from consumers' willingness to engage in knowledge sharing and their interest in utilizing new technologies in this regard.

The results of previous research on consumers and enterprises demonstrated that enterprises recognize the need to involve consumers in their operations (Eisenbardt, 2021; Eisenbardt, 2020; Mullins at al., 2020; Ziemba et al., 2022). However, consumer engagement alone may prove insufficient to effectively support business operations and acquire valuable knowledge. Therefore, it becomes imperative to discern the benefits associated with consumer engagement to develop a research tool for conducting studies within enterprises. However, enterprises also experience certain threats mainly due to the freedom with which consumers can share knowledge and experiences related to a given enterprise and its products or services.

Literature research indicates that researchers mainly focus on the perspectives and experiences of consumers (Eisenbardt et al., 2018; Hernández-Serrano et al., 2017; Potra et al., 2018; Rayna, Striukova, 2016; Wolny, 2019). As a result, there is a significant number of studies focusing on consumers, especially regarding their activities and the benefits they gain from accessing and sharing knowledge (Eisenbardt, 2020). However, it has been noted that there is a lack of scientific studies analyzing this issue from the perspective of enterprises, and to the best of our knowledge, there is no published preliminary discussion or systematic review of such research. This constitutes a research gap, particularly concerning the benefits that enterprises derive from consumer engagement and the associated risks.

To address this identified gap, the study seeks to answer the following research questions:

RQ1: What benefits do enterprises derive from consumer engagement?

RQ2: What risks are associated with consumer engagement for enterprises?

As researchers suggest, literature reviews are crucial for advancing research in a given field because they enable researchers to focus on areas that warrant further investigation and can prevent inadvertent duplication of certain ideas (Rowe, 2014; Roztocki, Strzelczyk, and Weistroffer, 2023). Therefore, this study primarily focuses on conceptualizing the benefits and risks arising from consumer engagement and translating them into variables that can be utilized in the research process. The goal is to develop a framework of the benefits and risks associated with consumer engagement and, consequently, offer valuable insights for enterprises seeking to effectively leverage consumer knowledge while mitigating associated risks.

2. Research Methodology

The study aimed to operationalize the benefits and risks arising from consumer engagement. To achieve this, a systematic literature review (SLR) was conducted. As emphasized by researchers, such a review must include explicit criteria for the inclusion and exclusion of studies, explicit strategies for searching research reports, systematic coding and analysis of the quality of included studies, and should provide a synthesis of quantitative and/or qualitative research findings (Orłowska, Mazur, Łaguna, 2017). Following Krywalski-Santiago (2023), a multi-stage process was employed to review the existing literature, including searching databases and identifying the most active contributors (publishers and authors) using the Web of Science (WoS); the PRISMA-S checklist was applied to ensure the rigor of the systematic literature review; finally, this study proposes a comprehensive framework of benefits and risks for enterprises.

The WoS database was utilized. Searches were conducted using the phrase: "*benefits AND ((consumers OR prosumers) AND (involvement OR engagement OR participation))".* As a result, a search on Web of Science (WoS) yielded 624 publications (for the years 2023-2015) within the categories of Business, Management, and Computer Science Information Systems. Focusing on scholarly works for the purposes of this study, the search primarily targeted journal articles, books, book chapters, and conference proceedings, among which journal articles comprised 90% of the analyzed sample. Professional reports, datasets, and dissertations were excluded.

3. The Literature Review Results

Figure 1 illustrates the number of publications in the WoS database for each year. As depicted, the issue of benefits and risks arising from consumer engagement is gaining popularity.

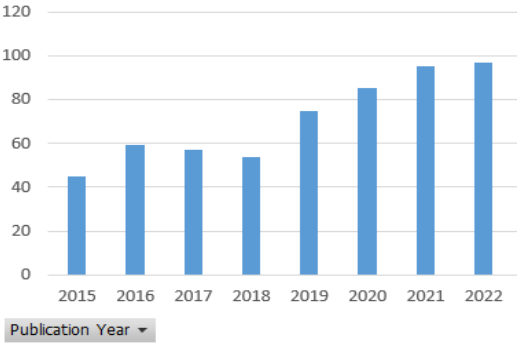

Figure 1: The WoS Database Publications over time

The WoS analysis generates a list of the most active publishers in the search area, with the first 10 presented in Table 1.

Table 1: The most active publishers

Journal title	Number of papers
JOURNAL OF BUSINESS RESEARCH	39
EUROPEAN JOURNAL OF MARKETING	23
JOURNAL OF RETAILING AND CONSUMER SERVICES	19
JOURNAL OF SERVICES MARKETING	17
JOURNAL OF PRODUCT AND BRAND MANAGEMENT	15
PSYCHOLOGY & MARKETING	13
JOURNAL OF CONSUMER BEHAVIOUR	11
INTERNET RESEARCH	10
INTERNATIONAL JOURNAL OF CONTEMPORARY HOSPITALITY MANAGEMENT	10
JOURNAL OF RESEARCH IN INTERACTIVE MARKETING	10

The keywords extracted from the publications are depicted in Figure 2. The word cloud was generated using PowerBI software.

Figure 2: Keywords listed in analysed publications

A detailed analysis of abstracts and article content (where available in open access) was conducted for 250 articles according to the WoS list, sorted by the Relevance criterion. The research scope for this study exclusively centers on the benefits and risks for enterprises arising from consumer engagement. Therefore, articles focused solely on consumer research without reference to the benefits and risks for enterprises were excluded.

The research approach for the current study is presented in Figure 3. The current study builds upon previous research on knowledge and ideas from consumers. Past research considered the demographic characteristics of consumers, the sources of knowledge they utilized, their willingness to share knowledge and ideas, and the ongoing development of ICT, which serve as primary knowledge sources for consumers and enterprises.

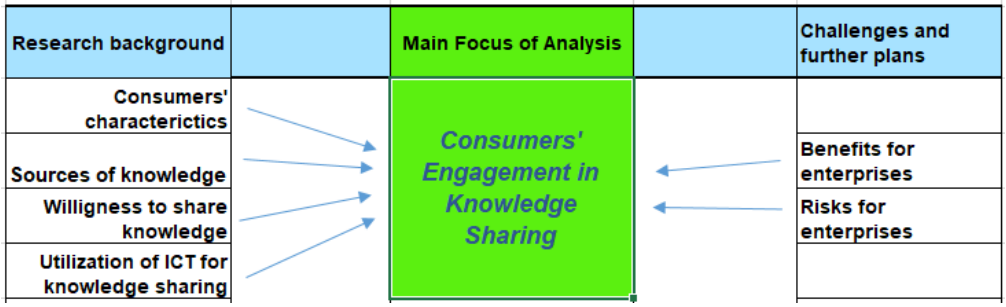

Figure 3: Research approach adopted for the study

As depicted in Figure 3, building upon foundational research, the current focus shifts towards exploring the benefits and risks for enterprises associated with consumers' knowledge. This involves understanding how enterprises can utilize consumer knowledge to enhance product development, refine marketing strategies, improve customer service, and enhance overall business performance. Concurrently, it entails examining potential risks. By delving into these aspects, the aim is to provide valuable insights for enterprises seeking to effectively leverage consumer knowledge while mitigating associated risks. In this endeavor, the study aims to address the following research questions: RQ1. What benefits do enterprises derive from consumer engagement? RQ2. What risks are associated with consumer engagement for enterprises?

To address these questions, Table 2 presents the literature review findings regarding the conceptualization of benefits and risks arising from consumer engagement, as well as their operationalization into variables. Upon analyzing the data, it was observed that variables could be grouped into categories, as also indicated in some of the publications. Thus, variables were categorized into four benefit categories: product-related, reputational, economic and social, informational and technological. Moreover, risks were also identified.

Table 2: Theoretical Framework for Further Research

Benefits and Risks	Category
• New ideas for products and services • Product life extension • Co-creation of products and their value • Enhanced level of product and service modernization • Tailoring offerings to customer needs • Customer testing of products and services • Minimizing last-minute product changes	***Product-related***
• More effective promotional and advertising activities • Better understanding of customer needs • Offering products and services that stand out from the competition • Building lasting relationships with customers • Improving customer retention rates • Loyalty towards the company and brand • Aligning customer interests with company interests • Improving customer service quality • Enhancing the company's image and reputation • Promoting innovative thinking within the company • Involvement of celebrities in promotional campaigns • Predicting trends	***Reputational***
• Financial benefits, e.g. increased financial profits for the company • Customer willingness to pay a higher price (premium price) • Risk minimization • New product distribution channels • Improving business processes within the company • Acquiring customers as business partners • Actions for sustainable development and corporate social responsibility • Increase in trust in knowledge from customers	***Economic and Social***
• Increase in the number of recipients • Direct posts and comments from customers • Diversity of information sources • Access to emerging market trends • Developing profiles on social media platforms (fan pages) • Developing company mobile applications • Developing a corporate blog • Continuous improvement in IT • Investing in modern information systems	***Informational and Technological***
• Excessive customer power • Threats to the security of company data • Too many changes in the company • Too fast pace of changes in the company • The need to share profits with consumers • Limited production flexibility linked to customer expectations • Customer takeover of product control • Customer-driven phenomena that operate independently of company-initiated actions • Excessive reliance on information and knowledge from customers • Excessive expectations towards company employees • Resistance from company employees	***Risks***

4. Concluding Remark

Building upon our previous research findings, engaging consumers in various aspects of business operations has been shown to yield numerous advantages for enterprises, albeit accompanied by certain risks. Through an extensive literature review, we were able to identify and categorize the benefits and risks associated with the current research into four distinct categories. In a broader sense, these benefits encompass areas such as product development, marketing, customer relationships, economic gains, and technological advancements. From generating innovative ideas to fostering customer loyalty and streamlining business processes, the potential benefits are considerable. However, it is essential to recognize the accompanying risks, including

challenges related to data security, employee resistance, and the need to maintain a balance of consumer power. Despite these risks, the rewards of consumer engagement outweigh the potential drawbacks. By strategically managing these risks and leveraging the benefits, enterprises can effectively harness the power of consumer knowledge to drive innovation and achieve success in the competitive marketplace.

This paper serves as a preliminary discussion laying the groundwork for further research, which will involve the development of a research tool and conducting studies within enterprises.

okeoghenemayowa@gmail.com
rexwhite.enakrire80@gmail.com

Abstract: Lecturers in Higher Education Institutions (HEIs) are constantly burdened with numerous responsibilities, including meeting students' information needs and performing their duties optimally. Addressing students' information needs and maintaining effective teaching and learning processes requires adequate tacit knowledge application. Therefore, knowledge sharing among lecturers is crucial for fostering and transforming activities within HEIs. The knowledge that is created and stored must be shared to retain its value; otherwise, it becomes useless. Despite the opportunities and benefits associated with knowledge sharing (KS), some lecturers still find it difficult and are reluctant to share their knowledge, learning experiences, and skills due to a lack of trust. It is on this premise, that this study investigates the determinants of knowledge sharing among lecturers in HEIs. The research is guided by two objectives: to establish why knowledge sharing is essential in HEIs and to determine strategies that could promote trust among lecturers to facilitate knowledge sharing. The social exchange theory underpins this study, which employs a literature review of articles within a qualitative research approach. The findings reveal that knowledge sharing helps to highlight each lecturer's unique contributions, particularly in problem-solving initiatives. Trust is identified as a fundamental strategy for enhancing collaboration among lecturers. When trust is present, lecturers are more likely to be open and committed to their responsibilities and maintain integrity, reliability, and effective communication. The study fosters mutual understanding and teamwork among lecturers to enhance collaboration and social interaction. This collaborative environment can pave the way for the exchange of knowledge, information, and skills, ultimately benefiting the entire HEI community.

Keywords: Determinant, Trust, Knowledge, knowledge sharing, Lecturers, Higher Education Institutions (HEIs)

1. Introduction

This paper reports on the determinants of knowledge sharing among lecturers in Higher Education Institutions (HEIs) in Nigeria. Lecturers in HEIs are constantly burdened with numerous responsibilities, including meeting students' information needs and performing their duties optimally. Addressing students' information needs and maintaining effective teaching and learning processes requires adequate tacit knowledge. Therefore, knowledge sharing among lecturers is a crucial factor in fostering and transforming activities within HEIs. The knowledge that is created and stored must be shared to retain its value; otherwise, it becomes useless. Despite the opportunities and benefits associated with knowledge sharing (KS), some lecturers still find it difficult and are reluctant to share their knowledge, learning experiences, and acquired skills due to a lack of trust in one another. HEIs encompass post-secondary or tertiary educational institutions, such as colleges, polytechnics, vocational institutes, and universities. These institutions aim to foster learning and generate knowledge to accomplish educational objectives (Alemu, 2018). HEIs have played an indispensable role in society, including providing information and guidance to meet students' varied information needs (Bantanur, Mukherjee, & Shankar, 2015). Students' information needs range from coursework and scholarships for further education to examination preparation, assignment completion, job opportunities, career development, and acquiring competencies/skills to address real-life problems (Khan & Jan, 2022). In Nigeria, where this study is situated, the educational sector is managed by the Federal Ministry of Education (Oyebade & Dike, 2013). Nigerian HEIs were established to develop skilled manpower, which, in turn, enhances the intellectual competence of individuals. The acquisition of physical and intellectual skills, promotion of scholarship, and community service are critical issues in the Nigerian economy (Oyebade & Dike, 2013).

To enhance teaching, learning, research, and knowledge transfer, diverse training programs need to be promoted among lecturers in HEIs. The Ministry of Education should effectively manage all educational institutions, regardless of their type. The National Universities Commission (NUC), which serves as the supervisory body for all tertiary institutions in Nigeria, should ensure that universities meet the needs of students and society at large (NUC, 2012). For academics in HEIs to achieve this objective, lecturers need to trust one another. Knowledge sharing, a key component of knowledge management (KM), is crucial for the growth and success of any organization due to its ability to improve products and services. KM fosters creativity, innovation, cost reduction, sustainability of competitiveness, and the achievement of organizational objectives

by building trust among lecturers. KS also helps HEIs respond to changes, promotes collaboration, and ensures they remain current with up-to-date information and developments both within and outside the institutions.

HEIs have become knowledge-intensive organizations focused on the creation and dissemination of knowledge through teaching, learning, research, published articles, curriculum development, administration, and sharing of knowledge (Ramjeawon & Rowley, 2018; Fullwood & Rowley, 2017). They also aim to make knowledge available to information seekers (Ozmen, 2010). Since created knowledge supports learning, teaching, and research, lecturers need to harness this success by providing education and training programs to students (Fullwood & Rowley, 2017; Ozmen, 2010). The authors of this paper emphasize that to meet the diverse information needs of students (both undergraduate and postgraduate) and other staff members, lecturers require versatile knowledge and skills in their areas of expertise. This would enhance their ability to perform their duties optimally. However, many lecturers, especially in Nigerian HEIs, are still reluctant to share their knowledge, learned skills, and experiences due to a lack of trust. Based on the authors' personal experience of over ten years working in HEIs, it has been observed that many lecturers view knowledge as power. They believe that sharing their knowledge might allow others to surpass them in various aspects of life, gain more power, and uncover new knowledge and secrets in their teaching fields. As a result, they prefer to keep their knowledge for personal self-interest. This reluctance to share knowledge is detrimental because adequate knowledge that is not shared cannot contribute to organizational growth. Sharing knowledge allows lecturers to learn and unlearn, which is crucial for their career progression.

2. Purpose of the Study

The purpose of this study is to investigate the determinant of knowledge sharing among lecturers in HEIs in Nigeria. To guide this further the following research objectives of "to establish why knowledge sharing is essential in HEIs and to determine strategies that could promote trust as a factor among lecturers in knowledge sharing in HEIs" were broken into sub-themes, namely:

- The understanding of what knowledge entails
- Why knowledge is essential in HEIs
- The effect of trust on knowledge sharing among lecturers in HEIs.
- Strategies that could promote trust for knowledge sharing among lecturers in HEIs.

The next section describes the literature review, theory adopted, methodology and conclusion presented in the study.

3. Literature Review

The literature review of this paper was guided by the sub-themes earlier mentioned in this study.

3.1 Knowledge

Knowledge has become an indispensable component for institutions to gain a competitive advantage over their competitors (Wang, Wang & Liang, 2014). The knowledge utilized by an organization advances its operations through the tasks carried out by employees. This knowledge can be categorized into explicit and tacit knowledge. Explicit knowledge is written, documented, and made available to the public or individuals through various means. Examples include knowledge published in books, journal articles, and magazines, and shared through seminars, meetings, and conferences. In contrast, tacit knowledge encompasses individual intuition, values, experiences, and beliefs, which are not easily communicated or transmitted (Nonaka and Takeuchi, 1995). While tacit knowledge gives an organization a competitive advantage, it is difficult to acquire, diffuse, observe, and share within organizations (Savolainen, 2008). Knowledge is crucial in any organization because it aids in the development and improvement of products and services (Ceylan, 2013). Managing knowledge effectively is important as it leads to positive outcomes. Knowledge management (KM) is a strategy that includes managing intellectual capital, generating, and transferring knowledge, adopting best practices, and fostering innovation, all of which are centered on knowledge sharing (Kimile et al., 2020).

KM is believed to help collect information about various facts and gain the skills and experiences of faculty members in HEIs, thereby enhancing academic activities. For lecturers to sustain their teaching, learning, and research practices, they require deep knowledge that aligns with global standards in the lectureship profession. Extant literature and the experiences of authors who have worked in HEIs suggest that the most effective way for lecturers to sustain their teaching, learning, and research practices while adhering to global standards is by

cultivating a culture of KS (Ali, Gohneim, & Al Ronbaie, 2014; Jeyanthi & Shrivastava, 2019) across their various domains. The acquisition of adequate tacit knowledge among lecturers in HEIs not only fosters and transforms the organization but also helps lecturers excel in their profession. Therefore, it is essential to share created, stored, and managed knowledge to maintain its usefulness and value within the organization. KS has become an indispensable tool in HEIs, enabling lecturers to exchange ideas and insights. The act of sharing lecturers' know-how with colleagues takes various forms (Adamseged & Hong, 2018), including face-to-face communication, group discussions, online forums, conferences, written correspondence, research publications, technical reports, media advisories, and training programs.

The outcome of the KS process can lead to competitive advantages, improved services, enhanced productivity, and better job performance for lecturers (Chikezie, Dibua, & Ihim, 2016). Achieving the overall objectives of an institution is closely tied to the opportunities associated with KS. However, despite these benefits, many lecturers in Africa, specifically in Nigerian HEIs, still find it difficult and are reluctant to share their knowledge due to a lack of trust (Awodoyin, Osisanwo, Adetoro & Adeyemo, 2016; Eiriemokhale & Idiedo, 2020). They fear that sharing their knowledge will diminish their fame and allow their colleagues to gain more knowledge and skills (Muqadas, Rehman, Aslam & Ur-Rahman, 2017). If lecturers refuse to share what they know and learn, they miss out on understanding the best practices in teaching, learning, and research. Continuous openness and sharing are necessary to perform tasks effectively and to learn new strategies. The implication is that one's current knowledge might become outdated compared to others. Sharing knowledge allows for correction and support from those who are more knowledgeable, which can be crucial during interactions and discussions.

The success of lecturers' expertise depends largely on their exposure, experiences, and engagement in various projects within and outside the organization. Drawing from their experiences working at different HEIs, the authors of this paper have observed that many lecturers are reluctant to share their tacit knowledge. They fear that such knowledge might be used against them in the future for promotions, writing articles, career growth, or gaining a competitive advantage. This knowledge is precious to lecturers because it takes a long time to build. Tacit knowledge includes personal knowledge, understanding, know-how, experiences, beliefs, values, and intuitions gained through learning, education, and experience. It is embedded in individuals' minds and can only be shared through interaction and communication with others. Kamal, Manjit, and Gurvinder (2007) emphasize the importance of KS in knowledge-based organizations like universities, where many employees are knowledge workers. In an educational environment, effective KS ensures that academics can realize and develop their potential to the fullest. HEIs play a key role in knowledge creation, especially tacit knowledge, which is difficult to create and is often innovative. This explains the reluctance to share it. Academic staff who have developed this embedded knowledge believe it constitutes the intellectual capital of an educational institution, crucial for its overall functioning and success (Kacperska & Łukasiewicz, 2020). Therefore, the only way to share this knowledge among colleagues is through trust, as the knowledge owners do not want their contributions jeopardized when shared (Kacperska & Łukasiewicz, 2020).

3.2 Why Knowledge is Essential in HEIs

Knowledge has become a critical factor in all organizations, especially HEIs. Like other organizations, HEIs heavily rely on knowledge to carry out various tasks. The types of knowledge crucial to these institutions include explicit and tacit knowledge. Explicit knowledge is routinely consulted by lecturers and students in fulfilling their responsibilities, whether completing academic tasks, managing teaching and learning, conducting research, engaging in community development, or participating in academic citizenship. Lecturers rely extensively on applying knowledge to execute their teaching and learning duties, such as developing course materials/modules, writing research papers, and engaging in interactions and presentations during conferences, seminars, and workshops. From students registering for courses to attending classes and participating in extracurricular activities until graduation, the application of knowledge underpins their achievements and progress. It is crucial to emphasize that knowledge is akin to the water humans drink daily. Just as water sustains human life, knowledge serves as the fundamental resource for everything in HEIs and professional life. Without knowledge, human existence, including that of lecturers in HEIs, becomes uncertain because every aspect of academic work involves the application of knowledge. The consideration of knowledge lies in how data and information available to lecturers are transformed into knowledge. Lecturers engage in searching for data, which consists of raw figures or factual details about events, while information is the result of interpreted, processed, or explained data (Pangil & Nasurddin, 2013). Knowledge, in turn, comprises experiences and actionable information that reduce uncertainty and enhance decision-making (Afolayan, 2020). There are two types of knowledge: tacit and explicit. Tacit knowledge resides in individuals' minds, acquired through experience in an intangible form

(Gamble, 2020). It is challenging to articulate, interpret, and formalize (Polanyi, 1962), often shared through regular interactions, discussions, workshops, and seminars (Ehijiabone & Olatokun, 2020). Explicit knowledge, on the other hand, is easily communicated, encoded, understood, written, documented, explained, and shared (Jain & Moreno, 2015).

3.3 Effect of Trust in Knowledge Sharing among Lecturers in HEIs

The concept of trust is often interpreted differently across the world. It holds deep significance in various contexts and to different individuals. Trust lacks a singular, universal definition that fully encapsulates its essence. Dirks and de Jong (2022) define trust as "a generalized expectancy held by an individual or group that another will behave in ways desired, promised verbally, or written statement." Dirks and de Jong (2022) suggest that trust is a psychological state involving vulnerability based on positive expectations of another's intentions or behaviour. These scholarly definitions illustrate that trust is cultivated through interactions, whether among individuals or within organizational settings. Indeed, trust cannot develop without interpersonal communication and engagement. It evolves gradually; the more individuals interact, the stronger their bonds and willingness to rely on each other's promises. Trust encompasses elements such as benevolence, reliability, competence, honesty, and openness (Dirks, & de Jong, 2022; Enakrire & Smuts, 2024). It's no surprise that every organization seeks trustworthy, dependable, and amicable employees with low self-orientation. Trust is built on honesty, reliability, integrity, and confidence in an institution or individual (Annansingh, Howell, Liu & Baptista, 2018). In HEIs, trust plays a crucial role in enabling lecturers to fulfil their duties in teaching and research. A culture of trust fosters increased interaction, communication, and strong bonds among lecturers, facilitating learning, growth, and improvement in their respective fields (Brown, 2014). Research has linked trust among employees to organizational support, heightened commitment, reduced turnover intention, and a more open organizational climate (Ferres, Connell, & Travaglione, 2004; Thomas & Zolin, 2009).

Trust is essential for KS because it serves as a crucial facilitator of collaboration and effective exchange of information. Studies by Akanbi and Ondari (2017), Akosile and Olatokun (2019), and Mutahar et al. (2022) have identified trust as a key factor that supports collaboration and KS. In HEIs, fostering KS activities requires a foundation of trust (Ogunmokun et al., 2020). Within knowledge-intensive environments like HEIs, lecturers highly value their time, position, and expertise, which are safeguarded through their skills, know-how, and years of experience. They are mindful of protecting their reputation and integrity and choose carefully whom they share knowledge with due to potential risks such as sabotage. If lecturers lack confidence in their colleagues' intentions, particularly fearing misuse of shared knowledge, they may hesitate to collaborate. Instances of mistrust among lecturers, perhaps stemming from societal divisions, can negatively impact KS initiatives. However, the positive effects of KS can also be profound. When knowledge is shared among colleagues, HEIs can demonstrate excellence and gain global recognition through achievements such as high-ranking scholarly publications and academic awards. Such outcomes highlight the positive impact of trust in facilitating KS among lecturers, supported by active participation in workshops, seminars, and conferences. This collaborative environment not only enhances individual reputations but also contributes to institutional success and recognition.

Elaimi and Persaud (2014) argue that a major reason why lecturers may hesitate to share knowledge is the fear of diminishing its value. Knowledge, whether tacit or explicit, is inherently valuable. Sharing tacit knowledge particularly hinges on trust, as the possessor must feel confident in the recipient's integrity and intentions. Tacit and explicit knowledge are indispensable in HEIs, working together to enable lecturers to achieve their goals effectively. Establishing trust fosters an environment where lecturers feel comfortable sharing their expertise, experiences, and skills, thereby promoting KS among peers. Holste and Fields (2010), Savolainen (2019), and Aruoren, Odiri, and Igemoha (2021) highlight the significance of trust in KS among lecturers. Trust among employees not only enhances their willingness to share knowledge and expertise but also stimulates creativity and fosters an open environment for the free flow of ideas and information. Conversely, a lack of trust can lead lecturers to withhold valuable information, resulting in decreased productivity. The presence of trust can enhance lecturers' capabilities through shared knowledge, boost research productivity, improve student grades through well-invested teaching materials, and contribute to institutional sustainability.

3.4 Strategies for Promoting Trust Among Lecturers for Knowledge Sharing in HEIs

Various authors have proposed strategies to foster trust among lecturers in HEIs, tailored to different contexts. Brewster and Railsback (2003) advocate for enhancing faculty communication, promoting collaboration, cultivating relationships, and engaging in discussions aligned with institutional vision and mission. They also

highlight the importance of nonverbal communication and the application of soft skills, such as soliciting feedback and asking questions among colleagues. Wong (2020) suggests fostering a culture of coaching and mentoring younger colleagues to cultivate inclusivity, transparency, and honesty within HEIs. Other strategies to build trust among lecturers include effective communication, team participation, leveraging reliable technology for interaction, promoting cultural inclusiveness, and fostering mutual respect (Kwaye, 2018). These strategies, when implemented, significantly enhance KS among lecturers in HEIs by creating an environment conducive to freely sharing knowledge, expertise, and skills through platforms like seminars, social interactions, inter-departmental collaborations, and accessible knowledge repositories (Mpanya, 2005).

4. Social Exchange Theory

This study is underpinned by the Social Exchange Theory developed by Homans (1958) and Blau (1964). Homans (1958) explained that the theory explores exchanges between parties, which involve tangible or intangible, profitable, or unprofitable transactions. Blau (1964) expands on this, emphasizing that the theory hinges on trust, personal obligations, gratitude, and mutual expectations between parties. Individuals regulate their interactions based on the perceived costs and benefits, without any binding contractual agreements ensuring rewards for efforts or interactions. Thus, employees' trust in an organization correlates with their willingness to invest energy, time, and effort (Blau, 1964). The theory elucidates how trust could facilitate KS among lecturers in HEIs. Trust catalyzes social exchanges, fostering interactions, relationships, intimacy, and cooperation among employees and colleagues. Kurtulus, Kruse, and Blasi (2011) suggest that employees trust their colleagues, supervisors, and managers to treat them fairly. Through KS, this treatment relates to honesty in their engagement in positive behaviours that impact organizational outcomes. Trust is pivotal for sustaining relationships and interactions, with the expectation that positive actions of honesty, fairness, and generosity will be reciprocated, despite the absence of formal contractual obligations (Gambetta, 1988; Tariq et al., 2012). In HEIs, trust empowers lecturers to engage vulnerably, fostering interactions, collaboration, and strong bonds as they exchange ideas, experiences, skills, and expertise, anticipating reciprocal gestures from their peers. Conversely, a lack of trust in HEIs can lead to dysfunction, and reluctance to interact, communicate, cooperate, or collaborate, fostering cliques within the organization and resulting in frustration, decreased productivity, performance anxiety, and a reluctance to share knowledge (Brown et al., 2015; Fang, 2021; Patmore, 2020). The Social Exchange Theory is highly relevant to understanding why and how KS among lecturers is crucial in Nigerian HEIs, as well as how trust facilitates this process. As a lecturer, before sharing experiences, skills, and know-how with colleagues, it must ensure that the knowledge is used appropriately. With trust, colleagues will reciprocate by sharing their own experiences and skills in the future. The theory is essential in the workplace, demonstrating honesty, trustworthiness, and willingness to share knowledge, and expecting the same among colleagues.

5. Methodology

This study applied a literature review method where the researchers harvested different articles from the online database of Google Scholar. The researchers read through the articles and internalised the content based on the topic under investigation. Most of what the researchers focused on were key terms of “Trust” ‘‘Effect of trust”, “knowledge sharing among lecturers”. and ‘‘strategies that could promote trust for knowledge sharing” in the literature gathered for the study. While reading through the various literature gathered for the study, the researchers used their observation method in selecting the various literature that speaks directly to the discourse of KS among lecturers in HEIs. The findings obtained while reading and internalizing the research papers harvested for the study were later used to buttress the understanding of various scholars' research studies. Starting from when the literature for the study was harvested up until when the paper was developed and edited took the authors three months. Since the literature sourced for the study was in an open database, there was no ethical consideration because a human factor was not involved.

6. Conclusion

The study identifies trust as a critical determinant that can enhance KS among lecturers in HEIs. Many lecturers hesitate to share their tacit knowledge due to fears of diminishing their recognition and allowing colleagues to gain an advantage. However, withholding knowledge means missing out on understanding best practices in teaching, learning, and research. The study emphasizes that trust among lecturers stimulates creativity and creates an open environment for the free flow of ideas and information. According to the Social Exchange Theory applied in this study, when knowledge is shared voluntarily without immediate reward, there is an expectation of reciprocal assistance in the future. Lecturers play a pivotal role in HEIs, initiating knowledge-sharing activities

as they fulfil their duties in teaching, research, academic citizenship, and community development. The study underscores the importance of lecturers sharing their knowledge, experiences, skills, and expertise under the condition that they trust their colleagues to handle this knowledge responsibly. KS involves lecturers willingly exchanging their knowledge and skills, which is essential for advancing tasks and transforming HEIs. To establish concrete and sustainable knowledge sharing among lecturers in HEIs, the study advocates prioritizing mutual understanding, collegiality, and teamwork. This approach is crucial as trust and knowledge sharing operate within social exchange relationships. By fostering mutual understanding and teamwork, HEIs can create a collaborative environment conducive to exchanging knowledge, information, and skills, ultimately benefiting the entire academic community.

Abstract: This article explores the potential of Generative Artificial Intelligence (GenAI) to improve knowledge management in organizations. Despite growing interest in GenAI, a thorough review of its applications and effectiveness in knowledge management is still needed. GenAI has shown promise in automating content creation, synthesizing information, and improving decision-making processes. However, its integration into knowledge management systems remains fragmented. This study seeks to consolidate existing knowledge and chart a path for future research in this area. The research uses a systematic literature review (SLR) following PRISMA guidelines, complemented by a thematic analysis to ensure a comprehensive assessment of the existing literature. We reviewed articles published between 2020 and 2024, focusing on GenAI applications in knowledge management. A thematic analysis was conducted to identify key themes and trends. This paper contributes to the academic and professional environment by providing a detailed review of GenAI applications in knowledge management, identifying best practices, and offering strategic recommendations for leveraging GenAI to improve organizational processes. The review highlights key areas where GenAI can improve knowledge management: automating the generation of knowledge assets, enhancing knowledge discovery and retrieval, supporting collaboration, and improving decision making through advanced analytics. In addition, it addresses ethical considerations and potential challenges, such as data privacy and the need for human oversight.

Keywords: Generative AI, Knowledge Management, Decision-Making, Organizational Innovation.

1. Introduction

Since the 1990s, firms adopted a knowledge-based view, transforming into systems for producing and applying knowledge, with outcomes as products and services (Zhou et al., 2024; Wang et al., 2023; Ji et al., 2024). Knowledge solidified as a cornerstone of organizational strategy, essential for competition and innovation (Sumbal and Amber, 2024; Hu et al., 2024; Bilgram and Laarmann, 2023). Despite diluted terminology, the concept of organizations as creators and applicators of knowledge endures (Pan et al., 2024; Zheng et al., 2024).

On this basis, generative artificial intelligence (GenAI) has revolutionized organizational knowledge management, offering unprecedented opportunities. The emerging GenAI tools are versatile and can be employed in diverse fields (Eloundou et al., 2023). This research addresses: What is the current state of research on GenAI in Knowledge Management, and what challenges does it currently face?

2. Methodology

Systematic reviews need to be updated periodically to stay relevant and incorporate the latest evidence. This review examines literature from 2020 to 2024, concentrating on gaps in Knowledge Management using GenAI, starting with the identification of pertinent keywords. A search for peer-reviewed English articles was conducted in the Scopus database. Keywords used included: (Generative Artificial Intelligence, Generative AI; Knowledge Management, Organizational Knowledge; Innovation). Articles related to business and management were selected. Following this, study selection, data extraction, synthesis, and interpretation of results were performed (Machado et al., 2019). 42 studies were included. The complete methodological process is shown in Figure 1.

