Using Digital Tools for Information Management in Higher Education

Naghmeh Aghaee
Lund University, Lund, Sweden

nam.aghaee@ics.lu.se

Abstract: In recent years, Knowledge Management (KM) has gained significant attention within the Information Systems (IS) community. The economic importance of data and information, often likened to "data as the new oil," underscores the critical role of data/information/knowledge management. KM is crucial in both educational and organizational contexts. Despite growing interest, research in KM in Higher Education (HE) remains fragmented, especially with the rapid evolution of digital tools and Artificial Intelligence (AI). This paper explores the intersection of KM and HE, emphasizing the use of digital tools and platforms for knowledge acquisition among university students. An open survey conducted in Sweden among bachelor students enrolled in a digitalisation course revealed that digital tools are used frequently for knowledge acquisition and communication. The study highlights the benefits, challenges, and suggestions about how to use digital tools in KM in HE and the need for structured educational training to facilitate KM processes. It also advocates for new research avenues emphasizing the role of digital tools in HE and provides guidance for integrating technology into KM principles in HE.

Keywords: Higher Education, Digital Tools, Knowledge Management, Information Management, Generative Artificial intelligence

1. Introduction

Knowledge Management (KM) has recently received considerable attention in the information systems community and is continuously gaining interest by industry and academia (Quarchioni, et al., 2022; De Bem Machado, 2022). The increasing importance of information/knowledge (defined differently by Zins, 2007) play a fundamental role towards the success of gathering, using and transforming information, in an organizational perspective, especially in educational settings (Metaxiotis & Psarras, 2003). Previous articles outline the basic concepts within KM (Metaxiotis & Psarras, 2003; De Bem Machado, 2022) and specifically KM in Higher Education (HE) (Quarchioni, et al., 2022; Brewer & Brewer, 2010) as a concept for an ever-changing environment (Katz et al., 2022; Laal, 2011). KM is a systematic process by which knowledge needed for an organization to succeed in creating, capturing, sharing and leveraging (Laal, 2011).

There are numerous definitions of data, information, and knowledge, with no universally agreed-upon definitions (Zins, 2007). In this study, "information" is defined as data that is communicated, contextualized, and has a purpose or effect, while "knowledge" refers to the cognitive framework that enables individuals to understand and utilize the information (Beynon-Davies, 2019; Bellinger, Castro & Mills, 2004; Davis & Olson, 1984). Since information gathering is part of the knowledge management process, the terms "information management" and "knowledge management" may be used interchangeably in this study. Furthermore, although differentiating between explicit, tacit, and implicit knowledge is important in KM, this study focuses on tools for general knowledge acquisition and communication.

The rapid evolution and emergence of digital tools like Learning Management Systems (LMS), social media, and Generative Artificial Intelligence (GAI) have revolutionized productivity in KM in education (Aljawarneh, 2020; Dhamdhere, 2015; Eloundou et al., 2023; Hamid, 2020; Kurtz et al., 2024; Ouyang et al., 2022; Ritala et al., 2023; Shawar & Al-Sadi, 2010; Thorne, 2024). The impact of these digital tools, especially GAI, on higher education and knowledge acquisition is significant and inevitable (Aljawarneh, 2020; Bahrini et al., 2023; Eloundou et al., 2023; Ritala et al., 2023). While GAI tools promise increased accuracy, efficiency, and productivity, their potential for misinformation and hallucinations underscores the need for cautious use, as Large Language Models (LLMs) struggle with comprehensive problem-solving and input uncertainty, may lead to inaccuracies (Thorne, 2024). The unclear mechanisms behind AI-generated responses affect the validation and reliability of answers, raising concerns about trustworthiness and biases (Bahrini et al., 2023).

The literature (e.g., Brewer & Brewer, 2010; De Bem Machado, 2022) covers the importance of KM, the challenges organizations face, and the key activities necessary for effective knowledge acquisition and communication. Despite growing interest in KM within higher education (HE) and its critical role in organizations and academia (Quarchioni et al., 2022; Brewer & Brewer, 2010), research on integrating new digital tools into KM in HE remains limited. There is a noticeable gap in studies addressing the structured use of digital tools in

HE, and it is unclear if universities have recognized or addressed the sources of students' acquired knowledge. Additionally, it is uncertain whether educational programs adequately facilitate access to reliable resources or teach essential soft skills such as critical thinking and problem-solving (Aghaee & Karunaratne, 2023). Therefore, higher education institutions must ensure that they prepare students for emerging job profiles and professional success by providing appropriate educational environments (Williamson, 2021).

Although many digital tools are available and their uses are extensively analysed, this study considers the tools focused by the respondents. This study examines what digital tools students use to facilitate their knowledge acquirement and communication in courses and what are their needs to make this use more structured and academic. To address the above-mentioned gap to use digital tools in KM in HE, this study seeks to answer the following research questions: *What digital tools and platforms are used for knowledge management in higher education? How can digital tools be used effectively in knowledge acquisition?*

2. Digital Tools in Educational Information Management

Digital tools and platforms are essential for knowledge management (KM) in higher education (HE), helping to compile, store, and disseminate information generated by academic institutions (Hamid, 2020; Dhamdhere, 2015). In the modern educational environment, the use of digital tools for creating, capturing, sharing and leveraging knowledge has become ubiquitous (Di Vaio et al., 2021; Aljawarneh, 2020; Laal, 2011; Brewer & Brewer, 2010). They leverage advancements in computing and Internet usage deliver knowledge and make education accessible (Shawar & Al-Sadi, 2010; Aljawarneh, 2020) as well as facilitate sharing educational materials, such as file and information sharing (Whalen, 2008). Digital and online tools for obtaining information and facilitating communication enable the exchange of knowledge and experiences, and sharing information and documents among students and faculty, thus improving teaching quality and learning outcomes (Hamid, 2020; Aljawarneh, 2020; Di Vaio et al., 2021; Whalen, 2008).

Learning Management System (LMS) (discussed by Shawar & Al-Sadi, 2010; Kung et al., 2012) and social media have been identified as effective tools for facilitating the distribution and management of knowledge in educational settings (Hamid, 2020). The effective utilization of digital tools and social media in KM ensures that valuable knowledge is accessible anytime and anywhere (Hamid, 2020; Dhamdhere, 2015; Thorne, 2024). These digital tools play an important role in KM by providing a centralized knowledge base system for knowledge acquisition, management, sharing, mapping, and collaboration (Dhamdhere, 2015; Di Vaio et al., 2021; Hamid, 2020). Platforms such as LMSs (e.g., Moodle or Canvas) develop a collaborative academic environment and support academic interactions and activities, as students increasingly rely on them for continuous access to academic information about courses (Aljawarneh, 2020; Hamid, 2020; Bahrini et al., 2023; Shawar & Al-Sadi, 2010).

In the era of KM, global impact spans various domains, including education, which has transitioned from traditional face-to-face approaches to online knowledge attainment and management. The structure and efficacy of KM in HE is enhanced by digital tools and ubiquitous learning environments that provide seamless and context-aware learning experiences (Hamid, 2020; Dhamdhere, 2015; Di Vaio et al., 2021). These digital and Web-based platforms and tools like LMSs for information sharing and communication, enhance personalized learning and facilitate the integration of both authentic and digital resources (Aljawarneh, 2020; Shawar & Al-Sadi, 2010; Kung, et al., 2012). However, studies on which digital tools and media are used as part of formal education in courses and how they are perceived to be utilized are still quite limited.

Recent advancements in Natural Language Processing (NLP) have led to the development of Large Language Models (LLMs) and Generative Artificial Intelligence (GAI) such as GPTs (Generative Pre-training Transformer), significantly enhancing KM in different areas such as education by providing extensive relevant information (Hu et al., 2023; Taticchi et al., 2009; Kurtz et al., 2024; Jin et al., 2024). Digital tools like ChatGPT, Midjourney, Copilot, and Gemini promise to revolutionize society and transform education by reshaping learning and teaching practices (Kurtz et al., 2024; Bahrini et al., 2023). While GAI and GPTs may enable students to acquire targeted knowledge, the quality of this information depends on the used methods and tools, which may vary based on students' digital skills (Bahrini et al., 2023; Jin et al., 2024; Thorne, 2024; Mohamed Hashim et al., 2022; Bergdahl et al., 2020; Katz et al., 2022). Integrating unconfirmed tools in HE settings presents challenges such as inaccuracy, bias, overreliance on technology, and unequal access to resources (Taticchi et al., 2009; Kurtz et al., 2024; Thorne, 2024). Therefore, HE institutions must ensure the quality and relevance of the acquired knowledge while addressing these challenges.

Academic library services in HE have recently been enhanced by digital tools for incorporating KM principles and to improve the use of organizational information for effective learning (Mavodza, 2010). KM practices involve capturing, retaining, organizing, disseminating, and reusing knowledge, using digital libraries and scientific databases to access resources for educational purposes. Such resources are referred to as research tools, including Google Scholar, JSTOR, and university library websites, which provide support for academic research. In addition, research tools include reference management tools, like Mendeley, EndNote, RefWorks, and Zotero, as discussed by Butros and Taylor (2010). These tools help students access academic papers, conduct literature reviews, and manage references easier and more effective (Mavodza, 2010).

Productivity tools, such as Google Workspace (Tamayo & Mosquera, 2024) and Microsoft 365 (Mahliyo, 2024), support various educational activities like writing assignments, project management, and resource sharing, while also facilitating document creation, task management, and group collaboration. Their integration into course tasks and projects makes them important for regular academic operations (Tamayo & Mosquera, 2024; Mahliyo, 2024; Zhakota et al., 2024; Aljawarneh, 2020). Despite existing studies on their functionalities, these tools are often used with minimal teacher oversight, and university authorities are typically unaware of the usage for such tools. Students often do not officially learn to use these tools as a structured academic context (Zhakota et al., 2024).

1. Methodological Approach

To achieve the objective of this study, an exploratory survey approach was utilized, measuring the frequency of using digital tool and including open-ended questions to gain deeper insights into students' perceptions and use of technology. As students' digital skills, understanding, and use of digital tools can vary among Gen Z (Katz et al., 2022), especially across different disciplines (Mohamed Hashim et al., 2022; Bergdahl et al., 2020), the selected case study focused on a digitalization bachelor course at a university in Sweden, covering students from international business, economics, and informatics programs, participating in the course. The case was conveniently chosen, and the data was collected during the course, in spring term of 2024.

A semi-structured survey was used to collect anonymous data, reducing potential respondent bias. The study examined students' general views and use of digital tools in education. To improve transferability, a representative sample was drawn based on Bryman's (2006) guidelines. Open-ended questions aimed to capture students' perspectives in their own words (Creswell, 1999), investigated students' experiences with digital tools, including benefits, challenges, and suggestions for better use of digital tools in HE. The study received a total of 72 responses (n = 72 out of N = 91), achieving an 80% response rate for most closed-ended questions. Response rates for open-ended questions however ranged from 54% to 76%, and the final two questions were excluded due to insufficient responses.

The questionnaire covered three main segments of 1) digital tools used for information gathering and knowledge acquisition, 2) digital tools for communication and information/document sharing, and 3) suggestions for facilitating effective use of tools. The structured questions assessed the frequency of using digital tools or platforms (in different categories) on a Likert scale with five levels: from 'less than once a week' (level 1) to 'several times a day' (level 5). Students were asked to honestly answer to the questions and a consent form was presented before students participate in the survey. The respondents were given the option to terminate participation or skip any questions, if they did not wish to answer or continue. In this course, the library services and even some lectures were provided by the experts to show students how to use the academic research tools and even included the reference criticism aspects and introduced the reference management systems. The questionnaire did not gather any sensitive or personal data.