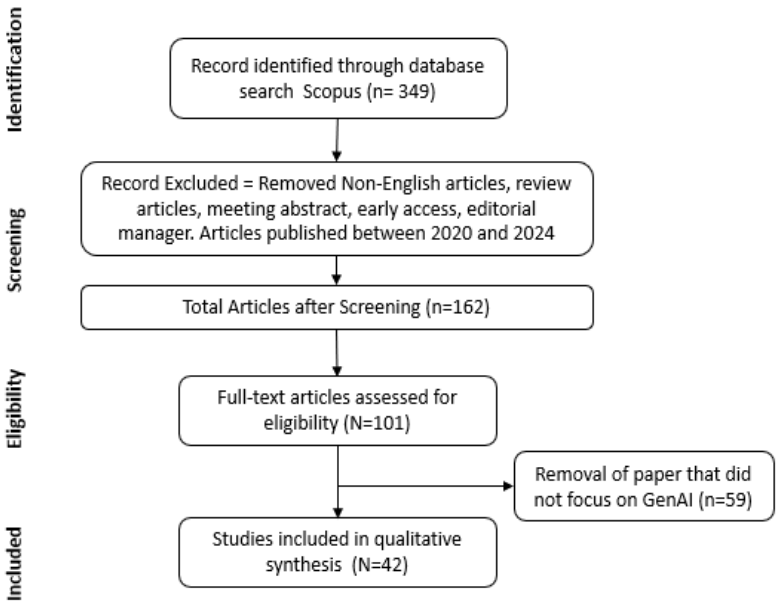

Figure 1: Flow Diagram Prisma

3. Findings

In organizations, knowledge is distributed among individuals' minds, social systems, procedures and computer files. Tacit knowledge resides in individuals and organizational culture, whereas explicit knowledge is documented in forms such as policies, procedures and information systems (Nazeer et al., 2023). Historically, the ability to store organizational knowledge was limited by the type and availability of data (Lee et al., 2024). GenAI is able to process huge amounts of data from reports, query responses and meeting notes (Kernan Freire et al., 2024) and manage it in different ways to create new and better content (Alavi et al. 2024), storing this information for future reference (Chen and Zhu, 2023; Vandelanotte et al., 2023) even GenAI excels at processing data, regardless of whether it is unstructured or well-structured (Xia et al., 2024). This advance facilitates knowledge access and management, but also presents new challenges, redefining the landscape of knowledge management in organizations (Yang et al., 2024; Ali et al., 2023).

The application of knowledge is a crucial aspect of knowledge management within organizations as it generates value (Jablonka et al., 2024). Simply storing and making knowledge accessible does not automatically improve productivity and performance (Benbya et al., 2024). Recent case studies and research indicate that GenAI systems are positively influencing knowledge work by boosting productivity and knowledge application. For example, GenAI can be used for the creation of interactive training material, thereby increasing the effectiveness of the process because the new employee can learn on his own and does not need another employee at his side, which consumes time and resources (Alavi et al. 2024). Furthermore Brynjolfsson et al. (2023) found that leveraging GenAI to capture, combine and apply customer service knowledge resulted in an overall productivity increase of 14% for customer service agents, with a 30% increase for novice agents. In addition, the quality of customer service improved, as seen in higher customer satisfaction scores. In addition, the quality of customer service improved, as seen in higher customer satisfaction scores. Initial use cases suggest that GenAI tools have the potential to improve knowledge application and performance. For example, Intercom, a company specializing in customer service solutions, has launched pilot programs using GenAI to improve customer engagement and drive corporate growth (Reid, 2023). Similarly, JP Morgan (2023) is employing GenAI to create synthetic data that trains machine learning models to detect new and emerging anomalies, which could be missed if trained on real data alone. The integration of GenAI into organizational knowledge management processes is expected to boost productivity and the quality of knowledge work in several industries.

Goldman Sachs (2023) predicts that widespread adoption of GenAI could increase annual labor productivity growth in the United States by almost 1.5 percentage points. Knowledge management of the future will depend more on the ability to efficiently search databases and obtain the desired results, rather than on the direct acquisition of knowledge (Jarrahi et al., 2023). This approach is driven by the ability of GenAI tools to interpret

natural language, thus enabling user needs to be met more accurately. Therefore, users will not need to internalize as much knowledge.

Successful adoption of GenAI in knowledge management requires staff buy-in, which can be difficult because some workers fear being replaced by software. The effectiveness of GenAI tools relies on their ability to be trained and to handle tacit and implicit knowledge, which makes employee buy-in crucial. If employees resist the use of new technologies, implementation will not be effective (Alavi, Leidner and Mousavi, 2024).

4. Expected Results and Future Plan

Integrating Generative AI (GenAI) into knowledge management systems is set to revolutionize how organizations manage and utilize their intellectual assets. By automating content creation, enhancing data analysis, and streamlining decision-making processes, GenAI enables organizations to transcend traditional knowledge management boundaries, leading to substantial improvements in operational efficiency, innovation, and competitive advantage. GenAI helps uncover hidden patterns and insights from large datasets, fostering more effective knowledge sharing and collaboration across teams. By automating repetitive tasks such as report generation and data entry, GenAI allows employees to focus on higher-value activities, thereby boosting productivity.

Organizations adopting GenAI can anticipate accelerated innovation cycles, enabling them to develop new products and services more quickly and efficiently. The flexibility of GenAI solutions ensures that organizations can scale their knowledge management practices and adapt swiftly to changing market conditions. To maximize these benefits, organizations should implement comprehensive training programs to equip employees with the necessary skills to utilize GenAI tools effectively and cultivate a culture of innovation.

Through this research, we aim to identify key trends in the impact of generative artificial intelligence on knowledge management. Our objective is to provide organizational leaders with critical insights that will help them address the ethical challenges associated with GenAI use, thereby facilitating the development of appropriate policies and guidelines.

john.mulyata@swansea.ac.uk

Abstract: Conversational Artificial Intelligence has disrupted higher education by fundamentally altering its landscape. Fuelled by natural language processing and machine learning this technology has gained widespread adoption particularly since the release of ChatGPT in November 2022. As universities embrace digital transformation, assessment practices must evolve to align with the capabilities of Artificial Intelligence-driven chatbots and virtual assistants. This paper explores how conversational artificial intelligence impacts higher education, in particular, student assessment. A fundamental shift in assessment and evaluation of student competencies is necessary to not only consider knowledge retention but also critical thinking, communication, and adaptability skills. A review of the literature was conducted to understand how assignments should change due to the emergence of this disruptive technology. Conversational Artificial Intelligence and its application within the higher education context is uncertain, with disparate practices—in terms of ethical consideration and understanding—across the sector. A case study was conducted in which MSc Management students undertaking a specific module were tasked to use three Artificial Intelligence tools in their report writing of a business, to verify the sources and content provided by the Artificial Intelligence tool, and to critically evaluate the process as well as the output received for each prompt. The paper proposes a collaborative approach to navigate the ethical implementation and utilization of conversational Artificial Intelligence in higher education, advocating for the co-creation of guidelines through forums like Knowledge Cafés, stressing the need to rethink student assignments and its assessment and the adoption of artificial intelligence technologies by students for assignments.

Keywords: conversational artificial intelligence, knowledge café, higher education, assessment, disruptive technology

1. Introduction

The launch of advanced models such as OpenAI's ChatGPT in November 2022 (OpenAI, 2023) has significantly accelerated the adoption of conversational Artificial Intelligence (AI) in higher educational settings. These models are capable of understanding and generating human-like text, making them useful for a range of applications from tutoring to administrative support. The introduction of these advanced models has become popular tools amongst both students and academic staff, who are using it to improve their academic practice, as Bahroun *et al*. (2023, p. 2) points out "In the domain of teaching, generative artificial intelligence showcases promising opportunities for lesson planning, personalized learning support, rapid assessment and evaluation, and addressing learners' queries".

Since traditional assessment methods—particularly in Business and Management courses—can easily be supported by AI, it presents higher education with a conundrum. Assessment serves multiple purposes beyond merely measuring what students have learned, however, it is becoming more difficult to measure what students have learnt or their ability to critically analyse texts, given the fact that AI can be employed to do so for them. In a study by Smolansky *et al.* (2023) it was found that educators favour assignments that are tailored to incorporate AI use and which promote critical thinking. However, students have mixed feelings about this approach, partly because they worry it might stifle their creativity. The results highlight the need to involve both educators and students in efforts to reform both assignments and its assessment, emphasizing the learning process rather than its outputs, fostering higher-order thinking, and encouraging real-world applications.

There is thus a need to rethink assessment in higher education to be agile in the current climate of AI as a disruptive technology, especially in subjects, where the essay and report are commonly used for student assignments. It is important that academic staff are given the autonomy to innovate and experiment with different forms of assignments and its assessment so that learning, creativity and development is measured. The main aim of the paper is to explore the impact of conversational AI on higher education, specifically focusing on how this technology influences student assessment practices. The paper seeks to understand the necessary shifts in evaluating student competencies to accommodate the capabilities of AI-driven chatbots and virtual assistants. Additionally, it aims to propose a collaborative approach for the ethical implementation and utilization of conversational AI within the higher education sector.

In this paper an example is provided where students were tasked with including conversational AI tools in their assignment. The usefulness of Knowledge Cafés to discuss and deliberate on assessment in higher education is proposed as a helpful platform to rethink assessment in general. An introductory review of the literature is presented next, with an example of how assessment was rethought by considering the reality of conversational AI.

2. Background

Recent research has underscored the significant influence of AI on teaching and learning within higher education, acknowledging both the favourable and unfavourable views of conversational AI. However, the consensus is increasingly recognizing the indispensability of AI tools. Crompton & Song (2023) highlight the considerable promise of AI to broaden and improve educational practices. Rudolph *et al.* argue that it presents substantial opportunities when both students and faculty are properly educated on using the technology ethically (Rudolph, Tan, & Tan, 2023).

2.1 Conversational artificial intelligence

Virtual assistants, conversational agents, and chatbots are all tools designed to facilitate interaction between humans and machines using natural language. However, the terminology used by different authors within the AI field can have varying meanings.

Gartner classifies conversational agents as Virtual Assistants (VAs) and notes that they are utilized for personal, educational, or business functions. According to Gartner, these VAs operate using semantic analysis and Natural Language Processing (NLP) and may also integrate chatbot technologies. By observing and interpreting human behaviours, conversational agents or VAs apply these models to predict outcomes and facilitate decision-making (Gartner, 2023). According to Basu conversational AI is a broad field that includes both open-domain and closed-domain chatbots designed for human-like interactions through conversation (Basu, 2019). Katsarou *et al.* (2023) refers to a specialized category of a virtual assistant called an embodied conversational agent (ECA) which is characterized by increased complexity, and which is primarily utilized for educational purposes. These agents are effective because they possess a deep knowledge base in specific fields and have the capability to assist learners by offering easy access to information and enhancing motivation. Amazon's Alexa, Apple's Siri, and Google Assistant are cloud-based, general-use Intelligent Virtual Assistants (IVAs) (Katsarou, Wild, Sougari, & Chatzipanagiotou, 2023). In this paper we refer to all the above as conversational AI agents.

2.2 Benefits of conversational artificial intelligence in education

According to Rudolph *et al.* artificial intelligence has the capacity to revolutionize teaching and learning methods, boosting student engagement by enabling experiential and experimental learning. For instance, by using AI tools such as ChatGPT, students can explore various strategies and methods for problem-solving and goal attainment (Rudolph, Tan, & Tan, 2023). The integration of conversational artificial intelligence, particularly chatbots, in education presents a wide array of benefits that can revolutionize the learning experience for students, enhance engagement, and provide personalized support. Thus, increased availability for students at any time, adaptability to cater to individual student needs, providing scripted education interactively, answering questions using natural language processing, chunking information into manageable segments, allowing for personalized learning experiences, enhancing student motivation, improving speech skills in foreign languages, reducing student anxiety, promoting self-paced learning, offering instantaneous feedback, and easing administrative procedures (Kaphings & Kohlmann, 2021; Sysoyev & Filatov, 2023; Gökçearslan, 2024; Lee, 2023; Ilieva, 2023; Babirye, 2024; Ghayoom, 2023).

2.3 Challenges of conversational artificial intelligence in education

Despite the advantages of conversational AI, it is important to acknowledge that chatbots, including advanced models like ChatGPT, may have limitations and can make mistakes, which could potentially lead to issues, especially in education. Therefore, careful consideration and analysis are necessary for the successful implementation of chatbots in educational settings. A further concern is that conversational AI can produce adequate text for students and that plagiarism checkers will not be able to detect it. However, these concerns might also stem from educators' reluctance to adjust to new methods for both student assignments and the assessment thereof. Traditional Business Management written assignments have often been criticized for being boring and unsuccessful at measuring student learning (McMurtrie, 2023). Ojha *et al*. (2023) suggest that the incorporation of artificial intelligence in education has prompted a reassessment of teaching methods and practices, which includes assessment strategies. The challenge is how does one design assignments to effectively measure student competency and not AI comptetency.

2.4 Impact of artificial intelligence on student assignments and its assessment

Assessments in educational and professional environments traditionally focus on measuring knowledge, skills, and abilities through tests, exams, interviews, and performance evaluations. With the more extensive use of AI tools currently, these practices will have to transform.

2.4.1 Traditional assessment practices

Paper-based exams, in-person interviews, and subjective evaluations: Human biases might influence traditional assessments which may not be uniformly administered as it relies on standardized formats and subjective grading criteria. Furthermore, these assessment methods may not always accurately reflect students' abilities since students could have used conversational AI to do assignments (Holzinger, Lettner, Steiner-Hofbauer, & Capan Melser, 2020). Scalability is another problem when assessing exams or tests since it requires significant resources, and it is very time-consuming for large classes. Feedback is thus often delayed, and sometimes not detailed or personalized (Hadibarata & Jusoh, 2023). Traditional methods of assessment may also not capture students' holistic development and individual learning needs, resulting in a one-size-fits-all approach that may not cater to diverse student populations (El Hashash, 2022).

2.4.2 Assessment using AI tools: online adaptive tests, AI-driven interviews, and simulations

The gap in traditional assessment practices could potentially be addressed by conversational AI, providing personalized learning experiences (Hadibarata & Jusoh, 2023). Although AI can reduce human bias, algorithmic bias can occur if not carefully managed. The consistency of AI tools is high, and it is standard since AI tools can apply the same criteria uniformly across all assessments. As far as scalability is concerned it is scalable to large numbers of users with automated processes for administering and scoring. Feedback is immediate and it can be detailed with AI identifying specific areas of strengths and weaknesses (Hadibarata & Jusoh, 2023). Furthermore, AI tools can analyse vast amounts of data to detect patterns, predict outcomes, and provide insights that are not readily apparent through traditional assessment methods.

2.4.3 Hybrid approaches

By using AI for initial screenings and practice, institutions can enhance efficiency and provide targeted educational support. Simultaneously, having human evaluators oversee more nuanced or critical decisions ensures that the grading and assessment of assignments maintain a necessary level of human insight and ethical consideration. This hybrid model not only optimizes resource use but also supports a more personalised learning experience. Students can receive immediate feedback from AI-driven tools, which helps them identify and focus on areas needing improvement. Meanwhile, educators can devote more time to complex evaluation tasks and personalised teaching, rather than routine grading/assessment (Ifelebuegu, 2023)

2.4.4 Group assignments

For collaborative or group assignments, it is possible to use AI to track and analyse individual contributions in group tasks, facilitating a more precise evaluation of each student's involvement in the collaborative task. Additionally, AI can oversee and guide online discussions, ensuring equitable participation from all students and fostering critical thinking and teamwork. However, AI deployment in such cases demands substantial investments in technology and training, which could worsen the digital divide and amplify inequalities in education (Ifelebuegu, 2023).

2.5 Ethical considerations

Some of the ethical issues with using AI for assessment in higher education concerns privacy, data security, bias in AI algorithms, transparency in decision-making processes, and the potential for AI to replace human judgment when providing feedback in the assessment of assignments (Holmes, et al., 2022; Franco D'Souza, Mathew, Mishra, & Surapaneni, 2024; Akgun & Greenhow, 2022). There are also ethical considerations related to intellectual property rights, ownership of AI-generated content, and the impact of AI on widening educational disparities (Akgun & Greenhow, 2022; Franco D'Souza, Mathew, Mishra, & Surapaneni, 2024; Ng, Wu, Leung, Chiu, & Chu, 2024). Issues such as accountability, fairness, and the ethical implications of using AI in educational settings need to be carefully addressed to ensure ethical AI use in higher education (Ng, Wu, Leung, Chiu, & Chu, 2024; Baker, Mills, McDonald, & Wang, 2023). These ethical considerations emphasize the importance of critically examining the implications of integrating conversational AI in higher education—particularly in the execution of assignments and assessment of assignments—to ensure that students are ethically supported and that their rights and well-being are safeguarded.

Teaching students to use conversational AI ethically poses a significant challenge, and leaving this to individual staff members may not yield the desired results. Integrating ethics education into business curricula can enhance

students' ethical decision-making skills and prepare them for future challenges (Eyal, Berkovich, & Schwartz, 2011), especially with the rise of conversational AI. This integration is important for fostering responsible business practices and corporate social responsibility (Olatoye, et al., 2024). Therefore, establishing frameworks for responsible AI use and embedding ethical considerations into business education would be essential for ethical business conduct (Olatoye, et al., 2024).

2.6 The concept of Knowledge Cafés

The Knowledge Café serves as a dynamic space where individuals can critically engage with ideas in a dialectical manner. It provides a unique opportunity for researchers to unobtrusively hear from numerous knowledgeable individuals about key topics, thus making it a valuable tool for both knowledge sharing and research (Singh, 2017). It convenes people to discuss topics of mutual interest, helping them to understand issues more profoundly and explore various possibilities with the objective to unearth collective knowledge, facilitate idea sharing, and deepen understanding of subjects. The Knowledge Café is a simple but flexible, conversational; compared to similar methodologies, it makes no definitive attempt at making decisions or trying to reach consensus as part of the Café itself. At its best, a Knowledge Café adheres to a set of principles that help create a relaxed, informal, conversational environment conducive to open dialogue and to learning (David Gurteen, n.d.). The attendees of such a café are empowered to express their genuine concerns without fear or judgment (Piskopani, Webb, & Caleb-Solly, 2023).

2.7 Current research on AI and assessment

The impact of conversational AI on student assessments is significant. Studies show that integrating AI in assignments leads to innovative and improved outcomes. For example, conversation-based assessments (CBA) use AI to evaluate students' comprehension (Yildirim-Erbasli, Bulut, Demmans Epp, & Cui, 2023) and tools like Artificial Intelligence–based student learning evaluation (AISLE) assess understanding through concept maps, revolutionizing assessment methods (Jain, Schroeder, & Faulkenberry, 2014).

AI in assignments enhances student engagement, motivation, and learning outcomes, with technologies like educational robots and conversational agents boosting interest and attitudes towards learning (Yang, Oh, & Wang, 2020). This integration also facilitates personalized learning, improves teaching efficiency, and provides valuable insights into student performance (Uluskan, 2023; Samuelsson, 2023).

AI has the potential to reshape traditional assessments, offering more interactive, personalized, and effective methods. By leveraging AI, educators can enhance the assessment process, provide customized feedback, and better align assessments with learning objectives, ensuring that student skills and learning are accurately measured.

2.8 Identified gaps in the literature

Gaps in the current literature around conversational AI in higher education and business management assessment methods include the need for 'authentic assessments' focusing on higher-order cognitive skills and problem-solving, rather than traditional methods (Ifelebuegu, 2023). There is a call for re-evaluation of the appropriateness of multiple-choice questions (MCQs) as an assessment tool in higher education due to the risks of academic dishonesty and dependence on AI models (Li & Chignell, 2022). Additionally, there is a gap in evaluating the environmental impact of AI applications in the chemical industry, given data gaps and challenges in choosing appropriate assessment methods (Odonkor, Kaggwa, Uwaoma, Hassan, & Farayola, 2024). Comprehensive qualitative assessments exploring the practical experiences, benefits, and challenges of academic professionals utilizing AI tools in engineering pedagogy remain limited (Hao, et al., 2024). There is a gap in assessing the readiness of conversational AI models for application in real-world clinical scenarios (Wang, et al., 2023)

These gaps highlight the need for further research to address the effectiveness, ethical considerations, and practical implications of integrating conversational AI in higher education and business management assignments and its assessment methods. This paper attempts to close this gap by undertaking research to understand how students would perform, and what their perceptions of the alternative assessment method was, which embedded the use of conversational AI platforms.

3. Methodology

Case study methodology allows for in-depth exploration of specific instances within real-life contexts, defined as intensive studies of single units (Gerring, 2004). Widely used in fields like nursing, marketing, and information systems (Crowe, et al., 2011; McCutcheon & Meredith, 1993), it enables investigation from multiple perspectives within a bounded context (Rashid, Rashid, Warraich, Sabir, & Waseem, 2019). This research utilised case study

methodology with participant observation, allowing for high-quality data collection through active engagement (Wilkinson, 2017). Following Fàbregues and Fetters' (2019) steps—literature review, research question formulation, case design selection, case boundary definition, data collection preparation, data analysis, report writing, and quality appraisal—the study aimed to understand how students would perform, and what their perceptions of the alternative assessment method was, which embedded the use of conversational AI platforms.

Objective 1: Analyse the impact of conversational artificial intelligence on student assessment practices in higher education**.**

Research Questions

1. How has conversational artificial intelligence disrupted higher education, particularly in terms of student assessment?
2. How should assignments and evaluations evolve to consider not just knowledge retention but also critical thinking, communication, and adaptability skills in the era of conversational AI?

Objective 2: Explore best practices for the ethical implementation and utilization of conversational AI in higher education assessments**.**

Research Questions:

1. What are the ethical considerations associated with the implementation and utilization of conversational AI in higher education?
2. How can AI technologies be incorporated into student assignments and integrated into assessment?

4. A Case: Rethinking student assignments and its assessment

4.1 Background

As part of the MSc Management programme at Swansea University, a module on Information Systems is taught. The module looks at ways in which information systems can be used effectively to achieve competitive advantage. The MSc Management cohort is usually a small cohort of not more than 45 students. In 2024 a cohort of initially 36 students enrolled for the module, with only 28 submitting to the final coursework. Most of the cohort are from the Indian and Nigerian descent—some of the students often have English as a third or fourth language and therefore find it difficult to use English both for communication and for writing reports. The assessment of this module has seen several changes over the years, in 2024, the module included two multiple choice/true and false online tests, as well as a business report that students needed to research and write up. Students ordinarily would be tasked in an assignment to research a company and provide a report on the various aspects of the information systems used within the company. With the popularisation of ChatGPT and other conversational AI tools, the module coordinator tried to incorporate AI tools in the assignment which required students to use AI tools for their report writing.

4.2 Integrating AI tools in assignments

Traditional report writing assignments face the problem of students using conversational AI tools to complete much of the work, making it hard for educators to assess learning. To address this, a module coordinator designed an assignment allowing AI tool use but requiring students to critically evaluate their prompts and AI responses, reducing the risk of plagiarism, and ensuring that critical skills were also being used.

Students were assigned to use three AI tools, verify sources, and critically evaluate the process and outputs. They also had to write a short report on the process and output validity and create a business report on a company and its information systems.

Students were advised how to undertake the coursework and what constituted the misuse of conversational AI tools. The importance of developing skills and critically analysing what they were doing and receiving as output of the tools was a required skill to develop. Students were advised of the structure of the coursework and how the process of using the AI platforms would be evaluated. A generic template for the process was provided.

Upon receiving the assignment, students found it interesting but challenging, requiring multiple briefing sessions for clarity. Both the process and the final report were part of the summative assessment.

At the International Congress & Exhibition on Current Trends on Science Technology Education SCITEED 2024 conference, similar assignments were discussed, emphasizing the evaluation of both the product and the process in assessments involving AI tools.

5. Data analysis and results

5.1 Objective 1 - Analyse the impact of conversational artificial intelligence on student assessment practices in higher education.

5.1.1 Fundamental shift required for student assessment in higher education

Given the ease of using conversational AI by students for their coursework, academic staff are uncertain who is writing the work, complicating the evaluation of student competencies. A fundamental shift in assessment practices is needed to address AI-driven technologies, but there is no program-level guidance, leaving academics to innovate at the module level.

Developing new assessment methods that evaluate student competencies rather than AI capabilities is challenging (Thurab-Nkhosi & Williams, 2018). This requires revisiting module objectives and transferable skills, focusing on practical demonstrations and interpersonal skills where AI falls short (Chen & Zhu, 2016). The syllabus and prompt-engineering techniques may also need revision.

Integrating AI in assignments necessitates rethinking evaluation criteria, faculty training, and resource allocation (Chow, 2024). Ensuring the validity and reliability of AI-driven assessments is crucial, as biases and inaccuracies in AI algorithms could affect fairness, effectiveness, and raise data privacy and security concerns (Sharma & Lin, 2022).

The Russell Group, in partnership with educational experts, developed principles to ensure students and staff are AI-literate, leveraging technological breakthroughs in teaching and learning. The five principles (Russel Group, 2023) are:

1. Support students and staff in becoming AI-literate.
2. Equip staff to help students use generative AI tools effectively.
3. Adapt teaching and assessment to include ethical AI use and support equal access.
4. Uphold academic rigour and integrity.
5. Collaborate to share best practices as AI evolves in education.

The fifth principle emphasizes collaboration, suggesting this approach should extend to program and module levels to share best practices. Knowledge Cafés, like those conducted by Swansea University academics at various international conferences, as well as at Swansea University, provide a platform for academics to share experiences with conversational AI in higher education.

5.1.2 Authentic assessment methods for appropriate skills development and effective assessment

In the era of conversational AI, leveraging conversational Artificial Intelligence in higher education institutions is essential for assessing knowledge retention, critical thinking, communication, and adaptability. Developing authentic assessment types requires innovation, creativity, and rethinking student skills and module intentions. Kasimatis & Papageorgiou (2021) describe authentic assessment as a dynamic evaluation focusing on skill development, suitable for evaluating critical thinking (Jingbo & Ying, 2023), while embedding it in curricula, can enhance employability by fostering reflection, communication, and collaboration (Manville, Donald, & Eves, 2022; Manville, Donald, & Eves, 2022). By incorporating real-life scenarios, universities can effectively measure critical thinking skills (Chusni & Suherman, 2021), engaging students in meaningful activities to improve learning outcomes (Vu & Dall'Alba, 2013).

5.2 Objective 2: Explore best practices for the ethical implementation and utilization of conversational AI in higher education assessments

5.2.1 Ethical considerations associated with the implementation and use of conversational AI in higher education?

Students included the output of their prompts in the coursework submission, ensuring transparency and a clear description of the process. Despite their interest, students expressed concerns about the difficulty and their lack of understanding, requiring multiple explanatory sessions. However, inconsistent attendance meant some students did not fully grasp the assignment.

Ethical considerations highlight the need for education to align with work life, ensuring students can apply their learning professionally. Neglecting this may hinder their real-world effectiveness. Integrating ethics education into business curricula enhances students' ethical decision-making skills and prepares them for future challenges (Eyal, Berkovich, & Schwartz, 2011; Lopez, Rechner, & Olson-Buchanan, 2005)

5.2.2 How can AI technologies be incorporated into student assignments and integrated into assessment?

For this case study, the coursework included assessing the process of developing the report. Students used three AI tools and traditional methods, with 30% of the assignment allocated to critically evaluating the AI output and creating the report. After setting the task, one author was invited to present at a conference on embedding AI in assignments, and it was at this conference that there were other instances of academics using a similar example of assessing process as well as the outcome. However, many students struggled to provide critical reflections, often just presenting alternative outputs with little analysis. This highlights the challenge of embedding AI in assignments. Academics are catapulted into radically changing and rethinking assessment due to the popularisation of AI. The importance of co-creating and sharing new assessment methods to evaluate different student competencies is key to academic prowess and success.

6. Discussion and conclusions

6.1 Major findings

While universities struggle to manage AI at the program level, academics are attempting to innovate assessment methods, there is a lack of consensus on the ethical use of AI, and there is a need for understanding the benefits of collaboration for co-creating authentic assessment methods. Developing new forms of authentic assessment methods to evaluate student competencies requires a collaborative approach, as suggested also by the Russel group guidelines.

Academics and universities must adapt to technological advances in the AI/digital age. This case study presents an example of integrating conversational AI into coursework and assessment, highlighting the necessary shift in higher education to assess student learning outcomes effectively. It emphasizes evaluating the process, not just the outcome, and the need for ethics teaching in business curricula for consistency across programs.

In this fast-paced digital era, rapid AI advancements make it essential for academics to share best practices and co-create ethical assessment methods. Knowledge cafés provide a collaborative framework for informal conversations and sharing best practices, including ideas for new forms of authentic assessment.

6.2 Limitations

The study may have research methodological limitations in that further focus groups and interviews would have provided a deeper understanding of the complexity of AI use within student assessment and authentic assessment development and perception.

6.3 Future research

Future research on conversational AI use in education could focus on two key areas: its adoption and effectiveness in higher education and developing guidelines for embedding conversational AI use for authentic assessment in an ethical way.

A Study on Usage of Formal Knowledge Sharing Systems in Project-Based Organizations

Anandasivakumar Ekambaram
SINTEF Community, Trondheim, Norway

siva@sintef.no

Abstract: Projects are one-time activities that have time and resource limitations. Projects are considered as arenas for learning. There are opportunities for creating new knowledge and utilizing existing knowledge in projects. Since projects are per definition unique, there is at least some degree of uniqueness associated with each project. This uniqueness provides opportunities to learn something new in each project. The known element in projects – such as existing solutions that have been proven to produce good results – can be shared and utilized to avoid using time and resources to create the same or similar solutions from scratch. Knowledge sharing and learning can play a notable role in improving the ability of project-based organizations to carry out their projects successfully and contributing to obtain higher productivity, profitability and sustainable competitive advantage. However, there are several challenges. This paper looks at one of the challenges, namely ineffective usage of formal knowledge sharing systems in project-based organizations. In this regard, the following two research questions are considered: (1) What are the challenges of using formal knowledge sharing systems? (2) How can the challenges be addressed? Formal knowledge sharing systems play an important role in supporting knowledge sharing and learning in organizations. Technological development has created many possibilities to enhance functions as well as benefits of such systems. However, there are several factors that are to be taken into consideration in order to make sure an effective usage of formal knowledge sharing systems in project-based organizations. This paper presents six factors in this regard and emphasizes the need to have a strategic view and a top management perspective of knowledge sharing and learning in project-based organizations. The study on which this paper is based, is of qualitative nature. In this regard, interviews have been conducted to gather information from five public project-based organizations in Norway.

Keywords: Knowledge Sharing, Learning, Project, Organizational Culture, Organizational Structure, Strategic Focus

1. Introduction

Projects are a popular form of work in organizations to achieve a clear goal within a certain time-period and cost. Projects are considered an arena for learning. Since projects are by definition unique, they have at least a certain degree of uniqueness that will lead to acquisition of new knowledge. At the same time, projects also include some known elements - for example known methods and solutions - which give the opportunity to utilize the existing knowledge. In other words, new knowledge can be developed (knowledge exploration) and existing knowledge can be shared (knowledge exploitation) in projects.

Exploring and exploiting knowledge can have positive effects on project-based organizations (PBOs) and the projects that they carry out. There are many benefits from sharing knowledge and focusing on learning in projects. Figure 1 shows some of the gains.

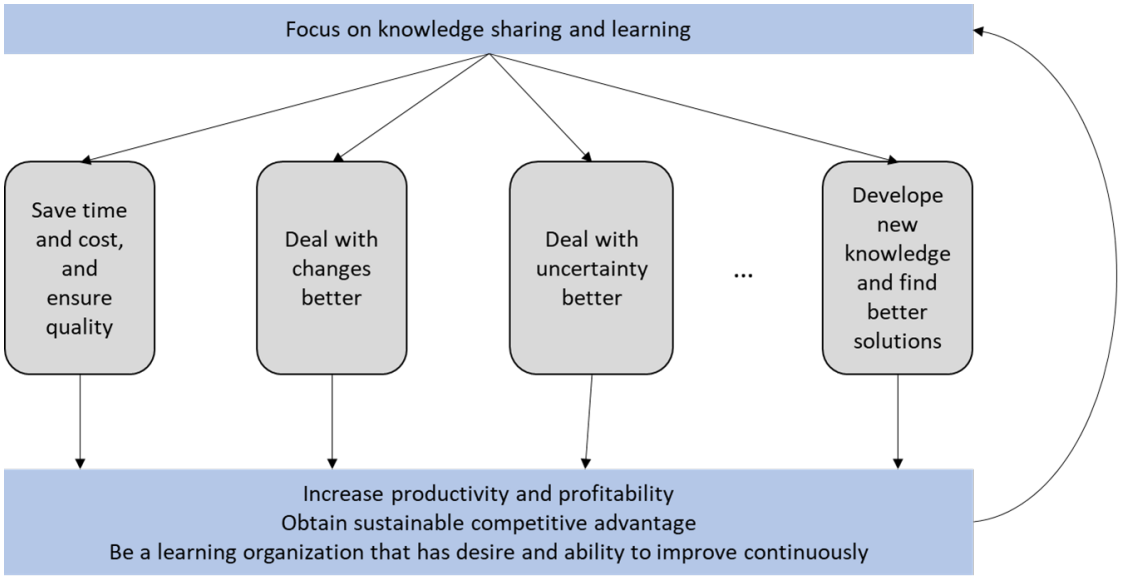

Figure 1: Positive effects knowledge sharing and learning

But the question is: Do project-based organizations get these benefits?

"If HP knew what HP knows, we would be three times as profitable." – A manager at Hewlett Packard (HP) mentioned this several years ago (Boshyk, 2000). Researchers also point out the importance of knowledge sharing and learning in project-based organizations and its positive effects. (Abdellatif et al., 2019; Mahura & Birollo, 2021; Kvålshaugen et al., 2021; Zhang et al., 2024). Although many measures have been implemented, PBOs still experience challenges related to knowledge sharing and learning. It is not always easy to share knowledge from projects to the base organization / the permanent organization (Williams, 2008; Duffield & Whitty, 2015; Evers & Chappin, 2020).

What prevents PBOs from achieving the benefits of knowledge sharing and learning? What are the barriers? How can the barriers be dealt with? A pre-project called *Experience sharing and learning in project-based organizations* (ELPO) – on which this paper is based – attempts to address this matter. This paper looks at one of the aspects of this research pre-project, namely usage of formal knowledge sharing systems in PBOs. The research questions hence are:

- What are the challenges of using formal knowledge sharing systems?
- How can the challenges be addressed?

The structure of the paper is as follows: After the introduction, background information including research method that is applied in this study is provided, followed by relevant concepts. And then, results, analysis and discussion are presented. Finally, concluding remarks wind up the whole discussion.

2. Background Information and Research Method

The pre-project ELPO is financed by Project Norway (https://prosjektnorge.no/). Project Norway is a national arena for the exchange of knowledge and experiences, where new knowledge about projects is developed through research-based collaboration with Norwegian business and industry.

This study applied qualitative research methods. Fourteen interviews were conducted in five public PBOs in Norway during 2023 to collect information. The interviews were semi-structured – having an overarching, flexible structure, and encouraging natural dialogue and discussion. The duration of the interviews varied between 1 and 1.5 hours. Those who were interviewed are anonymized and identified through a code (Respondent 1, 2, etc.). The respondents have experience of performing roles such as project member, project manager, project owner and department manager.

3. Relevant Concepts

3.1 Knowledge

Davenport & Prusak (1998, page 5) define knowledge as follows:

> "Knowledge is a fluid mix of framed experience, values, contextual information and expert insight that provides a framework for evaluating and incorporating new experiences and information. It originates and is applied in the minds of knowers. In organizations, it often becomes embedded not only in documents or repositories but also in organizational routines, processes, practices and norms."

This definition points out that knowledge provides a framework for evaluating, interpreting and gaining new experiences and information.

Another relevant term is experiential learning. Experience-based learning, introduced by Kolb, suggests that concrete experiences provide a basis for observation, reflection and abstract conceptualization. Kolb's experiential learning model is composed of four stages that go in a spiral (Kolb, 1984):

1. Concrete experience
2. Observation and reflection on that experience
3. Formation of abstract concepts after that reflection
4. Testing the new concepts

Figure 2 illustrates it.

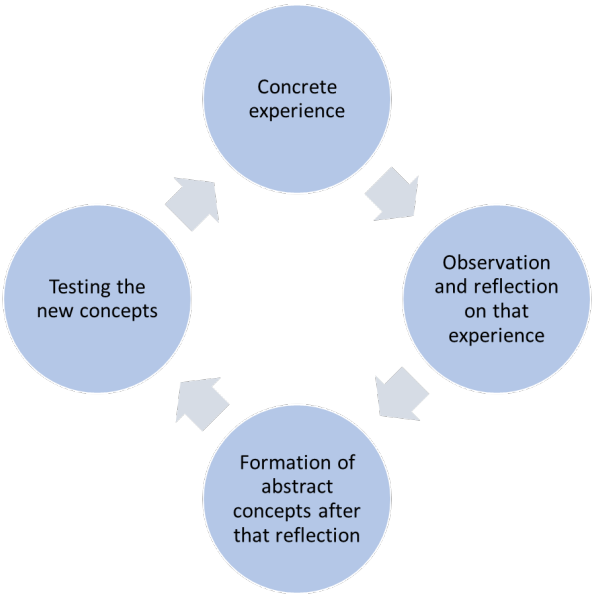

Figure 2: Experience-based learning (Kolb, 1984)

Knowledge sharing and learning can be addressed in organizations, not only at project level or operational level, but also at strategic level. In this connection, it is relevant to look at the term 'knowledge governance'.

Pemsel (2012) says that an organization can define means and support for knowledge-creating processes and activities. However, the creation of knowledge takes place through individual and collective interaction and reflection, which can be independent of such means and support. Organizations therefore need strategies for how to handle knowledge and learning effectively. Strategies are created through knowledge governance in an organization and are implemented through the management of knowledge.

According to Zhang et al. (2024), Knowledge governance can be defined as a governance mechanism to manage and influence knowledge management processes, for example knowledge acquisition, storage, transfer and creation.

Aslam et al. (2024) also point out that knowledge governance uses a broader perspective to address issues related to knowledge sharing and learning, and also has a strategic focus on managing knowledge sharing and learning in organizations – rather than finding simple solutions to individual problems.

3.2 The Iron Triangle

Projects are by definition unique. They are one-time activities that have time and resource constraints. Traditionally, project success was measured by taking into account how the project handled the use of time and costs, and quality (Navarre & Schaan, 1990; Ika & Pinto 2022; Karlsen, 2023). These 3 aspects form the so-called iron triangle of the project.

Citing Ika & Pinto (2022), Karlsen (2023, page 365) describes the components of the iron triangle:

- Cost: That the project is completed within the budget.
- Time: That the project is finished within the deadlines.
- Quality: That all deliveries meet the required quality standards.

Although other aspects that define project success have become prominent (such as stakeholder management and safety, health and environment), the iron triangle still influences the practical world of project management, at least to some extent.

3.3 Motivation

The degree of motivation, which individuals have, to carry out a task can be linked to their attitudes and behavior towards carrying out the task. Motivation plays an important role in knowledge sharing and learning. Motivation can be categorized as extrinsic motivation (for example praise, public recognition, money and promotion) and

intrinsic motivation, for example inner joy, interest and satisfaction in performing a task (Skyttermoen & Vaagaasar, 2015).

Incentive mechanisms can be used to motivate – to provide both extrinsic and intrinsic motivation to – organizational members to share knowledge. Karlsen (2023, page 175) presents some of the significant factors that can create job satisfaction and motivation for project team members:

- Meaningful work: When team members feel that their work is meaningful and contributes to a greater goal, they are more likely to be motivated and satisfied.
- Well-defined goal: When team members understand what they are working towards and what is expected of them, they are more likely to be motivated and have a sense of achievement when they achieve their milestones and goals.
- Autonomy: When team members are given autonomy and are trusted to make decisions, they are more likely to be motivated and have a sense of ownership over their work.
- Feedback: When team members receive positive feedback for their work, they are more likely to feel motivated and engaged.
- Recognition: When team members feel that their work is recognized and appreciated, they are more likely to be motivated and satisfied.
- Opportunities for learning and development: When team members have opportunities to learn new skills and take on new challenges, they are more likely to be motivated and feel meaningful about their work.
- Supportive team culture: When team members feel they are trusted and supported by their colleagues and have a positive team culture, they are more likely to be motivated and satisfied.

4. Results, Analysis and Discussion

Here, our primary focus is on formal systems that have been implemented in PBOs to support knowledge sharing; for example, knowledge databases, lessons learned reports, project evaluation reports and knowledge registers. Such systems are used to register and obtain knowledge and experiences. Results from the interviews show that there are challenges of using the systems effectively, and indicate how the challenges can be dealt with.

4.1 Challenges

First, we will look at six key challenges that hinder effective use of formal knowledge sharing systems in PBOs.

4.1.1 Attitudes and Culture

If one's personality and attitudes towards sharing knowledge and learning are negative, then this will become a barrier. Several of the respondents mention this as one of the central barriers. Respondent 4 mentions that there are different personalities and attitudes, and not all of them support knowledge sharing and learning. Respondent 2 gives an example of this:

> "[…] perhaps it is also because I have been project manager for 10, 15 projects. So I know this from A to Z, and I don't need someone to teach me my profession – When you have that attitude, it becomes a barrier to learning."

Respondent 8 says that it is difficult to motivate people who really do not want to use systems that were implemented to promote knowledge sharing and learning. Respondent 12 says:

> "Knowledge is not registered all the time. There can be several reasons for this. There is a structure to register knowledge, but not a sufficient culture or attitudes to do so."

Respondent 6 says that if a project manager prioritizes knowledge sharing and learning in his / her projects, then that project manager will facilitate it. This depends on the person, clarifies respondent 6. Based on own experiences, respondent 8 says:

> "Managers who focus on or prioritize knowledge sharing allocate time for knowledge sharing in project meetings. However, it depends much on individuals and their choice […]. There is a lack of culture for learning."

Kjeilen (2021), Mahura & Birollo (2021), Alves et al. (2022) also points out the importance of culture for learning.

Respondent 13 says that not everyone is curious about learning something new and sharing their knowledge. Respondent 2 says the following:

> "It's not everyone who really sees the importance. You either forget about sharing knowledge or don't prioritize it".

Here it is relevant to refer to one of the barriers to knowledge sharing and learning that Maryse & Chappin (2020) mention: Lack of interest in other projects and not understanding the necessity for sharing knowledge with other projects.

Lack of motivation can also be due to negative attitudes towards the use of formal knowledge sharing systems. In connection with this, respondent 8 says the following:

> "It's hard to motivate people who really don't want to. I don't think it's just a lack of knowledge that they can't do it here. But a lot depends on personality and will. You have people who want to learn new things, use new systems, see new opportunities and just jump at it. You also have some people who see problems (in knowledge sharing systems) and just focus on the problems and stop there. They don't want anything more to do with the systems."

This statement points out the importance of developing a positive organizational culture which helps to create positive attitudes towards knowledge sharing and the use of formal knowledge sharing systems.

Personality and attitudes can affect motivation. Several respondents say that a lack of motivation among people to work with or participate in activities related to knowledge sharing and learning in projects is one of the barriers. In this context, respondent 13 says that there is a lack of curiosity among project members.

4.1.2 Training

Respondent 12 says that although there are very good procedures, there is a lack of motivation to use knowledge sharing systems. There could be several reasons for that. One of them is attitudes and culture that we have seen earlier. Another is a lack of knowledge about how to use the systems. Respondent 8 mentions that a low level of knowledge on how to use the knowledge sharing systems effectively in projects is one of the barriers. In this context, it is relevant to look at another barrier that respondent 4 mentions: Lack of training related to the use of systems. Training programs can provide knowledge and guidance that are necessary for effective use of knowledge sharing systems.

4.1.3 Awareness of the Usefulness of the Systems

In addition to providing the necessary knowledge on using formal knowledge sharing systems, it is also important to raise awareness of the usefulness of the systems. Respondent 14 mentions a lack of this awareness as one of the barriers to knowledge sharing. Furthermore, respondent 14 mentions that creating commitment and motivation is extremely important in this context. One of the factors that can influence motivation to use knowledge sharing systems is the systems' user-friendliness.

4.1.4 User-Friendliness

Respondent 2 says that it is cumbersome to register 'lessons learned' in knowledge sharing systems. Respondent 13 points out a lack of structure that can guide what and how one should register in such systems. This respondent further says that one may not see the value of registering one's experiences / knowledge in such systems. We'll look at this matter more in Chapter 4.2.2.

Those who want to acquire knowledge may also experience certain challenges. Respondent 2 mentions that it is difficult to find topics / the needed solutions because of too much information (information overload). This type of challenges can lead to little use of lessons learned reports according to respondent 1. Respondent 4 says:

> "If you have a database or a system in which it is very difficult to find the needed knowledge, then I think that the system will be very poorly utilized. If you want to obtain knowledge from such difficult systems, then you try a little, and then you don't want to spend so much time on it before giving up."

4.1.5 Incentive Mechanisms

Motivation can be created in several ways. One possibility is to implement relevant reward systems. Respondent 11 mentions a lack of reward systems / incentive mechanisms as one of the barriers to knowledge sharing and

learning. Filstad's (2010) study also points this out. Incentive mechanisms can motivate project members to use formal knowledge sharing systems and participate in activities that promote knowledge sharing and learning in organizations. Some important factors that can create motivation are presented in chapter 3.3.

4.1.6 Adequate Time and Priority

One of the topics that is connected to motivation is performance measurement. This is about what a project member and manager are measured against. In this context, it is relevant to see a statement from respondent 7:

> "It's very nice to say that everyone should register their knowledge and experiences in the knowledge databases and everyone should talk to someone to gain or share knowledge. But, it's never followed up. No. It's clear that in a busy day-to-day work in projects, you prioritize (to do) what you're measured against."

This statement indicates that knowledge sharing and learning is not a usual criterium to measure performance of project managers and project members. Project managers (and project members) are normally measured in terms of their ability to deliver the project within the agreed deadline (time), cost and quality. Here, we look at projects from a project delivery perspective or a project manager perspective. The priority is project delivery, not knowledge sharing and learning in the project. In this regard, it is relevant to refer to the iron triangle that we have seen in Chapter 3.2.

The above statement from respondent 7 also shows that there is a need to use a higher perspective (for example top management perspective / senior management perspective) than a project manager perspective or a project delivery perspective to address knowledge sharing and learning in PBOs effectively. Several respondents mention involvement, commitment and support from top management / project owners / senior managers in this context. We will look more at this topic in chapter 4.2.

4.2 Improving the Usage of Formal Knowledge Sharing Systems

Many factors can be considered when one tries to find possibilities for improving the usage of formal knowledge sharing systems in PBOs. In this regard, we will look at one of the overarching factors: Involvement and support from the top management.

As we have seen in Chapter 4.1.6, there is a need for using a higher perspective (for example top management perspective / senior management perspective) than a project manager perspective or a project delivery perspective to address knowledge sharing and learning in PBOs effectively. Several respondents mention involvement, commitment and support from top management / project owners / senior managers in this context. The top management perspective provides a strategic view of knowledge sharing and learning in PBOs – that is, considering knowledge sharing and learning as a means to increase productivity, effectiveness, profit and competitive advantage (refer Figure 1 in Chapter 1). The concept called knowledge governance that we have seen in Chapter 3.1 can be considered here in this regard.

Top management's involvement and support can be seen in two dimensions: Organizational structure and culture.

4.2.1 The Structural Dimension

Top management can make sure – with the practical assistance from project managers – that project members (as well as project managers) get adequate time for knowledge sharing and learning in projects. It is important to note that project managers may not have the mandate / authority / priority to allocate time and resources for knowledge sharing and learning in their projects. Several respondents point out that the time aspect / time restriction is one of the barriers to knowledge sharing and learning in PBOs. More on this matter can be found in Ekambaram (2024). In addition, other recent scientific literature (scientific articles and reports) also mentions this barrier – for example, Kjeilen (2021), Sunnemark et al. (2024), Iftikhar & Lions (2022), Alves et al. (2022), and Pinkhasik & Herrmann (2021).

As respondent 5 indicates, obtaining knowledge from a source (for example, from a task, a colleague or a report) itself may not automatically lead to learning. There may probably be a need for reflection (refer Kolb's model on experience-based learning in Chapter 3.1). And reflection requires a certain amount of time. Therefore, there should be adequate time and priority for knowledge sharing and learning, and ensured by the top management.

Top management can also contribute to making sure effective use of knowledge sharing systems by investing in obtaining knowledge sharing systems that are not only relevant, but also user-friendly. Top management can ensure that the organization has user-friendly formal knowledge sharing systems that can help project managers and project members to find information about knowledge sources (where to find the needed knowledge) and obtain the knowledge that they need. Knowledge sharing systems can also provide clear instructions and guidance for registering and finding knowledge so that the knowledge can easily be found, understood and applied by future knowledge seekers in a proper way.

Another contribution from the top management can be establishing appropriate training programs that provide the needed knowledge and competence to the users, so that they can use the knowledge sharing system effectively. In connection with user-friendly systems, respondent 4 mentions an important point regarding the effective use of knowledge sharing systems: It is necessary to provide employees with sufficient training to ensure effective use of (recently introduced) knowledge sharing systems. A strategic focus on the implementation of training programs for employees can help to create a common understanding of how to use a knowledge sharing system and thus lead to common work practices, increase productivity and achieve competitive advantage. Here it is relevant to mention a statement from respondent 8:

> "There is an incredibly big difference in how people perceive working in such a system (a knowledge sharing system)."

This statement emphasizes the importance of creating a common understanding of the use of formal knowledge sharing systems.

When management implements measures to promote knowledge sharing and learning, it is important to ensure that project members actually use / practice the measures and follow up on the measures. Respondents 2 and 7 mention that the follow-up plays a significant role in the effective use of knowledge sharing systems. Kjeilen (2021) also says that work with knowledge sharing requires management to follow it up.

4.2.2 The Cultural Dimension

With the strategic focus on knowledge sharing and learning, the top management can greatly influence creating an organizational culture (that encompasses components such as attitudes, norms, values and behavior) that encourages and promotes knowledge sharing and learning in the organization. A clear communication of the strategy (that focuses on knowledge sharing and learning in and between projects in the organization) and why this strategy is important, action-plan for implementing the strategy as well as concrete measures, and the signals (emphasizing the importance of knowledge sharing and learning) that are sent by the top management regularly can play an important role in developing a positive culture for knowledge sharing and learning in PBOs.

Another measure that top management can take in connection with the use of knowledge sharing systems is to motivate organizational members to use knowledge sharing systems actively and effectively. There are several ways to motivate organizational members by providing extrinsic and intrinsic motivation (see Chapter 3.3). One way to create intrinsic motivation, according to some of the respondents, is to highlight the benefits of registering valuable knowledge in a formal knowledge sharing system. If a project member knows that his / her knowledge has helped someone else in the organization, it will bring some kind of recognition and joy to the project member. Sanboskani & Srour (2022) also mention this type of measure and positive effect of it in their study. Many of the motivating factors presented in chapter 3.3 – in particular, meaningful work, feedback, recognition, opportunities for learning and development, and supportive team culture – can contribute to creating a positive effect. This (that is, making visible the positive effect of using the knowledge sharing system) can encourage that project member (who has helped others), and possibly other organizational members to use the knowledge sharing system actively. They can then clearly know that the time they spend registering their knowledge is valuable, and that the registering activity actually helps their colleagues and the organization.

Pinkhasik & Hermann (2021) and Iftikhar & Lions (2022) mention the importance of motivation and incentive mechanisms to promote knowledge sharing and learning. Several respondents mention that it is important to motivate project members and managers to share knowledge. One of the reasons for this is that project members are not measured on knowledge sharing, says respondent 7. Respondent 9 points out that knowledge sharing is not seen as a key performance indicator. Project members do not naturally get motivated to spend time and energy on sharing knowledge due to busy everyday life in projects and the prioritization of completing project tasks. If the top management / project owners motivate project members and managers in the organization by using relevant incentive mechanisms (reward systems), then the situation can change.

Respondents 6, 11 and 13 mention that rewarding those who share knowledge with others can make a positive difference in knowledge sharing and learning in project-based organizations. Factors that provide motivation, which we have seen earlier in chapter 3.3, can be referred to here.

5. Concluding Remarks

This paper looks at one of the barriers to knowledge sharing and learning in PBOs, namely ineffective formal knowledge sharing systems. Six key challenges that hinder effective use of formal knowledge sharing systems in PBOs are described, and the importance of top management's involvement and support can address the challenges are discussed.

Top management's support and contribution to promote knowledge sharing and learning in PBOs should be operationalized at all professional levels in PBOs (for example, top management, project owners, project managers, project members, etc.). In order to do the operationalization effectively, both the structural and cultural aspects of organizations are to be taken into consideration.

Further study can include focusing on the research questions (presented in Chapter 1) in one or more case projects in order to get a detailed and context-specific understanding of the topic of consideration.

Impact of Chatbots on Satisfaction and Loyalty in Lima's Telecom Sector

Catherine Alexandra Herrera Fallaque
University of Lima, Peru

20190938@aloe.ulima.edu.pe

Abstract: The migration towards digital environments has transformed the expectations of consumers, who now not only look for quality products and services, but also convenience, personalization and efficiency in each interaction with the brand. This change presents significant challenges for companies, as they need to constantly adapt to meet their needs and thus maintain loyalty in a highly competitive market. The pressure to offer added value and maintain customer preference is intensified by the ease with which consumers switch to competitors. which drives companies to innovate and adapt AI such as chatbots, which could be the answer to this challenge. The objective of this research work is to know if the use of chatbots positively influences the satisfaction and perceived loyalty of consumers of telephone services, since in this case the speed, quality of the service and the customer's need for understanding. They are critical and represent a greater challenge to differentiate. The methodology used for this research maintains a quantitative, correlational, non-experimental approach. The type of sampling was non-probabilistic, and the strategy was snowball. The instrument used was a questionnaire with a sample of around 130 consumers in the city of Metropolitan Lima in Peru. The findings suggest that chatbots are not only innovative tools, but also strategic ones for telephone companies seeking to improve customer satisfaction and loyalty. The implementation of appropriate chatbots can transform the customer experience, providing a more agile, personalized and effective service, thus seeing a close relationship between the dimensions of the chatbot with the satisfaction and loyalty perceived in consumers. In a world where these variables are key to business survival, chatbots represent an opportunity to create exceptional experiences. Uncover how cutting-edge AI chatbots are revolutionising customer satisfaction and loyalty in the competitive telephone service industry, offering transformative, personalised, and efficient interactions.

Keywords: Chatbots, Customer Satisfaction, Loyalty, Telephone Services, Digital Innovation

1. Introduction

Today, we live in an era where consumers spend more time in digital environments, seeking services in an accessible and fast way, regardless of location, time or channel (Escobar, 2016). In Peru, delays in customer service and low information accuracy have negatively impacted sales and customer satisfaction (Gestión, 2018). Consumers value convenience, personalisation and efficiency in all their interactions with brands. Companies face the challenge of remaining robust and efficient in all their digital channels to attract and retain customers, seeking their preference and loyalty (Hasberg et. al., 2016). In response to digitalisation and business issues, several countries have incorporated chatbots as an effective solution to address customer queries and concerns through AI (Dhaoui, 2014).

The main purpose of the paper is to draw insight into the relation between the use of Chatbots and the perception of customer satisfaction and loyalty, with a focus on the telephone service sector that has been criticized for poor customer care. This is further echoed by the study by Anda Peru (2021), stating issues such as slow service, poor customer care, and bad processes. This study tries to comprehend the relationship that the use of chatbots, satisfaction (S), and loyalty (L) perceived in consumers of telephony services in Metropolitan Lima (LM) would have in 2024. The research studies three dimensions: dimensions such as chatbot interactions (I), personalization (P), problem resolution (RP) capabilities, which are related to influences on perceived S and L. The following will present the research objectives of analysing such relationships and its effect on perceived S and L. Overall Objective: To analyse the relationship between the use of chatbots, "S," and "L" in consumers of telephony services in "LM" in 2024. The specific objectives vary along the above-mentioned dimensions. The research aims at extending theoretical knowledge on customer satisfaction by using chatbots, aligning with Feine et al. (2019). It also aims to update the conceptual framework on chatbots and customer experience, identifying gaps and establishing a solid foundation for future research, as suggested by Xu et al. (2023). Furthermore, it seeks to provide information on tools to improve customer satisfaction in business strategies, following Dhaoui (2014). The research has practical relevance, as it will analyse the usefulness of chatbots in customer satisfaction among users of telephony services in Lima, influencing investment decisions and strategies of consolidated entities, like Sanny et al. (2020). According to Antonio et al. (2022), the results will provide guidance and practical knowledge for domestic and international consumers, helping them to understand the benefits of chatbots and their proper employability. The migration of customers to digital channels has increased interest in chatbots in the Peruvian economy because of their novel nature and the improvements they promise

in digital offerings (Medina, 2019). Chatbots stand out not only for their 24-hour availability, but also for their ability to collect valuable information from users (Guzmán, 2020). The importance of chatbots as an additional method of customer service in the Peruvian market is underlined, with high growth potential in digital developments aimed at improving customer satisfaction, according to INEI (2023).

Regarding the background, it can be mentioned that relevant findings with similar views were found among several authors, such as the studies by Surjandy & Cassandra (2023), Naqvi et al. (2023), Bhattacharya & Sinha (2022) agree on the idea of a positive relationship in the e-commerce context, highlighting factors and such as response time, reliability and chatbot usability as key factors of the customer's "S" and "L". Meanwhile, Naqvi et al. (2023), in their study entitled "Impact of service agents on customer satisfaction and loyalty: mediating role of Chatbots", with focus on the essence of fashion retail brands in Pakistan, find that chatbots can provide personalised treatment that improves the quality of communication and, consequently, the customer's "S" and "L". Bhattacharya & Sinha, looking at the banking sector, find that chatbots are crucial for improving customer interactions, aiding and recommendations that increase customer's perceived "S" and "L".

Naqvi et al. (2023) and Antonio et al. (2022) agree on the importance of the "P" in the customer-chatbot "I" to increase customer "S". Naqvi et al. emphasise that chatbots can offer personalised treatment by adapting to individual customer needs, leading to a higher "S" and "L". Antonio et al., in "Study Literature Review: Discovering the Effect of Chatbot Implementation in Ecommerce Customer Service System Towards Customer Satisfaction", further argue that the implementation of chatbots does not guarantee high levels of "S" if there is no adequate "P" in the conversation with the user.

Sanny et al. (2020), in "The analysis of customer satisfaction factors which influence chatbot acceptance in Indonesia", Zhang et al. (2023), Eren (2021) and Feine et al. (2019) provide a measured view of the elements that affect the customer's "S" with chatbots. Sanny et al. recognise factors such as usability, brand image development, personality and ease of use as crucial determinants of the customer's "S". Zhang et al. (2023), in "Emotional expression by artificial intelligence chatbots to improve customer satisfaction: Underlying mechanism and boundary conditions", highlight the importance of emotionality in the "I", while Eren (2021) highlights the relevance of received performance, perceived trust and company reputation. Feine et al. (2019) introduces sentiment analysis as a tool to improve customer "S", demonstrating its usefulness in understanding chatbot behaviour and being able to adjust it according to the user's needs.

Huang et al. (2023) and Xu et al. (2023) address the comparison between chatbots and human service in relation to customer "S". Huang et al., in "Can chatbot customer service match human service agents on customer satisfaction? An investigation in the role of trust", find that, while chatbots contribute to improving customer "S", there is room for improvement compared to human attention. On the other hand, Xu et al. (2023) explore the mixed effects of chatbot-human "I" on customer "S", concluding that chatbots with accurate responses are preferred over those with social orientation biases, highlighting the importance of accuracy in "I".

Chung et al. (2020), in "Chatbot e-service and customer satisfaction regarding luxury brands", and Xu et al. (2023) focus on the importance of accuracy in chatbot responses. Chung et al. find that the accuracy of the information provided by chatbots, along with the credibility of the information, significantly affects the customer's "S". Xu et al., on the other hand, highlight that chatbots with concise responses are more highly valued, evidencing that the accuracy of responses is a crucial component in influencing the customer's "S".

In the theoretical framework of this research, three key variables are presented: the independent variable, which are the service agents (chatbots), and the dependent variables, which are the customer's "S" and the customer's "L". Chatbots are defined as a type of AI that use Natural Language Processing (NLP) to understand and process human language, enabling conversations in text or voice format (Shawar and Atwell, 2007). ELIZA, the first chatbot, was developed in 1960 by Joseph Weizenbaum at MIT. Since then, significant advances have been made with systems such as WeChat (2009) and personal assistants such as SIRI and Alexa. In real life, chatbots are AI systems that interact with users through a chat interface, designed to simulate human conversations, help, answer questions or perform specific tasks. They are widely used in customer service, sales and technical support.

The qualities of a chatbot can be assessed in four dimensions: entertainment, trendiness, customization and problem-solving accuracy, credibility and communicative competence, i.e. the ability to converse effectively (Chung et al., 2020). Naqvi et al. (2023) proposed four dimensions of service agents: Interaction as a social quality, Personalisation for adapting to customer needs, Problem Resolution (RP) as an effective solution, and the last one which it was not taking into consideration is Entertainment. These dimensions are essential to verify

the ransmission and processing of language by chatbots. The design of chatbots uses NLP techniques and AI algorithms, such as machine learning and neural networks, to improve their interaction capabilities. Human-Computer Interaction (HCI) theory is also relevant, focusing on the design of interfaces that facilitate effective human-computer interaction (Dix et al., 2004). The dependent variable of customer "S" is defined as the emotional reaction to the quality of the product or service received (Silva et al., 2021). Mora Contreras (2011) extends this definition by considering a sequence of emotional states that culminate in a positive or negative response before and after the purchase. Chiou and Droge (2006) suggest that customer "S" occurs when products or services meet or exceed expectations. In practice, customer "S" reflects how well a product or service meets prior expectations. In light of the above, this research prefers the Chiou and Droge definition over that of Silva et al. (2021). However, it is pertinent to mention that the cognitive-affective customer "S" model, developed by Caro and Garcia (2007), considers that the behaviour behind the "S" is marked by rational judgements (cognitive) and emotional aspects (affectivity). The dimensions of this model include perceived information quality, perceived delay time and positive emotions during the interaction with the chatbot. There are two approaches to how emotions influence on "S": one view sees emotions as mediating the relationship between cognition and "S" (Bigné and Andreu, 2002), while the other sees them as independent sources of "S" (Oliver, 1993).

As for the dependent variable of customer "L", this refers to the degree to which a customer remains loyal to a company or brand and continues to purchase its products or services over time. Customer "L" is closely related to customer "S", as a satisfied customer is more likely to develop "L". According to Dick and Basu (1994), the customer "L" can be understood as a deep commitment to repurchase or continue using a product or service in the future, despite situational influences and marketing efforts that might cause a change in behaviour.

Customer "L" can be measured along several dimensions, such as repurchase intention, recommendation of the product or service to others, and resistance to switching to competitors. According to Oliver's (1999) "L" Model, "L" develops in four stages: cognitive, affective, conative and action. The cognitive stage is based on the consumer's beliefs about the quality of the product or service; the affective stage includes the consumer's feelings towards the brand; the conative stage refers to the customer's intention to continue purchasing; and the action stage involves the performance of loyal behaviours, such as repurchase and recommendation.

In practice, customer "L" can also be measured through metrics such as customer retention rate, purchase frequency, market share, willingness to recommend the brand (NPS) and price sensitivity. In addition, surveys and purchase behaviour analysis can be conducted to assess "L" (Zeithaml et al., 1996)

The general hypothesis of this research is: "The use of chatbots positively influences the perceived "S" and "L" of consumers of telephony services in Metropolitan Lima 2024". In line with was previously stated with the problem and objectives, there are six specific hypotheses in relation to the three dimensions brought about using chatbots.

The first hypothesis would be "the interaction of chatbots positively influences the "S" in consumers of telephony services in Metropolitan Lima in the year 2024". The second hypothesis would be "the interaction of chatbots positively influences the "L" in consumers of telephony services in Metropolitan Lima in the year 2024".

Both hypotheses are in line with Sanny et al. (2019), Antonio et al. (2022) and Naqvi et al. (2023).
The third hypothesis would be "the "P" of chatbots positively influences the "S" in consumers of telephony services in Metropolitan Lima in the year 2024". The fourth hypothesis would be "the "P" of chatbots positively influences the "L" in consumers of telephony services in Metropolitan Lima in the year 2024", both according to Chung et al. (2020), Eren (2021) and Naqvi et al. (2023); rejected by Xu et al. (2023).

The fifth hypothesis would be "The "PR" provided by the chatbot positively influences the "S" in consumers of telephony services in Metropolitan Lima in the year 2024". The sixth hypothesis would be "The "PR" provided by the chatbot positively influences the "L" in consumers of telephony services in Metropolitan Lima in the year 2024". Both according to Zhang et al. (2023) and, Moran and Agüero (2022), rejected by Huang et al. (2023).

2. Methods

The focus of this research was quantitative because it could contribute to the resolution of practical problems, knowing the reality through limited and measurable data. In relation to the scope, it is descriptive-correlational with a "non-experimental" cross-sectional design, where data can be placed in space-time. In this study, the focus was on consumers of telephone services in Metropolitan Lima in the year 2024.

In relation to the design of the model, we considered the population data of Metropolitan Lima up to January 2024, where we found that the capital had 10,292,408 inhabitants (Gestión, 2024). It was also further narrowed down to those people who used the internet via mobile phone in the capital, as it is understood that by using and having access to the internet, users could make queries to their mobile phone company's chatbots. To this end, it was found that 94.1% of the population of Metropolitan Lima that is older than 6 years of age complies with the above (INEI, 2023). Therefore, by performing a simple multiplication, we have a population of 9,345,507 inhabitants.

According to this population a sample of 130 observations is adequate for PLS-SEM as it ensures reliable and robust estimates (Hair et al., 2017). In relation to the type of sampling it will be non-probabilistic, as the present research will be bounded with certain parameters seen above, and finally regarding the sampling strategy, this will be Snowball. The data collection instrument was an improved, adapted, and refined version based on an instrument by Naqvi et al. (2023). The article has been tested and published in the English Language, so it was translated into Spanish (free translation) for practical research purposed. It is also important to mention that moderating variables are not being considered as part of the model.

On the data collection side for the present research, it was through dissemination via email and social networks. The results collected were tabulated in Excel for better data manipulation, coded and the PLS-SEM method was used. Finally, descriptive statistics were used, taking into consideration Cronbach's Alpha, estimated parameters and correlation coefficient to analyse the results.

3. Results and Discussion

The JAMOVI platform was used to calculate the previously collected data, which has been tabulated both in filter questions and in relation to the questions asked for each variable, in the case of the dependent variables, and to the independent variable in relation to its dimensions, both on a Likert scale. Thus, the structural equation model (SEM) is presented in Figure 1, where each circle represents each variable. Recall that, Personalisation is manifested by the letter "P", Problem Solving is "RP", Interaction is "I", Loyalty is "L" and Satisfaction is "S".