Both closed- and open-ended responses were analyzed qualitatively. Digital tools categories were developed based on the available literature and the intended use of them in coursework, knowledge acquisition, and group work and communications. The themes and sub-themes from the open-ended responses, summarized in Table 1, were developed to complement the developed categories.

2. Results and Discussion

Digital tools were categorized into five different categories to cover the information acquisition, communicating information and sharing files. The categories reflect students' insights into the tools students use for academic pursuits, knowledge acquisition, communication, and information sharing.

2.1 Categories of Digital Tools Used for KM in HE

Based on the result of this study, the first identified category is Learning Management System (LMS), a Moodle-based platform, specifically Canvas that is commonly used in Swedish universities in modern education to support KM and academic communication. This digital tool facilitates knowledge sharing and communication among different students and faculty staff (as also discussed by Shawar & Al-Sadi, 2010; Kung, et al., 2012). LMS adoption has surged in most Swedish higher education institutions. As discussed by earlier studies (Shawar and Al-Sadi, 2010; Kung, et al., 2012), the result shows that students use LMS platforms primarily to access course materials, submit assignments, and participate in discussion forums. However, this platform is not rated as an often used for communications in the courses. The daily use of LMS reflects the essential role of such platform in managing coursework and staying updated with academic requirements and gaining knowledge about the course and from the available materials. It also provides students to share their knowledge through forums or ask questions or add reflections. LMS platform: average scale of daily use due to their integral role in coursework.

The second category is social media and communication tools, which have become indispensable, especially for virtual learning and knowledge acquisition and sharing (as also discussed by Hamid, 2020). The result shows that these platforms enable students to join group meetings and interact with instructors during the online sessions. The indicated frequent use of social media including Zoom, Microsoft Teams, Messenger, Google Meet, highlights the importance of such tools as a complement to the physical meetings, in maintaining knowledge management and communication. While these tools are primarily used for interactions, students seem to use these tools often for sharing knowledge and resources, following educational content, and learning in their formal learning through discussion forums such as Discord and WhatsApp. The common use of such social media and communication tools for educational purposes indicates their important role in the academic toolkit and knowledge management. Communication through social media and different tools varied much with a result from several times a day to less consistently used for educational purposes. This is in confirmation of previous studies claiming the use of digital tools may vary based on students' digital skills, understanding, generation, and disciplines (Katz et al., 2022; Mohamed Hashim et al., 2022; Bergdahl et al., 2020).

The third category is Generative AI-based tools, which are increasingly being adopted by students in HE (Bahrini et al., 2023; Jin et al., 2024; Thorne, 2024). Based on the results of this study, this category of tools has quite high frequency use for various academic purposes. The result shows that AI-based tools or GAIs such as ChatGPT and Gemini, assist students for instance in generating ideas, drafting essays, and providing explanations for complex topics. The use of ChatGPT and similar AI tools shows the growing importance of AI in supporting students' learning processes both in the closed- and open-ended questions in this study and the frequency of mentioning GAI tools in the survey was noteworthy (in line with the studies such as Bahrini et al., 2023; Jin et al., 2024; Thorne, 2024). The result shows that GAI Tools are regularly used (toward a daily use), as some respondents mentioned especially during writing-intensive tasks.

The final two categories in this study address productivity tools and research tools. Results indicate that productivity tools, such as Google Workspace (Tamayo & Mosquera, 2024) and Microsoft 365 (Mahliyo, 2024), are frequently used for document creation, task management, and group collaboration, with usage varying according to project needs and deadlines. In contrast, research tools like Google Scholar, scientific databases and university library websites (Mavodza, 2010) are used periodically for academic research, assisting in research, accessing academic papers, and managing references with tools such as Mendeley (Butros & Taylor, 2010). As confirmed by earlier studies (Mavodza, 2010; Butros & Taylor, 2010; Tamayo & Mosquera, 2024; Mahliyo, 2024; Zhakota et al., 2024; Aljawarneh, 2020), the result also confirms the importance and use of both productivity and research tools for tasks like writing research reports and accessing course materials and scientific references. However, while productivity tools are used daily (quite frequently), research tools are indicated by lower frequency use in Figure 1, compared to all other categories of tools.

Figure 1 shows the frequency of use for each category mentioned above. The name of the categories in the survey, as shown in Figure 1, were simplified to enhance student understanding and were later modified based on data analysis and the results of open-ended questions. Category 1, "Learning Management System (LMS)," was "Online learning platform (e.g., Canvas)." Category 2, "Social media and communication tools," was "Scientific search platforms like Google Scholar and library websites." Category 3, "Generative AI-based tools," was "GPT or any AI-based system to obtain information and clarifications (such as ChatGPT, MS-Copilot)." Category 4, "Productivity tools," was "Online platforms for sharing files (e.g., Google Docs)." Category 5, "Research tools," was "Online forum for peer discussion/chat (Discord, WhatsApp)". Figure 2 displays the most frequently mentioned digital tools as a word cloud, based on 156 words provided by respondents. Although the

word cloud is frequency-based, the focus is not on quantitative analysis; instead, the text size indicates the prominence of specific digital tools.

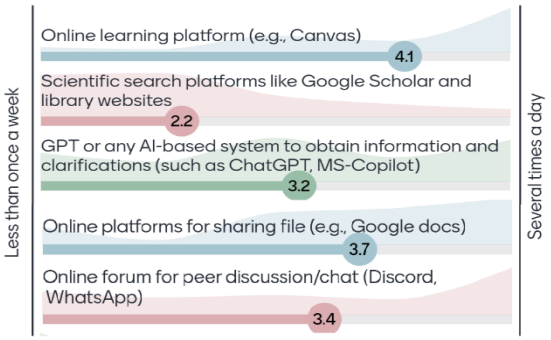

Figure 1: Frequency of the use of digital tools

Figure 2: The most frequently used digital tools

2.2 Themes and sub-themes Presenting the Purpose of Using Digital Tools

Based on the thematic analysis of qualitative data obtained from open-ended questions, the following primary themes, each with associated sub-themes, were developed. A summary of these themes and sub-themes is presented in Table 1. However, these themes and sub-themes are not mutually exclusive and may have some degree of overlap. This thematic framework provides a structured summary of students' perceptions regarding the benefits and challenges of digital tools and summarizes students' suggestions for enhancing the effective utilization of digital tools in higher education.

Table 1: Themes and subthemes to present the purpose of using digital tools

Theme	Sub-theme	Study result and respondents' reflections	Relevant literatures
Benefits of digital tools in KM in HE	Course Management	Accessing Canvas LMS for managing course information: essentially used for tracking course materials, submitting assignments, and checking grades. This tool helps students stay organized and meet academic deadlines.	Williamson, 2021; Shawar & Al-Sadi, 2010; Laal, 2011; Kung, et al., 2012
	Accessing Academic information	Research tools like Google Scholar and library databases provide access to trusted and reliable scholarly source of information and academic contents; crucial for academic learning, conducting research and gathering information for the assignments.	Quarchioni, et al., 2022; Mohamed Hashim et al., 2022; Brewer & Brewer, 2010; Mavodza,2010
	Resource use and information management	Access sources of information anywhere/anytime, both academic resources and AI-based generated information. Use of reference management and online documents enable students to share information and resources (such as reference management tools); essential for maintaining academic flexibility, integrity, and collaboration producing good quality work.	Hamid, 2020; Whalen, et al., 2008; Metaxiotis & Psarras, 2003; Dhamdhere, 2015; Thorne, 2024; Laal, 2011
	Virtual learning and real-time interactions	Social media such as Discord and even messenger facilitate live online discussion, collaboration, and getting clarifications. Other platforms such as Zoom and Microsoft Teams provides supports for real-time meetings and discussions among group members, which enhance collaborative learning and even online supervisions and getting guidelines.	Di Vaio et al., 2021; De Bem Machado, 2022; Aljawarneh, 2020; Tamayo & Mosquera, 2024; Mahliyo, 2024; Zhakota, et al., 2024;
	Project coordination	Managing group tasks and collaborating on common documents and streamlining project coordination. Tools like Google Workspace are part of the project coordination and knowledge management and sharing in group assignments.	Whalen, et al., 2008; Metaxiotis & Psarras, 2003; Dhamdhere, 2015; Butros and Taylor, 2010

Theme	Sub-theme	Study result and respondents' reflections	Relevant literatures
	AI-based information resources	Generative AI tools like ChatGPT and Gemini assist in knowledge acquisition, getting quick reply, access to responses and knowledge developed by GAI anywhere/anytime. GAI tools support brainstorming and drafting, which may increase efficiency and productivity.	Taticchi, et al., 2009; Ritala et al., 2023; Kurtz et al., 2024; Jin, et al., 2024; Hu et al., 2023
Challenges of digital tools in KM in HE	Negatively influence on students' soft skills	Influencing negatively on students' soft skills such as problem-solving and innovative thinking due to overreliance. Enabling a seamless transition to use GAI as a virtual learning environment more than using the assigned academic or scientific resources.	Kurtz et al., 2024; Eloundou et al., 2023; Bahrini et al., 2023
	Reliability of resources and unproved resources for knowledge acquisition	Digital tools which are not certified by academia or teachers may mislead students due to potential inaccuracies and the lack of reliable sources and references to the answers they provide. Assistance with complex problem-solving and the explanation of questions can negatively impact students' development of soft skills, particularly those related to knowledge management skills.	Thorne, 2024; Jin, et al., 2024; Bahrini et al., 2023; Kurtz et al., 2024; Taticchi, et al., 2009; Aghaee & Karunaratne, 2023
	Technical Issues	Students reported problems with internet connectivity and software glitches, hindering their ability to utilize digital tools fully, which is also connected to varies digital skills.	Katz et al., 2022; Laal, 2011; Zins, 2007.
	Learning Curve	Adapting to new tools and platforms without academic and clear instructions would pose difficulties for some students and create barriers to efficient usage and productivity.	Bergdahl et al., 2020; Katz et al., 2022
Suggestions for Improvement	Guidelines for Reliable Resources	Providing guidelines to use existing tools and reliable resources can lead students to formal learning channels and prevent reliance on unproven knowledge.	Hu et al., 2023; Zhakota et al., 2024
	Better Training	More training and tutorials, such as workshops or additional lectures about the use of tools to help students utilize digital tools effectively; enhancing ability to navigate and critically learn from using such tools and maximize these technologies' potential.	Aljawarneh, 2020; Bergdahl et al., 2020: Zhakota et al., 2024
	Integration of Tools	Better integration between digital tools in different categories of tools and academic courses to streamline the learning process, reduce the complexity of managing multiple tools, and improve efficiency. Integrate using tools such as ChatGPT as an educational help and explain the benefits and risks, to make students understand how to use them pedagogically in courses.	Hu et al., 2023; Bahrini et al., 2023

2.3 Benefits and Challenges of Using Digital Tools

Building on prior research (Hamid, 2020; Bahrini et al., 2023; Jin et al., 2024; Thorne, 2024; Tamayo & Mosquera, 2024; Mahliyo, 2024; Zhakota et al., 2024; Aljawarneh, 2020), the result of this study emphasizes the critical role of digital tools in knowledge acquisition and communication in higher education. As previous studies reflect on the positive impact of digital tools on education (Mohamed Hashim et al., 2022; Bergdahl et al., 2020; Williamson, 2021; Quarchioni et al., 2022), this study confirms that most students frequently use technology and digital tools, even for on-campus courses. This extensive use of digital tools underscores the importance of their integration into educational activities and the need of clarifying their role for an effective learning environment.

The results indicate that digital tools like Canvas LMS are primarily used for effective course administration and knowledge management, confirming prior research (by Williamson, 2021; Shawar & Al-Sadi, 2010; Laal, 2011; Kung et al., 2012). Canvas enhances student organization and adherence to course deadlines and tasks by facilitating access to academic resources, managing course materials, facilitating assignment submissions, and enabling grade tracking. This underscores the importance of linking LMSs to other digital productivity and research tools, such as Google Scholar and library databases, to instruct students on how to access and use scholarly resources for academic knowledge.