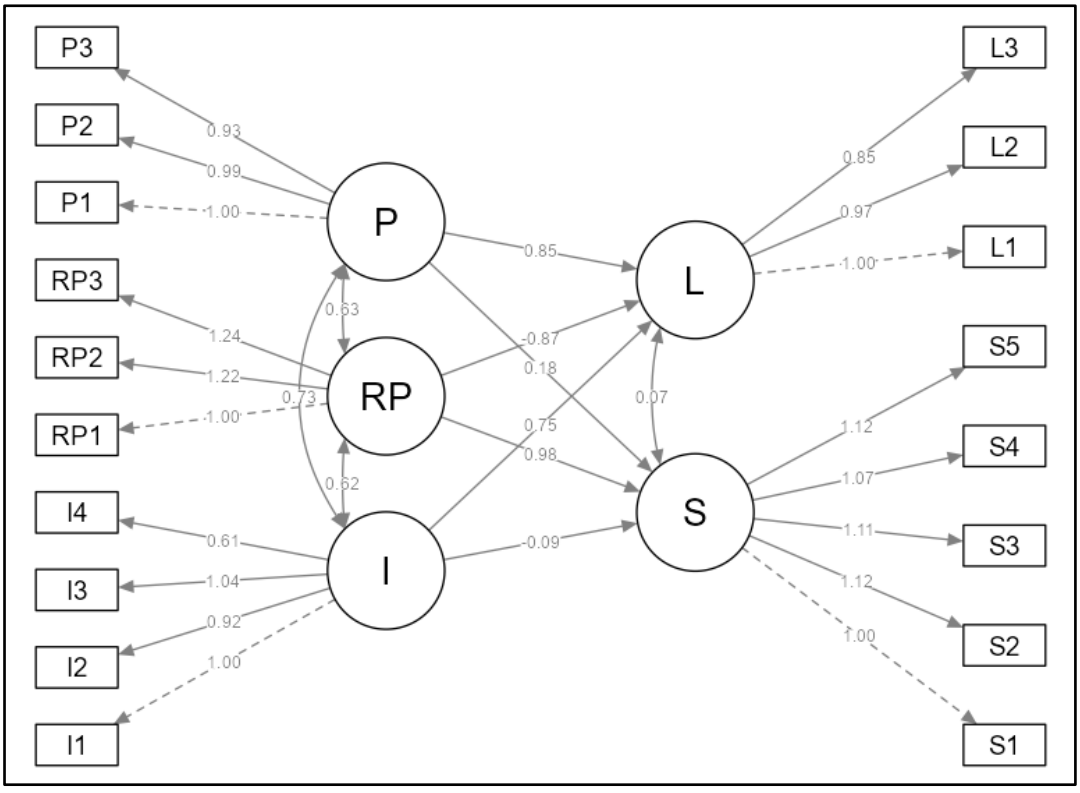

Figure 1: SEM Model

Dashed lines in the model generally represent hypotheses that are being tested and do not have strong empirical confirmation.

Table 1: Estimated model parameters.

			95% Confidence Intervals		
Type	**SRMR**	**RMSEA**	**Lower**	**Upper**	**RMSEA p**
Classical	0.055	0.053	0.027	0.074	0.394
Robust	0.052				
Scaled	0.052	0.100	0.083	0.117	< .001

Table 4: Model used vs reference model

	Model
Comparative Fit Index (CFI)	0.999
Tucker-Lewis Index (TLI)	0.999
Bentler-Bonett Non-normed Fit Index (NNFI)	0.999
Relative Noncentrality Index (RNI)	0.999

	Model
Bentler-Bonett Normed Fit Index (NFI)	0.996
Bollen's Relative Fit Index (RFI)	0.995
Bollen's Incremental Fit Index (IFI)	0.999
Parsimony Normed Fit Index (PNFI)	0.814

Regarding the RMSEA indicator, which, according to Xia and Yang (2019), "assesses how well the model, with the estimated parameters, fits the covariance matrix if it were available". In this case, the value came out to be 0.051 which indicates an acceptable model fit. Also, in relation to the CFI (Comparative Fit Index), which is an "(…) incremental fit index that compares the fit of a hypothetical model with that of a reference model" (Xia and Yang, 2019), a value of 0.999 it can be concluded that the model has a very strong fit and is adequate to explain the relationships between the variables being analysed.

The results of this research provide an interesting insight into the influence of chatbots on the "S" and "L" of consumers of telephony services in Metropolitan Lima in 2024.

The provided PLS-SEM model analyzes the relationships between several dimensions: Personalization (P), Problem Solving (RP), Interaction (I), Satisfaction (S), and Loyalty (L). The analysis of the results shows that the interaction has a non-significant negative relationship with customer satisfaction (coefficient: -0.0913, p-value: 0.718), which could be because the quality of the interaction is not consistently perceived as positive. by clients. On the other hand, the ability to solve problems has a positive and significant relationship with customer satisfaction (coefficient: 0.9773, p-value: 0.017), suggesting that effective problem-solving increases satisfaction. Personalization has a positive but non-significant relationship with customer satisfaction (coefficient: 0.1768, p-value: 0.272), indicating that customization alone is not a determining factor in satisfaction.

Regarding loyalty, interaction has a marginally significant positive relationship with customer loyalty (coefficient: 0.7503, p-value: 0.066), suggesting that good interaction can influence loyalty, but not conclusively. The ability to solve problems has a non-significant negative relationship with customer loyalty (coefficient: -0.8684, p-value: 0.170), which is counterintuitive and could indicate that problem solving does not always translate into loyalty. In contrast, personalization has a positive and significant relationship with customer loyalty (coefficient: 0.8512, p-value: 0.004), indicating that personalization is a key factor in fostering loyalty.

The results of the measurement model show that the construct indicators have high and significant loadings, except for the Interaction indicator I4, which has a lower loading (0.607), which could suggest problems with this item, this is an opportunity to improve future research. The Problem Solving and Personalization constructs have indicators with high and significant loadings, which indicates that they adequately measure the constructs. Customer Satisfaction, measured by indicators S1 to S5, and Customer Loyalty, measured by L1 to L3, also present very high and significant loadings, indicating that they are good measures of their respective constructs.

A negative coefficient on structural relationships, such as RP to L, may indicate an unexpected inverse relationship and may be due to problems with the operationalization of the constructs, cultural differences, or unmet customer expectations. Given that this research is original in a geographical context not extensively explored, this finding constitutes an opportunity to explore this phenomenon in detail rather than a weakness.

Values of 1 in the indicator loadings indicate that these are perfect reflections of their respective constructs, which can occur when the construct is measured by a single indicator or when the model has been standardized in this way.

For the results that we will call unexpected, the following alternative explanations are proposed.
Interaction and Satisfaction: The negative relationship could indicate that the quantity of interaction is not as important as its quality. Excessive interactions could be perceived as annoying or invasive by customers.
Problem Solving and Loyalty: Problem solving could be linked to previous serious problems that reduced initial loyalty, and even if they are resolved, the damage to loyalty could already be done.

4. Conclusions

In conclusion, personalization is a critical factor for customer loyalty, the ability to solve problems significantly increases customer satisfaction, although it does not have a significant impact on loyalty, and interaction has a marginal impact on loyalty and has not a significant impact on satisfaction, which suggests that the quality of

the interaction must be improved. It is recommended to improve the quality of the interaction, encourage personalization and review the problem resolution strategy to understand why it does not translate into loyalty.

It is necessary to note that analysis has highlighted both the expected and unexpected results of structural equation modeling using PLS-SEM for these study variables in a little explored geographic context. Alternative explanations for the unexpected results have been proposed and future lines of research have been suggested to address these issues. Based on the findings and the proposed alternative explanations, the following lines of future research are suggested: Quality vs. Quantity of Interactions, to investigate the influence of the quality and quantity of interactions on customer satisfaction, differentiating between types of interaction.
Delve into the impact of Previous Problems, thus studying the impact of previous problems on loyalty and how problem resolution can restore, but not necessarily improve, loyalty. Although further research is crucial to better understand these dynamics and incorporate cultural or geographic variables in future research.

Abstract: In the era of a knowledge-based economy, effective knowledge management, including knowledge sharing, is one of the determinants of organizational performance. Therefore, the task of companies should be to optimize the process of knowledge sharing, which is achieved by, among other things, a thorough understanding and use of the factors that affect this process. **Aim**. The purpose of the article was to study the relationship between the level of occupational stress and readiness towards knowledge sharing among IT Sector Employees. **Method.** A cross-sectional study model was applied. The study included 98 employees from the IT industry. The study used the Perceived Stress at Work Scale (PSaW) by Chirkowska-Smolak and Grobelny and a self-designed survey including: demographic data, work-related variables and questions about knowledge sharing with co-workers. **Results**. In the surveyed group of IT workers, greater readiness to share knowledge was found among employees who showed lower scores on the PSaW scale. In addition, significant relationships were found between the study variables according to the selected variables, including that among women with low rates of perceived stress at work, older women showed greater willingness to share knowledge compared to younger women. Furthermore, in terms of work-related variables, the results showed that among men declaring high rates of stress, those with shorter seniority were more willing to share knowledge compared to men with longer seniority. **Conclusions:** The research findings significantly broaden knowledge in the sphere of the factors influencing the effective organization of the knowledge management process, particularly knowledge sharing under stressful work conditions. This knowledge can be useful especially for IT managers.

Keywords: Knowledge Sharing, Stress Level, Employees

1. Introduction

Contemporary socio-economic conditions (e.g. rising inflation, turbulent global political situation) make it difficult for businesses to function and force them into strong competition to maintain their position. It is in an organization's interest to take care of every aspect of its functioning in order to keep up with market demands and ensure its competitiveness. One important aspect of an organization's functioning, especially in the era of a knowledge-based economy, is effective knowledge sharing (KS). KS involves the exchange of knowledge between at least two parties in a reciprocal process that allows the knowledge to be reshaped and made meaningful in a new context (Willem, 2003). Importantly, proper implementation of KS can be particularly important for organizational performance (Muhammed, Zaim, 2020). Organizations should therefore ensure that this process is carried out taking into account both the impact of various KS determinants, as well as solutions to improve the process (e.g. in the IT sector knowledge transfer is strengthened by extending the individual beyond the formal communication channels, such as: computer networks, electronic bulletin boards, etc. (Zheng, 2017)). The quality of KS implementation in an organization can be affected by technological, organizational, as well as individual factors (Paroutis, Al Saleh, 2009). One of the factors determining KS may be the level of stress experienced by individuals at work. This article attempts to verify the significance of selected KS determinants by answering the following question: is there a relationship between the level of perceived stress at work and readiness to share knowledge? When testing the aforementioned relationship, selected demographic and work-related factors were also taken into account.

2. Literature Review and Research Background

The unstable economic situation due to recent events, such as the pandemic, war, rising inflation, and the cost of living, has significantly affected the labor market and working conditions. Workplace stress has become a common experience. The results of a survey conducted in 2022 by GoodHabitz together with the research agency Markteffect on a sample of 24,235 employees in various positions, industries, and countries around the world indicate that one in five employees (18%) experienced significant signs of stress or burnout in the previous year (GoodHabitz, 2022). For Polish employees, this rate was 23%. Work-related stress generates a serious financial burden for societies around the world. The results of a narrative review indicate estimates that range from €54 million to €280 billion depending on the country (Shaholli, Mantione, La Torre, 2023). The results also suggest that lost productivity due to absenteeism and presenteeism has a greater economic impact compared to the medical expenses.

In practice, it is observed that there is still a prevalence in certain organizations of the tendency to accumulate knowledge rather than to share it (Ismail, Yusof, 2009). This is because knowledge can be perceived by an employee as private property – a valuable resource – which results in a greater tendency to hoard it rather than share it (Zhang, Song, Song, 2020). At the same time, this propensity may become more pronounced especially in stressful situations. To the author's knowledge, few empirical works verify a direct relationship between stress experienced and readiness towards KS, so there is still a lack of research in this area. This relationship was confirmed in a study by Marques et al. (2019) which revealed a positive relationship between organizational stress and disengagement from knowledge sharing and between stress and maturity in knowledge management. In contrast, research by Ford et al. (2015) indicated that poor health and worries are associated with more disengagement from knowledge sharing. Fang (2017), on the other hand, highlights the role of negative affect, such as anxiety, in knowledge hiding.

In an attempt to clarify the basis of the relationship between stress experienced at work and readiness towards KS, it is worth noting some characteristics of stress. Stress, which is an integral part of a person's life, including a professionally active person, can be defined using the words of Lazarus and Folkman (1984) as: "a particular relationship between the person and the environment that is appraised by the person as taxing or exceeding his or her resources and endangering his or her well-being". Stress is therefore the result of the interaction between the individual's capabilities and the demands of the environment. In turn, according to Hobfoll's (2006) theory, stress is recognized when: 1) there is a threat of resource loss, 2) there is an actual resource loss, or 3) there are no gains following resource investment. Stress is therefore an internal state of the individual determined by the perception of the aforementioned circumstances. The stress response involves three levels: physiological (including: accelerated heart rate, increased blood pressure, bronchodilation, pupil dilation), psychological (including: narrowing of the attention field, reduced concentration, impaired ability to adequately assess the situation, impaired memory, anxiety attacks), and behavioral (including: appetite disorders, sleep disturbances, nervous tics) (Kashubska, 2023). In the area of stress-induced psychological changes, the consequences for the functioning of cognitive processes, including attention, may be particularly relevant to the issue at hand. Research suggests that in a situation of heightened tension, an individual may experience a restriction or narrowing of the field of attention – so-called *attentional tunneling*. This phenomenon can be defined as "the allocation of attention to a particular channel of information, diagnostic hypothesis, or task goal, for a duration that is longer than optimal, given the expected cost of neglecting events on other channels, failing to consider other hypotheses, or failing to perform other tasks" (Wickens, Alexander, 2009). In a stressful situation, the perceptual field may be narrowed, and the scope or span of behavior tends to be restricted to those elements which contribute most to the direction of behavior, or to those elements which appear to be the most dangerous (Staal, 2004). Thus, under stressful conditions, employees may be particularly preoccupied with aspects that constitute the content of stressful experiences, while they may be less focused on other activities, especially extracurricular work activities. Based on this, it can be suspected that readiness towards KS under conditions of experienced occupational stress may be lower than under conditions of perceived psychological comfort in the workplace. In order to verify this relationship, the following research question has been formulated:

Is there a relationship between the level of perceived occupational stress and readiness towards knowledge sharing among IT sector employees?

Exploring the indicated relationships and their determinants among Polish IT sector employees is also justified by the lack of similar empirical work, at least to the knowledge of the author, conducted with the participation of such a group of respondents. . Thus, the findings would constitute an important supplementation of research gaps in this sphere.

3. Methodology

3.1 Participants

The research was conducted among the employees of an IT sector company based in central Poland. The conditions for participation in the study were employment in the company for at least six months, knowledge of written Polish and voluntary consent to participate in the study. The research was conducted using online technology, anonymously. Respondents who agreed to participate completed questionnaires that were made available to them remotely. Among the employees invited to the study, consent to take part in the research was expressed by 103 people. Ultimately, the research group consisted of 98 people (5 people did not complete all questionnaires): 36 women and 62 men declaring Polish citizenship. The sample was heterogeneous in terms of

age, workplace education and job seniority (aged between 28 and 56: M=40.9; SD=8.7, the seniority of the employees surveyed ranged from 0.5 to 11 years: M=5.3; SD=2.8). Detailed characterization of the analyzed group is presented in Table 1.

Table 1: Characteristics of the study group

		N	%
Employees	women	36	36.7
	men	62	63.3
Education	higher	69	70.4
	secondary	29	29.6
Workplace	IT application specialist	34	34.7
	service support specialist	12	12.2
	designer and computer systems analyst	25	25.5
	programming specialist	27	27.6
		M	**SD**
Age (years)		40.9	8.7
Job seniority (years)		5.3	2.8

3.2 Measures

The study used a self-designed survey that takes into account the following data: sex and age of the person surveyed, education, as well as position held and job seniority in the firm analyzed. The survey also included the following question relating to knowledge sharing: *How often do you pass on your specialized knowledge to other employees (apart from situations when passing on the knowledge results directly from your superior's instructions)?* Respondents answered the aforesaid question on a five-point scale as follows: 1-never, 2-rarely, 3-sometimes, 4-often, 5-very often.

The *Perceived Stress at Work (PSaW) Scale* by Chirkowska-Smolak and Grobelny was used to measure perceived stress at work (Chirkowska-Smolak, Grobelny, 2016). The scale consists of 10 questions which the respondents use to evaluate their beliefs about unpredictability, lack of control and being overwhelmed by events at work in the month preceding the survey. Respondents answer the questions using a five-point scale (0 – never, 1 – almost never , 2 – sometimes, 3 – quite often, 4 – very often). The scale scores obtained in the survey range from 0–40, where a higher score indicates a higher rating of stress severity. The Cronbach's alpha reliability coefficient in the survey conducted with 537 people was 0.85.

3.3 Data Analysis

The study had a cross-sectional design. Due to the failure to fulfill the assumptions of the normality of distribution, as well as the unequal distribution of the numbers of the sub-groups compared, non-parametric tests were used for statistical analysis. Spearman's rank correlation was used to assess the relationship between the level of perceived stress at work and readiness towards KS, as well as to evaluate the association of selected factors with readiness towards KS in study groups with different levels of stress. The level of statistical significance was accepted as $p<0.05$. The calculations were performed using STATISTICA 13.3 statistical software by StatSoft.

4. Results

The study revealed an overall average level of stress in both the female and male study groups (respectively: M =26.72, SD = 10.5; M = 24.96, SD = 9.42). When considering the distribution according to the severity of perceived stress in both groups, the highest number of respondents showed high levels of perceived stress at work. The detailed test findings are presented in Table 2.

Tabel 2: Results of the perceived stress at work (PSaW) severity survey by gender

Level of Stress		n	M	SD
women	total	36	26.72	10.5
	low	6	7.67	3.39
	medium	14	20.50	3.44
	high	16	34.81	2.67
men	total	62	24.96	9.42
	low	10	10.00	2.00
	medium	14	20.36	3.15
	high	38	34.89	4.30

The results of testing the relationship between perceived stress at work and readiness towards KS revealed a negative statistically significant relationship between the variables ($p<0.05$). This means that the higher the level of perceived stress at work, the lower the readiness to share knowledge among the employees surveyed. The results of the study are presented in Table 3.

Table 3: Relationship between severity of perceived stress at work and readiness towards KS

Spearman's r	P
-0.732	0.000

Groups of respondents with different levels of perceived stress at work (low, medium and high) were distinguished in order to find out the significance of selected factors (age, seniority) for the variable readiness towards KS in relation to the level of perceived stress at work. Subsequently, the relationships of factors (age, seniority) and readiness towards KS were verified in the specified groups of respondents. As a result of testing the relationship between age and readiness towards KS in the study group (men and women) according to the level of perceived stress at work, a statistically significant correlation ($p<0.05$) was obtained only in the group of women reporting low levels of perceived stress at work. The results indicate that in the group of women with low stress levels, older age is associated with greater readiness towards KS. On the other hand, in terms of the seniority variable, a statistically significant negative correlation ($p<0.05$) was revealed only in the group of men reporting high levels of perceived stress at work. This relationship means that in this group, shorter seniority is associated with greater readiness towards KS. Details of the relationships tested are shown in Tables 4 and 5.

Table 4: Relationship between age and readiness towards KS in the study group (men and women) according to the level of perceived stress at work (PSaW)

	Level of stress	Spearman's r	p
women	low	0.198	0.043
	medium	0.346	0.224
	high	0.376	0.150
men	low	0.577	0.080
	medium	-0.249	0.389
	high	0.001	0.993

Table 5: Relationship between seniority and readiness towards knowledge sharing in the study group (men and women) according to the level of perceived stress at work (PSaW)

	Level of stress	Spearman's r	p
women	low	0.097	0.854
	medium	0.198	0.496
	high	-0.149	0.579
men	low	-0.073	0.839
	medium	-0.089	0.759
	high	-0.655	0.000

5. Discussion

Based on the survey, it can be concluded that there is a relationship between the level of perceived occupational stress and readiness towards KS among IT Sector Employees. Lower levels of perceived stress at work promote readiness towards KS among the employees surveyed, while higher levels of perceived stress are associated with lower readiness towards KS. This result is consistent with other studies cited in the literature review (Fang, 2017; Ford et al., 2015; Marques et al., 2019), which emphasize the negative impact of stress and negative affect on readiness towards KS. The results obtained can be explained by referring to the phenomenon of *attentional tunneling* which justifies the narrowing of the scope of attention and the amount of information processed in a

stressful situation. Easterbrook (1959) explained this mechanism in his theory, arguing that in a situation of strong emotional arousal, there is a focus on the most important stimuli associated with the arousal and a disregard for stimuli less relevant to the situation. The mechanism of changes associated with selective attention under stress is confirmed by numerous empirical studies (Chajut, Algom, 2003; LeBlanc, 2009; Vedhara et al., 2000).

On this basis, it can be concluded that employees who experience high levels of stress at work focus primarily on the source of the stress and the possibility of removing it. In contrast, knowledge sharing undertaken voluntarily between employees is an extracurricular activity that requires cognitive engagement and strains attentional resources. According to the concept of attentional selectivity, voluntary KS-related activity may therefore be overlooked in favor of content that is prioritized in light of the stress experienced. As an extracurricular and optional activity, it may also give way to meeting occupational requirements that are obligatory and determine one's continued employment. Interesting results were also obtained regarding the relationship of selected factors and readiness towards KS according to the level of perceived stress at work. The study revealed that in the group of women with low levels of stress, older age was associated with greater readiness towards KS, while in the group of men declaring high levels of perceived stress at work, shorter seniority was associated with greater readiness towards KS. The higher propensity to share knowledge among older women compared to younger women is also confirmed by the results of other studies (Burmeister, Fasbender, & Deller, 2018; Dunham, Burt, 2011; Krzyżowska, 2023). This propensity can be explained by the soft skills expertise increasing with age, especially in terms of cooperation, as well as the development of empathy (in women it can be stimulated through motherhood), all of which are conducive to KS behaviors.

At the same time, the above-mentioned relationship became apparent only in the group of women declaring low rates of perceived stress at work. This may mean that experiencing stress plays a key role in readiness towards KS in the surveyed group of IT employees – in the least stressed group, older women are more willing to share knowledge than younger ones, while in the groups with medium and high levels of stress, similar relationships did not emerge. It is likely that the moderate and intense stress experienced reduces readiness towards KS in a similar way regardless of the age of the respondents. In men, no correlation between age and readiness towards KS emerged in any of the groups due to the level of perceived stress at work, which means that for women who report minimal stress at work, age will be more important for readiness towards KS than for those men who rate their stress at work at a similar level. Furthermore, it can be concluded from the results that age does not determine the readiness towards KS of the men surveyed, both for those who experience and those who do not experience stress at work.

In contrast, seniority proved to be a significant variable in the group of men indicating high rates of stress, where the shorter the seniority, the greater the readiness towards KS. The result may be surprising in view of some studies that indicate that professional experience and job security are conducive to KS (Bartol et al., 2009; Doulani, Mohammadi, Bradar, 2020; Mehrizi, 2016), or other studies by the author, where employees with more than 5 years of seniority showed greater readiness towards KS than employees working for less than 5 years (Krzyżowska, 2023). Indeed, seniority determines the development of one's professional competence, sense of efficacy and confidence in one's professional functioning, thus influencing the growth of work experience which has a strong effect on knowledge sharing in the workplace (Oye, Salleh, Noorminshah, 2011). However, the aforementioned studies did not take into account the stress factor, which may have a significant moderating effect on the relationship in question (the relationship was revealed only in the group that indicated the highest rates of stress at work). It is worth noting that very severe stress can affect one's way of responding, resulting in a greater tendency toward automatic, instinctive reactions, the kind that aim at survival (Bourne, Yaroush, 2003). Perhaps younger men who are still uncertain of their competence and their professional position when confronted with a highly stressful situation are more inclined to share the knowledge they already have, hoping that, according to the rule of reciprocity, other employees will also share their knowledge with them. Moreover, they want to get into the good graces and win over the community of co-workers in this way. Thus, this may be a kind of automatic reaction "aimed at survival" and ensuring a stable professional position in a relatively new professional environment, which ultimately results in a greater readiness towards KS in this group than in the group of highly stressed employees with longer seniority.

This relationship therefore points to more detailed connections with readiness towards KS resulting from the influence of variable coexistence, which can be found against the background of the main relationship studied – stress and readiness towards KS. Interestingly, similar relationships did not emerge in the women's group; it is possible that women are less likely than men to evaluate work as a resource that they would have to care about first under conditions of severe threat. However, these suppositions require detailed empirical verification.

6. Conclusions

The aim of the research presented herein was to provide an answer to the following research question posed in this paper: *Is there a relationship between the level of perceived occupational stress and readiness towards knowledge sharing among IT sector employees?* The research findings acquired from a group of employees of the IT sector indicates that in the surveyed group of IT employees, a higher readiness towards KS was found among employees who scored low in terms of perceived stress at work. Furthermore, when testing the relationship in question, significant connections were found when selected variables were taken into account, such as age (among women with low rates of perceived stress at work, older women showed greater readiness towards KS compared to younger women) or seniority (among men reporting high rates of stress, those with shorter seniority showed greater readiness towards KS than those with longer seniority).

Conclusions drawn from the results of this study highlight the importance of the stress experienced for the functioning of the employee in the workplace and the organization as a whole. As highlighted in the introduction, KS is important for organizational performance, and workplace stress is a factor that generally has a negative impact on employees' readiness towards KS, especially the kind of readiness that does not stem from anxiety. In the IT industry, this is all the more important because IT services are among the knowledge-intensive services in which most activities are intellectual tasks (Khatri et al., 2010). The process of knowledge exchange in IT organizations should therefore be constantly improved, and this should be achieved, among other things, by understanding the determinants of KS.

The conclusions from the research imply significant practical recommendations for the managers of the IT sector:

1. It is important that they are aware of the negative impact of stress on employees' intrinsic motivation towards KS and thus that they implement stress prevention programs in the workplace and measures to counteract the consequences of stress experienced by employees at work.
2. It is important that, in the context of stimulating positive motivation towards KS, they pay particular attention to younger women who do not declare high stress and men with high rates of perceived stress at work with long seniority.

Informal Learning and its Moderating Effect Between Employability and job performance of Young Recent Graduates in Their First job

Giancarlo Medroa Delgado
University of Lima, Peru

gmeddel@ulima.edu.pe

Abstract: The purpose of this paper is to examine the effects of knowledge management through informal learning on the relationship between employability and job performance of recent graduates in their first jobs. A quantitative, cross-sectional survey of 392 graduates of business school management programs at 4 universities in Lima, Peru was conducted to study the relationship between employability and job performance as moderated by informal learning inside and outside the work environment. It is confirmed that informal learning positively moderates the relationship between employability and job performance of recent graduates. However, informal learning impacts the employability dimensions differently. The results challenge traditional methods of learning and training inside and outside the work environment and provide new insights for knowledge management, talent management and their induction, training and development programs for a dynamic workforce with digital skills developed since the university stage. The implications of limiting employees' access to informal learning activities may limit future employability and job performance; employees can develop knowledge and competencies through informal learning activities on their own initiative, however, it is important to facilitate this process within the organization's processes. This study provides further evidence of the relationships between employability, informal learning and job performance in young recent graduates. In addition, it provides knowledge on how business schools can include informal or non-instructional learning activities in their curricula, thus generating self-learning skills for upcoming graduates and improving their skills and competencies.

Keywords: Knowledge Management**,** Informal Learning, Employability, job Performance, Recent Graduate, First job.

1. Introduction

Currently, the increase in local competition, the globalization process and the constant changes in the field of management, have highlighted the need to emphasize the importance of investing in the development of employees' skills to ensure the survival of organizations and achieve business sustainability. In this sense, it confirms the importance of human resources development to ensure the development of employees' skills and prepare them for the current operational, commercial and administrative requirements that the environment demands. Likewise, it is important that the development of these skills be generated from a university preparation stage and thus establish a transition from university to the most productive career for all stakeholders. It is stated that learning as a means for personnel development leads to this achievement by promoting the Employability (EMP) of the collaborator and his performance in the workplace (Dunphy et al., 1997). Kolb (1984) defines learning as a process in which knowledge is generated through the transformation of experiences through a cyclical process involving experience, observation, conceptualization and experimentation. The theory emphasizes the central role of experience in learning. This cycle is continuous, and individuals can enter it at any stage. The theory also suggests that individuals have different learning styles based on their preferences for these stages, known as divergent, assimilative, convergent and accommodative.

Learning can have a place both inside and outside an organization and offers the possibility of improving Job Performance (JOB). It is stated that the ability to learn is one of the fundamental attributes of human beings and involves them in their development. Much of this development is informal, occasional, sporadic and in some cases random. Learning on the job can occur in several different ways, not just formally (Leslie et al., 1998).

As business becomes faster and faster and the rate of innovation accelerates, employees feel a certain degree of pressure to be competitive within their organization as well as in the labor market by seeking to improve their skills and competencies to develop their EMP levels and improve their JOB. EMP is based on a broad range of competencies, EMP is also defined as the continuous fulfillment, acquisition or creation of work through the optimal use of competencies, in other words, the possession of certain competencies should enable employees to obtain, retain or create work for themselves (Brockner et al., 2006). Collaborators who perceive themselves as highly employable feel less threatened by the environment, experience less stress and improve their JOB (Gerken et al., 2015). In that sense, recent graduates by developing employability competencies can develop attitudes of adaptability towards new work experiences and thus be more prepared to an increasingly demanding and competitive work dynamic. To address this dynamic, the concept of EMP has generated great interest in talent management departments and in the academic environment, the same interest has been received by studies that analyze the development of skills and competencies of employees through effective

and novel learning processes (Kyndt et al., 2009).

For the moment the debate has concluded that the traditional methods of training in the work environment should be questioned, and further research should be done on the importance of using competence development strategies that are based on an integration of Formal Learning (FL) and Informal Learning (IL) as determining tools in knowledge management (Kock and Ellström, 2011). Underestimating IL can undermine the spontaneous nature of learning, claims that one type of learning is better or worse than the other should be avoided, both types of learning can be applied in organizations, both have advantages (Malcolm et al., 2003). IL is fundamental in the performance of collaborators in organizations, but it is not a replacement for FL or institutional education; although FL is more productive if it is designed and planned, the need for organizations to have informal information that increases learning based on experience is evident (Marsick and Watkins, 2016). It is stated that much of the knowledge and learning that occurs in organizations is accidental and informal, this characteristic does not contribute to the sustainability of these companies in the medium and long term; based on this context it is proposed to use knowledge-based learning methods that give an IL structure for the benefit of companies (O'Brien et al., 2019).

Just as various types of learning influence performance, it is also argued that learning is essential for improving EMP. There is sufficient evidence finding several positive outcomes of learning on employees' EMP, such as confidence, openness to change, and competitiveness (Crouse et al., 2011). Van der Klink et al. (2014) have studied the effects of education and training on EMP among employees and found positive effects. Van Der Heijden et al. (2009) affirms the positive effect between IL and EMP of employees. Similarly, Lecat et al. (2018) report positive relationships between IL and occupational specialization and optimization. These findings confirm the relationship between IL and its positive influence with EMP.

Recent studies have analyzed the relationship between EMP, JOB and IL, finding a strong relationship between the variables; however, no research has addressed the moderating relationship of IL between EMP and JOB of young recent business school graduates in their first work experience.

The research questions are:

- Is IL a suitable knowledge management method to foster the EMP of newly graduated employees?
- What are the most appropriate learning methods to improve the JOB of newly graduated employees in their first work experience?
- Are there learning methods that intervene positively or negatively in the relationship of EMP and JOB?

2. Literature Review

Formal training programs cannot adequately prepare employees for all possible scenarios and are usually not designed to equip people for continuous learning on the job; employees need to acquire new knowledge and skills continuously through informal programs as non-curricular means (Tannenbaum and Cerasoli, 2013). In Sambrook's (2005) research, it is suggested that for the achievement of JOB, the use of both FL and or IL should be encouraged, in other words, both forms of learning should be integrated to maximize the benefits of employee development. Individual learning in the workplace takes place through the dynamic interaction between FL and IL, so it may be difficult to conceive of either form being successful without adding another form of component. In the same vein, employee learning has a profound impact on the success of modern organizations. Well-designed, timely, and novel formal and non-formal training programs can drive JOB (Cerasoli et al., 2018). Staff development was found to have an indirect effect on JOB through informal methods learning. Moreover, the indirect effect of staff development on JOB through IL became stronger in small and medium-sized firms. (Choi and Jacobs, 2009). It is confirmed that IL as a process within staff development practice positively impacts on JOB. It can be concluded that learning strategy is key to JOB, and that IL is of particular importance (Lejeune et al., 2021).

EMP skills encompass a range of competencies that are crucial for individuals to succeed in the labor market. Although formal education has traditionally been considered the primary means of acquiring these competencies, there is growing recognition of the importance of IL in enhancing EMP (Bates et al., 2004). IL, which takes place outside of traditional educational settings, plays an important role in the development of personal and professional competencies that can improve an individual's confidence and overall EMP (Bates et al., 2004). Research suggests that EMP competencies are most effectively developed when they are integrated into the academic curricula of different disciplines, rather than being limited to stand-alone "EMP courses" (Wickramasinghe and Perera, 2010). This integration ensures that students are explicitly taught and

encouraged to cultivate these skills alongside their academic pursuits, thus enhancing their preparation for the labor market (Wickramasinghe and Perera, 2010). EMP skills encompass a wide range of competencies, such as teamwork, problem solving, adaptability, and resilience (Scott et al., 2017). Employers highly value communication and problem-solving skills, indicating the importance of these competencies in curriculum design to meet labor market needs. Furthermore, combining FL with feedback-seeking behaviors, a type of IL is particularly advantageous for developing the complex skills needed in the workplace (Elsen et al., 2022). While formal education remains essential for acquiring professional skills, IL complements formal training by fostering interpersonal skills, decision-making abilities, and problem-solving skills, which are in high demand by employers (Taute, 2014). The synergy between formal training and IL not only improves people's EMP, but also contributes to their continuous professional development (Taute, 2014). Therefore, the relationship between IL and EMP is increasingly recognized as a vital element in preparing individuals, by integrating EMP competencies into formal education, recognizing the value of IL experiences, and emphasizing the development of a diverse set of competencies, individuals can improve their EMP and stand out in today's competitive labor market.

Previous studies, although they have not empirically examined the relationship between IL, EMP and JOB, in recent business school graduates in their first jobs, have provided several findings suggesting a positive association between the variables. However, it is noteworthy that IL had a more significant impact compared to formal training; that is, the research results clearly demonstrate that IL activities play a crucial role in individual JOB than FL activities. Therefore, it can be concluded that IL is a key factor in improving job performance by developing relevant competencies. The studies by Froehlich et al. (2014) and Van Der Heijden et al. (2009) collectively suggest that both FL and informal are expected to have a positive impact on individual JOB. This study, like Froehlich et al. (2014), considers that employees are employable, have extensive technical knowledge about their field of work, are attentive to contextual changes and are resilient to the changes imposed on them. In this sense, only 3 of the 5 dimensions of the (Van der Heijde and Van der Heijden, 2006) model linked to the characteristics indicated above will be analyzed.

3. Theoretical Framework

3.1 Formal Learning and Informal Learning

The learning theory proposed by Marsick and Watkins (2016) points out 2 types of learning; the first one is the FL that is characterized by being a planned learning, certified and developed in courses provided in higher education institutions; and the second one the IL is the one that is learned in the daily activities at work, where the learning is given by the active participation of workers in the organization's projects, as well as the rotation of personnel within the organization. It has been known for some time that more learning occurs in the workplace than just what happens in formal training classrooms. Brockner et al. (2006) have identified the different forms of workplace learning as formal, informal and incidental. FL (training), of course, are discrete planned events (experiences) used to instruct people on how to perform specific defined jobs. It is usually institutionally sponsored and highly structured. IL can occur in institutions, but it is typically not classroom-based or highly structured, and control of the learning is in the hands of the learner, not determined by the organization. AF includes an expressed goal of the organization and a defined process.

Workplace learning occurs through a dynamic interaction between FL and IL. They feel that FL stimulates IL, and that IL often leads to engaging in more structured learning activities (Shipton et al., 2002). The two types of learning complement each other and lead to new improvements and innovations, workplace learning does not occur for its own sake, but to achieve organizational and individual goals. Organizational goals include increasing worker participation in decision making and expanded job responsibilities. Workplace learning is defined as a means of addressing employee development that is consequently designed to improve the likelihood of achieving individual and/or organizational performance, or as an individual process designed to achieve learning toward the attainment of personal and professional goals (Park et al., 2019).

3.2 Employability

The concept of EMP focuses on three areas: labor market outcomes, the individual's responsibility to develop and maintain transferable skills due to the increasing prevalence of inter-organizational careers (Hall, 2004), and the relativity of EMP in terms of both supply and demand in the labor market (Rothwell and Arnold, 2007). Based on extensive literature and empirical research, five employable employee competencies (or dimensions

of EMP), knowledge, work experience, anticipation and optimization, personal flexibility, corporate sense and balance, were identified (Van Der Heijden et al., 2009). EMP is conceptualized as a form of job-specific active adaptability that enables workers to identify and take advantage of career opportunities. Thus, EMP facilitates movement between jobs, both within and between organizations. Although EMP does not ensure actual employment, it improves the likelihood that an individual will obtain a job. An individual is employable to the extent that he or she can effectively leverage personal factors to negotiate environmental demands (Fugate et al., 2004).

3.3 Job Performance

For Tsui et al. (1997), the JOB is generated in four dimensions, from the employer's perspective, on the relationship between them and their subordinates. These become, firstly, the Quasi Spot Contract defined as the pure economic exchange, where the employer offers short-term economic incentives in exchange for specific contributions from the employee. Secondly, the Mutual Investment, which involves unspecified, broad obligations open to both parties, where the incentives offered by employers go beyond monetary rewards. Third, the Underinvestment type relationship, where in the employment relationship the employee is expected to assume broad and unlimited obligations while the employer reciprocates with specific, short-term monetary rewards with no commitment to any investment in the subordinate's training or career life. Finally, within the unbalanced approach is the overinvestment relationship, where the employee is characterized by performing only a specific set of work-focused activities while the employer offers open-ended and wide-ranging rewards that include benefits such as training and commitment to a lifetime of career opportunities.

On the other hand, the theory of Rich et al. (2010) defines the variable of JOB as that "additional value attached to a company from a set of behaviors or behaviors that an employee contributes both directly and indirectly to the objectives of the organization". In this study, the author conducted an analysis that supports the hypothesis that job engagement is related to perceived organizational support, value congruence and core self-evaluations, and the two dimensions of job development, which are task performance and organizational citizenship behavior. It is also mentioned that JOB does not only include task performance, but also includes behaviors that contribute to companies in a less direct way such as a favorable social and psychological environment for the performance of work involved to the core tasks. It has also been determined that JOB is made up of 3 components. The first is role behavior, the second is organizational citizenship behavior that benefits the organization, and the third is organizational citizenship behaviors that benefit the individual (Williams and Anderson, 1991).

In view of the above, this research work formulates the following hypotheses.

H1: EMP is positively and significantly associated with JOB.

H2: IL is positively and significantly associated with JOB.

H3: IL positively moderates the relationship between EMP and JOB.

4. Methodology

4.1 Sample Design

A cross-sectional quantitative survey was conducted among 392 graduates of business school management programs from 4 universities in Lima, Peru, to study the relationship between employability and job performance moderated by informal learning inside and outside the work environment. A quantitative methodology was applied where a structured questionnaire was used to collect responses from the subject of interest, which required between 8 to 10 minutes to complete. All respondents were informed of the objective of the research and the strictly academic purposes of the present investigation were confirmed. The characteristics of the cases surveyed are shown in Table 1. The first section of the research instrument included filter and control questions, in this section it was verified if the respondents were in their first work experience and if they were recent graduates. The following sections contained a section for the evaluation of the hypotheses of this article. The responses for the constructs were measured through Likert methodology, under a 5-point scale (1=strongly disagree, 5=strongly agree). The constructs measured were the following: Informal Learning (Froehlich et al., 2014), Employability (Van Der Heijden et al., 2009) and Job Performance (Williams and Anderson, 1991).

Table 1: Descriptive statistics

	Frequency	%
Number of employees per company		
Less than 10	218	55.6%
Between 11 to 20	46	11.7%
Between 21 to 50	128	32.7%
Company's Operating Time		
3 to 5 years	70	17.9%
5 to 10 years	167	42.6%
More than 10 years	155	39.5%
Genre		
Male	199	23.7%
Female	193	76.3%

4.2 Measures

In the context of this study, IL is operationally defined as respondents' subjective perception of the extent to which they actively participate in unstructured or spontaneous learning activities in their workplace, as well as the level of support provided by the organization to foster a culture conducive to learning at work. The study examined 4 dimensions of IL, including actively seeking information (IS), seeking feedback from both supervisors (SF) and colleagues (CF), as well as seeking help (HS) when needed (Froehlich et al., 2014). The measurement of the variable EMP focuses on a competency-based approach, emphasizing its advantages for both career and company outcomes (Van Der Heijden et al., 2009). EMP is considered a multidimensional concept with five correlated dimensions: (occupational expertise, anticipation and optimization, personal flexibility, corporate meaning and balance). For this research, priority is given to how employees themselves value their employability (Fugate et al., 2004). This is in line with previous studies, which suggest that perceived employability is more important than appraisal (equally subjective), since employees act on their own perceptions. Occupational experience (EXP), anticipation and optimization (ANT), and personal flexibility (FLEX) will be considered.

JOB refers to the perception that individuals have of their ability to fulfill the assigned tasks and responsibilities conferred on them by the employing organization. To assess and gauge the level of JOB, this research used the 3 dimensions of performance originally conceived by Williams and Anderson (1991), where 3 dimensions are identified as in-role behavior (IRB), organizational citizenship behavior that benefits the individual (OCBI) and organizational citizenship behavior that benefits the organization (OCBO).

5. Results

5.1 Validity and Reliability

The conceptual model (Figure 1) was tested using Smart PLS 4.0, a sophisticated and widely recognized software tool). To assess the efficacy and reliability of the model, a comprehensive evaluation was conducted, including measurement of item loadings, internal consistency, reliability, convergent validity, and discriminant validity. The detailed results of these evaluations are meticulously presented in Tables 2 and 3, providing an overview of the model's performance.

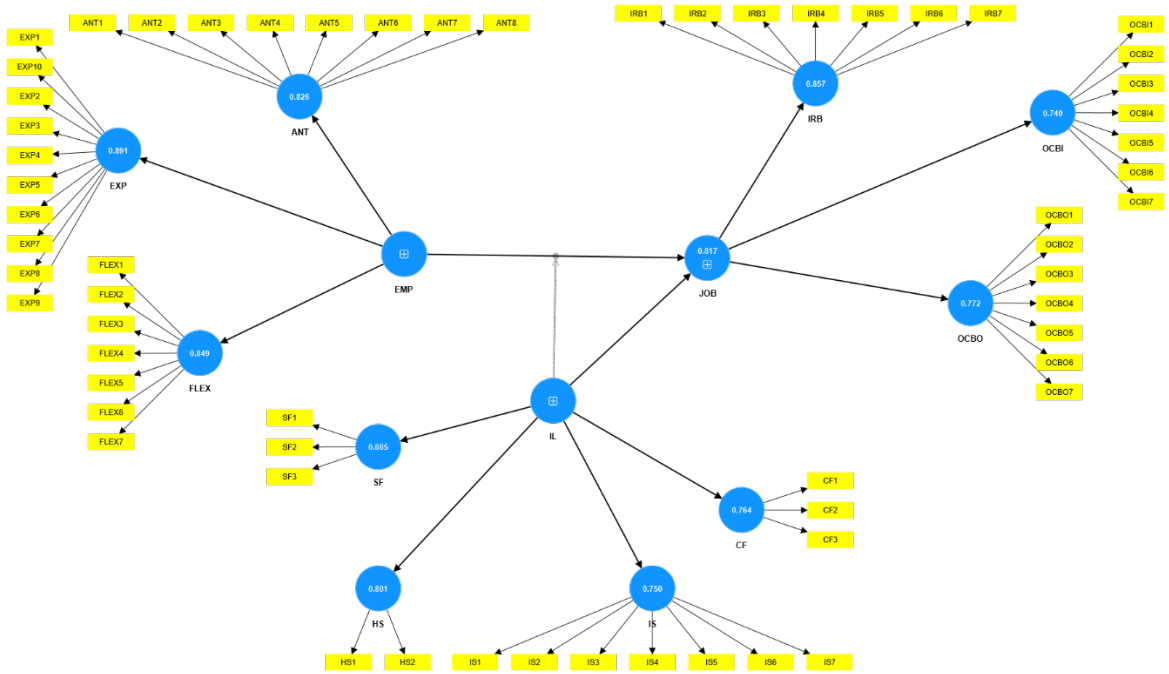

Figure 1: Structural Model

A crucial aspect that was examined during the evaluation was the loadings of the items used. It was observed that all item loadings exceeded the threshold of 0.50, which is considered statistically significant and indicative of convergent validity (Hair et al., 2014). This finding is highly relevant and reinforces the validity of the model, as it demonstrates that the constructs investigated accurately measure the intended concepts. This is a significant finding, as it provides further support for the robustness and reliability of the conceptual model.

Reliability was another important criterion assessed in this study and was evaluated using two widely accepted metrics: Cronbach's alpha and AVE composite reliability. The results of these assessments revealed that the model exhibits a high level of reliability. Specifically, an AVE value equal to or greater than 0.5 and a Cronbach's alpha indicator greater than 0.7 are considered indicative of an adequate model. In this case, all AVE values and Cronbach's alpha indicators exceeded these thresholds, which further reinforces the reliability and validity of the conceptual model investigated (Hair et al., 2014).

In addition to assessing the reliability and convergent validity of the model, an analysis was also performed to determine its discriminant validity. This analysis was intended to measure the differences between each construct and to assess whether they were distinct from each other. The results of the discriminant validity assessment were very encouraging, as they indicated that the square root of each AVE was greater than the correlations of the constructs. This result is significant, as it suggests that the constructs investigated measure unique and distinct concepts, which demonstrates the model's ability to discriminate between different constructs effectively (Hair et al., 2014). Overall, the results of this comprehensive evaluation strongly support the investigated conceptual model. The robustness and reliability of the model offers favorable results obtained in terms of convergent validity, reliability and discriminant validity.

Table 2: Measurement properties

Construct	Dimension	Cronbach's Alpha (>0.7)	AVE (>0.5)	CR (>0.7)
EMP	ANT	0.938	0.699	0.940
	EXP	0.960	0.734	0.960
	FLEX	0.927	0.697	0.929
IL	HS	0.855	0.874	0.857
	IS	0.894	0.613	0.903
	CF	0.935	0.884	0.935
	SF	0.942	0.896	0.942
JOB	IRB	0.946	0.758	0.948

Construct	Dimension	Cronbach's Alpha (>0.7)	AVE (>0.5)	CR (>0.7)
	OCBI	0.917	0.669	0.921
	OCBO	0.887	0.596	0.893

Note: Average variance extracted (AVE), composite reliability (CR).

Table 3: Discriminant validity Fornell - Larcker analysis

	ANT	CF	EXP	FLEX	HS	IRB	IS	OCBI	OCBO	SF
ANT	0.836									
CF	0.588	0.94								
EXP	0.784	0.62	0.857							
FLEX	0.753	0.621	0.815	0.835						
HS	0.594	0.699	0.69	0.719	0.935					
IRB	0.702	0.665	0.807	0.751	0.773	0.871				
IS	0.642	0.666	0.691	0.675	0.731	0.731	0.783			
OCBI	0.666	0.645	0.653	0.647	0.596	0.696	0.708	0.818		
OCBO	0.658	0.571	0.703	0.639	0.654	0.739	0.648	0.643	0.772	
SF	0.527	0.684	0.586	0.562	0.642	0.618	0.541	0.567	0.579	0.947

5.2 Structural Equation Model and Hypothesis Testing

The coefficient of determination was 0.817 (see Figure 1) for JOB, which indicates a substantial level of determination (Hair et al., 2012) generated by EMP and IL. That is, there are other determinants for JOB that will need to be the product of further research.

The first hypothesis, H1, indicates that EMP has a positive and significant effect on JOB. Table 4 indicates that a positive and significant effect can be traced between the variables (β = 0.429; T-value = 6.607 and p = 0.000). Therefore, H1 should be accepted. The second hypothesis, H2, indicates that IL has a positive and significant effect with JOB. Table 4 indicates that a positive and significant effect can be plotted between the variables (β = 0.454 T-value = 6.942 and p = 0.000). Therefore, H2 should be accepted. The third hypothesis, H3, indicates that IL has a positive and significant moderating effect with EMP and JOB. Table 4 indicates that a negative and significant effect can be traced between the variables (β = -0.035; T-value = 3.026 and p = 0.002). Therefore, H3 should be not accepted.

Variance inflation factors (VIF) were also calculated to detect multicollinearity between variables. VIFs greater than 10 indicate high and unacceptable levels of multicollinearity between constructs (Hair et al., 2014). The VIFs for the relationship between variable items ranged from 1.415 to 4.803, suggesting that the level of multicollinearity between these variables is acceptable.

Table 4: Hypothesis testing

	Coefficients	T-Value	p-Value	Hypothesis
EMP → JOB	0.429	6.607	0.000	H1 - Accepted
IL → JOB	0.454	6.942	0.000	H2 - Accepted
IL x EMP → JOB	-0.035	3.026	0.000	H3 – Not Accepted

5.3 Discussion

Driven by the increasing presence of demands for goal achievement, the competitiveness of local markets, the high rate of innovation, EMP, among other factors, put human resource managers on alert to develop efficient human talent management strategies to cope with all these demands of the labor market. Therefore, this research paper set out to investigate the effects of IL activities on the EMP and JOB of business school management program graduates in their first work experiences. Two general conclusions can be drawn from the results. First, the performance of learning activities generates EMP increases JOB; this relationship is driven by IL.

This study provides strong evidence supporting the thesis that IL play a crucial role in improving EMP and overall, JOB, which highlights the importance of continuous workplace learning and the development of employability competencies in business schools through IL. The relationship between IL, EMP and employee

JOB has been extensively studied in the literature. Research by Froehlich et al. (2014) highlights that IL contribute significantly to improving EMP, which in turn improves job performance. This conclusion is corroborated by Heijden et al. (2009), who highlight the importance of IL in increasing employee performance. In addition, Eldor and Harpaz (2015) discuss how learning climate influences performance behaviors, indicating a strong connection between learning environments and employee performance. In addition, Rowden's (2002) study confirms the dynamic interaction between IL in the workplace, further highlighting the importance of both types of learning in improving job satisfaction and, consequently, job performance. In addition, Raykov's (2014) research suggests that employer support for innovative work positively influences employees' job satisfaction, which can lead to improved JOB. Furthermore, the study by Sukor et al. (2018) demonstrates a positive relationship between workplace IL and job satisfaction, indicating that continuous workplace learning contributes to increased levels of job satisfaction. This aligns with the findings of (Daryoush, 2013), which suggest that workplace learning directly influences employee task and contextual performance.

The acquisition of EMP competencies is influenced by factors such as transformational leadership, IL and reflective practice (Elsen et al., 2022). EMP competencies are not only crucial for job acquisition, but also for job retention and career progression. The learning environment, curriculum design and teacher quality significantly influence the competencies acquired by students. In addition, lifelong learning plays a vital role in the improvement of EMP, especially in self-employment scenarios later in life. In conclusion, the development of EMP competencies is a multifaceted process that involves a combination of IL, reflective practice, soft skills and a conducive learning environment. These competencies are essential not only for getting a job, but also for career advancement and adaptability in a constantly evolving labor market.

Contrary to what was initially formulated, IA is a tool that, according to the results, decreases the relationship between EMP and JOB. Thus, further research should be carried out to analyze the different types of learning and their moderating relationship; it is possible that formal learning is a determining factor in completing the analysis model as analyzed by Froehlich et al (2014)

The results of this research provide additional support for previous research on the relationship between IL, EMP, and JOB of business school management program graduates in their first work experiences. Few studies examine learning outcomes in this segment; in fact, previous studies have only paid attention to employee performance without specifying the timing of the work experience. The findings suggest that schools and academic departments should develop employability competencies through informal learning to produce more efficient and productive graduates; this development can be generated through extra-academic activities such as study circles, seminars, workshops and lectures. Likewise, extra-academic activities can be developed through the technological tools of distance education.

Abstract: Cities of tomorrow are planning a smart city framework in order to drive urban growth and social innovation. The aim of the study is to elucidate that cities aim at dealing with urban innovation issues, designing a smart city view in order to shape the city an urban community as an engine of collaborative and innovative spaces. The study relies on the analysis of one case study. The city of Firenze is rethinking on the urban future, adopting a smart city framework that supports a collaborative view for social innovation, enabling smartness as a capability to develop social issues and contribute to urban value. The findings elucidate that a smart city framework enables the city to evolve as urban community and engine of social innovation, shaping urban collaborative meeting places for innovation.

Keywords: Smart Cities, Smart Communities, Urban Innovation, Social Innovation.

1. Introduction

The future of a smart society relies on cities able to play a proactive role in engaging the urban stakeholders that contribute to constructing a virtuous pathway for social innovation within urban spaces. Cities of tomorrow will be intelligent, smart, socially innovative by driving community-led and people-driven innovation, leading to smart city development and shaping collaborative urban ecosystems for innovation (Mora *et al.*, 2023; Dolmans *et al.*, 2023; Nam and Pardo, 2011; Eger, 2005), fostering smart innovative communities (Caragliu and Del Bo, 2019; Appio, Lima and Paroutis, 2019; Paskaleva, 2011). Sustainable urban future relies on social innovation for good life, by promoting collaborative and multi-actor innovation, and following a human-centred view to smart urban innovation (Yigitcanlar, 2021; Sørensen and Torfing, 2018; Nilssen, 2019). As organizational spaces (Knox, 2010), and net action (Czarniawska, 2002), cities shape urban communities that contribute to supporting collaborative spaces for social innovation, adopting a smart view to urban growth to improve the quality of social life for citizens (Lazariou and Roscia, 2012), and following a human-centric view for a smart, socially innovative urban community (Costales, 2022). Smart city planning supports the city to shape an urban community (Gil-Garcia *et al.*, 2016), and relies on driving community development (Stratigeia, 2012) and fostering urban collaborative innovation (Dolmans *et al.*, 2023). The smart city enables the city as human-centred, collaboration-driven and socially innovative community. Urban innovation refers to a sociotechnical innovation (Meijer and Thaens, 2018). Cities use the potential offered by digital and intelligent technologies to shape human-centred, innovation-led urban communities that enhance collective intelligence and cooperation (Yigitcanlar *et al.*, 2023), leading to net action and multi-actor collaborative spaces and processes, opening up to knowledge-led and technology-driven social innovation, by involving civil society, research, private and public organisations (Czarniawska, 2002; Zhang and Wang, 2022; Sørensen and Torfing, 2018).

While there are many studies that focus on smart city visions and approaches as means to drive sustainable urban development, few studies investigate the role of smart city planning and vision as a driver of urban innovation. Which urban future development do cities aim to achieve? How do cities interpret a smart social vision to urban innovation and growth? The research question refers to how cities are rethinking the urban future, shaping the city as socially innovative urban community. As intelligent communities, cities are planning the future urban development by selecting a smart view to driving urban growth and innovation, and shaping future urban innovative communities. The case study concerns the choices of *Firenze Smart City Plan*. It is analysed and presented. The aim of this study is to elucidate how smart city urban planning enables cities to rethink on the urban future, by designing smart socially innovative communities. Cities are adopting a smart city framework, becoming engines of sustainable, social growth and innovation by strengthening urban multi-actor collaboration. Smart city strategy, planning and policies contribute to shaping the city as socially inclusive and innovative urban community. The paper is articulated in five sections. After introduction and theoretical background, in the third section methodological section follows. Findings, discussion and conclusions are set out.

1.1 Towards Cities as Smart Social Innovation-led and Collaboration-Driven Communities

As organisational spaces (Knox, 2010), arenas of innovation (Zhang and Wu, 2019), cities are following a smart view in order to drive urban competitiveness, ensure better quality of life and support innovation in long-term horizon (Appio, Lima and Paroutis, 2019; Paskaleva, 2011). Sustainable urban development relies on cities that adopt a smart city vision in order to contribute to public value creation and innovation (Pardo, Gil-Garcia, Gascó-Hernández, Cook and Choi, 2021). The smart city is emerging as the hub for driving smart global societies (Joss *et al.*, 2019). A city is going smart by shaping a smart community in order to drive urban innovation and achieve sustainable and inclusive growth, focusing on people and human capital, and shaping innovation-led as well as inclusive and people-centred communities (Nam and Pardo, 2011; Paskaleva, 2011), by fostering collaborative planning and innovation towards citizen-centred and societal smart cities (Alizadeh and Sharifi, 2023). Smart cities contribute to enhancing the role of the urban community as an agent of collective action, as the driver and the issue of smart city initiatives, policies and applications in order to promote the urban wellbeing for citizenry and drive the city a better place for work and life, encouraging public and private actors that work together Gil-Garcia, Pardo and Nam, 2016; Stratigeia, 2012). Smart cities contribute to bottom-up, cooperative and multi-actor innovation (Dolmans *et al.*, 2023; Sørensen and Torfing, 2018). As engines of social innovation (Anttiroiko, Valkama and Bailey, 2014), human-centric smart cities help enable urban platforms for technology-driven social innovation (Costales, 2022). Smart-led urban innovation relies on cities that intentionally and proactively shape technology-driven processes for new and creative ideas and qualitative urban change, enhancing collaborative approaches (Meijer and Thaens, 2018; Mora, Deakin, Reid and Angelidou, 2019). Smart urban innovation relies on city's smartness as the ability to attract and mobilize human capital in collaboration with urban actors and stakeholders by using information and communication technologies (Meijer and Bolívar, 2016). Promoting a smart city growth supports cities to meet social challenges and urban sustainability priorities, following collaborative approaches and developing capabilities within smart urban ecosystems for innovation (Mora, Appio, Foss, Arellano and Zhang, 2020; Gupta, Panagiotopoulos and Bowen, 2023). As smart innovative communities (Eger, 2005; Nam and Pardo, 2011), cities contribute to the community development and transformation driving urban innovation and supporting stakeholder collaboration, leading to multi-actor and cooperative processes for urban wellbeing (Nilssen, 2019), by engaging citizens in social open innovations (Paskaleva, 2011), and focusing on smart, sustainability-oriented, social and human-centred innovation (Tura and Ojanen, 2022).

2. Methodological Section

The study employed a qualitative, descriptive and exploratory methodology to analyse how cities are rethinking on the future urban development, shaping smart urban innovation and communities, rediscovering the smart city framework as an opportunity to drive social innovation issues. As engines of urban innovation and socially inclusive growth, cities are adopting a smart city vision to support urban innovation and growth, revitalising the city as a community. The study focuses on one exploratory and illustrative case study with regards to Firenze, a city which is planning urban growth by going smart by rethinking on smart urban future for becoming a smart socially innovative urban community in order to explore and provide a comprehensive understanding of a phenomenon still in progress and emerging in contemporary times, whereas the boundaries between the phenomenon and the context are not clearly evident, by following a case study methodology through an empirical inquiry without the rigidity of a predefined structure for observations and analysis (Yin, 2009). The study relies on the analysis of a document related to urban planning framework. The research method involved case selection and data collection from policy document as the smart city strategy framework drawn from *Firenze Smart City Plan* as the information source in order to collect and analyse data and information, and to investigate how an Italian city is planning the urban future development, shaping the urban community as an engine of urban innovation and social growth, coherently with a smart city view. Investigating smart city strategy design helps to understand the pathway of cities shaping urban social innovation (Angelidou, 2017; Mora and Bolici, 2017; Sancino and Hudson, 2020). The case study refers to the smart city vision as urban development framework in order to revitalise the city as socially innovative community towards urban sustainability.

3. Findings

Cities are planning the future urban development by selecting a smart vision to urban growth and innovation. In particular, in Firenze the pathway for a smart city-led urban innovation is following a social innovation view. The urban community aim at becoming an agent of social change by strengthening information, involvement, integration and innovation, and relies on reinforcing urban energies and competences provided by private, no

profit, business, research and academia, public actors that are involved in collaborative processes for urban value creation. Rethinking smart innovative cities relies on driving smart city planning and implementation in order to shape cities as smart-driven, innovation-led and human-centred communities. One single case study is analysed and presented. In Europe, cities are rethinking about the urban future by adopting a smart vision planning in order to support innovation and drive sustainable urban development, shaping innovative and intelligent communities.

In Italy, the city and the municipality of Firenze is understanding the importance of designing the urban planning as hub for innovation by following a smart city framework, and using the potential of digital and contemporary technologies in order to shape the city as community which is working to stimulate and drive urban innovation processes, by involving private and public urban stakeholders to build collaborative spaces for innovation and value co-creation for wealthy urban communities and better quality of urban life. The idea of urban planners is to provide guidelines that contribute to freeing urban energies, competences and intelligences in order to create spaces for social innovation and change, empowering citizens, private, public and no profit actors to identify innovative solutions for policy and services co-production that help contribute to improving the urban life and sustainability of a city that is becoming a socially innovative community.

In the *Firenze Smart City Plan*, cities are living organisms made up of people within the process of urban transformation, leading to intelligent urban communities. Smart urban innovation relies on citizens who are able to play a proactive role in identifying some pathways for urban development and quality of life improvement. In particular, planning a smart urban vision supports the city as an engine of innovation and a community of people able to produce meanings and culture, and to enhance human and civil progress. Promoting smartness relies on using information and communication technology in order to make cities more innovative, sustainable and intelligent communities that are capable to drive innovation, reinforcing social relationships within urban ecosystems. A smart city refers to a city that is changing and constructing new social, urban, and economic responses to environmental and historical pressures. The smart city plan is an open space for debate, confrontation, exchange of information and knowledge among all urban stakeholders which support urban, social and economic development. A smart city master plan helps the city to drive a continuous pathway for sustainable urban innovation, and to improve the quality of life within community, and relies on distributed and collective leadership and vision. Planning a smart city framework for urban growth should support city to image its future focusing on a city learning to becoming a community where all the urban stakeholders contribute to urban value creation processes and issues, advancing towards social innovation view. Smart urban innovation relies on promoting collaboration among all the involved stakeholders (public administration, research centres, cultural institutions, businesses, associations, groups, citizens) along the urban value chain. A smart city strategy and practice relies on promoting open innovation by involving the urban stakeholders and embracing the four *Is*: the *integration* of all possible aspects in charge of a municipality's competences and background; the *innovation* as the development of innovative services and solutions through digital and interactive information technology; the *involvement* as a means to enable stakeholders to identify, plan, share, and implement strategic, long-terms vision and goals; and the *information* relies on the use of information and communication technology as a way to reinforce and consolidate the relationships between municipality and citizens, by monitoring the implementation of urban smart strategy.

This analysis elucidates that the city of Firenze is designing the urban planning and rethinking about the future of urban communities, adopting a smart vision in order to shape the city as sustainable and innovative community by strengthening a collaborative framework, and designing urban collaborative spaces that enable various stakeholders to drive innovation processes in order to improve the quality of life of citizens within urban communities.

4. Discussion and Conclusions

The concept and practice of smart city is related to urban innovation issues. The smart city planning enables a way to drive social innovation within urban spaces. Thereby, the smart city framework is emerging as a platform and label that is encouraging the efforts, the competences and organisational arrangements of cities towards social innovation as the issue for achieving urban sustainability beyond the potential offered by technology. Cities of tomorrow are planning the urban future as well as smart innovative urban communities that contribute to ensuring high quality of urban life, shaping urban communities as *loci* of social innovation. Smart cities and communities contribute to sustainable urban growth and social innovation. As engines of urban innovation and smart communities, cities drive multi-actor collaborative innovation, transitioning from a technology-enabled to a community-oriented and human-centric approach, putting the people first, focusing on human and social

capital, promoting community development, shaping urban collaborative and socially innovative spaces, and strengthening stakeholder participation and involvement to drive urban collaborative, inclusive and innovation-led communities.

In the city of Firenze, the smart city planning focuses on searching for bringing together integration, innovation, involvement, and information. The smart city framework enables several urban stakeholders to work together for shaping the urban community as an engine of social innovation. Planning a smart city view means enhancing the potential of technology as an enabler of urban, social and collaborative innovation and community development. As engines of innovation, cities are tracking a smart city-led pathway for future urban innovation, by strengthening community participation and driving social and collaborative innovation within urban spaces for urban wealth. Socially inclusive and technology-led innovative urban communities make the city a better place for social value creation and social innovation. Cities of the future will aim at understanding the potential of information technology in order to adopt a human-centred vision to developing the city as smart, socially innovation-driven community. Further research perspectives imply to investigate how other Italian cities are planning the urban future, following a smart city vision and framework to urban innovation and growth.

Becoming Reflective Practitioners in the Music Business

Tone Vold, Hanne Haave, Ole Jørgen Ranglund and Carl-Henrik Wahl
Inland Norway University of Applied Sciences, Rena, Norway

Tone.vold@inn.no
Hanne.haave@inn.no
Ole.ranglund@inn.no
carl-henrik.wahl@inn.no

Abstract: This case study is from the music business production where we have investigated how supervisors at music camps develop as reflective practitioners. We have investigated the process of how the supervisors gradually become aware of their tacit knowledge and are able to make it explicit, following the SECI-model through reflecting. It is also interesting to identify how they maintain a production focus throughout each process of conducting the music camps, but at the same time opens up for reflection and learning. As the lecturers also work at a music production company, and we have sought to unveil how becoming reflective practitioners have made a difference when it comes to executing their profession. Hence, trough qualitative investigations we have interviewed the supervisors and their co-workers in their organization to unveil how this has had an impact in their organization and contributed to enhanced organizational knowledge.

Keywords: Reflection, Reflective Practice, Tacit and Explicit Knowledge, Reflective Practitioners

1. Introduction

At the Inland Norway University of Applied Sciences, Business School, Norway, we offer a bachelor's degree in music business and production. One of the courses is about developing and producing songs. In this course, the lecturers being from a professional music production company (The Woods) offer the students music camps lasting from 10 am in the morning till 10 pm in the evening. After a short introduction to the theme for the music camps, the students are divided into groups. These groups are carefully put together by the lecturers. Their experiences from music camps at their company and previous experience at the university have provided them with insights that allow them to organize the groups in such a way that they are able to develop a song during the camp.

Although experienced the organizing nearly 100 music camps, they are still developing within their trade, also due to their work at the university. The experiences they gain from working with the students provide them with input as the students vary in their experience with developing songs. Not only do they provide their students with work like settings such as music camps (Vold et al., 2023), they also learn more themselves for each camp held.