In line with earlier studies (Di Vaio et al., 2021; Whalen et al., 2008; Metaxiotis & Psarras, 2003; Dhamdhere, 2015; De Bem Machado, 2022; Aljawarneh, 2020), this study highlights the role of social media and communication tools in virtual learning environments and project coordination. Platforms like Zoom, Microsoft

Teams, Google Meet, and messaging apps like Discord, WhatsApp, and Messenger facilitate live discussions, collaborations, and interactions among students and instructors. Tools like Google Workspace streamline group tasks and project management, promoting knowledge sharing within group assignments and adhering real-time communication and collaborative learning

As in previous studies (e.g., Ritala et al., 2023; Kurtz et al., 2024; Jin et al., 2024; Hu et al., 2023; Zins, 2007), the results of this study indicate that GAI tools facilitate rapid information acquisition, by providing quick responses and easy information access. Tools such as ChatGPT and Gemini were frequently used by respondents, despite their relatively recent emergence. Respondents reported using these tools for brainstorming and report drafting, potentially enhancing their productivity (also noted by Taticchi et al., 2009; Ritala et al., 2023; Kurtz et al., 2024). However, the uncertainties and risks associated with the use of GAI-based tools, including the potential to diminish students' soft skills such as critical thinking and independent problem-solving, which are already underemphasized in higher education (discussed also by Aghaee & Karunaratne, 2023).

2.4 Research Contributions

The study results reveal an overreliance on social media and GAI tools, with a higher frequency of use compared to research tools (Figure 1: 3.2 vs. 2.2). Figure 2 highlights ChatGPT, Google Docs, and Google as the most frequently mentioned tools, comparable to the official LMS platform (Canvas), while fewer students mention the use of scientific resources like Google Scholar and library databases, which are crucial for higher education (as indicated by Mavodza, 2010; Butros & Taylor, 2010; Tamayo & Mosquera, 2024; Zhakota et al., 2024). This underscores a cautionary note as social media and GAI tools, which may lack academic certification and reliable references, are more frequently used for formal learning and educators need to provide guidelines on using these tools pedagogically.

Consistent with other research (Kurtz et al., 2024; Taticchi et al., 2009; Thorne, 2024; Jin et al., 2024; Bahrini et al., 2023), the integration of GAI tools must be carefully considered to avoid negative impacts on skill development and ensure information credibility. The lack of systematic integration into academic workflows is a concern. As summarized in Table 1, while GAI tools assist with complex problem-solving and question explanations, their use may hinder the development of crucial knowledge management skills (as indicated by Kurtz et al., 2024; Eloundou et al., 2023; Bahrini et al., 2023), affecting students' ability to independently manage and evaluate information.

The study's findings emphasize the need for instructional academic sessions to teach students the how to use digital tools effectively and academically. Katz et al. (2022) noted the variation of digital proficiency within Gen Z, and respondents in this study highlighted the role of digital skills in today's educational landscape. Therefore, integrating education and training on digital tools into academic curricula can streamline learning processes, simplify tool management, enhance efficiency, and bridge the gap in digital proficiency.

3. Concluding Remarks

This study has explored the landscape of digital tools for knowledge management (KM), shedding light on the use of various tools and applications in higher education (HE). To answer the first research question, the findings highlighted the important role of digital tools often used daily by students in five main categories: Learning Management Systems (LMS), social media and communication tools, generative AI-based tools, productivity tools, and research tools. These tools facilitate knowledge acquisition and sharing, interactions among students and faculty, enhancing accessibility to educational resources and developing the collaborative learning while exceeds physical boundaries.

In addition, to answer to the second research question, the study reveals the benefits and challenges associated with the integration of digital tools. The challenges include issues of knowledge reliability, overreliance on technology, and the need for comprehensive training to optimize the digital tools' pedagogical impacts. There is a clear imperative for HE institutions to strategically integrate digital tools into their curricula while addressing these challenges. This integration should be accompanied by training programs, workshops and educational sessions, to empower students to use these tools pedagogically for academic purposes.

Moreover, educators must ensure that digital tools supplement, rather than replace, traditional methods of knowledge acquisition, thereby facilitating the development of soft skills such as critical thinking and independent problem-solving as well as motivating students to use reliable scientific and peer reviewed references which are more evidence-based. By doing so, KM in HE can employ the full potential of digital tools

to prepare students for the complexities of modern workplaces and cultivate lifelong learners capable of navigating the evolving landscape of knowledge management.

This study contributes to the ongoing discourse on digital transformation in education, highlighting both the opportunities and responsibilities associated with leveraging digital tools for educational purposes. As educational settings continue to evolve, adopting digital tools in a purposeful and balanced manner will be essential for enhancing learning outcomes and preparing students for success in a knowledge-driven society. Further studies would be valuable to explore student's experiences and perception of using digital tools in-depth.

Knowledge Exchange in the Context of Remote Work: Generation Z Perspective

Anna Albrychiewicz-Słocińska
Department of Applied Sociology and Human Resource Management, Faculty of Management, Częstochowa University of Technology, Poland

a.albrychiewicz-slocinska@pcz.pl

Abstract: The key element of knowledge management is that all knowledge, both explicit and tacit, accumulated by an organization becomes easily accessible to each of its members. This is important for decision-making processes and allows the organization to become more agile. In the literature there is an increasingly common attitude that more attention should be paid not only to the technological but also to the human aspect of knowledge management. The processes of knowledge exchange among employees have been subject to extensive research and studies, yet the recent years have added another thread to the discussion about the matter, i.e. a significant proportion of employees switching to the online work model. The aim of this article is to demonstrate how issues of knowledge exchange and learning influence preferences in choosing the form of work in the future. Based on the findings of the studies conducted on a group of employees representing Generation Z, the Principal Component Analysis (PCA) technique and was applied to organize the factors with the highest relevance for the respondents in online work. Cluster analysis was used for segmentation purposes. PCA demonstrated that the components recognized as most important were those relating to knowledge transfer and their impact on employee efficiency, and on the other hand employee relations as a factor that supports the learning processes. Cluster analysis proved that learning and knowledge exchange opinions have an impact on the form of work preferences.

Keywords: Learning, Knowledge Exchange, Remote Work, Generation Z

1. Introduction

The knowledge resources of the organization and its members constitute the heart of the organization's functioning. However, this potential can be used and used up to build a competitive advantage only when it is diagnosed, located, developed and multiplied through permanent exchange. Knowledge is currently treated as a type of enterprise resources and therefore an element that is subject to management rules to the same extent as other organizational resources. The characteristic features of knowledge according to G. Probst, S. Raub, K. Romhardt (2004, p.26) are that it is: ordered, complex, context-dependent, dependent on the person using it and is reflected in behavior models. However, this division does not take into account the remaining basic universal principles of knowledge, namely:

- knowledge is born and located in the minds of people;
- sharing knowledge is based on trust;
- new technologies create new knowledge exchange behaviors;
- knowledge sharing must be supported and rewarded by the organization;
- knowledge exchange initiatives must be implemented in a planned manner, with quantitative and qualitative evaluation metrics defined;
- knowledge and innovation are the result of creativity, which should be encouraged and developed in many unusual and unconventional ways.

There are two basic knowledge management strategies: a strategy based on codification and personalization. The first one assumes the use of computer techniques as a basic tool for acquiring, processing and storing knowledge. This approach is characterized by a high level of centralization of knowledge management. The second type of knowledge management strategy is based on the assumption that knowledge is closely related to the person who possesses, processes and shares it. The main goal of this strategy is to create an appropriate organizational climate that favors direct contacts between organization members.

The aim of this article is to demonstrate how issues of knowledge exchange and learning influence preferences in choosing the form of work in the future.

2. Theoretical Foundations of the Issue

According to the concept of I. Nonaka, R. Toyoma (2007), people do not acquire knowledge passively; they interpret it and adapt it to their own situation and perspective. Referring to the personalization strategy in the field of knowledge transfers (which will be the research assumption of this study), we focus on individual

employees, their characteristics and mutual relations that favor or limit knowledge flows (social capital, human capital, intellectual capital) and on intra-organizational factors (tangible and intangible) that support these processes (i.e. IT systems, physical work environment, human resources management, project management, etc.).

The basic division of knowledge that can be found in the literature on the subject (Akhmadi & Tsakalerou, 2022; Bloodgood & Chen, 2021; González-Ramos et al., 2023) is the division into explicit and hidden, as well as declarative and procedural knowledge. Declarative knowledge, most often in an explicit form, is knowledge of the "I know what" type, while knowledge of a procedural and tacit nature is knowledge of the "I know how" type. Explicit and declarative knowledge, due to its verbalized nature, has existed in organizations for a long time and is subject to management processes. Tacit and procedural knowledge and methods of its transformation towards explicit and declarative knowledge are currently attracting greater attention of researchers.

Therefore, one of the key elements of knowledge exchange is the transformation of unnamed knowledge (which is "owned" by each employee) into named knowledge. This is a necessary process so that tacit knowledge can be passed on. It is in the process of transforming tacit knowledge into accessible and back into tacit knowledge that organizational knowledge is created. In this approach (identified with the Japanese approach (Nonaka & Takeuchi, 1995)), we treat the organization as a living organism - knowledge "must be felt", it must be experienced, it cannot be acquired only through education and training. Western companies believe that the organization is a machine serving only for processing information and knowledge and not for generating knowledge. The result of this approach is the assumption that only available knowledge is important, which is communicable, ordered and formalized in the form of hard data, scientific formulas and universal principles. According to the Japanese approach, knowledge should be treated differently. It is believed that knowledge expressed in numbers and words is just the tip of the iceberg. The most important is hidden knowledge, difficult to notice and verbalize. This is individual knowledge, difficult to formalize, based on the subjective participation of intuition and premonitions. It results from individual action and experience and is deeply hidden in individual ideals, values and emotions. Tacit knowledge can be understood in two dimensions (Hau et al., 2013):

- technical - know-how (often people who have it cannot express it based on scientific and technical principles) and
- cognitive – composed of patterns, mental models, beliefs and perceptions that are so deeply rooted that they are taken for granted.

Taking into account the above, knowledge exchange in the context of remote work can be understood in two ways. Adopting a codification approach, this form of work does not pose major obstacles to locating, storing or even creating knowledge, information processes and learning. However, if we analyze the problems of knowledge exchange from the perspective of the personalization approach (and this is the approach shared by the author of the study), remote work creates numerous obstacles to the exchange of knowledge between employees, their development and, consequently, effective work.

These regularities are confirmed in the publications of Kucharczyk (2023) based on "The Economist". Many publications, especially those created during the pandemic and earlier, raised the advantages of remote work, basing their conclusions on the publication by Emanuel & Harrington (2020), which emphasized the increase in productivity and efficiency among employees working remotely compared to stationary employees. These opinions expanded their circles of popularity even in the face of the fact that the same authors, in their subsequent publications based on more accurate and detailed data (Emanuel & Harrington, 2023b, 2023a), revised their views, pointing to opposite conclusions, which was also confirmed by research (Atkin et al., 2023;Gibbs et al., 2022). The cited research results emphasize, among other things, that remote communication is not conducive to solving everyday matters at work, and teleconferences are only an imitation of office meetings (Szombathelyi et al., 2023). In remote work, the coordination of many processes takes longer, becomes more complicated, formalized and therefore less effective. Remote work causes stagnation in development, both professional and social (Yarbrough & Ramos Salazar, 2023). According to Emanuel et al., (2024), people working on-site acquire the skills needed to effectively perform their duties more quickly.