In this case study we have followed the informants over a period of 3 years. During this period, we have watched the lectures develop into what we would associate with "reflective practitioners". Johns (2009) states that "*A reflective practitioner Is someone who lives reflection as a way of being*" (p. 3).

In this paper we will present data collected from the different types of informants; the lectures/practitioners and their colleagues at The Woods. Through these investigations we will establish if they have indeed become reflective practitioners and if they are able to utilize the knowledge and being reflective practitioners back in their work at The Woods.

We have drawn on theory on reflection and reflective practice (Schön, 1987, Schön, 1991, Johns, 2009, Moon, 2004), as well as looked at how they are able to articulate their tacit knowledge (Polanyi, 1967, Tsoukas and Vladimirou, 2001, Cook and Brown, 1999) on their way of becoming reflective practitioners. We have also observed how they share knowledge and experiences with their colleagues at The Woods, much similar to theory on Communities of Practice (Lave and Wenger, 1991).

Through utilizing qualitative research methods, we will present and discuss our data before we conclude.

2. Theoretical Foundations

As a basis for becoming a "reflective practitioner" lies reflection. Reflection offers a deeper learning opportunity and may provide us with different perspectives. Being able to reflect – and not just think (Dewey, 1910) – both prior to an action, during an action, after an action, and even a while after action allows us to learn from different viewpoints and each will contribute with something somewhat different.

Donald Schön is a major contributor within the area of understanding the importance reflection (Schön, 1987, Schön, 1991). Schön presented different approaches to reflecting such as reflection-in-action and reflection-on-action, the first being to reflect during the course of the action – with the opportunity of changing the action, the latter being reflection posterior to an action – then to see if it would be other solutions.

A definition of reflection is provided by Boyd and Fales (1983) as : "the process of creating and clarifying the meaning of experiences [present and past] in terms of self [self in relation to self and self in relation to the world]. The outcome of the process is changed conceptual perspective. The experience that is explored and examined to create meaning focuses around or embodies a concern of centra l importance to the self." (p. 101). They further points to stages of reflection, such as identification or clarification of concern, openness to new information from external and/or internal sources, and deciding upon acting on the outcome of the reflective process (Boyd and Fales, 1983). Hence, this perspective also takes in a constructivist approach.

Another theorist, Johns (2009), claim: "Learning trough reflection also takes place on a more deliberative level. Indeed, through reflection, practitioners become more mindful and increasingly sensitive to their intuitive responses." (p. 6). Hence, Johns are arguing for an intuitiveness which may resemble or build on tacit knowledge. Tacit knowledge is knowledge that is hard to explain and to make explicit (Polanyi, 1967). Often it is embedded in actions and reactions. It is also a part of the total knowledge base of a person.

Johns also brings in mindfulness as a perspective regarding reflection. According to Holmes (2017) "reflection require mindfulness" (p. 22). One must understand the "Self" in order to understand how learning will affect oneself and how to utilize the learning from experiences. Hence, learning is ultimately about creating connections between synapses in the brain (Bransford et al., 1999) and research shows that the neuroplasticity of the brain is affected by self-reflection and mindfulness (Holmes, 2017).

Hence, both to understand the physical explanation of learning as well as understanding how this is connected to identification, increasing a knowledge base through experiencing and reflecting shows how complex the process of becoming a reflective practitioner may be.

Regarding developing reflective practitioners Boud, Keogh and Walker (1985) allows for enabling practitioners to see their development through three key stages; 1) returning to experience, 2)attending to feelings, and 3)re-evaluating experience. In the latter it is about re-examining experiencing, associating new knowledge to previous knowledge, integrating new knowledge with previous knowledge, and change behaviour according to the new knowledge.

However, it is also about being open to and curious about new knowledge and practices. Gadamer (1975) claims : "*the opening up and keeping open of possibilities is only possible because we find ourselves deeply interested in that which makes the question possible in the first place. To truly question something is to interrogate something from the threat of our existence, from the centre of being*". We interpret this to be about being willing to learn and to change.

Understanding is also important although there are resisting factors that will work against change (Johns, 2009). One of these factors is tradition. To change beliefs and perceptions are difficult. Creswell (1998) claims that knowledge is embedded in the interpretations people create; it is acquired through discussions about these interpretations. It is influenced by personal biases and values, expressed in a personal and intimate manner, and it evolves and emerges, deeply connected to the context in which it is examined. Hence, change is depending on the ability of doing the "double loop" learning (Argyris and Schön, 1996). Argyris and Schön (1996) developed the model of single and double loop learning. They then also coined the terms "espoused theory" and "theory in use". "Espoused theory" is about values and views that *guide* the behaviour and "theory in use" is about how one actually behaves (Argyris and Schön, 1996).

According to Daniels (2002) a tool for reflecting on practice is peer coaching or cognitive coaching. Cognitive coaching comprises three key components: (a) establishing a trusting relationship, (b) fostering a desire for learning and growth, and c) collaborating autonomously while maintaining interdependence with others.

Lastly, we would like to include a typology of reflection based on Johns (2009) which describes different types of reflecting:

Reflection on experience	Reflection on a situation or experience after the event with the intention of gaining insights that may inform the future practice in positive ways	Doing reflection
Reflection in action	Pausing within a particular situation or experience in order to make sense of and reframe the situation in order to proceed towards desired outcomes	
The internal supervisor	Dialoguing with self whilst in concersation with another in order to make sense	
Reflection within the moment	Being aware of the way one is thinking, feeling, and responding within the unfolding moment whilst holding the intent to realise my vision. It involves dialoguing with self to ensure interpreting and responding congruently to whatever is unfolding and having mental acuity to change ideas rather than being fixed to certain ideas	
Mindfulness	Seeing things for what they really are without distortion, whilst holding the intention of realising desirable practice	Reflection as a way of being

Figure 1: A typology of reflective practices, based on Johns (1991, p. 10)

This theoretical foundation has been important for our understanding of how to do research on developing reflective practitioners. To see if we are able to understand their "Self" in the educational setting and to support their reflections about their previous practices, their present practice and to record if/how this has affected their way of reflecting about how they perform their jobs.

3. Method of Inquiry

In this study, we are four researchers who have followed an education program, bachelor's degree in music business and production over the period from 2021 to 2023. In particular we have studied the part of the study program that organizes music camps. The camps are carried out in five sessions over an academic year. We have followed two cohorts of students and their teachers. In total, 4 teachers and 20-25 students have participated per year. The group of teachers are the same four, while the students group change each year. Our methodological approach has been qualitative with a longitudinal design (Patton, 2002). We have followed the teaching program as observers and carried out participatory observation (Patton, 2002). In addition, we have conducted several formal recorded semi-structured interviews along with informal individual conversations and group conversations with both students and teachers during the sessions (Patton, 2002, Dalen, 2011). Our respondents are three of the teachers and three student groups, as well as a number of individual students. We also have interviewed the teachers in between the music camps. The data consists of transcripts from the recorded interviews, field notes written during and us after participating in the lessons. The data material has been analyzed by reading through field notes, and transcripts, as well as listening to the recordings. This has resulted in findings that show how the teacher- student relation is conducted and developed. We have also findings that give us insight in the development of the teachers as reflective practitioners. Along in the process we have discussed our findings in the research group. Our findings are also presented and discussed with the two teachers to have their opinion on the subject of a deeper understanding of the process of becoming better reflective practitioners.

4. Results and Discussion

Here we will present the results from our longitudinal investigations. The findings show two different relations; the relationship between students and lecturers/supervisors, and the relationship between the researchers and lecturers/supervisors.

4.1 The Practical Supervision – Student – Teacher Relationship

We joined the teachers in the studios and observed the tutoring situation. The students and the teacher discussed ideas for arrangements for the song they were to create. We experienced that they had a good communication and dialogue where the students received feedback from the teacher on their ideas and they developed them together. Afterwards, we asked the students how they perceived the teachers' feedback. They expressed that they perceived him more as an experienced colleague who gave some good advice than as a teacher who gave instructions.

This may indicate that the teachers have been able to create an understanding of collegial equality. The teacher is a music producer like the students are, only more experienced. This is similar to the phenomenon that Solberg (1996) describes, where she is able to incorporate the role of researcher into a type of producer role that she takes part in together with her informants. The production setting means that they meet as equal participants, in our case it is about the students accepting the feedback, (for the most part) and agreeing. This resembles also the peer coaching and cognitive coaching (Daniels, 2002). They have established a trusting relationship; they have fostered a desire for learning and growth and the supervisor is able to appear as collaborating with the students.

The lecturers/supervisors also appear to aid the process of reflection with their students. They encourage the students to evaluate and rethink if they are heading the "wrong" way. Much like Boud et al. (1985) they allow for "enabling practitioners to see their development as reflective practitioners through three key stages; 1) returning to experience, 2)attending to feelings, and 3)re-evaluating experience". Sometimes this require the students also to do a double loop (Argyris and Schön, 1996) in the learning process as they may rethink and maybe change some of the basic knowledge they brought with them to the university. It may be that their basic assumptions are wring and that they require that they are open and curious. They thus sometimes need to do as Gadamer (1975) suggest; to open up and keep open for possibilities, as they are generally truly interested in developing as songwriters even if they need to reset from time to time. Some students find this very hard as they may have thought they were good songwriters when they applied for university, only to discover that they still have a lot to learn.

4.2 Developing the Reflective Practitioner – The Researcher – Lecturer Relationship

When we started out doing research on our colleagues and the particular feature of song camps in this study program, the lecturers were very positive and welcoming. However, it took some conversations before they were able to reflect on their own practice. When they did start their reflections, they started to emerge as reflective practitioner (Schön, 1987, Schön, 1991). Statements like: **"**These are things I didn't know I could do until you and I sat down and talked about it" show how they are then able to open up for peer coaching. They have of course been students themselves at one time, having to come to terms with the fact that they were not necessary the best songwriters when they entered their own education. Although having evolved and had quite a few hits on the billboards, they are still humble to the fact that they keep learning. A statement such as: "It was only after we spoke that I could visualize what was going to happen.... the stages in how to make a song." Here it is referred to an interview where we as researchers pushed one of our informants (lecturer/supervisor) out of his comfort zone and asked him to explain to us why he behaved differently in the different groups. He then had to explain that he knew how far they needed to have developed the lyrics, the melody, the recordings and the production in order to manage to make a song within the time frame. This turned out to have been *tacit knowledge* (Polanyi, 1967) as he "just knew this by experience". This is knowledge obtained by hosting, supervising and producing hundreds of groups professionally in his organization (The Woods) and at the university. By being enabled to explain and externalize this knowledge, we as researchers were able to take part in this knowledge.

Our informant also claimed: "I wouldn't have been able to make this model if we hadn't had that conversation" and "The model has helped me a lot in my work" which indicate that the SECI-model (Nonaka and Takeuchi, 1995) has been in use. By socializing, externalizing, allowing his colleagues take part in this knowledge and combine it with their own knowledge, they can by reflection and utilizing it, be able to internalize this knowledge and make it their *tacit knowledge.* It has also been of use to them in their work at the university as they are now able also to explain this to their students in order to make *them* understand and comply to this model.

Hence, we see a development with our colleagues that follow the typology of Johns (2009). They are able to reflect on experience as well as in action and pause to make sense and reframe if necessary. They are dialoguing with us as well as with themselves. They have become very aware of how they are thinking and feeling and

responding and have been clear about discussing different interpretations with us after themselves having reflected. They even seem to have obtained a certain mindfulness as they are trying to make sense and understand different behavior both within the university setting and within the frames of their organization (The Woods). They have largely absorbed *reflection as a way of being* and thus become *reflective practitioners.*

5. Conclusion

We find that the arrangement around the song camps has developed from being more of a purely production perspective, to also incorporating and placing great emphasis on the learning perspective where reflection leads to tacit knowledge being externalized. The teachers are well on their way of becoming stronger aware about their "Self" as reflective practitioners and they seem to have a better understanding of their own developmental process and learning process. The schemes have always had clear structures, these have now become more conscious and thus subject to developing and improvement.

The different aspects of reflections have been implemented by the lecturers/supervisors and they are now imposing this way of learning to the students at the university by making also the students become more aware of their capabilities, who they are as songwriters and how they can learn to become better practitioners as well as reflective practitioners.

The lecturers ability to embrace reflection as a tool for change in themselves as well as in their practice has allowed them to become reflective practitioners that has adopted reflection as a way of being.

avestam@gmail.com

Abstract: Purpose: This research delves into the intricate challenges of knowledge management (KM) within technical departments of knowledge-intensive firms (KIFs), with a specific focus on preserving critical knowledge amidst employee turnover. Recognizing the four main components of KM—people, process, content/IT, and strategy—and emphasizing the paramount importance of individuals in KM alongside the human-centric approach of design thinking (DT), the study aims to enhance KM processes, particularly knowledge sharing (KS), utilizing DT to fortify organizational success. **Methodology:** This study utilizes mixed method action research, which includes in-depth interviews and observations, immersion and questionnaire to collect employee insights. Thematic analysis is utilized to identify key challenges. Employing the DT framework, the research progresses through problem definition, ideation, prototyping, testing, and iterative refinement stages, following the structured steps of DT. **Findings:** Thematic analysis identifies persistent KM challenges, encompassing individual, organizational, and technology barriers. These challenges are effectively addressed through innovative solutions developed with DT principles, leading to tangible enhancements in KM processes. Iterative cycles of prototyping and testing further refine these solutions, particularly in facilitating KS among employees. **Originality:** This research demonstrates the efficacy of DT in addressing KM challenges within KIFs. Through prioritizing human-centric problem-solving, DT's iterative and learning-oriented nature boosts organizational efficiency and stimulates innovation. The direct engagement of end-users in solution design further highlights the cost-effectiveness of this approach, ultimately enhancing KM outcomes. **Contribution:** The study presents solutions tailored to the unique challenges of KM, transferable not only within the technical department but also across KIFs. Given the prevalence of unsuccessful KM implementations, the human-centric ethos of DT emerges as a pragmatic and economical approach for diagnosing and mitigating KM obstacles. Nonetheless, the study highlights the adaptability of DT in addressing specific KM issues, offering a pathway for other departments to tackle their KM challenges effectively.

Keywords: Knowledge Management, Knowledge Sharing, Knowledge Intensive Firms, Design Thinking, Innovative Solutions.

1. Introduction

KM has become a crucial factor in ensuring organizational success and the continuity of their operations (Xue, 2017). KM encompasses the processes of creating, generating, capturing, storing, sharing, and utilizing knowledge to enhance individual performance (Ismail & Yusof, 2010). KS has been recognized as the key process for enabling organizational learning and innovation, which is particularly essential. It is crucial for organizations aiming to leverage their knowledge as an asset to gain a competitive advantage, such as KIFs. These firms depend heavily on knowledge and expertise to function, innovate, and compete in their markets. They prioritize knowledge creation, acquisition, transfer, and application to support their business goals and secure a competitive edge.

Maintenance departments play a crucial role in ensuring optimal equipment performance and sustainability. The knowledge of maintenance employees is invaluable for identifying problems, preventing breakdowns, and enhancing performance. With rapid technological advancements, KM in maintenance is becoming increasingly important.

Problem-solving skills are recognized as essential for innovative organizations in the 21st century. These skills enable organizations to overcome challenges, seize opportunities, and maintain a competitive edge. DT, a non-linear, collaborative, and iterative process, is a problem-solving approach that addresses complex problems and creates new human-centered solutions (Boersma, 2017). DT combines what is desirable from a user perspective with what is technically feasible and economically viable to generate innovative ideas. The values that DT can provide include innovative solutions, customer orientation and integration, asking the right questions, divergent thinking, tangible results, an agile approach, and risk reduction. As people are the most critical element in KM and the DT process is a human-centered approach specifically for solving complex problems, this study aims to

revisit the challenge of improving KM through the lens of DT. The integration of KM and DT became the central theme of this research.

Given the risk of knowledge loss, revisiting the topic of KM in the maintenance department has been prioritized. Prior to this research, although some steps had been taken towards KM in the maintenance department, the results were not tangible, and voluntary KS was not a common practice (Roham et al.). In other words, despite the high value placed on knowledge within the organization, KS was not an ingrained value. The investigation into the practical challenges encountered by knowledge users in maintenance departments of KIFs revealed insights into the enablers and barriers to KM and KS. The results highlighted various factors influencing efficient KM and KS, including the lack of a standardized language for recording experiences, the fear of sharing unsuccessful outcomes, and the reluctance of technical personnel to document reports (Roham et al.). Their findings indicate that KS is uncommon in maintenance departments. In these departments, individuals are often rewarded for their knowledge rather than their willingness to share it, presenting a complex problem. This study explores KM challenges in maintenance department of a KIF, particularly in preserving critical knowledge during employee turnover. This study demonstrates that by integrating DT and engaging employees throughout the process, along with utilizing iterative refinement, it aims to enhance KS with a focus on human-centric solutions. This approach is especially effective in preserving critical knowledge during employee turnover.

2. Literature Review

2.1 The Role of People and Communication in KM and KS

KM fundamentally revolves around people—how they develop, exchange, and utilize information. Therefore, KM programs should address both the gathering and communication aspects. The gathering aspect focuses on connecting individuals to knowledge, involving the capture and dissemination of specific information. Conversely, the communication aspect emphasizes connecting individuals with other knowledgeable people, thereby enhancing the flow of tacit knowledge through improved human interaction and communication processes (Mostofa et al., 2020). The success of KM initiatives hinges on effective KS (Wang & Noe, 2010). Even the most advanced technology will be ineffective if individuals are unwilling to share their knowledge (Zheng, 2017).

2.2 Unveiling DT: Unleashing Creativity

DT is a specialized approach used to address complex challenges and to cultivate innovative solutions through a human-centered approach involving multidisciplinary teams. It is termed "human-centered" because it places the needs and interests of people at the core of its strategy (Mostofa et al., 2020). It is commonly referred to as an iterative problem-solving and innovation process within organizations. This approach is rooted in specific principles, such as prioritizing user needs and embracing multidisciplinary, while employing distinct methods like creative thinking, visualization, and experimentation (Rösch et al., 2023). In this research, the double diamond process model, developed by the UK Design Council in 2005 was used in the DT process. This model is represented by a simple diagram illustrating the divergent and convergent stages of the design process, giving it the distinctive shape of a double diamond (Tschimmel, 2012). The model is also known as the 4D model because each phase begins with the letter 'D': Discover, Define, Develop, and Deliver. Figure 1, presents this model.

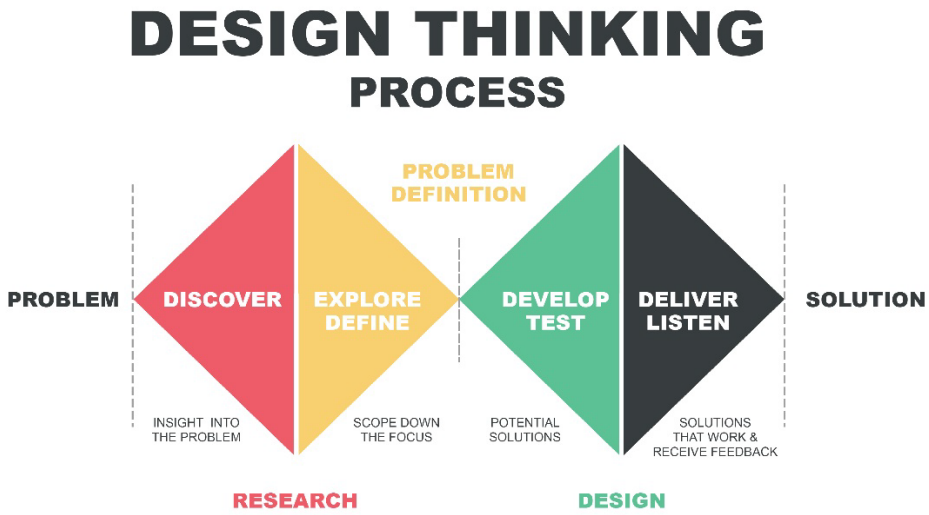

Figure 1: Double diamond model (based on UK Design Council).

DT stages have been defined as follows (Tschimmel, 2012):

1. Discover: The first quarter of the Double Diamond represents the project's initial divergent phase, where the designer explores new opportunities, gathers information, identifies trends, and uncovers insights. This stage involves developing empathy maps and personas to deeply understand the employees' needs, frustrations, and motivations.
2. Define: The second quarter, which concludes the first Diamond, is the Definition stage. Here, initial insights are reviewed, selected, or discarded, serving as a filter for refining ideas. This stage synthesizes the findings from the empathy phase into a clear problem statement.
3. Develop: In this stage, multidisciplinary teams use DT tools such as brainstorming, sketches, scenarios, renderings, and prototypes to develop, iterate, and test solutions within the company. Creative techniques encourage innovative thinking. Prototypes are iteratively refined based on feedback from the testing phase, involving multiple cycles of prototyping and testing until the solutions are optimized to meet employees' needs effectively.
4. Deliver: In the final phase, the convergent Deliver stage, the final concept undergoes final testing, is approved, produced, and launched.

2.3 Applying DT to KM

The trend of KS fostering innovation extends to design consultancies, where the fast-paced environment pressures designers to produce innovative solutions rapidly (Wu, 2020). Many believe that KM is struggling to survive, but the emergence of human-centered DT offers a revitalizing solution (Boersma, 2017). By incorporating the core elements of DT—Experimentation, Collaboration, Human-centeredness, and Optimism (ECHO)—KM can flourish. This powerful combination maximizes the value of knowledge in ways that truly connect with individuals. It enables KM practitioners to develop solutions that better resonate with the people they serve (Boersma, 2017). The future of KM has been apparent for quite some time: it lies in DT and may well be recognized as Knowledge DT (Boersma, 2017). Some KM systems already embody this human-centered philosophy (Mostofa et al., 2020). By incorporating essential knowledge into every phase of the DT process, organizations can develop innovative solutions that adjust to changing customer needs and provide more effective results (Numprasertchai & Numprasertchai, 2024) .

2.4 Research Gaps, Research Objectives and Research Questions

2.4.1 Research Gaps

Exploring the literature reveals that employing DT for addressing KM and KS challenges is a relatively novel approach. The research delves into the intricate challenges of KM within technical departments of KIFs, Traditional methods have dominated the strategies used to tackle KM issues, with minimal exploration into the integration of DT. This study highlights the paramount importance of individuals in KM, aligning with the human-

centric approach of DT. The research demonstrates the efficacy of DT in enhancing KM, presenting a significant gap and potential for further innovative research in this underexplored area.

2.4.2 Research Objectives

Facilitating KS in the maintenance departments has always been one of the challenges for KIFs and several initiatives have been undertaken in this regard. The objective of this research is to enhance KS within the maintenance department of KIFs.

2.4.3 Research Question

How can DT principles be effectively applied to overcome KM challenges, specifically in KS, within the technical departments of KIFs amidst high employee turnover?

3. Method

3.1 Research Design

This study employs mixed method action research to explore and address the challenges of KM and KS within maintenance department of a KIFs, with a particular focus on preserving critical knowledge amidst employee turnover. Action research is chosen for its iterative, participatory nature, which aligns well with the objectives of engaging researchers and employees in the process of identifying problems and developing practical solutions. Additionally, DT is integrated into the action research method to leverage its human-centric and innovative approach to problem-solving. Action research in this study follows a cyclical process of planning, acting, observing, and reflecting, which is conducted collaboratively with participants from a maintenance department. This methodology is particularly suitable for addressing real-world problems in a dynamic environment, allowing for continuous feedback and refinement of solutions. DT is incorporated into the action research process to enhance the development of KM solutions. The DT framework involves four key stages: discover, define, develop and deliver. These stages are embedded within the action research cycles to ensure a thorough understanding of user needs and iterative improvement of solutions.

3.2 Questionnaire Design

The research questionnaire was designed with three objectives: (1) identify problems employees face in KS, (2) evaluate changes in knowledge levels pre- and post-prototype implementation, and (3) measure improvements in KS due to the proposed idea. The construction of the questionnaire was guided by prominent references, including Fullwood (2014), Karamitri et al. (2020), Oyemomi (2017), Wu (2020), and Welschen (2014). Leveraging the expertise and findings from above mentioned sources, the questionnaire was crafted and then refined through multiple feedback rounds by three experts in KM and DT, enhancing its validity and relevance to the research objectives. To quantify attitudes and opinions, a 7-point Likert scale was employed for the closed-ended questions.

Data Collection: This study was conducted in a KIF with 1,250 employees, including 108 maintenance personnel. Out of these, 25 maintenance employees were selected for interviews and to answer the questionnaire, alongside 5 stakeholders and KM experts.

Data collection used four primary tools:

1. **In-depth Interviews:** Semi-structured interviews with stakeholders to gather insights into their experiences and perceptions of KM and KS.
2. **Observations:** Direct observation of daily operations and KM practices to identify unspoken challenges and behaviors.
3. **Immergence:** Researchers immersed themselves in the work environment to uncover informal practices and subtle dynamics.
4. **Questionnaire:** Distributed to collect quantitative data on KS behaviors and assess the effectiveness of KM strategies.

3.2.1 Data Analysis

A thematic analysis is conducted on the collected data to identify recurring themes and patterns related to KM challenges. This involves coding the data and categorizing it into key themes. The findings from the thematic analysis guide the subsequent stages of the DT process.

3.2.2 Validation and Reliability

Multiple data sources (In-depth interviews and observations, immergence and questionnaire) are triangulated to ensure the validity and reliability of the findings. Additionally, participant feedback is continuously sought during the DT stages to validate the relevance and practicality of the proposed solutions.

3.2.3 Biases

Biases in research can lead to misleading conclusions, but efforts were made to minimize them. Collecting data from a single company introduces potential bias, so diverse participants from various power-interest levels were included. To reduce interpretation bias, targeted questions evaluated proposed solutions, and stakeholder interview responses were mapped onto empathy maps (Thinks, Says, Feels, Actions).

4. Results

In this section, the results obtained from combining action research and DT have been presented according to DT stages Initially, the primary problem statement in the DT process was defined as follows: How can the process of recording and retrieving experiences and lessons learned by maintenance personnel of key equipment and machinery be transformed to be user-friendly and efficient? The goal is to reduce equipment downtime, minimize redundant work and associated costs, and mitigate the risk of losing valuable knowledge from experienced individuals in key areas. This problem statement was defined with the following objectives:

- Enhance the user-friendliness and efficiency of the system for recording and retrieving experiences and lessons learned.
- Reduce equipment downtime.
- Minimize redundant work and associated costs.
- Lower the risk of losing valuable accumulated knowledge when experienced personnel leave the organization.

A crucial aspect of the DT process is empathy. At the beginning of the DT process, it is essential to accurately identify user needs, where empathy plays a key role. Empathy is crucial to correctly define user needs, as these often differ from what users explicitly state. Proper empathy can uncover these actual needs.

4.1 Discover

In the first stage of the double diamond model, stakeholders were analyzed based on their power and interest regarding KM and their influence on the subject. The main stakeholders were then identified. Thirty in-depth interviews were conducted with these stakeholders. The results led to identifying of the primary user needs and a refined problem definition.

The revised problem statement is as follows:

How can the process of recording and retrieving experiences and lessons learned in the maintenance and repair of key equipment and machinery be transformed to enhance human interactions, facilitate network communications, and be user-friendly and efficient? This transformation should mitigate the risk associated with losing key knowledge and, over time, decrease equipment downtime, rework, and associated costs.

This problem statement was defined with the following objectives:

- Long-term improvement: Enhance methods for recording and retrieving experiences in the maintenance unit to reduce equipment downtime and associated costs.
- Enhanced interactions: Improve human interactions and facilitate communication to boost the effectiveness of KS.
- Quality reporting: Increase the number of high-quality reports on equipment failures, including detailed work descriptions, technical data, lessons learned, and ineffective methods.
- Frequent referencing: Encourage frequent referencing of the recorded histories of key machinery.

The results indicated that maximizing participation in the designed KM process requires creating conditions that enhance human interactions and network communications.

In the first stage of the double diamond model (Discover), two categories of information were collected: primary information from in-depth interviews, observation, and immersion, and secondary information from studying various sources, benchmarking three successful organizations and interviewing experts.

This research involved a comprehensive review of KM literature, benchmarking of three successful companies, and interviews with several experts. Key insights include:

- Rewarding collective performance: A common barrier to improving KS is the tendency of companies to reward individual performance, which promotes the notion of "knowledge is power" and contradicts a KS culture. Rewarding collective performance can mitigate this issue.
- Granting ownership rights: Acknowledging and granting ownership rights to knowledge creators fosters a sense of value and responsibility.
- Building trust and commitment: Establishing trust and commitment in communications is crucial for effective KS.
- Real-time reporting: Emphasizing the importance of recording reports in real-time ensures accuracy and timeliness.
- Sharing failure experiences: Normalizing the sharing of failure experiences can provide valuable learning opportunities and prevent repeated mistakes.
- Contextual best practices: Recognizing that best practices from other organizations may not be suitable for your organization highlights the need for tailored solutions.
- People Over Processes: Prioritizing people over processes, infrastructure, and other elements is essential for the effectiveness of this project.

These insights underscore the importance of a supportive culture and strategic practices in enhancing KM.

4.2 Define

In the second phase, insights gathered from in-depth interviews, observations, immersion techniques, articles, books, expert interviews, and company benchmarks were thoroughly reviewed and analyzed. Given the high volume of insights, to converge the results, they were categorized into four groups: People, Process, IT/Content, and Strategy. Classifying all insights into these four categories not only helped converge the information but also assisted in identifying more suitable solutions for existing problems. Additionally, insights that were frequently mentioned were given higher priority. Table 1 summarizes the most frequently mentioned insights.

Table 1: Summary of key insights from primary and secondary sources

Category	Insight
People	• Maintenance operation and planning conflict resolution • Collaboration • Enhancement of communication between maintenance employees and operators of equipment • Importance of recognition methods • Employee engagement • Importance of face-to-face training • Lack of time • Considering generation gap in KS • Retention and promotion of experienced employees • Variety of motivational methods • Considering individuals' interests in training • Building trust among employees • Normalization of discussing failure experiences • Developing a customized KM process • Attention to diverse learning styles
Process	• Employee empowerment • Valuing KS in addition to knowledge • Embedding KM in process • Talent management • Avoid Knowledge Silos • Embed KS into performance evaluation • On-the-job training • Rewarding collective performance rather than individual performance • Management commitment to KM

Category	Insight
	• Empowering employees with soft skills • Learning by teaching • Considering knowledge-based intellectual property • Validation of knowledge by experts
Content & IT	• Inefficiency of the current KM system • Attention to information security • Easy access to the KM system from anywhere • Personalized KM system
Strategy	• Strategy alignment

4.3 Develop

In the third phase, the ideation process commenced, drawing from the insights obtained. Five ideation techniques were employed to generate and explore innovative ideas: reverse and combine from the SCAMPER method, brainstorming, the 666 method, and brain writing were employed to generate innovative ideas. Over 100 initial ideas were generated and reviewed using three lenses (desirability, sustainability, and feasibility), leading to a few final solutions being selected. Prototypes were then developed, tested, and refined through several iterations. Table 2 illustrates the existing problems, previously employed solutions aimed at improving KS but which have yielded unsatisfactory results, and finally, the innovative solutions derived from the integration of KM and DT. Further detailed explanations of each solution are provided below.

Table 2: Summary of problems, previous ideas, and new proposed solutions through the integration of DT and KM.

Problem	Previous ideas/ Solutions	New proposed ideas/ solutions through the integration of DT & KM
• Difficulty in typing reports • Character limits for report entries in the current KM system • Potential for forgetting repair details due to the inability to record reports immediately • Overlooking the gap between knowledge generation and application	• Attaching a Word file to the repair report in the software. • Providing requirement to use checklists during repairs	Solution 1: Easy access and diverse report recording (leveraging technological tools)
• Loss of knowledge development opportunities due to time constraints, lack of research, study, and trial and error conditions for solving equipment issues. • Difficulty of knowledge transfer between novices and experienced workers during key equipment repairs or construction projects.	• Training by novices • presence of novices alongside experts during key equipment repairs	Solution 2: Maintenance lab
• Risk of losing valuable knowledge from experienced staff • Insufficient documentation of successful actions and failures • Inability to differentiate between high-quality and mediocre work • Increased costs due to repeated failures from unshared lessons • Lack of a suitable platform for planning informal interactions that foster camaraderie	• Holding semi-formal meetings for various occasions, such as working breakfasts • Rewarding repair reports that are considered high-quality, outstanding, and valuable by unit managers	Solution 3: Organizational social network components including: - Success stories - Lessons learned from failures - Informal KS circles
• Infrequent consultation of previous documents and reports due to lack of motivation • Inadequate validation or insufficient review of prepared reports • Poor quality of generated reports	• Requiring the validation of reports produced in each department by the unit head • Rewarding high-quality reports as assessed by unit managers	Solution 4: Creating a collaborative environment for report validation

4.3.1 Solution 1: Easy Access and Diverse Report Recording (Using Technological Tools)

The solution utilizes technological tools such as a head camera, voice recorder, and speech-to-text software to record breakdown reports. The advantages of this solution include eliminating the need to type reports after work fatigue and ensuring that no details are overlooked during report recording. In many maintenance departments, their staff often view writing as an adversary, preferring hands-on problem-solving over documentation and formal KS.

4.3.2 Solution 2: Maintenance Lab

In maintenance departments, the emphasis is often on quick solutions to return equipment to production rapidly, leaving little room for trial and error, timely KS, or testing innovative problem-solving methods. This research proposes the establishment of a dedicated maintenance lab, which will significantly enhance KS by providing a structured environment for these activities. The maintenance lab will emphasize practical and research-oriented KS, enabling experienced and novice employees to collaborate effectively. By working together, novices can learn from seasoned professionals, facilitating KS and fostering teamwork and collaboration. This approach ensures that valuable knowledge and skills are transferred seamlessly between employees. In the lab, maintenance staff can perform repair maneuvers without risking damage to equipment, allowing for safe experimentation and knowledge generation. The lab's collaborative nature, with teams researching specific topics, will promote a stronger team spirit. Ultimately, the maintenance lab will serve as a hub for KS, where both practical experiences and research insights are shared and developed.