The discussed issues gain additional value if employees representing the youngest generation of employees are taken as a reference point. For representatives of this generation, communication tools used in remote work dominate over the form of direct communication (Zeer et al., 2021). Through them, young employees build relationships, learn, acquire knowledge and share it. It should be noted, however, that for representatives of Generation Z, knowledge is sometimes identified with the category of information (Szymkowiak et al., 2021). Interestingly, for this generation, knowledge is not a competitive good (Albrychiewicz-Słocińska, 2022;

Bloodgood & Chen, 2021). However, the research results draw attention to the fact that in relation to Generation Z, there may be problems related to the exchange of knowledge understood as learning and teaching others (Sekala et al., 2023), which may result from different generational characteristics, including the values they profess, attitude towards work and expectations towards it, and adaptability to the work environment (Maloni et al., 2019; Cresnar and Nedelko, 2020; Chillakuri, 2020; Barhate and Dirani, 2021; Snieska et al., 2020). Noteworthy are the lack of competences in naming and expressing knowledge, which is tacit knowledge and often not realized by the employee himself, i.e. deficiencies in social and communication skills (Hegade & Shettar, 2022; Steyn et al., 2020). The above-mentioned competence deficiencies undoubtedly disturb their efforts to acquire professional experience early, engage in various types of activities, including volunteering, and believe in the need to build social capital, i.e. a network of contacts (Sidor-Rządkowska, 2023, p. 31).

3. Methodology

The research results presented in the study are part of a quantitative survey on "Managerial aspects of remote work management", carried out among young people working remotely, representing Generation Z. The most popular division in the literature assumes that Generation Z includes people born after 1995, although some researchers sometimes include among its representatives those born in 1990, and in others only those who were born in 2000 and later (Dreyer & Stojanová, 2022; Skýpalová et al., 2023; Urick et al., 2017) .

Due to the fact that there is no statistical data on the number of people representing Generation Z, the size of the population of people working in Poland in the age range of interest to researchers (15-34 years of age) was established at 4,802,000 people (GUS, 2022). For the population estimated in this way, with the following statistical assumptions: fraction size: 0.5; confidence level: 95%; maximum error: 5%, the size of the research sample was set at 384 people.

The study was carried out using quantitative research methods, using the CATI (Computer Assisted Telephone Interview - 50% of respondents) and CAWI (Computer Assisted Web Interview - 50% of respondents) techniques in December 2022. The study covered young people from Generation Z whose experience of remote work lasted at least year 2022.

The research tool used is a standardized questionnaire consisting of 57 closed statements and 8 questions regarding the socio-demographic characteristics of the respondents. A Likert scale was used for the responses (Kaczmarek, 2013), which allows determining the relative intensity of different responses (Babbie, 2004, p.192). The research tool (questionnaire) is original and was prepared by members of the research team - employees of the Department of Applied Sociology and Human Resources Management, Faculty of Management, Częstochowa University of Technology.

In the process of developing the research results, the principal component analysis (PCA) method was used, which is one of the most popular statistical techniques used as part of factor analysis, used in the area of analyzing respondents' behavior and attitudes (Pupelis & Šeinauskienė, 2023). The analytical procedure in the principal components method is described in the literature on the subject, especially in the field of psychological and social research methodology (Capecchi et al., 2023; Lloyd et al., 2023; Okóń, 1968). The use of principal components analysis requires variables measured on an interval scale, but it can also be used for measurements carried out on five- and seven-point ordinal scales (Sagan 2004, p. 89).

Cluster analysis was used for segmentation purposes. The cluster analysis method, also called feature and object segmentation, is an example of an analysis consisting in searching for and extracting clusters from data, i.e. groups of similar objects. Correctly performed cluster analysis allows for dividing the data set into groups in order to better understand the information contained therein and to determine the properties of groups of similar objects and their synthetic characteristics. (Korzeniewski, 2012, p. 5). However, the idea of cluster analysis (Zakrzewska, 1994, p. 21) is to divide a set of objects or variables into classes without a pre-existing external criterion. Both statistical methods were implemented using the STATISTICA program.

4. Research Results

According to the principal components analysis algorithm presented earlier, 57 variables were analyzed. The scale used in the responses was as follows: 1 - I completely disagree, and 5 - I completely agree. Four questionnaire validity procedures have been used: content (Rossiter 2008), face (Czakon 2014), construct (Cronbach and Meehl 1955) and nomological (Czakon 2014) ones. The scale reliability was validated using Cronbach's alpha that is a measure of internal consistency (α = .970019). The correlation analysis was preceded

by an assessment of the values of the obtained descriptive statistics, in particular the standard deviation. In both conducted measurements, standard deviation values other than zero were obtained for all variables. Based on the correlation analysis, two low-correlated items were eliminated from the set of 57 statements: "remote work leads to a feeling of isolation" and "remote work places emphasis on written communication (e-mails, text messages, etc.)". There were few statistically significant correlations for these variables. The obtained values of the KMO index = 0.968 (Kaiser-Meyer-Olkin) and the Barlett's Test of Sphericity (result close to zero) for 55 variables allowed a positive decision to be made regarding the possibility of using principal components analysis to explain the structure of the correlation matrix.

After performing the scree test and using the Kaiser's eigenvalue criterion, 7 factors (components) were isolated, which explain a total of 72.23% of the variance (Table 1).

The analysis of the main components allows us to conclude that the opinions on remote work expressed by Generation Z employees, in relation to the conducted study, can be reduced to seven dimensions, the first two of which: (1) "knowledge, information and efficiency" and (2) "relationships and learning" refer to the issue of knowledge exchange in the context of efficiency and the social work environment. The first factor explains as much as 45.54% of the variance and the next factor 11.71% of the variance. The substantive construction of factors in terms of scale test items took into account both variable contributions, based on correlations, and common variable resources, based on correlations.

The remaining isolated factors, which do not provide such important information, are: (3) formal/task communication, (4) work-life in the context of time commitment, (5) work comfort and feedback communication, (6) stress-producing/disruptive elements and (7) professional development and work-life elements.

Table 1: Eigenvalues

Factor No	**Eigenvalues (correlations), related statistics**			
	Eigenvalues	% of total Variance.	Cumulative Eigenvalues	Cumulative %
1	25,05095	**45,54719**	25,05095	45,5472
2	6,44129	**11,71143**	31,49224	57,2586
3	2,63789	4,79617	34,13013	62,0548
4	1,74604	3,17462	35,87617	65,2294

…	…	…	…	…
55	0,07432	0,13513	55	100

Source: own work

Chart 1 shows factor loadings, i.e. correlations between primary variables and principal components. The correlation coefficients have values in the range [-1;1] and are distributed within the so-called unit circle, also called correlation circle (Stanisz, 2007, p.192-193). The further a given point is from the center of the circle, the higher the correlation of a given variable with a given principal component. As can be seen from the presented graph, most of the variables are negatively correlated with the first component, in the case of the second component, some of the variables are positively correlated, some negatively. The angles between the vectors representing the studied variables indicate that these variables are correlated, acute angles (vectors located close to each other) indicate a positive correlation, a right angle (perpendicular vectors) indicates a lack of correlation, and obtuse angles (vectors on opposite sides of the center of the correlation circle) indicate a negative correlation. Analysis of the correlation circle reveals high correlation of variables.

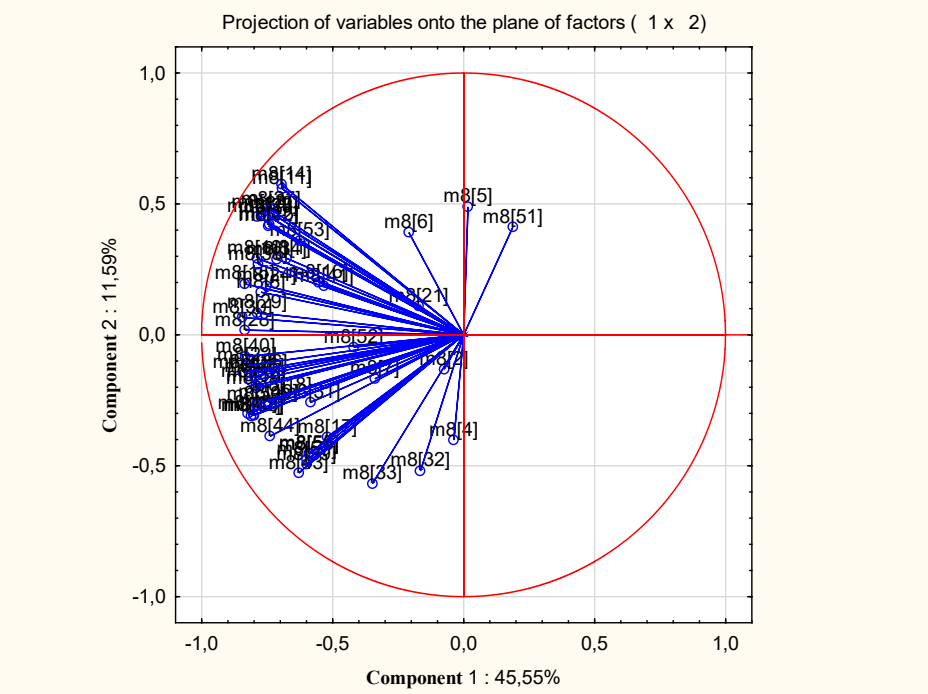

Figure 1: Correlation circle for components 1 and 2.

Source: own work

In the next step of the statistical analysis, representative variables were selected for individual components based on the highest values of factor loadings, i.e. the variables that had the greatest impact on individual components were selected. In relation to these variables, the cluster analysis method was used to diagnose how the respondents' attitude to individual dimensions of remote work influenced their preferences in choosing the form of work in the future. The cluster analysis carried out using the Ward method using percentage inconsistency as a distance measure led to the identification of three clusters of respondents with the characteristics presented in Table 2.

Table 2: Respondents profile.

Claster	Form of Work* %	Components** %						
		1	2	3	4	5	6	7
1	34,4 H 25,8 R 39,8 S	98,9 (4)+(5)	74,2 (4)+(5)	89,3 (4)+(5)	63,4 (4)+(5)	89,2 (4)+(5)	67,7 (4)+(5)	84,9 (4)+(5)
2	63,2 S 22,1 H	27,9 (3) 50,0 (1)+(2)	83,1 (1)+(2)	87,5 (5)	43,4 (1)+(2)	70,6 (4)+(5)	72,8 (1)+(2)	44,9 (4)+(5) 36,8 (1)+(2)
3	55,1 S 29,7 H	58,9 (3)	48,0 (3)	26,0 (3) 63,9 (4)+(5)	47,5 (3)	28,5 (3) 42,4 (4) 26,6 (2)	44,3 (3)	49,4 (3)

*H- hybrid, R-remote, S- stationary

** Scale: I fully disagree (1), I rather disagree (2), Neither (3), I rather agree (4), I fully agree (5)

Source: own work

Group 1 - in this group, as the only one, almost 26% of respondents reveal that the preferred form of work in the future is remote work, although the remaining respondents distributed their declarations in similar proportions in relation to hybrid and stationary work. Interestingly, this group is the only one with such a high percentage expressing positive opinions on the issue of access to knowledge and information, shaping employee relations and learning, similarly to the other components.

Group 2 - in this group, the vast majority of respondents declare their willingness to provide work in the future in a stationary form, and 22% - in a hybrid form. Respondents from this group mostly represent a negative

attitude towards the opportunities offered by remote work in terms of the flow of knowledge and information and their impact on efficiency and the possibility of shaping employee relations and learning.

Group 3 - this is a group that, similarly to group 2, declares to undertake full-time and hybrid work in the future, with a slightly greater share of the latter. This group is characterized by an ambivalent attitude towards most of the defined dimensions, including components 1 and 2.