4.3.3 Solution 3: Organizational Social Network

This solution involves creating an organizational social network comprising three sections: success stories, failure stories, and informal knowledge circle. Particularly beneficial for novices and newcomers, the solution offers opportunity for sharing successes and failures, with ratings from supervisors and other colleagues. It encourages participation through the review of shared stories, increase the ability to give supplementary suggestions and comments. Knowledge circle offers a platform for sharing experience to enhance informal communication, build empathy, and reduce hierarchical barriers, and build trust.

4.3.4 Solution 4: Fostering a Participatory Environment for Validation of Reports

This solution enables report validation and rating by supervisors and other colleagues, with rankings displayed to reflect report quality. All participants in the report validation process receive points, fostering a participatory environment where individuals earn points by reviewing reports, providing supplementary suggestions, commenting, and validating them. The gamification approach to the award system has been integrated in all above-mentioned solutions to provide continuous motivation for engagement.

Simple and scalable prototypes are used instead of final products to examine how users interact with the designed solutions. User interactions and reactions are observed and measured. Prototyping helps avoid the time and cost associated with producing a final product. This study utilized some prototyping tools, such as a storyboard. Notably, the produced prototype, encompassing all proposed solutions, was presented in a focused group session attended by 30 stakeholders, receiving feedback. Each proposed solution was also individually tested and evaluated in various forms (qualitative and quantitative), with results discussed below.

4.4 Qualitative Evaluation

4.4.1 Solution 1: Easy Access and Diverse Report Recording

This solution was tested and validated in two iterations: audio recording and video recording using a mobile phone followed by recoding with a GoPro camera during repairs. The repair processes of two pieces of equipment were selected for testing and validation. Tables 3 and 4 summarize the results from in-depth interviews, immersion and iterations.

Table 3: Easy access and diverse report recording (iteration 1-audio recording)

Positive feedback	• Faster and easier report recording • Ability to express feelings during the work process by recording audio • Less time is needed for editing the report after converting audio to text compared to typing the entire report
Negative feedback	• Inadequate efficiency of solely recording audio reports for certain repairs • Need for editing the transcribed text due to spoken language • Influence of ambient noise, background noise, and noise from others on report quality
Improvement suggestions	• Enhance the ability to save images and files in various formats, alongside audio files • Suitable devices to improve the quality of recorded audio.
Actions taken in iterations	• Add an option for converting audio to text and enable editing of the transcribed audio reports

Table 4: Easy access and diverse report recording (iteration 2-video recording with mobile phone and headband)

Positive feedback	• Faster and easier report recording • Ability to capture all details and repair methods • No need to write down essential repair notes on paper • Transfer of helpful knowledge with little time
Negative feedback	• Causing headaches and pressure on the spine due to the weight of the camera on the head • The uncomfortableness of the camera holder • Effect of environmental noise • Need for high camera or mobile memory to record videos • Reluctance to use a head camera due to limitations in attaching hair implants or hair gel
Improvement suggestions	• Utilize suitable headgear and Go-Pro cameras for their lightweight nature and built-in stabilization features • Incorporate film editing capabilities • Employ a videographer assistant • Use headgear or camera mounts on pockets or chest straps • Ensure oversight of the quality and quantity of generated content

In the next iterations, head-mounted Go-Pro cameras were utilized due to their lighter weight compared to mobile phones and their advanced stabilization features. This simpler and more efficient equipment increased the likelihood that visual reports were consistently used, enhancing documentation and communication processes.

4.4.2 Solution 2: Maintenance Lab

To test and validate this solution, maintenance employees were asked to use this lab for repairing and testing machine components. The effectiveness of solution was evaluated using in-depth interviews and immersion, with the results summarized in Table 5.

Table 5: Maintenance lab

Positive feedback	• Practical learning is more effective than theoretical learning • experienced and novice staff • Possibility of team building with multidisciplinary members • Preventing potential damage from testing on equipment • Possibility for creativity and further learning in repair methods • No time constraints for immediate results • Opportunity for trial and error • Enhancing teamwork and covering each other in order to achieve goals
Negative feedback	• Concerns and worries about the volume of daily tasks and routines • Lack of standardization in the environment for conducting specific tests and laboratory conditions • Lack of concentration due to environmental noise
Improvement suggestions	• Consider environmental requirements for specific tests. • Ensure all documents and technological facilities are available in the laboratory

4.4.3 Solution 3: Organizational Social Network

This solution consists of two parts: 1) success and failure stories and 2) knowledge circle. To test success and failure stories, a specific group in the organizational social network was used. Initially, the group's purpose was announced to all users via a message from the department's deputy. Recognizing that managers should lead by example in KM and normalize sharing failure experiences, a manager shared a personal failure story. Subsequently, other group members began sharing their success and failure stories. The summary of the in-depth interviews and actions taken in iteration based on observation and analysis is presented in Table 6.

Table 6: Success and failure stories

Positive feedback	• Facilitates individuals in gaining visibility with managers and colleagues • Boosts motivation by allowing individuals to express themselves within the group • Offers the opportunity for direct communication with managers • Enables appreciation of individuals for their valuable work • Serves as a suitable platform to replace individual and group meetings
Negative feedback	• Lack of active participation in the solution due to insufficient trust and transparent reward mechanisms • Fear of being Judged by colleagues • Distress and discouragement stemming from the undervaluation of individuals' stories • Neglect of the importance of introducing teammates in group narratives • Failure to record details of experiences
Improvement suggestions	• Focus more on improving interpersonal relationships.
Actions taken in iterations	• Allocate more scores for group stories compared to individual ones. • Increase manager participation in documenting stories • Assign double scores for documenting failure stories compared to success stories. • Establish a specific format for documenting stories

Knowledge circle solution was tested and validated by organizing informal circle focused on discussing various topics. A summary of the in-depth interview results with users is presented in Table 7.

Table 7: Knowledge circle

Positive feedback	• Effective learning has occurred • Improvement in the quality of relationships and better understanding of colleagues and its impact on facilitating KS
Negative feedback	• The effect of the volume of daily tasks and routine on attendance
Improvement suggestions	• Create a method for receiving participant feedback • Increase manager participation and have them serve as role models in the knowledge circle • Foster two-way interaction between presenters and audiences
Actions taken in iterations	• Hold two sessions led by two managers in a semi-formal setting. • Organize at least four more knowledge circles with a larger number of participants • Allocate time for discussion and knowledge exchange after presentations

4.4.4 Solution 4: Fostering a Participatory Environment for Validation of Reports

Due to time constraints in this research, testing and validation of this solution were conducted in a focused session and presented to users as a storyboard. User feedback is summarized in Table 8.

Table 8: Fostering a participatory environment for validation of reports

Positive feedback	• Expressing user satisfaction due to the possibility of increasing scores by studying other people's reports and commenting on them
Improvement suggestions	• Utilize a monitoring system for the reporting system rating given by users

4.5 Quantitative Evaluation

The quantitative results from the questionnaire are summarized in Table 9.

Table 9: Quantitative results

Measured parameters / Solutions	Improvement in KS atmosphere among colleagues	Willingness to share personal knowledge	Increase in personal knowledge compared to before	Recommendation to Implement the solution in other departments	Willingness to continue participation
Maintenance laboratory	61.8%	93%	90.4%	85.6%	100%
Easy access and diverse report recording	71.3%	87.9%	76.1%	77%	65.7%
Organizational social network	60.7%	53.5%	39.2%	86%	78.5%
Knowledge circles	85.4%	57.1%	80.9%	90.4%	90.5%

The quantitative results reveal significant findings: Maintenance Laboratory notably enhanced the KS atmosphere among colleagues, prompting a strong recommendation for implementation in other departments. Easy access and diverse report recording led to substantial improvements in the KS environment, albeit with somewhat lower recommendation rates and willingness to continue participation. Success and failure stories yielded moderate improvements in KS, with a high recommendation rate for implementation elsewhere. The Knowledge Circles concept showed the highest improvements in the KS atmosphere and personal knowledge, supporting its broad implementation across departments. These results affirm the effectiveness of various strategies in bolstering KS and advocate for their widespread adoption.

4.6 Deliver

Based on the results obtained, the solutions incorporating the GoPro camera and Knowledge Circle have successfully advanced to the delivery stage, which is now operational. The remaining solutions require further iterations to reach this stage.

5. Conclusion

The purpose of this research is to enhance KS within the maintenance department of a KIF. Facilitating KM in the maintenance department has consistently been a challenge for KIFs. The expertise and experiences of the staff are considered a major asset in problem diagnosis, failure prevention, and equipment performance improvement. Given the risk of knowledge loss, employing a creative solution to facilitate KM and KS was chosen as the focus of this study.

The innovative solution presented in this paper is using a human-centered DT approach, specifically tailored for solving complex problems. DT combines user desirability with technical feasibility and economic viability to generate innovative ideas. One of the strengths of the DT approach is empathy, which helps identify the real needs of individuals. In this study, three tools—interview, observation, and immersion—were used to empathize with users. The insights gained from these tools led to a reevaluation of the initial problem based on the users' actual needs.

Following the Double Diamond model, a wealth of information was discovered and converged into four categories: People, Process, IT/Content, and Strategy. Ideation then commenced, and all ideas were evaluated through the lenses of desirability, sustainability, and feasibility, ultimately selecting the most effective solutions. The selected solutions were tested and evaluated, yielding significant qualitative and quantitative results.

Based on the research objectives and results, it can be concluded that employing DT can enhance KM and KS within maintenance settings. The study reveals that DT, with its emphasis on empathy and user-centered design, is particularly effective in addressing complex and human-related problems.

Overall, the creative aspect of this paper lies in the application of the DT approach to solving the complex issue of KM and the effective integration of these two concepts. The results demonstrate the effectiveness of using the DT approach in this context. However, it is worth mentioning that the solutions derived are specific to the maintenance department of the reviewed KIF. Other organizations should customize their own KM systems with the DT process to fit their specific needs.

Limitations of study:

- Time-consuming testing and evaluating solutions with multiple iterations in the DT process.
- Limited target population to one company.
- Due to article length constraints, not all solutions could be presented despite their creativity and innovation.

Given the critical role of the maintenance department in maintaining the optimal performance and sustainability of industrial equipment and systems, the high value of the knowledge possessed by employees in this department, and the importance of having an effective KM system, continuing this process is part of this team's future plan. As mentioned in the limitations, further repetition and testing of each solution until optimal results are achieved, remain part of the pathway to the final goals of this research.

Simulation of Discovering Market Opportunities Using AI Methods

Stefan Trzcielinski and Grzegorz Pawlowski
Department od Management Systems, Faculty of Engineering Management, Poznan University of Technology, Poznan, Poland

stefan.trzcielinski@put.poznan.pl
grzegorz.pawlowski@put.poznan.pl

Abstract: Due to the strong turbulence that exists in the business environment, the view is sometimes articulated that the time horizon of decisions is no longer a hallmark of strategic management. Opposing views argue that a turbulent environment changes the trajectory of reaching future objectives determined by strategic decisions. Such trajectories require the company to be agile, which is manifested by seizing opportunities. Opportunities arise because the environment is volatile. An example of market opportunity is the unsatisfied demand for products. Buyers are driven by different motives when choosing between products that are alternative to them. From the producer's point of view, the purchase is therefore random. As a consequence, the alignment of the offered product portfolio with the actual purchasing decisions of customers is undetermined. In this article, we address the problem of determining the product portfolio structure expected by customers, i.e. one that is consistent with their future purchasing decisions. We hypothesise that this problem can be represented by a model of flows between alternative resources. Problems of this type are solved using Markov Chain Monte Carlo (MCMC) methods. In order to discover the expected demand (opportunity), we simulated the flow model we developed using the Metropolis-Hastings algorithm, which is a special case of the MCMC method used in AI. Due to operating on numerical data, such simulations fall under quantitative research. In the article, we present a model of customer flows between alternative products and then the simulation result, which is the expected value of these flows (stationary point). We convert this value into the structure of the product portfolio using a model of customer purchasing decisions that we have developed. The obtained results confirm the effectiveness of our method and have significant practical value, especially for SMEs. It also enables the assessment of the company's product strategy based on real sales data. The application of our methodology is limited to discovering opportunities in situations where purchasing decisions are influenced by variable environmental factors, causing irregular purchases by individual customers. It is useful, for example, in discovering opportunities in markets such as Household Articles, Furniture, Vehicles, Equipment Repairs, Construction, and many others.

Keywords: Opportunity Discovery, Artificial Intelligence, Markov Chain Monte Carlo Method, Metropolis-Hastings Method, Alternative Products Portfolio

1. Introduction

Within contemporary decision support systems (DSS), several IT technologies are starting to clearly dominate due to the rapid increase in access to large amounts of data and the techniques for processing them with the help of artificial intelligence (Provost & Fawcett, 2013). Among these are commonly used tools such as Business Intelligence, Big Data Analytics, and Data Mining, which aim to conduct in-depth analysis of previously collected or real-time data. These are usually employed for forecasting based on historical data, with further analysis conducted using established techniques such as regression analysis, time series analysis, data flow, or qualitative modelling.

Simultaneously, in many areas of economic activity, research is being conducted on prediction in the absence or insufficient amount of data. The approaches used in such studies include data imputation technologies, bootstrap techniques, Bayesian techniques, and generative learning (Jha et al, 2022). They supplement the dataset with artificial data and rely on meta-learning focused on improving the efficiency of learning (Arulkumaran et al, 2017), on the principle of trial and error based on random events, where the search for the optimal decision can be achieved, for example, by sampling the model using the Monte Carlo simulation method (Vodopivec et al, 2017).

The detailed aim of this paper is to describe a decision system related to variable demand for selected goods under random information about possible customer choices (their purchasing preferences). This problem can be framed in terms of resource flow with a specific probability of changing the decision on the selection of a product group. Resource flow research is successfully described by System Dynamics models (Gary et al, 2008), which allow iterative determination of resource changes over time, where an essential condition for describing the model system is the explicit knowledge of differential-integral equations determining the system's dynamics, i.e., the flows between resources. Unfortunately, the analysed problem of variable demand for selected product groups does not adhere to strict analytical records. The issue studied in the work is non-deterministic and an effective way to solve it is the stochastic approach. Here we will limit ourselves to probabilistic techniques based on Bayesian inference (Box and Tiao, 2011), the essence of which is to take into account uncertainty and assign

probabilities to various decision hypotheses or parameter values based on available data. The practical implementation of the above idea is Markov chains (Baum and Petrie, 1966), which describe the evolution of a system in which future events depend only on the current state of the system, and not on the entire history. It is assumed that the state of the system is determined by a set of current parameters, which are a sufficient basis for making a decision (via a flow matrix defining the probabilities of change) in order to create a space of solutions in successive steps. Usually, Markov chains converge to a so-called stationary state—a specific expected value (Kurtz, 1981). However, it should be noted that there are particular cases where, for example, the system behaves periodically and exhibits several stationary states (cyclically following each other) for the same set of input data and exceptional situations where a Markov chain does not become stationary in finite time (Cappé et al, 2005).

2. Literature Review

The modelling of sales and demand creation has been the subject of numerous analyses, considering product characteristics, customer preferences, financial conditions, economic indicators, and market conditions. Methods and techniques used in this area include classical time series models (Rippe et al., 1976), analysis of non-deterministic business cycles and turning points (Hamilton, 1990), the application of dynamic programming to study demand cycles (Briffaut and Lallement, 2010), monitoring changes in demand using the Monte Carlo method (Klug, 2011), and forecasting macroeconomic variables on the stock market using hidden Markov chains (Nguyen and Nguyen, 2015).

Decision models are the subject of numerous theoretical studies (Fülöp, 2005). Depending on the form and functional description of the optimisation problem, traditional optimisation techniques, linear programming, non-linear programming, or discrete optimisation can be used (Nemhauser et al., 1989). For studying supply and demand issues, so-called Multiple Criteria Decision Making methods (MCDM) are used. These methods involve examining a decision matrix in which the set of all admissible decisions is a discrete set containing a finite, predetermined number of possible solution variants.

Since 2015, there has been a rapid increase in the use of AI in financial analysis, marketing, and business (Ellefsen et al., 2019; Bahoo et al., 2024; Stone et al., 2020). AI is now widely used in the field of analysing customer decision processes, although the problem is posed more broadly and concerns the comprehensive analysis of customer behaviours. The result is targeting customers to tailor offers to target customers, including policies of setting individual prices (discounts) to maximise profit per unit (Marinchak et al., 2018). Methods used to determine potential customer decisions and influence them include quantitative research (surveys, interviews), focus groups (studying feelings about products, services, brands), customer observations, and online behaviour analysis (A/B testing). Using AI tools, individualised relationships with customers are built, paying close attention to factors such as trust, satisfaction, commitment, engagement, and loyalty (Yau et al., 2021).

Another approach that supports decision-making processes is computer simulations. They are used, for example, to estimate the probability of achieving different levels of return on investment, considering various factors such as market conditions, costs, and technological uncertainty (Platon and Constantinescu, 2014). Decision modelling using the Monte Carlo (MC) method allows comparing different options in terms of their expected value and risk, such as comparing different investment strategies related to asset allocation (Cesari et al., 2003). The use of multi-attribute decision-making methods supported by computer simulations enables the identification of potential threats to a project or decision, identification of specific negative factors and determining how they will impact the project's outcome (Mojtahed et al., 2010). In the case of reinforcement learning (Sutton & Barto, 2018), the simulation scenario models a range of decision sequences, which is currently one of the most dynamic areas of artificial intelligence development.

MC modelling can also be applied more broadly within so-called probabilistic programming, which has now become one of the main branches of machine learning and an important element of data analysis (Ghahramani, 2015). Learning from data involves transforming previously defined probability distributions—by observing real data—into posterior distributions generated artificially after observing the data (this is called the application of probability theory to learning from data). The importance of this method is growing rapidly due to the possibility to train very complex models based on computer simulations to classify and predict events in such systems. In the case studied in this paper, these techniques allow searching for business solution spaces to identify opportunities.

It is also worth noting that the use of simulations in learning processes will soon enable the implementation of so-called embodied artificial intelligence, which is a step towards realising the idea of artificial general intelligence (AGI) (Duan et al., 2022).

3. Research

3.1 Materials and Methods

We present the discovery of opportunities using AI methods on the example of global production of jackets made of alternative materials, which are cotton, leather, cashmere and agave fibres. The necessary data on the production volume and demand flows between market fractions corresponding to these products, as well as demographic characteristics of buyers, were obtained using Chat 4.0. We used this technology due to its capabilities of searching and analysing distributed and fragmented databases.

We simulate the states of the system, which is created by customer flows and thus purchase streams between market fractions. The expected result is the proportion between these streams. In order to represent the full characteristics of the studied system, simulation modelling is employed using the Monte Carlo method (Kroese and Rubinstein, 2012). Data collected in this process allows for obtaining higher-level statistics - they are the basis for cluster analysis, multiple regression or correlation (Newbold et al, 2013), which in turn leads to the use of AI technology.

The most popular simulation method with wide application, and appropriate for solving the problem presented in this work, is the Markov Chain Monte Carlo (MCMC) algorithm (Chib, 2001). Monte Carlo Methods are numerical techniques used to approximate solutions to problems that may be difficult to solve analytically, using random samples. Markov Chains is a subset of stochastic models used in Monte Carlo methods. They describe systems transitioning between different states where the probability of transitioning to a given state depends only on the current state. The Metropolis Algorithm is a specific case of Markov Chains (Metropolis and Ulam, 1949; Hastings, 1970. It is a technique used to generate samples from a difficult-to-sample probability distribution by iteratively proposing new states and accepting or rejecting them with a certain probability. The transition from the current state A to a new state B satisfies a proposed symmetric transition function, meaning that the probability of transitioning from A to B is the same as transitioning from B to A. The Metropolis-Hastings Algorithm (M-H) is an extension of the Metropolis algorithm that allows the use of any proposal function, not just a symmetric one. This means that the probability of transitioning from A to B can be different from transitioning from B to A. By allowing asymmetric transition functions, the Metropolis-Hastings algorithm is more flexible and can be more efficient in sampling from complex probability distributions. The state space determined in this way forms the basis for the mathematical analysis of the system, allowing for the creation of higher-order statistics. Modelling the studied system using variable output parameters ultimately allows for the construction of a state diagram.

3.2 Modelling Purchase Flow Streams

In this article we will focus on the example of jackets made from four types of materials: cotton, leather, cashmere, and agave. Purchase decisions are influenced by a range of factors, which can be grouped into the following categories:

1. Economic Factors
    - Price: Cotton jackets are usually cheaper, making them more accessible to a wider range of consumers. Leather jackets are more expensive, limiting their purchase to those with higher incomes. Cashmere jackets are among the most expensive, classifying them as a luxury product. The price of agave fibre jackets varies, but due to the rarity of the material, they can be more expensive.
    - Buyer's Income: Buyers with higher incomes are more likely to purchase more expensive materials, such as leather and cashmere.
2. Demographic Factors
    - Age: Younger consumers may prefer cheaper and more common materials like cotton. Older consumers may be more inclined to purchase durable materials like leather and cashmere.
        - Gender: Men may more frequently choose leather jackets, whereas women might prefer cashmere due to its softness and elegance.

3. Cultural Factors
    - Fashion and Trends: Fashion plays a significant role in material choice. Fashion trends may promote a specific material in a given season. Marketing campaigns greatly influence the perception of a material as fashionable or luxurious.
    - Lifestyle: People leading active lifestyles may prefer cotton for its comfort and ease of care. Conversely, buyers who value elegance and prestige may choose leather or cashmere.
4. Ecological Factors. Environmental Awareness: Growing ecological awareness may prompt buyers to choose more environmentally friendly materials, such as organic cotton or agave fibres. Additionally, they may avoid leather due to concerns about animal welfare.

Taking into account the partial overlap of the characteristics of the above-mentioned groups with the characteristics of such buyer types as Fashion Enthusiasts, Tech-Savvy Consumers, Professional and Business Executives, Health-Conscious Consumers, Luxury Lifestyle Seekers Kotler and Armstrong (2010), Rogers (1983) and Euromonitor (2021), Chat GPT 4.0 estimated the share of these four groups in the global market as follows: Pragmatists - 36%; Extravagant - 17%; Prestige Seekers - 34%; Eco-conscious - 13%.

People enjoy variety, so although they have preferences, they also buy substitutes to meet their diverse expectations. For instance, when purchasing jackets or clothing more broadly, the shift from cotton may occur as more buyers seek ecological alternatives. In the case of leather, growing ethical awareness encourages buyers to avoid products made from this material. Additionally, the high price of leather may drive people to seek cheaper alternatives. The move away from cashmere to alternative materials may be due to its high price and fashion trends. Although agave fabric is ecological, its relatively small supply might prompt buyers to purchase alternative products.

Taking into account the above trends influencing the change of purchasing decisions, Chat GPT 4.0 estimated the potential redistribution of preferences and the flow of the customers stream between the market fractions, which is the result of random purchase decisions (Figure 1). The share of each fraction is 100%. Such data can be obtained from sales reports as well as through market condition surveys in individual market fractions. It is important to note that we are dealing with percentage shares rather than absolute values.

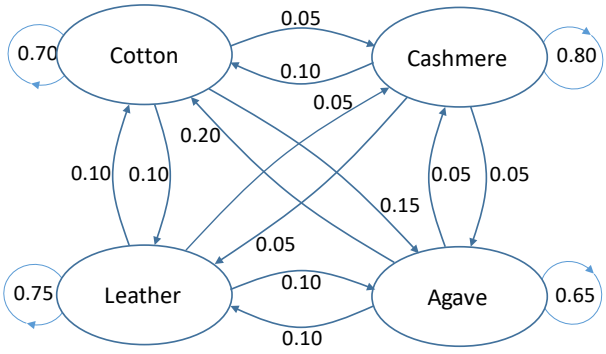

Figure 1: Model of potential flow of the purchase streams of jackets between market fractions

3.3 Modelling Buyers' Purchase Decisions

When making a purchase, customers take into account a number of functional, economic, and social features of these products, assigning different ranks to these features (Table 1).

Due to the preference for the highest-ranking features, four groups of buyers can be distinguished:

1. Pragmatist – These buyers choose cotton for its softness and breathability, making it comfortable to wear, especially in warm conditions. Cotton is relatively easy to wash and iron, and its versatility allows it to be used in various styles, from casual to more formal.
2. Extravagant – These buyers prefer leather jackets because of their elegant and luxurious look, which is highly valued in fashion. Leather is very durable and can last many years with proper care. Each leather product has a unique appearance due to natural variations in the leather, adding to its uniqueness.

Table 1: Ranks of features of four types of materials

Material	Breathability	Comfort	Durability	Warmth	Ease of Care	Affordability	Sustainability	Style/Aesthetic	Status Symbol
Cotton	5	5	3	2	5	5	4	4	2
Leather	3	4	5	4	3	2	3	5	5
Cashmere	4	5	3	5	4	1	2	5	5
Agave	2	3	4	2	3	4	5	3	3

The individual ranks mean: (1) Very Low, (2) Low, (3) Moderate, (4) High, (5) Very High.

Source: Own study based on: Peterman (2024), Sewport Support Team (2024a), Leather Naturally (2024), Endorfeen (2024), Sewport Support Team (2024b), Hulle, Kadole, and Katkar (2015).

3. Prestige Seeker – These buyers opt for cashmere as it is a symbol of high status. Cashmere is exceptionally soft and pleasant to the touch, making it one of the most luxurious materials. It is also lightweight and warm, which is especially valuable in colder months, and ensures good breathability.
4. Eco-conscious – These buyers choose agave because it is a fast-growing plant, making it a more sustainable material option. Agave fibres are very strong and durable, although less commonly used in clothing compared to other materials.

Taking into account the partial overlap of the characteristics of the above-mentioned groups with the characteristics of such buyer types as Fashion Enthusiasts, Tech-Savvy Consumers, Professional and Business Executives, Health-Conscious Consumers, Luxury Lifestyle Seekers Kotler and Armstrong (2010), Rogers (1983) and Euromonitor (2021), Chat GPT 4.0 estimated the share of these four groups in the global market as follows: Pragmatists - 36%; Extravagants - 17%; Prestige Seekers - 34%; Eco-conscious - 13%.

Despite preferring certain products, people also buy alternative products that meet their diverse needs. For jacket buyers, and more broadly clothing, the following external factors influence changes in purchase preferences: shifts in fashion trends, seasonal changes, effective marketing campaigns, economic downturn, income level, increasing ecological awareness, and corporate social responsibility initiatives. Under the influence of these factors, buyers make purchase decisions based on the following criteria:

1. Value for Money – 0.16 (Nielsen Global Survey, 2024)
2. Functionality and Maintenance – 0.14 (McKinsey & Company, 2024)
3. Comfort and Reliability – 0.14 (Cotton Incorporated, 2024)
4. Budget Sensitivity – 0.10 (Sheehan, 2023)
5. Luxury and Exclusivity – 0.09 (Bain & Company, 2023)
6. Statement and Uniqueness – 0.09 (Euromonitor International, 2021)
7. Status and Sophistication – 0.09 (Avery and Gupta, 2022)
8. Material Quality and Craftsmanship – 0.09 (MarketResearch.com, 2024)
9. Sustainability and Eco-friendliness – 0.04 (Nielsen, 2024)
10. Ethical Production and Sourcing – 0.04 (Ethical Consumer, 2024)
11. Natural and Organic Materials – 0.04 (Busalim, Fox, Lynn, 2022)

The weights of these criteria were proposed by Chat GPT 4.0 considering the importance of features of the four products for the types of buyers: Pragmatist, Extravagant, Prestige Seekers, and Eco-conscious. Using these weights and the impact of these criteria on purchase decisions, the weighted average purchase decisions for each buyer type were determined (Table 2).

Both the criteria and their weights as well as the impact on purchasing decisions can be determined by examining buyers' preferences and their tendency to purchase alternative products. The data in Table 2 corresponds to the following buyer profiles:

- PRAGmatist – Middle-income earners who prioritize practicality and cost-effectiveness. Often found in professions that require durability and comfort in clothing, such as teachers, office workers, and manual laborers. Generally middle-aged adults, around 30-50 years old equally distributed between male and female. They are typically from regions with moderate to warm climates, such as parts of North America, Europe, and Asia. They represent a significant portion of the population, likely around 30-40% of the market.

Table 2: Weight matrix of purchase decision of jacket buyers

Type of customer	Fabric	Fabric			
		Cotton	Leather	Cashmere	Agave
Pragmatist	Cotton	0,65	0,10	0,05	0,20
Extravagant	Leather	0,10	0,60	0,25	0,05
Prestige Seekers	Cashmere	0,05	0,20	0,70	0,05
Eco-conscious	Eco-conscious	0,30	0,05	0,10	0,55

- EXTRAvagant – Higher-income individuals who can afford luxury and statement pieces. Typically involved in high-paying jobs such as executives, artists, and celebrities. Younger to middle-aged adults, around 25-45 years old with a small predominance of men who often purchase leather jackets. They live in urban areas and regions with a strong fashion culture, such as major cities in the United States, Europe, and Asia. They represent smaller niche market, possibly around 10-15% of the market.
- PRESTige Seeker – Wealthy individuals who seek high-status and premium quality products. Common among high-ranking professionals like executives, lawyers, and entrepreneurs. They are older adults, typically 35-60 years old with predominance females, as cashmere is often associated with luxury women's fashion. They presumably live in affluent areas worldwide, such as upscale neighbourhoods in North America, Europe, and Asia. They represent a very niche market, likely around 5-10% of the market.
- ECO-conscious – Middle to upper-middle-income individuals who can afford to prioritize sustainability. They can be found among a variety of professions but with a higher representation among educators, healthcare professionals, and those in the environmental sector. They are younger to middle-aged adults, around 25-45 years old with small predominance of females who are often more active in sustainability efforts. They live in urban and suburban areas with a strong focus on sustainability, often found in parts of North America, Europe, and Oceania. They represent the growing segment, potentially around 15-20% of the market.

3.4 Simulation

Using the data on the flow of purchase streams (Figure 1) the potential demand for jackets made of cotton, leather, cashmere and agave was generated. The demand was determined using a method developed by us, based on the Markov Chain Monte Carlo (MCMC) and the Metropolis-Hastings (M-H) algorithm in 1000 steps of simulation (Figure 2). Each step can be interpreted, for example, as one day. Then this figure shows the fluctuation of the purchase stream of each product on subsequent days.

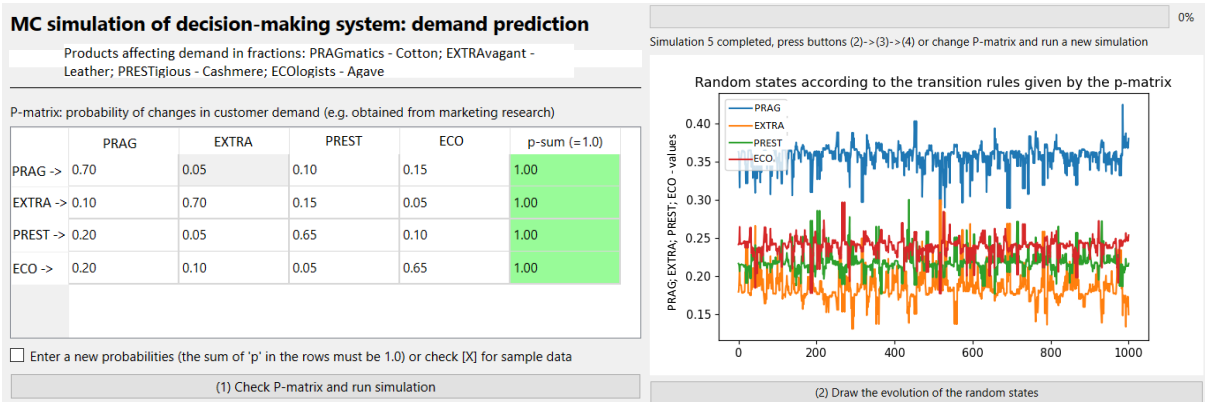

Figure 2: Probability of the flow of the purchase stream and the random distribution of this stream

Figure 3 shows simulated random states of the purchase stream of the four products under consideration. Each point on the horizontal axis of Figure 2 corresponds to one point in Figure 3. The coordinates of these points determine the proportions between the purchase streams of the products under consideration in the individual market fractions. Since the figure is made in 3D, one fraction (PREST) has been omitted. Despite this, the density of points in this figure shows well how the system is approaching the state represented by the stationary point, which is the expected state (averaged from 1000 iterations). This point corresponds to the proportion of purchases, amounting to 36%, 18%, 21% and 24%, respectively for the Pragmatist, Extravagant, Prestige Seeker,

and Eco-conscious fractions. It is worth noting that there can be an infinite number of distributions (Figure 2), but for each of them the stationary point of the system will be the same.