5. Discussion

The survey results reveal that among employees with experience of remote work, this type of work is not the most frequently mentioned form of work in the future. This debunks the myth regarding Generation Z employees, for whom the use of modern technologies at work seems natural and obvious, and that they are much better suited to remote work (Albrychiewicz-Słocińska, 2022). It seems that the dominant preferences of young respondents in terms of stationary and hybrid forms of work should be associated with the importance of organizational learning (i.e. exchange of knowledge, information and learning) and employee relations presented in the study.

Table 3: Kendal's tau correlation index

Variable	Kendall's tau correlation p <,001 for components						
	1	2	3	4	5	6	7
Form of work	**-0,201751**	**-0,223657**	0,067872	0,023048	0,011060	**-0,149418**	**-0,136288**

Source: own work

An element that brings additional interpretive value to the results of the conducted analyzes is Kendall's tau correlation coefficient (an indicator recommended for examining the relationships between variables expressed on a Likert scale, the value is between -1 and 1 (Błażejczyk-Majka, 2018)), which shows numerous connections between components, however with a raised p (for p<.001) provides insight into strong relationships only between selected components (Table 3). The areas of knowledge, information and efficiency and relationships and learning have the strongest influence on the preferred form of work in the future. However, the minus sign next to all correlation coefficients draws attention to the direction of the correlation, according to which it should be interpreted that the worse the respondents rated individual dimensions of remote work, the more often they moved towards stationary or hybrid work.

These principal components analysis factors explain 57% of the total variance. This is confirmed by research (Dreyer & Stojanová, 2022; Hegade & Shettar, 2022) which emphasizes the importance of personal contacts and direct communication along with the related skills (Hans et al., 2023).

The importance of organizational knowledge exchange is also confirmed by the results of cluster analysis. It seems that the respondents from the first group, who were the only ones who indicated potential interest in remote work, based their preferences primarily on positive opinions regarding the exchange of knowledge, information and learning. In the remaining groups where these opinions were neutral or negative, remote work did not appear as a preferred form of work in the future. Therefore, organizations should particularly analyze the processes of organizational learning in relation to Generation Z employees, so that they meet the expectations of these employees.

6. Conclusions

The conclusions drawn by the author of the study from the analysis of the research results are positive. The analyzed group of young people with experience in remote work, not forced due to the pandemic, but chosen consciously and voluntarily, appreciates the importance of knowledge and information in the context of increasing their own effectiveness and learning in connection with building personal relationships. Therefore, even representatives of the youngest generation of employees understand how important direct contact with other people and their knowledge is. Such transfer of knowledge allows for a faster learning process, adaptation of knowledge to the requirements of organizational practice and verification of the acquired information without leading to information overload. The presented attitude of young employees towards the issue of knowledge and learning creates a platform for intergenerational knowledge transfer, which should undoubtedly be of interest to both researchers and practitioners, with particular emphasis on HR department employees.

Assessing the Impact of Science and Technology Parks on Firm Profitability: A Comparative Study of On-Cluster and Off-Cluster Dynamics

Mousa Al-kfairy
College of Technological Innovation, Zayed University, Abu Dhabi, UAE

Mousa.al-kfairy@zu.ac.ae

Abstract: Science and Technology Parks (STPs) are pivotal in driving regional development, primarily through fostering innovation and enhancing regional wealth. However, the impact of STPs on regional development remains a contentious topic with inconclusive findings. This study digs into the contribution of STPs to the profitability of firms by conducting a comparative analysis of profitability and salary data between firms located within these parks (on-cluster) and those outside them (off-cluster). The research adopts a two-pronged approach: initially, it examines firm profitability and employee salaries at an aggregate level to understand the overall economic impact of STPs. Following this, it models the various factors that influence firm profitability, offering a nuanced understanding of the dynamics at play. The findings are revealing – being located within an STP (on-cluster) appears to significantly boost a firm's profitability, but only up to a certain size of the cluster. This suggests that the benefits of being in an STP diminish beyond a certain scale. At a more granular, micro level, the study finds that a firm's previous innovation output has a positive impact on its profitability. This underscores the importance of continuous innovation for sustained economic success within these clusters. Conversely, a larger firm size seems to negatively impact profitability within STPs, indicating a potential strategy for growing firms to relocate off-cluster to mitigate this effect. For firms operating outside STPs (off-cluster), the scenario differs. Here, innovation plays a partial role in influencing profitability, and interestingly, the size of the firm does not significantly impact its profitability. This distinction between on- and off-cluster firms highlights the unique economic ecosystems fostered by STPs and their varied effects on firm performance. Overall, this study contributes to the ongoing debate on the role of STPs in regional development, offering new insights into how these entities affect firm profitability and suggesting potential strategies for firms operating within and outside these parks.

Keywords: Science and Technology Parks (STPs); Firm Profitability; Innovation Output; Cluster Dynamics; Knowledge Management

1. Introduction

The foundational Resource-Based View (RBV) of firms stems from an industrial organization approach, positing that businesses operate within a tangible reality. Managers can collect and process information within this reality to make informed decisions and implement strategies (Wernerfelt, 1984). However, when it comes to fundamental innovation and change, the RBV stumbles, struggling to grasp these pivotal concepts. In contrast, the Knowledge-Based View (KBV) centres around a firm's dynamic capability to innovate and adapt, an area ripe with debate and exploration for knowledge management theorists (Grant, 2002).

Industrial clusters, specifically, have undergone a fascinating evolution over the last 40 years. Once primarily spontaneous and grassroots ("bottom-up"), clusters have increasingly become focal points of scholarly and governmental attention for spurring innovation and regional development, particularly since Porter highlighted their competitive advantage. These clusters, such as Science and Technology Parks (STPs), now often materialize through planned ("top-down") initiatives, sometimes fuelled by taxpayer investment, with firms choosing whether to join these hubs or remain independent (Mondal et al., 2024; Mondal et al., 2023; Porter, 2003).

There are generally three acknowledged types of industrial clusters. First, "pure agglomeration industrial districts" are characterized by proximity-based firm networks that facilitate free labour movement and knowledge sharing. Second, the "industrial complex model" is distinguished by supply-demand relationships between co-located firms, aiming to minimize transportation costs but at times risking inflexibility. Finally, "social network clusters" thrive on trust-building through formal or informal networks, fostering cooperative work and potentially reshaping the cluster's organizational structure through shared investments (Gordon and McCann, 2000; Kolehmainen, 2002; McCann et al., 2002).

Historically, clusters aimed to reduce transaction and transportation costs by streamlining the flow of information and knowledge. They also served to minimize the hurdles in knowledge transformation and cost savings, such as infrastructure and specialized labour availability, which in turn fostered an environment conducive to knowledge sharing and cooperation (Barkley and Henry, 1997; Cojocaru and Ionescu, 2016).

At a regional level, clusters are lauded for their potential to enhance wealth by supporting entrepreneurship, attracting multinational corporations, and boosting employment. However, such initiatives also carry risks and potential downsides, such as the possibility of economic "lock-in," space constraints, and the misallocation of financial resources (Barkley and Henry, 1997; Sunley and Martin, 2010; Breschi and Malerba, 2001; Tallman et al., 2004).

Regarding financial returns, the examination of Science and Technology Parks (STPs) across Europe, which employ significant numbers and represent a considerable investment, has been a major focus of scholarly inquiry (EU Commission, 2018). Studies have scrutinized various performance indicators, including employment growth and innovation outputs, to gauge the success and influence of clusters on regional economic vitality (Al-kfairy et al., 2017; Temouri, 2012; Porter, 2003).

This study seeks to illuminate the factors influencing the profitability of on-cluster firms by analysing financial data at both the aggregate and micro-levels. It endeavours to understand the interplay between innovation and profitability within clustered environments. By employing panel data analysis and contrasting on-cluster with off-cluster firms, the study aims to extract nuanced insights into the drivers of firm success within these unique ecosystems.

2. Related Work

Innovation expenditure and output significantly influence firm profitability, and their impact is often moderated by the firm’s location within or outside of industrial clusters such as Science and Technology Parks (STPs). This section explores how these factors interplay to shape financial outcomes for firms, emphasizing the distinctive effects of being situated on-cluster (within STPs) versus off-cluster (outside STPs).

Innovation expenditure, encompassing R&D spending, technology acquisition, and related investments, is a critical determinant of a firm's capability to develop new products and processes, which can lead to a sustainable competitive advantage (ÖZKAN, 2022). However, the immediate impact of such expenditures on profitability can be complex. Initially, high innovation expenditures might not translate into immediate profits due to the time lag between spending and the realization of benefits through commercialization (Schäper et al., 2023). This delay can be attributed to the development cycles required to innovate and subsequently market the innovations effectively. Previous studies have highlighted that while R&D intensity is a strong predictor of future revenue growth and market valuation, its direct impact on short-term profitability is often negative or neutral, as these investments take time to yield returns (Tung and Hoang, 2024).

Innovation output, typically measured by metrics such as patents, licenses, and product launches, directly correlates with enhanced firm performance, especially in technology-oriented sectors. Firms that successfully commercialize their innovations can secure substantial profits and market share. The effect of innovation output on profitability is more pronounced when these outputs are successfully aligned with market needs and are adequately protected through patents or copyrights, which prevent competitors from eroding the innovator’s market position. Empirical studies suggest a positive correlation between patent outputs and firm profitability, emphasizing that firms with higher patent counts tend to exhibit better financial performance, assuming these patents are of high quality and market relevance (Song et al., 2024).

Being located within an STP (on-cluster) can significantly affect a firm's profitability. STPs are designed to foster an environment conducive to innovation and business growth by providing infrastructure, networking opportunities, and access to knowledge and resources. Firms located on-cluster benefit from proximity to other innovative companies and research institutions, which facilitates knowledge spillovers and collaborative opportunities. These interactions can enhance the firms' innovation output and, consequently, their profitability (Aydemir, 2024).

Moreover, firms in STPs often have better access to funding sources, including venture capital and government grants, which can enhance their ability to invest in innovation. However, the benefits of being on-cluster might diminish as the cluster grows and becomes congested, potentially leading to increased competition for the same resources and talent, which might initially decrease profitability for some firms. This dynamic underscore the importance of managing growth within STPs to maintain an environment that continues to support each firm's profitability (Mondal et al., 2023).

In summary, both innovation expenditure and output play crucial roles in determining firm profitability, with these effects significantly influenced by the firm’s location within industrial clusters. The strategic benefits of on-cluster location can provide firms with competitive advantages through enhanced innovation capabilities and

access to collaborative networks and funding. Understanding these dynamics is essential for firms deciding on their location strategy and for policymakers aiming to foster successful innovation ecosystems within STPs.

3. Methodology

Using the dataset obtained from the Swedish database (Ratsit) for industrial code 62X, we collected firms' financial data for 2007-2015. The data includes on- and off-cluster firms for Linkoping Science Park (Mjardevi). Using porter's definition of business clusters, firms were either identified as on-cluster if they are either:

- Located inside the business cluster postcode area.
- Or is part of the STP organisations.
- Otherwise, they are considered off-cluster.

Then, we categorise the data every year and sum up the firms' profit using the following formulas:

$$Profit_y = \sum_{i=1}^{n} Profit_i \text{ , y is the year and } i \text{ is the firm.}$$

Equation 1

After that, the average profit-per-Employee and the average salary-per-employee, as well as the Average Patent and License income per-employee and Average R&D investments per-Employee, was calculated for both on and off-cluster firms in order to make a systematic comparison between on- and off-cluster firms. Then, we run a correlation analysis to understand the factors that influence the overall firm's profitability for both on- and off-cluster firms using SPSS.

Finally, we used Stata to build a fixed and random effect model using panel data analysis for both on- and off-cluster firms. Hausman test was used to choose between the fixed and random effect models (an approach similar to Al-kfairy et al., 2019b).

4. Results

After executing equation 1, we obtained the results in Table 1. Table 1 shows that the firms' total profit for on-cluster are much better than off-cluster at the aggregate level. This proves that, at the aggregate level, firms located on-cluster – financially - perform better than off-cluster firms.

Table 1: On- and Off-cluster Financial Data Summary (Salaries and Profit are measured as KSEK (thousands Swedish Krona)

Year	Number of Emps (Off-cluster)	Total Profit for all Firms (Off-cluster)	Number of Employees (On-Cluster)	Total Profit for all Firms (Off-cluster)
2008	466	91,775	1,203	781,009
2009	552	68,271	1,281	308,624
2010	607	-34,480	1,353	324,679
2011	696	64,703	1,340	207,752
2012	818	56,956	1,468	119,717
2013	863	87,420	1,610	273,235
2014	987	51,830	1,630	-80,207
2015	1,130	69,928	1,470	57,872
2016	1,145	71,075	1,463	-2,362

However, in order to get a better understanding of the obtained results, we calculate the average per-employee, which should give a better understanding of the firms' performance. Figure 1 shows that On-cluster outperforms off-cluster profit up to the year 2012, when the on-cluster profitability started to decline, and off-cluster firms become – on average – more profitable than on-cluster firms. Thus. We compared the growth in the number of employees to findout if the drop in the average profit is related to higher growth rate in the number of employees as shown in Figure 2.

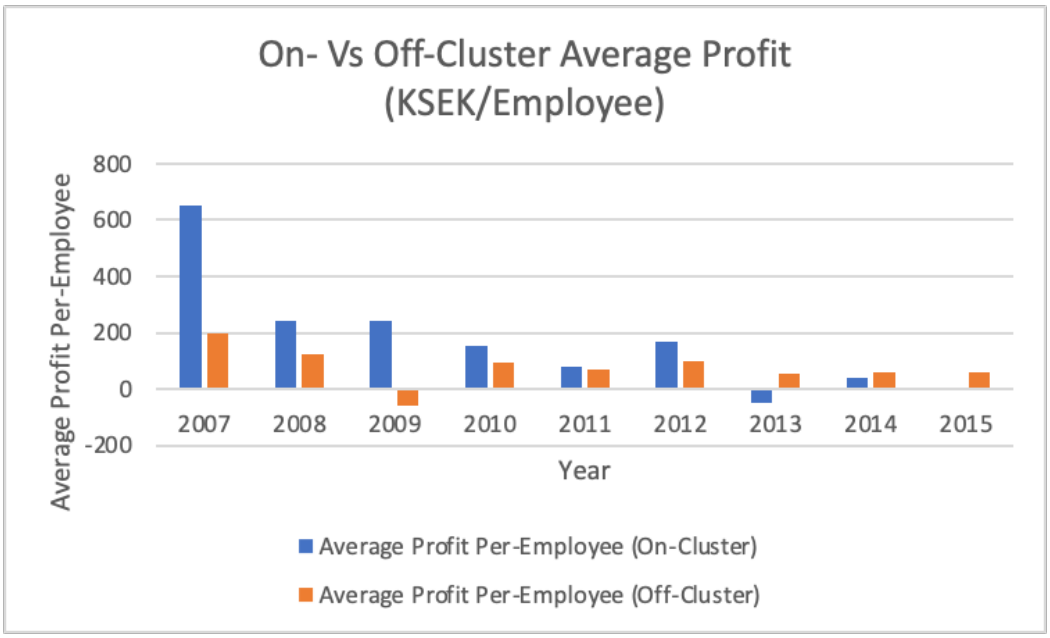

Figure 1: On-VS Off-Cluster Average Profit Per-Employee

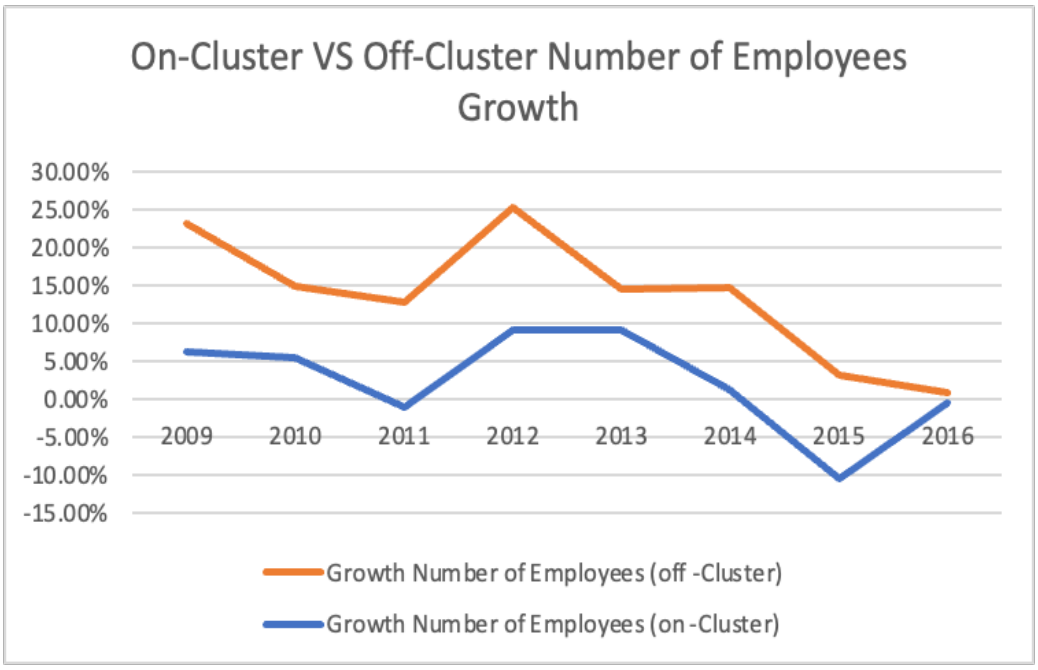

Figure 2: On-Cluster VS Off-Cluster Number of Employees Growth

Although the comparison shows that on-cluster firms – on average- are more profitable than off-cluster firms, the picture is still not clear, especially in understanding how time (age of the cluster) impacts the firms' profitability. Thus, SPSS was used to understand if there is a correlation between the growth in number of firms (size of the cluster) and firms profitability (in average). Figure 3 proves that there is an initial decline in the firms' average profitability as more firms are joining the cluster, which causes the average profit to decline, which is normally because firms take time to start generating profit. This can be explained by the lag between innovation generation and licensing innovation (Al-kfairy et al., 2019b).

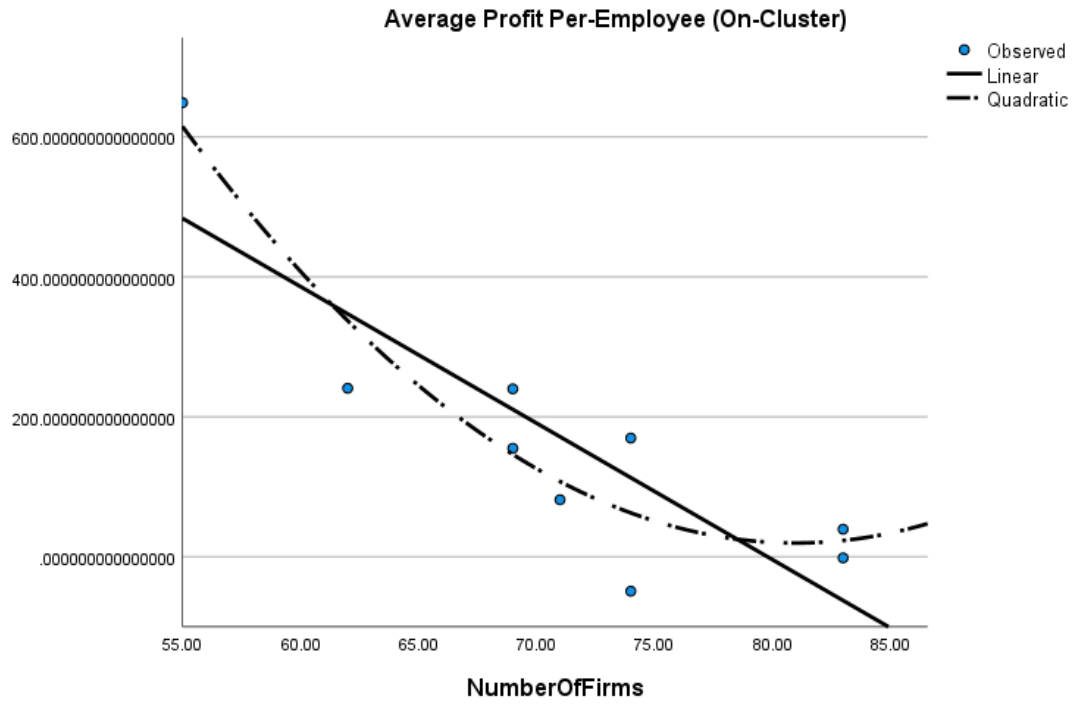

Figure 3: On-Cluster Number of Firms VS Average Profitability

Then, we analyzed the impact of the average innovation output on both on-cluster and off-cluster firms profitability, we run Spearman regression analysis between the average innovation output measured as patent and license income with firms profitability. Surprisingly, the results show a significant negative correlation between average patents and license income and firms' profitability for on-cluster firms (Rho = -0.783, p-value = 0.013). This indicates that the more innovation income the less profitable the company. However, as Al-kfairy et al., 2019b argued that there is a positive correlation between innovation output and Turnover, but a negative initial correlation, these results are compatible with their results, and the on-cluster firms will start benefiting from innovation output later in the cluster development. On the other hand, no significant correlation was identified between off-cluster firms' profitability and innovation output, which is again indicates that off-cluster firms financial return does not depend on how innovative is the firm, but on the nature of the firms' business which is most likely a consultation company.

Furthermore, we calculated the innovation capability per firm using the following equation:

$$Innov_{i,t} = \frac{P\&L_{i,t}}{Turnover_{i,t}}, i\ is\ the\ reporting\ firm, and\ t\ is\ the\ year\ (2007, 2008 \ldots 2015)$$

Equation 2

Then, we apply panel data analysis techniques with both fixed and random effect model to firms' profit data at both on-cluster and off-cluster firms. The final obtained regression model for on-cluster firms profit using fixed-effect model (Huasman test returned p-value of less than 0.001 and concludes that random effect model is not appropriate) is summarized in Equation 3:

$$Profit_{i,t} = C_1\ Innov_{i,t-1} + C_2 R\&D_{i,t-1} + C3GroupContribution_{i,t} + C4NumberofEmployees_{i,t} + Const$$

Equation 3: On-Cluster Firms Profit Regression Model

Table 2: Coefficient Values Obtained from the Regression Model (Equation 3)

	Coef	p-value
C_1	579.045	0.005
C_2	0.310	0.080

	Coef	p-value
C_3	0.520	0.001
C_4	-1139.154	0.000
const	21050.710	0.000

The model shows a positive lag effect of innovation parameters for Innov measured as patent and License outcome ratio to Turnover and the R&D investments. The model results support the results at the aggregate level, which shows no immediate effect of innovation output on the firms' profitability. Moreover, it shows a positive impact of firms' group contribution on firms' profitability, which further support the hypothesis that a firm is more likely to be profitable if it is part of a group. These results are in line with earlier results of Al-kfairy et al., 2019b, who shows a positive relationship between innovation and turnover for on-cluster firms.

In order to understand if there is a difference between the on- and off-cluster firms, we run the same model for off-cluster firms. The model shows a significant positive relationship between innovation (Patents and License Ratio to Turnover) as well as group contribution and firms' profitability, but no significant relationship between R&D investments and firm size (measured as a number of employees) and firms' profitability.