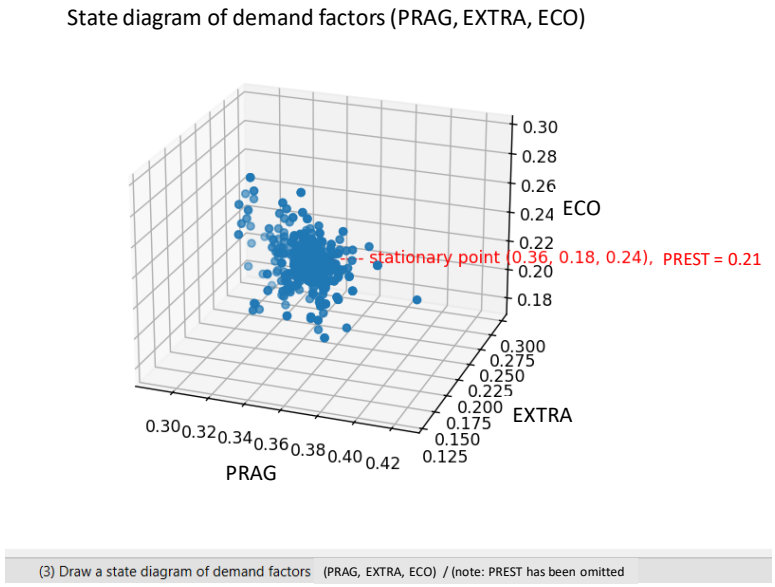

Figure 3: System state diagram in 1000 simulation steps

The stationary point shown in Figure 3 abstracts from the profile of buyers making purchases in the different market fractions. In each fraction, purchases are made by various buyers, not just those who prefer the product specific to that fraction. This is why there are flows between fractions, which in our case are shown in Figure 1 and also in the table in Figure 2. However, this does not mean that there is no buyer profile behind the stationary point. In our case, we identified this profile based on the purchasing criteria, their weights, and their impact on purchasing decisions, as presented in Section 3. 3, particularly in Table 2 and the table in Figure 4. Taking into account the profiles of Pragmatist, Extravagant, Prestige Seeker, and Eco-conscious buyers, the proportion between the purchase flows of the four considered types of products is 40%, 14%, 20%, and 26% respectively.

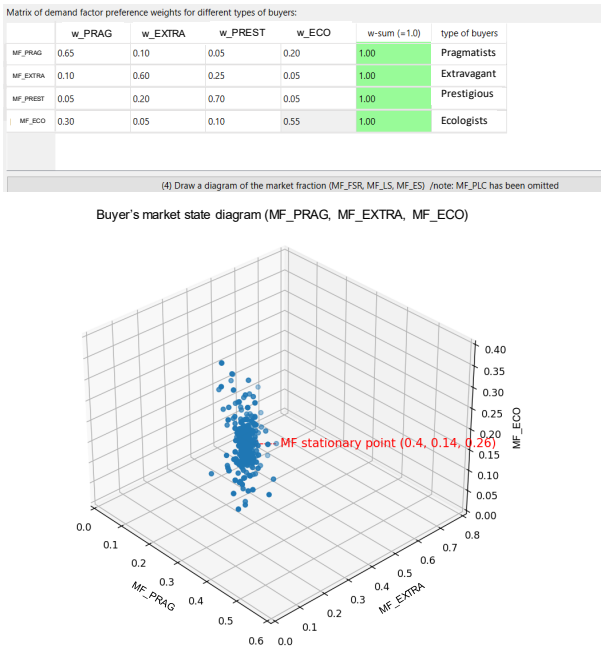

Figure 4: Stationary pint of the jackets buyers' market state

4. Discussion and Conclusions

In the problem that is the subject of this article, the opportunity is the gap between the proportion of products available on the market and the proportion expected by buyers. Taking into account: (1) the global production volume of cotton, leather, cashmere and agave fibre in 2023, (2) the consumption of these raw materials for clothing production, (3) the share of jacket production in clothing production, (4) the material consumption standards for the production of one jacket, it is possible to estimate the number of jackets made of cotton, leather, cashmere and agave produced on a global scale. The share of production of these products is 95.065%, 4.748%, 0.164%, 0.023%, respectively. The summary of the expected and available shares and thus the opportunity constituting the demand gap is presented in Table 3.

Table 3: Demand gap in the jacket segment

Fabric	Expected demand	Estimated current supply	Gap	Opportunity
Cotton	40,00%	95,07%	-55,07%	
Leather	14,00%	4,75%	9,25%	Increase production
Cashmere	20,00%	0,16%	19,84%	Increase production
Agave	26,00%	0,02%	25,98%	Increase production

In order to define the profile of buyers, we have formulated the following criteria: financial status, type of work, education, living conditions, gender, age, and potential population. According to these criteria, based on the following reports: Statista. "Apparel Market Report"; Nielsen, "Consumer Research Report"; U.S. Bureau of Labor Statistics, "Consumer Expenditure Survey"; Urban Institute, "Urban and Suburban Population Reports"; Verified Market Reports, "Formal Wear Market Size, Share and Trends"; Market Research.com, "Trusted market research and industry insights", Chat GPT 4.0 has developed demographic profiles of current and potential jacket buyers. The current supply of jackets is targeted to buyers with middle financial status who perform jobs that require comfortable clothing, like teachers, administrative workers, and service sectors. They live in cities and suburbs and have access to a wide range of clothing stores and shopping centres. These are both men and women with slight predominance of women, who might be more interested in clothing variety all the specified criteria. On the other hand, buyers with expectations consistent with the results of our simulation have a higher financial status and are entrepreneurs, professionals in technology, creative industries, or managers. They have higher education. They are residents of large cities and metropolises with access to stores offering luxury and ecological clothing products. These are people aged 30-45, mostly women, who are more likely to lead in eco-movements and sustainable fashion. This population constitutes 5-10% of buyers of jackets. Promotion should be directed to this group to take advantage of the opportunity of unmet demand.

The methods and AI algorithms we employed yielded results that enable the identification of opportunities for producers of alternative products. This opportunity arises from the existence of unfulfilled demand for certain products. In our case, this applies to jackets made from leather, and especially from cashmere and agave fibres. For these latter two, the differences between the simulated demand and the analytically estimated supply are very significant. Their rational reduction requires market segmentation and identification of segments whose demand is not satisfied. In our case, the basis for segmentation is the demographic profile of buyers. Comparing the buyer profiles for the simulated and actual proportions of purchase flows for each product allows us to identify the customer types whose satisfaction of needs leads to the use of a market opportunity.

Our analysis of the global market case confirmed that the challenge of discovering opportunities arising from unmet demand for alternative products and shaping a product portfolio to balance this demand can be effectively addressed using MCMC methods, particularly the Metropolis-Hastings algorithms. This method can be employed even when data is limited to the probability of purchase flow between market fractions corresponding to these products. Such data can be obtained from sales reports or through conducting marketing research. This characteristic makes the method particularly useful for SMEs, which typically do not employ AI methods based on Big Data. This is possible because the method generates its own dataset based on the previously defined purchase flow matrix. A significant modification we introduced is the consideration of purchase decision weights, which means taking into account the buyer profile. This provides data for market segmentation and thus the basis for identifying segments with unmet demand, creating a market opportunity.

While MCMC and M-H algorithms are fully adequate for identifying opportunities with defined probabilities of purchase flow between market fractions, the reliability of the solutions obtained depends on the accuracy of the data on these flows and the weights of purchase decisions. The data in the purchase flow matrix is relatively easy to obtain, especially for SMEs. However, determining the weights of purchase decisions requires a multi-criteria assessment of the factors influencing buyers. Our experience indicates that these weights are correlated with the purchase flow, but the mechanism of this dependency is not defined. This issue is the subject of our ongoing research because even small changes in weights significantly impact the simulated production portfolio.

A Guideline Enabling Knowledge Managers to Communicate Better with Business Managers

Pavel Kraus[1] and Manfred Bornemann[2]
[1]Swiss Knowledge Management Forum, Bern, Switzerland
[2]Knowledge Management Global Network KMGN and Intangible Assets Consulting GmbH, Graz, Austria

p.kraus@skmf.net
bornemann@ia-consulting.at

Abstract: Aligning Knowledge Management (KM) with overarching business strategies is considered as important for organizational success and sustainability. But this crucial element is often missing in the implementation and operation of KM. This paper explores the concept of "business alignment" within the context of KM, elaborating its critical role in enhancing collaboration, minimizing errors, and supporting optimal outcomes across the enterprise. We suggest a comprehensive definition of KM alignment, where KM activities are strategically integrated with business objectives, ensuring visible and measurable benefits to employees and executives. The research addresses key questions such as what constitutes an organization and how KM can facilitate its survival and growth. An organization is not merely a standalone entity but a collective endeavor that thrives on managing internal and external relationships. We argue that the effective alignment of KM with business strategies ensures that these relationships are optimized, thereby enhancing organizational resilience and adaptability. This holistic perspective visualizes the interconnected nature of businesses and highlights the essential role of KM. Our approach involves a systematic examination of business relationships and their alignment with KM practices. We analyze one case study from the construction industry, illustrating how strategic KM initiatives contribute to their sustained success. Additionally, we propose a set of Key Performance Indicators (KPIs) derived from real-world scenarios, linking them to specific business needs and challenges. These KPIs serve as a roadmap for C-level managers, guiding them in integrating KM into their strategic frameworks. The findings underscore the value of KM in mitigating risks associated with poor relationship management. We provide a process and actionable insights for business leaders on leveraging KM to foster innovation, streamline processes, and enhance overall performance. The paper concludes with practical recommendations for implementing KM solutions tailored to different organizational maturity levels and industry contexts.

Keywords: Knowledge Management, Business Alignment, Organizational Strategy, Key Performance Indicators, Relationship Management, Business Sustainability

1. Introduction to business alignment

The discipline of Knowledge Management (KM) has often struggled to become a top priority for C-level managers. Several factors contribute to this, including organizational, cultural, and economic challenges. Drucker (1999) noted that many organizations prioritize short-term financial performance over long-term strategic initiatives. Similarly, Davenport and Prusak (2000) observed that KM initiatives require substantial investment in technology and human resources, with returns that are not immediately visible. Dalkir (2011) reiterated that KM often yields primarily intangible benefits that are hard to measure in the short term.

C-level executives typically focus on initiatives with clear, quantifiable returns on investment. Additionally, according to Nonaka and Takeuchi (1995), KM is sometimes perceived as misaligned with core business goals or as a support function rather than a strategic initiative.

Other topics, such as digital transformation, cybersecurity, innovation, R&D, sustainability, corporate social responsibility, customer experience, and operational efficiency, are often perceived as having a more immediate impact on the organization's bottom line. Consequently, they dominate top executives' agendas.

For knowledge managers, the contribution of "knowledge" to all these tasks seems obvious – yet it is not prioritized. One way to change this situation is to improve communication. Following Bornemann et al. (2007), this usually starts with some form of inventory – identifying available knowledge assets – and connecting them to the business model. Once the contribution of knowledge becomes visible and understood in terms of its impact on the bottom line, both knowledge workers (experts) and C-level managers can align their efforts and collaborate more effectively.

1.1 Challenges in the C-Level

Over the past decades, many KM initiatives have failed (Kraus, 2015), sharing the same fate as other change management initiatives (Kotter, 1996). Consequently, economic and corporate growth have been lower than expected, and organizations face survival threats. One reason for this failure is that knowledge managers did not

adopt the business perspective of C-level managers and thus failed to effectively communicate the relevance of knowledge management. The link between organizational threats, operational problems, and KM as a solution needs to be demonstrated and firmly established.

We formulate the following hypotheses:

- H1: KM can improve the operational situation of organizations.
- H2: Linking KM to organizational problems and vice versa is an effective way to get management's attention.
- H3: Connecting KM solutions to organizational problems and tying them to Key Performance Indicators (KPIs) increases value creation.
- H4: Tying KM to the personal priorities and KPIs of C-Level executives increases chances for implementation.

The foundations for H1 are discussed in the conceptual background section and are supported by cited literature. Similarly, H2 aligns with mainstream KM thought, culminating in Drucker's frequently cited adage, "what gets measured gets done," implicit in his early work (e.g., Drucker, 1967). H3 follows these ideas, similar to the strategy implementation recommendations by Kaplan and Norton's "Balanced Scorecard" (BSC) since 1992. While not all attempts to implement BSCs have been successful, the general idea has become part of the business mainstream. Since the early 2000s, measures and KPIs for KM have been developed. The remaining challenge is to suggest a scalable method to implement H4 and test the results, which will be demonstrated in section two. Some of the operations problems, which increase the chance to get the attention of business managers are listed in random order in **table 1**.

Table 1: Selection of operational problems that typically attract management attention

Project teams exhibit slow progress due to insufficient collaboration among individuals or business units	Frequent reinvention of solutions due to inefficient information retrieval or lack of oversight
High rate of specialist retirements	Prolonged onboarding time for new employees
Need for upskilling through cross-domain knowledge or information transfer	Lack of comprehensive oversight for effective action
Increasing complexity in process coordination due to insufficient communication between administrative units	Customers struggle to find answers independently, leading to excessive reliance on human support
Inefficient information retrieval	High turnover of knowledge workers
Suboptimal resource utilization	

Linking KM solutions to these operational problems and contributing to resolving them will increase the likelihood of not only winning C-level attention but also becoming a long-term partner. A detailed guideline was presented by a KMGN project team (Kraus, 2024).

1.2 Interpreting Value as more then Shareholder Value

The concept of maximizing shareholder value, developed by Rappaport (1998) and others, builds on Jensen's Agency Theory (1986) and Stewart's Economic Value Added (1991). However, these authors did not emphasize Drucker's crucial point: the importance of prioritizing customer interests to generate profitable outcomes. Drucker expanded the idea of value creation from merely focusing on financial metrics to considering the entire value chain, including the customer perspective (Drucker, 1954). He further elaborated on the essential role of knowledge workers in value creation (Drucker, 1969), a discussion that continues today (Denning, 2022).

Corporations should focus on their purpose ("Why are we here?") and how value is created. The alignment of knowledge workers emerges from clear leadership on vision, transparency on resources and processes, and performance status (Drucker, 1973). Principles of self-organization (von Foerster and Zopf, 1962) may apply but require the context of the organization and KM systems (ISO 30401). These are all prerequisites for a sound business model that defines how and through which processes value is created.

2. Conceptional Background on KM and Alignment

We follow Kraus et al. (2020) and Oberschmid (2007) in their definitions of Knowledge Management (KM) as the "targeted design of framework conditions and processes in an organization, with special consideration of the production factor knowledge. The focus here is on creating and networking individual knowledge and applying this in value creation processes" (Oberschmid, 2007). This definition aligns with ISO 30401 (2018) and other academic scholars such as Drucker (1959), Mandl (1998), and Probst (1999).

To continue the discussion in the context of "business aligned KM", we suggest the following working definition:

Knowledge management (KM) is considered business aligned when:

1. The strategy of KM activities is firmly tied to the business strategy or other relevant aspects that ensure the survival of the organization.
2. This alignment is clearly visible to the business personnel, especially to executives.

Business alignment, particularly in the context of KM, is a well-studied field. The alignment of KM strategies with business strategies is crucial for ensuring organizational survival and effectiveness. Several authors in the field of KM have discussed this topic:

- Nonaka (1994) emphasized the importance of aligning knowledge creation processes with business strategies.
- Teece (1997) discussed the dynamic capabilities framework, which includes the strategic management of knowledge resources to align with business strategies for innovation and competitiveness.
- Davenport and Prusak (1998) presented research on the strategic management of knowledge and how aligning KM practices with business strategies can enhance organizational performance.
- Zack (1999) explored the necessity of aligning KM initiatives with organizational strategies to support decision-making and innovation.

These discussions connect organizational knowledge and capabilities with implications for innovation, competitiveness, and strategic decision-making.

2.1 Storytelling and KM

For successful KM, it is ideal that executives and knowledge workers support each other in achieving organizational objectives. Storytelling is an effective management method to facilitate this alignment (Brown, 2004; Schein, 2010). When both groups tell the same stories, alignment is more likely to be achieved. This supports our hypotheses H1 and H2.

Storytelling is effective in KM because it narrates and explains the connection between KM and business operations:

- Simplifies Complex Ideas: Storytelling translates complex KM concepts into tangible narratives, making them easier to understand.
- Engages Stakeholders: Stories are engaging and can capture the attention of both knowledge workers and executives.
- Creates a Shared Vision: When knowledge workers and executives share the same stories, it fosters a shared understanding and vision.

2.2 KM emerges in four levels as suggested by David Gurteen

David Gurteen's framework for KM includes four levels: Information Management, Knowledge Sharing, Sensemaking and Decision Making, and Behavior, Community, and Leadership (Gurteen, n.d.). While Gurteen presents these levels in an ascending order, we believe they can be implemented flexibly. Importantly, the fourth level—Behavior, Community, and Leadership—is crucial for the success of the other levels.

Four Levels of KM:

- **Information Management**: Centralized capture, storage, and distribution of information using IT systems and databases.
- **Knowledge Sharing**: Peer-to-peer learning through tools like peer assists and communities of practice, emphasizing personal knowledge sharing.
- **Sensemaking, Decision Making, and Innovation**: Utilizing facilitated discussions to create shared context, make informed decisions, and innovate.
- **Behavior, Community, and Leadership**: Empowering individuals to act on knowledge and fostering a community where leadership is a shared practice, not confined to formal positions of authority.

The four-level categorization is useful because many organizations have very different understandings of KM. In some organizations, KM is limited solely to information management and information technology. This corresponds to the “basic KM level” by Gurteen. Other companies might focus mainly on “networking among experts”. According to Gurteen, the third and fourth levels have almost nothing to do with technology or IT.

2.3 Connecting MBO and KPI to align KM with business objectives

The role of knowledge managers is to take a holistic view, identify critical areas, and determine how to make targeted improvements in knowledge and information management. Defining these targets involves selecting KPIs that align with those agreed upon with C-level executives during their annual performance appraisal.

2.3.1 Define MBO and KPI:

- **Management by Objectives (MBO):** A performance management approach where managers and employees work together to set, monitor, and achieve specific objectives.
- **Key Performance Indicators (KPIs):** Measurable values that indicate how effectively an organization is achieving its key business objectives.

2.3.1 Steps to Align KM with Business Objectives:

1. Identify organizational objectives and goals.
2. Define specific KM targets that support these objectives.
3. Develop KM KPIs that align with C-level executives' KPIs.
4. Monitor and adjust KM activities based on KPI performance.

2.3.1 Categories of Goals and KPIs:

- **Viability:** Ensuring the organization's survival is a top priority.
- **Operations:** Enhancing the organization's value creation capacity is essential.
- **Market:** Addressing stakeholder impacts, including customers and suppliers.
- **Technology:** Managing technological constraints and leveraging enablers.
- **Regulation:** Integrating regulatory requirements that impact the organization's opportunity space.

Table 2 provides examples of goals, challenges, and KPIs categorized into four perspectives: Viability, Operations, Market, Technology, and Regulation. Each perspective includes specific goals and KPIs that align with business objectives and help measure the effectiveness of KM initiatives.

Table2: Challenges and KPIs relevant for survival of organizations grouped in four levels

Perspective	Information Management	Knowledge Sharing	Sensemaking, Decision Making, and Innovation	Behavior, community and leadership
Viability	Analyzing financial risk for the organization	Lack of employees for sustainable a viable operation	Underestimated application of AI	Foreseeing and counteracting lack of business continuity
Operations	Media disruption	Processes improvements	Increased productivity or capacity, incl. time and cost savings	Missing technology adoption / Low technological adoption
Market	Ambiguity	Disregarded changes in customer needs	Loss of relevance in the market in growth or market share	Sales discontinued due to impaired social acceptance of products or operations
Technology	Lack of shared taxonomies and information architecture	(not addressed)	Sales discontinued due to outdated technology (process or product)	Resistance to change
Regulation	Lack of compliance regarding information storage and regulatory standards	Legal and regulatory risks	Limited freedom of operation	Underrated ecological sustainability and related regulatory aspects

Tables 3-6 contain the KM reference points related to our categories. We found a positive influence of these reference points to attracting C-Level attention. Please note that not all categories are supported by reference points.

Table3: KM reference points on level 1 by category

Category	**Reference points on level 1**
Viability	Simultaneous change management from old status to the new one.
	Securing management consensus on the impact (KPIs) of this action upon the business process and context.
	Continuous improvement on the guidelines and information management process.
	Capture measurable impact directly within a business process and context.
Operations	Bring all the stakeholders together and harvest their expectations and needs.
	Harvest all previous and current good practices regarding business initiatives.

Category	**Reference points on level 1**
	Fast access to relevant information based on the business context and user needs.
	Fast understanding and learning from information within context.
	Speedy operational action based on understood information.
Market	Become aware of all types of information relevant to the business context.
	Continuous communication of the impact (KPIs) of KM actions on the business process and context.
Technology	Selection of IT Tools and IM practices that support all the following steps.
	Create an information architecture and taxonomy relevant to the business context.
	Creation of high-quality information (Guidelines and Training).
Regulation	Clarify who needs what kind of information access and how quickly.
	Agreed rules among stakeholders for information handling and management.

Table 4: KM reference points on level 2 by category

Category	**Reference points on level 2**
Viability	Identify and focus on areas where there are business risks.
	Capture the benefit of learning activities and resulting actions and make them tangible.
	Continuous communication of tangible results to executives, thus further promoting and embedding these activities.
	Time to competence (time it takes for employees to be fully productive in their jobs).
	Pre- and post-measurement intervention.
Operations	Help people to turn their personal learnings (from work) into re-shareable and re-usable learnings (Teaching + Documentation).
	Motivation for knowledge sharing by SMEs and willingness to learn on the part of knowledge recipients.
	Promote a culture of turning failures into learnings.
	Foster learning activities within a shared context with SMEs (1:1 or as a CoP).
	Making personal access to internal subject matter experts affordable (1:1).
	Connect sharing activities and SMEs to defined processes and process steps (Anchor Points).
	Platform connecting SMEs with learners using business context, e.g., regular CoP meetings. Trust is essential through rules and culture.
	Define time and place to share knowledge and learn that leads to actions within business process and context.
	Use mentors to promote 70-20-10 learning, which will make knowledge more redundant and prevent re-inventing the wheel.
Regulation	Create a list of subject matter experts and a taxonomy of internal subject matters.

Table 5: KM reference points on level 3 by category

Category	**Reference points on level 3**
Viability	Advocate Innovation as a masterstroke to remain ahead of competition.
	Measure the impact of context decisions both qualitatively and quantitatively.
	Develop feedback mechanisms on all of level 3 activities to become a learning organization.
Operations	Promoting a culture of cross-silo collaboration, enabling CoPs.
	Build an environment to co-create/manage and contribute to innovation, growth and satisfaction.
	Set-up CoPs that use a portfolio of innovative KM techniques, interaction formats or workshop designs aimed at supporting business strategy and processes.
	Resulting in sense-making through alignment, conversations, visualizations and workshops leading to decisions out of shared context.
	Make this KM portfolio a standard methodology that is systematically used and integrated within daily business processes.
	This means bringing people together within business and subject matter context (CoP).
	Leading to business and bottom-line relevant decisions and actions based on understanding of shared context.
Regulation	Alignment of business needs and strategy with CoPs providing knowledge to cover key business areas.
	Continuously communicating CoPs and KM techniques to management as standard procedure to make decisions.

Table 6: KM reference points on level 4 by category

Category	**Reference points on level 4**
Viability	Empowered leadership by either executives or collaborators - company culture and trust.
	Support the deeper understanding of people and the business case.
Technology	Regular utilization of KM techniques and their enforcement in day-to-day business processes by employees and line managers.
Operations	Connected to current business campaigns.
Market	Establishing customer understanding to make sensible trade-offs among contradictory factors (quality, cost, time).
Regulation	Create the ability to act on regulation based on practical and conceptual experience.

Level 4 (behavior, community and leadership) has a strong impact on all levels before. For example, without leadership support, we cannot implement a sound information management system. Additionally, collaboration is required to implement any solution at any of the first three levels.

Empowered leadership by both executives and collaborators is fundamental to fostering a company culture based on trust. Solid psychological security within the organization ensures that individuals feel capable and confident in their actions. Leaders, human resources (HR), and organizational development (OD) professionals must be well-versed and trained in knowledge management (KM) techniques and methods. The regular application and enforcement of KM techniques in everyday business processes by employees and line managers is essential. Transformative behavioral change should be built upon a shared understanding and deep insight. Finally, it is important to support a deeper understanding of both individuals and the business case at hand.

3. Example and Discussion of aligning KM to C-level concerns

This section illustrates how aligning KM initiatives with C-level concerns can be achieved using a case study from the construction industry (Schoos, 2018). We will discuss the use of storytelling and connecting KM activities to management goals and KPIs.

3.1 Case Study: Construction Industry

In the construction industry, a significant challenge was identified: a lack of knowledge among employees, leading to financial risks for the organization. This problem was broken down into specific causes and consequences using methodologies like Root Cause Analysis (RCA) and Failure Mode and Effects Analysis (FMEA) – see figure 1.

3.1.1 Problem Identification

- **Primary Problem:** Lack of knowledge among employees.
- **Causes:** Insufficient experience as contractors and project managers; Limited direct personal interaction; Isolation on construction sites.

3.1.1 Consequences

First Tier Consequences:

- Loss of time due to inquiries and insufficient experience.
- Waiting for information due to limited interaction.
- Repeated errors in construction and project management due to isolation.

Second Tier Consequences:

- Delays in construction completion and additional costs for the building owner.
- Work overload for employees due to repeated errors.

Third Tier Consequences:

- Lack of resources for follow-up projects.
- Increased reliance on external resources to compensate for internal inefficiencies.

Fourth Tier Consequence:

- Financial risks for the organization.

The structure of this problem-resolution process aligns with RCA and FMEA principles by demonstrating how initial problems propagate through a series of intermediate effects to impact organizational objectives. This cascading effect is crucial for understanding the broader implications of seemingly isolated issues.

3.2 Connecting KM to Management Goals and KPIs

To align KM initiatives with management goals, it is essential to identify relevant KPIs and demonstrate how KM can impact these metrics. Based on this case study the following goals and KPIs support our categories:

- **Viability:** Reducing project delays and costs to ensure organizational survival.
- **Operations:** Enhancing knowledge sharing to improve operational efficiency.
- **Market:** Improving customer satisfaction by delivering projects on time and within budget.
- **Technology:** Utilizing advanced KM tools to streamline information flow.
- **Regulation:** Ensuring compliance with industry standards through better knowledge management.

Linking KM activities to these goals and KPIs allows knowledge managers to demonstrate the value contribution of KM. For example, reducing project delays through improved knowledge sharing can be directly tied to financial performance metrics, making it easier to justify KM integration to C-level executives.

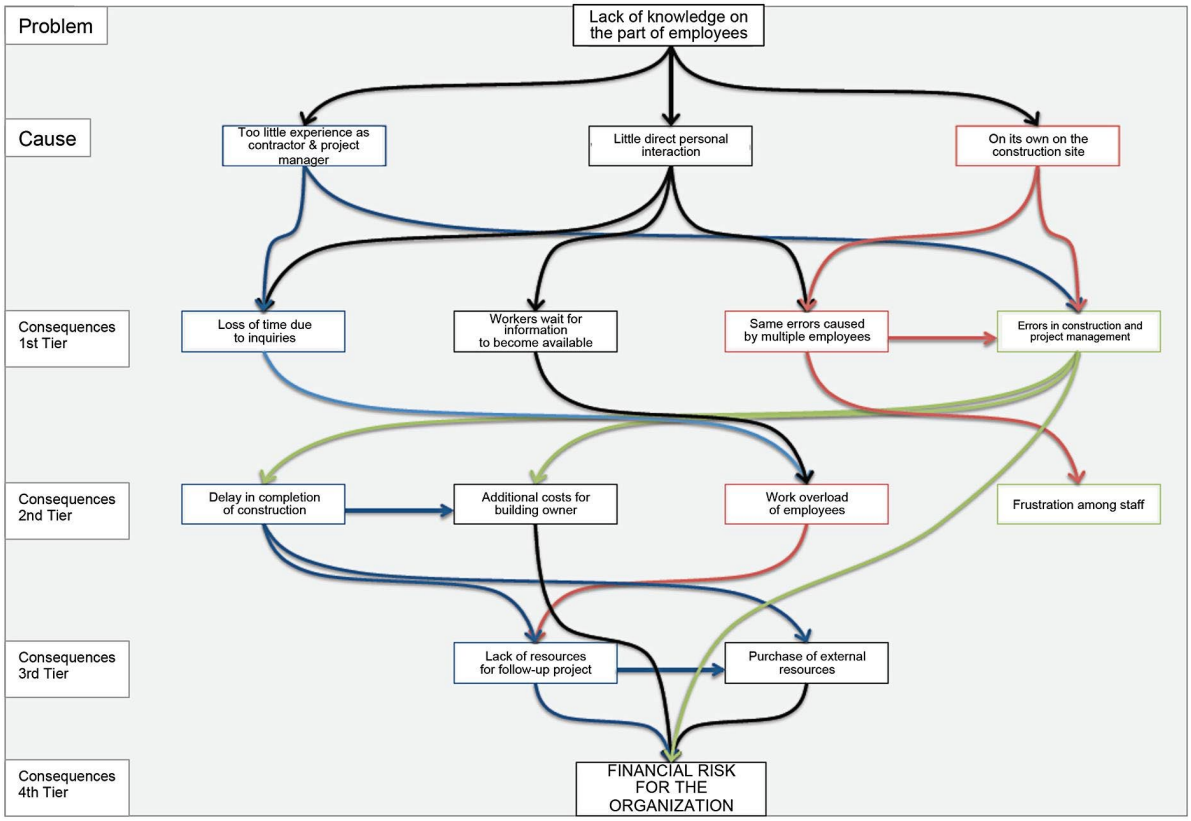

Figure 1: KM story example from construction industry (based on Schoos, 2018)

3.3 Practical Implementation

To implement KM solutions effectively, knowledge managers should follow a structured approach:

1. **Identify Critical Areas:** Use methodologies like RCA and FMEA to pinpoint key knowledge gaps and their consequences.
2. **Develop a Narrative:** Create a compelling story that links KM initiatives to organizational challenges and goals.
3. **Define KPIs:** Establish clear KPIs that align with management goals and measure the impact of KM activities.
4. **Engage Stakeholders:** Communicate the narrative and KPIs to C-level executives and other stakeholders to gain their support.
5. **Monitor and Adjust:** Continuously monitor the impact of KM initiatives on the defined KPIs and adjust as needed.

Aligning KM initiatives with C-level concerns requires a clear understanding of organizational goals and the ability to communicate the value of KM through compelling narratives and relevant KPIs. A structured approach helps knowledge managers to demonstrate the impact of their activities on the organization's success.

4. Conclusion and recommendations

This paper explored the alignment of Knowledge Management (KM) activities with organizational objectives, underscoring the importance of aligning KM efforts with the goals of senior management. Our findings indicate that alignment is achieved when KM activities meaningfully contribute to organizational success. This necessitates an initial analysis of managerial goals to facilitate this alignment.

To bridge the gap between KM initiatives and organizational priorities, we developed a method for knowledge managers to articulate the necessity of KM to C-level executives. This method maps knowledge gaps to critical business issues, empowering knowledge managers to demonstrate the essential role of KM in achieving organizational objectives. The direct effect of KM activities on business outcomes surpasses the opinion of Davenport that KM returns are not immediately visible.

The effectiveness and efficiency of this method were illustrated through real-world case studies, each clearly linking knowledge issues to their consequences across four tiers. The hierarchical structure of these consequences supports building a compelling narrative. The more KM solutions address these consequences, the more relevant the KM program becomes.

4.1 H1: KM can improve the operational situation of organizations.

Our case study showed that KM initiatives, such as improved knowledge sharing and information management, led to more efficient operations. For example, reducing project delays and errors through better knowledge management resulted in increased operational efficiency. The positive impact on operational efficiency, as demonstrated in the construction industry case study, confirms that KM can significantly improve the operational outcome of organizations.

4.2 H2: Linking KM to organizational problems and vice versa is an effective way to get management's attention.

Linking KM initiatives directly to organizational challenges, such as financial risks and project delays, supports capturing the attention of C-level executives. This connection was crucial in demonstrating the relevance of KM to business performance. The use of storytelling and clear communication of how KM addresses specific business problems effectively gained management attention and support.

4.3 H3: Aligning KM solutions to organizational problems and tying them to Key Performance Indicators (KPIs) increases value creation.

Establishing KPIs that align with organizational goals and measuring the impact of KM initiatives on these KPIs helped in demonstrating the value of KM. Tracking the reduction in project delays and cost savings provided tangible evidence of KM's contribution to value creation. The alignment of KM activities with KPIs related to organizational goals, such as operational efficiency and financial performance, increased the perceived value of KM solutions among C-level executives.

4.4 H4: Tying KM to the personal priorities and KPIs of C-Level executives increases chances for implementation.

Personalizing KM initiatives to address the specific priorities and KPIs of C-level executives, such as improving operational efficiency and reducing costs, increased the likelihood of implementation. This personalized approach ensured that KM initiatives were seen as directly relevant to executive priorities. Tailoring KM activities to the personal goals of C-level executives facilitated their buy-in and support, leading to successful implementation of KM solutions.

Acknowledgements

This paper benefits from a project to develop a guideline for "Business Aligned KM" by the Knowledge Management Global Network (KMGN) during 2023 with an international team led by Dr. Pavel Kraus (SKMF, Switzerland) and Dr. Manfred Bornemann (GfWM, Austria) including the following contributors: Joshua Azaki, South Africa; Sergio Gisbert, United Kingdom; Dr. Moria Levy, Israel; Glenroy London, Trinidad & Tobago; Sabyasachi Parida, Hong Kong; Dr. Gil Regev, Switzerland; Lynne Schneider, USA; Bart Verheijen, Netherlands.

The authors would like to acknowledge the use of OpenAI's GPT-4.o for assisting in the development and refinement of the manuscript. The AI provided suggestions and edits to enhance the clarity and coherence of the text. All final content, interpretations, and any errors remain the sole responsibility of the authors.