The previous results suggested that regardless of being on-cluster or off-cluster, innovation is always positively impacting the firms' profitability. However, one significant difference between being on-cluster and off-cluster is the R&D investment impact, which shows a positive effect in the case of being on-cluster. At the same time, no significant relationship was reported in case of being off-cluster. Thus, innovation is more influential in case of being on-cluster, which indicates that on-cluster firms are more innovation-driven than off-cluster firms.

Another significant difference is the size impact, which proves that on-cluster firms can be profitable but once it grows more, then it might need to move off-cluster to stay profitable as size does not have any significant impact on off-cluster firms.

5. Discussion

5.1 Theoretical Implications

This study enriches the theoretical landscape surrounding the Knowledge-Based View (KBV) of firms by elucidating the mechanisms through which knowledge management and innovation catalyze firm success within clusters. By highlighting the nuanced effects of on-cluster locations on innovation outputs and profitability, it offers empirical support for the KBV's assertion that proximity to similar and complementary businesses amplifies a firm's capacity to leverage external knowledge for competitive advantage. Additionally, the relationship between innovation outputs, such as patents, and firm profitability extends resource-based theories. This alignment underscores the necessity of not only possessing but also strategically deploying firm-specific capabilities and resources to achieve superior performance. The findings also contribute to cluster theory by illustrating how clustering benefits, like increased collaboration and access to specialized knowledge, impact firm profitability. This introduces a more balanced perspective on cluster dynamics, acknowledging potential drawbacks like resource saturation as clusters expand.

5.2 Practical Implications

From a practical standpoint, the insights from this study are invaluable for managers, policymakers, and entrepreneurs engaged with or considering involvement in Science and Technology Parks (STPs). Managers are advised to optimize their innovation strategies by aligning R&D investments with market demands and protecting intellectual property to fully capitalize on innovations. The study also informs location decisions, suggesting that firms evaluate the benefits and potential challenges of situating within an STP. While smaller firms and startups may find critical support in these environments, larger organizations might reconsider their placement as clusters become congested. For policymakers, these findings highlight the importance of designing and managing STPs to support sustainable firm growth and innovation, suggesting policies that adapt to the evolving needs of firms and the technological landscape. Furthermore, recognizing the diverse innovation profiles across different types of firms, both policies and management practices should be tailored to maximize the economic and competitive benefits of innovation activities within the cluster. These practical and theoretical insights collectively offer a robust framework for enhancing firm profitability through strategic innovation management and thoughtful engagement with STP ecosystems.

6. Conclusion and Future Work

STPs are considered as a regional tool for fostering regional development by stimulating regional employment and financial growth. During the last couple of decades, many regional authorities tried this tool. For example, IASP reported more than 350 members worldwide and more than 115,000 employees (IASP,2021). While the STPs organisation structure impact on firms' innovation has been well studied as in Al-kfairy et al., 2019a; Al-kfairy et al., 2020 and Al-kfairy and Mellor, 2020. However, the impact of STPs on financial growth is still debatable, especially if locating inside STPs will enhance the firms' probability to generate more profit. Thus, this study tried to uncover that by comparing on- and off-cluster firms' profitability.

The results indicate that locating on-cluster will increase the firms' profitability in general. However, as more firms join the STP over time, this will have a temporary impact on firms profitability which causes it to decline, then grow again. This conclusion which further support Al-kfairy et al., 2019b which indicated that STPs growth is not linear and moves between different stages. Furthermore, the results show that off-cluster firms provide better salaries on average to their employees than on-cluster, which can be explained by the fact that on-cluster firms spend more on innovation investment in the form of R&D than on employees salaries.

This study indicates that locating on-cluster will enhance the firms' profitability than selecting to locate off-cluster. However, the results show a positive impact of innovation for both on-cluster and off-cluster at the micro level, but this impact is partial on the off-cluster firms. Moreover, the firm size is negatively impacting firms' profitability in case of on-cluster firms, which means that cluster innovation impact on firms' profitability is temporary.

Although this study contributes to understanding how location can positively impact firms' profitability, it is crucial to understand firms' profitability for different industries as well as study business clusters at different development stages rather than a mature business cluster.

The Factors That Affect the Knowledge-Sharing Behaviours of Female and Male Academics in Higher Education Institutions

Huda N. Almutairi, Paul Gooding and Adele Redhead
School of Humanities, University of Glasgow, Glasgow, UK

h.almutairi.1@research.gla.ac.uk

Abstract: For academics to be successful in a university career, it is generally acknowledged that relevant professional development is a necessity. Research by academics should be innovative and demonstrate an understanding of current issues and developments in their subject. Sharing such knowledge with others who are also endeavouring to learn, to understand or to keep abreast of current developments is as important. Knowledge management and knowledge-sharing in commercial settings, together with the elements that influence these practices, have been investigated by numerous researchers over a long period. However, there are few studies which have evaluated knowledge-sharing in an educational environment, and even fewer in relation to academics in Saudi Arabia. Saudi Arabia is, however, exceptional, in respect of knowledge management and sharing in the academic ecosystem, due to its atypical, prevailing socio-political environment and this may impact on the mechanisms and patterns of professional development amongst academics. Research in this social context, of behaviours well understood in conventional environments, is therefore merited in order to identify similarities and differences, filling an important literature gap and potentially contributing insights which may improve academic success in Saudi and stimulate new ways of thinking in other contexts. The aim of this paper is to determine the factors that affect knowledge-sharing behaviours amongst female and male academics in one of the higher education institutions in Saudi Arabia. A theoretical framework is proposed which is based on the Theory of Planned Behaviour (TPB; Ajzen, 1985). The factors which are commonly considered to be the most influential on both gender's knowledge-sharing behaviours will be analysed and discussed in this exceptional setting. A survey will be distributed amongst academics to gather information for this research. The findings of this study will contribute to the body of published knowledge relating to the practice of knowledge-sharing among academics through the differentiation and quantification of factors which affect it. This will offer academics the opportunity to enhance their understanding of this topic and subsequently, to optimise their part in knowledge exchange processes.

Keywords: Knowledge Sharing Behaviour,Higher Education,Knowledge Sharing Attitude, Academic Staff.

1. Introduction

Knowledge is an essential asset of institutions, and since economic dependence on knowledge is well established, it is also recognised as a precious and valuable resource (Fullwood et al., 2013; Amayah, 2013; Howell & Annansingh, 2013; Bello & Oyekunle, 2014). Commercial enterprises have long recognised that, from the perspective of gaining a competitive foothold, the possession and appropriate management of knowledge is extremely advantageous (Iqbal & Mahmood, 2012 ; Nielsen & Cappelen, 2014). The benefits are multiplied when knowledge-sharing (KS) is a routine practice (Nonaka & Takeuchi, 1995) and numerous initiatives pertaining to knowledge management (KM) have been based on facilitating and improving KS (Hislop, 2013). Educationally, KS can be broadly defined as a societal exchange which advocates optimal practice and sustainability, whilst disseminating both established and novel information. KS in an academic context ensures that up to date research and pedagogical practices, as well as many other proficiencies, are exchanged, in an attempt to guarantee their success in a competitive environment (Tan & Ramayah, 2014).

KS is a major contributor, which ensures a positive outcome from processes pertaining to KM and related agendas. There is a societal expectation that universities are knowledge-rich institutions, and so an absence or diminution of KS could be perceived as detrimental and as well as affecting both research performance and pedagogical commitments (Ali et al., 2014), could cause institutional reputational damage. Thus the practice of concealing or stockpiling knowledge, which is considered prevalent by some academics in a number of disciplines, causing either a direct or secondary effect on innovative skills (Bogilovic et al**.**, 2017; Malik et al., 2019) and professional abilities (Nguyen et al., 2022), is widely considered an institutional hindrance. Furthermore, such secrecy may harm social interactions and create a circular lack of trust which precipitates additional undesirable consequences (Cerne et al., 2014; Bogilovic et al., 2017). This practice of the accrual of unshared knowledge has, nevertheless, continued to plague and adversely affect academic establishments (Cheng et al., 2009; Fullwood et al., 2013; Carband and Jafari Navimipour, 2018; Fauzi et al., 2019).

A number of studies have suggested that there is little research relating to KS, compared to other aspects of KM (Jain et al., 2007; Amayah, 2013; Fullwood et al., 2013), a view substantiated by Ali et al. (2014) in their review. This is especially the case with respect to KS in universities and between academics (Al-Kurdi et al., 2020). The

lack of essential research into KS specifically is demonstrated by scarcity of studies which address educational KS and the relevant influential factors (Fullwood et al., 2013; Ali et al., 2014; Akosile & Olatokun, 2020).

The aim of this paper, therefore, is to determine, from the broad spectrum of factors established as important in other sectors and socio-political environments, those that most affect KS behaviours amongst female and male academics in one of the most important higher education institutions in Saudi Arabia.

In view of the lack of studies on this subject and, specifically, research relating to KS within educational establishments in Saudi Arabia, a major objective of this study is to recognise openings for further research. Analysis of the factors that affect KS processes would also be of value for the improvement of a positive university environment that advocates KS and optimises productivity. It will also enable the KS behaviours, positive and negative, of academics to be identified. These findings will contribute to the development of an educational ethos that supports the process of obtaining de novo knowledge, and the better sharing of such knowledge between academics.

2. Knowledge Sharing in Higher Educational Institutions

Although a number of endeavours have been made to offer descriptions of knowledge, KM and KS, controversy remains regarding agreed definitions, the latter varying according to the standpoint or setting to which they are applied (Iqbal & Mahmood, 2012; Ragab & Arisha, 2013; Ali et al., 2014). One academic-context definition of KS is that it comprises the basic method utilised by employees to participate in the effective implementation of knowledge and the development of creativity within the institution, to the latter's competitive benefit (Jackson et al., 2006). Accepting this definition means that KM and KS can be construed as being key elements for maximising competitivity (Al-Kurdi et al., 2018).

Typically knowledge-rich institutions, universities are major players in the discovery of knowledge via their research programmes, and in KS, through their published literature. Their engagement with commercial enterprises and other bodies facilitates both KS and development, as well as social and cultural profitability. University curricula also offer education and training courses for potential researchers. It could be anticipated that because of this reliance on KS, universities would take the initiative with respect to approaches to KM and that they would have an advanced and rich understanding of ways of dealing with and maximising their knowledge worth (Fullwood et al., 2013).

Academics are expected to be knowledge leaders, who should not demonstrate any reticence regarding KS, with the objectives of their university given primacy above their personal preferences (Al-Kurdi et al., 2018). The goals of higher education facilities include facilitating the development of de novo concepts through collaboration, encouraging KS and optimising learning proficiency through their academic staff, to benefit both the university and the academic staff themselves and to promote the institution's wider agenda (Tan & Ramayah, 2014; Dyer & Nobeoka, 2000).

3. Research Model and Hypothesis Development

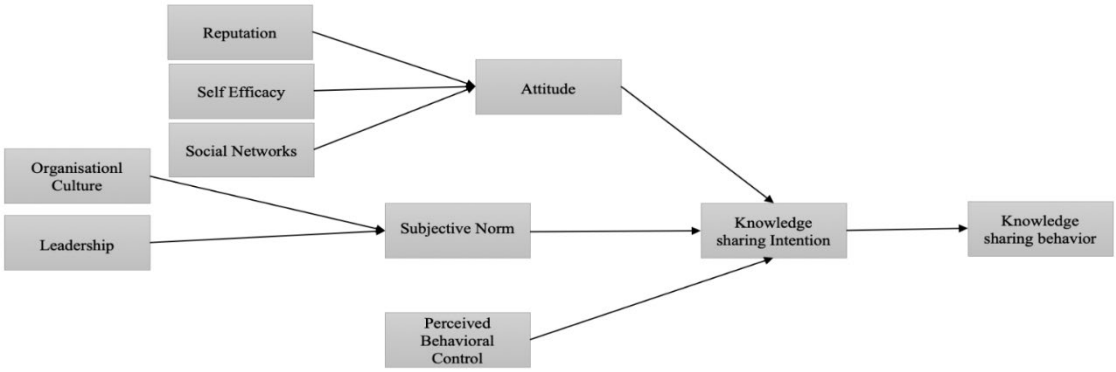

Figure 1: Research model

The TPB is the most commonly referenced explanation for why people act in certain ways (Sussman & Gifford, 2019) and postulates that behavioural intention can be used to predict, and is the best determinant of, certain actions. TPB has been frequently employed in relation to KM. According to the TPB (Figure 1), behavioural

intention is impacted by a triad of components: (i) attitude with respect to the behaviour; (ii) subjective norms relating to the behaviour; and (iii) perceived behavioural control affecting the behaviour (Sussman & Gifford, 2019). KS has been described in terms of the TBP by numerous researchers (Jolaee et al., 2014; Bock et al., 2005; So & Bolloju, 2005) and evidenced in a wide range of settings. In a similar manner, the TPB will be applied in the current study, which will investigate a number of pertinent covariates (elements or factors) identified in the literature as being influential on behavioural intentions. These elements, which were used to extend the research model, comprise reputation, social networks and self-efficacy, which are thought to influence an individual's attitude to KS, as well as the culture and leadership of an organisation thought to influence subjective norms towards KS intention. The aim was to identify those elements which had the greatest impact on KS behaviours practised by academics in higher educational establishments.

3.1 Intentions

within a KM domain, intention refers to a practitioner's enthusiasm and desire to share knowledge (Wu & Zhu, 2012). Many studies have evaluated this characteristic in academics with respect to KS, and determined that, overall, academics express positivity regarding their KS intentions. The first hypothesis arises from this.

H1. Intentions greatly influence knowledge sharing amongst academics.

3.2 Attitude

according to Kuo & Young (2008), attitude refers to the extent to which an individual makes a positive or negative assessment of a certain phenomenon. It has also been described as a psychological leaning with respect to any entity that is influential on intention (Hepler, 2015). A number of important studies have evaluated the association between attitude and KS practice (e.g. Fullwood et al., 2017; Jolaee et al., 2014). Their results demonstrate how people's attitudes about sharing knowledge reflect how ready they are to participate in the process. In particular, the more positivity a person demonstrates with respect to KS, the greater their intention (Afshar Jalili & Ghaleh, 2021; Stenius et al., 2015). Consequently, a second hypothesis is proposed.

H2. Attitude greatly influences the academic's intentions to share knowledge.

3.3 Subjective Norm

This term describes a person's subjective evaluation of how specific others anticipate that they should act, or how they should respond themselves in an equivalent context, i.e. a normative belief (Stenius et al., 2015). A number of studies have demonstrated that KS intentions are positively affected by subjective norms (e.g. Bock et al., 2005; Stenius et al., 2015; Igbinovia, 2018; Afshar Jalili & Ghaleh, 2021). These findings lead to the third hypothesis.

H3. Subjective Norm greatly influences academics' intentions to share knowledge.

3.4 Perceived Behavioural Control (PBC)

It is the degree to which an individual views their competence to engage in a specific behaviour (Ajzen, 1985). It has also been suggested that if individuals had enough control over their behaviour, they would be likely to follow through with their intentions when practical (Jolaee et al., 2014). Goh & Sandhu (2013) studied the effect of PBC on KS in a higher education establishment in Malaysia, and surmised that it was a powerful positive factor with respect to KS. A further hypothesis was therefore postulated.

H4. PBC greatly influences academic's intentions to share knowledge.

3.5 Reputation

Reputation has been shown to be linked with behaviours related to KS (e.g. Dezdar, 2017; Wasko & Faraj, 2005). Such studies have concluded that reputation is a powerful incentive to KS behaviour, findings substantiated by Tan & Ramayah (2014) who found that as an academic's reputation grew, she or he engaged in KS with peers more frequently. These results underpin the fifth hypothesis.

H5. Reputation greatly influences the attitudes of academics towards knowledge sharing.

3.6 Self-Efficacy

A definition of self-efficacy is an individual's confidence that they have the proficiencies required to be successful in a specific setting (Jolaee et al., 2014). This characteristic has also been demonstrated by several researchers to be an important influential factor on the attitude of university academics with respect to KS (e.g. Lin, 2007; Omojowolo, 2014; Dezdar, 2017). Akosile & Olatokun (2020) considered the relationships of self-efficacy and KS practice in the academic environment to merit additional study. A further hypothesis has therefore been proposed.

H6. The self-efficacy of academics greatly influences their attitudes towards knowledge sharing.

3.7 Social Networks

Fauzi et al. (2018) indicate that another factor that has a bearing on the academics' attitude towards KS is social networking. According to (Jolaee et al., 2014), social networks have a favourable and significant correlation with academics' attitudes on knowledge sharing, they stated that academic staff members may develop a propensity for good attitudes toward knowledge sharing if they expand their social networks. The following hypothesis was therefore constructed.

H7. Social networks greatly influence the attitudes of academics towards knowledge sharing.

3.8 Organisational Culture

Promoting an organisational culture that supports knowledge sharing (KS) is one of the main tasks of knowledge management (KM) (Angeloni & Grotto, 2009). According to several studies (e.g. Bousari & Hassanzadeh, 2012; Cheng et al., 2009; Noor et al., 2014), organisational culture is one of the key elements that greatly influences the success of knowledge sharing. A hypothesis was, therefore, postulated in relation to these findings.

H8. Organisational culture greatly influences the subjective norms of academics towards knowledge sharing.

3.9 Leadership

A substantial amount of literature in this field has emphasised the significance of leadership support and its favourable effects on desired knowledge-sharing behaviour inside an organisation (Muhammed & Zaim, 2020). Al-Kurdi et al.'s (2020) study amply demonstrated the beneficial impact of leadership on academic knowledge sharing. Thus, the following hypothesis.

H9. Leadership greatly influences academics' subjective norms towards knowledge sharing.

4. Methodology

A quantitative approach will be employed for this study. Data collection will be carried out using a questionnaire survey, using questions that were adapted from previously published studies to fit this research context. The proposed hypotheses will then be tested by analysing the resultant data using appropriate statistical tools to identify the factors that influence KS behaviour amongst Saudi academics and their relative strengths.

5. Expected Results and Benefits

The context of this research project is rare. It differs from previous studies on KS in that the aim is to determine the factors that have the greatest impact on KS behaviours of both female and male academics in a Saudi university that operates a gender segregation policy. Female academics work on a separate campus to their male counterparts. The results will be important because the importance of KS has been recognised in previous research and emphasised as vital to the success of KM in universities and to universities achieving their objectives. There is, consequently, a prerequisite for academic institutions to create tools that engender an academic atmosphere that promotes KS between academics.

The results of this research will, therefore, be of value to higher management in universities, as they will greatly assist them to identify the factors that have the greatest impact on the KS practices of Saudi academics. In addition to describing an institutional environment that encourages KS, this study will support the development of programmes and the use of incentives to improve knowledge behaviour amongst Saudi academics and their colleagues. The findings will provide administrators with a solid evidence base upon which to build their policies.

Assessing the Moderating Role of Organizational Culture on the Effect of Knowledge Networks on Firm Innovation in Visegrad Countries: The Perspective of Knowledge Production Function

Emmanuel Ebo Arthur and Jan Stejskal
University of Pardubice, Pardubice, Czech Republic

emmanuel.arthur@upce.cz
jan.stejskal@upce.cz

Abstract: Among the elements of Knowledge Production Function (KPF), R&D remains one of the highly studied factors. In an era of interdependence and collaborations, no firm or enterprise can survive the prevailing highly competitive business environment by not networking with firms of similar interest, values, and goals. The unanswered question in prior literature on firm co-operation is what kind of firm co-operation best works? In finding an answer to fill this gap in literature, we examined the impact of R&D co-operation, innovation co-operation (excluding R&D) and co-operation based on other business activities on radical and incremental innovations. We further examined the moderating role of organizational culture on the effect of firm co-operation on innovation. Our study is based on open innovation theory and the KPF. Adopting the 2018 cross-sectional CIS data from the Eurostat database for the four Visegrad countries (Czech Republic, Poland, Hungary, and Slovakia), the OLS regression and Average Marginal Effects models were used for the analysis. We confirmed that when firms co-operate on R&D, there is a positive and significant effect on radical innovation but negative significant effect on incremental innovation. Firm co-operation on innovation activities excluding R&D has positive and significant effect on both radical and incremental innovations. Other business co-operations had positive and significant effect on incremental innovation but not on radical innovation. We further confirmed a positive significant moderating role on the effect of R&D co-operation on radical innovation. We proposed theoretical and practical implications of our study to firm managers, government, and policy formulators.

Keywords: R&D co-operation, Training and Development, Radical and Incremental Innovations, OLS, Visegrad

1. Introduction

Firms network or co-operate for varied reasons. Some include knowledge sharing, cost sharing and joint projects and other activities of mutual interest. Firm co-operation through strategic alliances spurs innovation and firm performance. Over the years, firms have co-operated in the areas of information technology and biotechnology (Boh, Huang & Wu, 2020). Effective firm co-operation has seen firms gained in the areas of creativity and innovation, market expansion and access, risk and cost sharing and enhanced competitiveness. (Boh, Huang & Wu, 2020; Shafi, 2021; Singh, 2022). One key area identified by extant literature for firm co-operation is on R&D and its impact on general innovation. Van Beers and Zand (2014) used the random-effects panel Tobit estimates, in Netherlands and found that, partner diversity in R&D had positive impact on radical and incremental innovations. But in Portugal, investments act as a constraint to SMEs collaboration in R&D towards product innovation (Paiva, Ribeiro & Coutinho, 2020). Despite the growing literature on R&D, Negassi (2004) argues that firm network and R&D co-operation remain limited. With the existence of few studies on R &D co-operation and innovation (Negassi, 2004; Pham et al., 2021; Bragoli, Cortelezzi, & Rigon, 2024; Peiró-Signes, Díez-Martínez & Segarra-Oña, 2024), the empirical relevance of the moderating role of organizational culture has rarely been considered. Not only that, but the diversity in R&D and non-R&D cooperation has also not been studied. The emphasis has been on firm heterogeneity in R&D co-operation. The neglect of examining the varied R&D and non-R&D firm co-operation is an issue because the other forms of firm network or co-operation also play a role in firm innovation performance.

The objective of this paper is to examine how networking or co-operation in the determinants of knowledge production function (R&D co-operation and non-R&D co-operation) impact on radical and incremental innovations in the Visegrad countries. We further aim to produce evidence on the moderating effect of organizational culture (expenditure on training and development) on the relationship between R&D co-operation and innovation. Our study contributes to the body of literature in three diverse ways. First, we prove that variations in firm co-operation (R&D and non-R&D) have heterogeneity effect on radical and incremental innovations. It is important to differentiate the impact of R&D co-operation on innovation and from that of non-R&D to give effective alternative to firm managers and stakeholders. It helps to inform and direct investment decisions on the kind of co-operation to engage. Second, we add to the understanding of existing literature on organizational culture by examining the extent to which it moderates the relationship between R&D cooperation and innovation in the Visegrad region. Thirdly, the study contribute enhances the KPF

concept, Resource Based View (RBV) and Collaborative Advantage Theory (CAT). We explained R&D as a knowledge-based determinant of KPF. Our study is based on RBV and CAT. RBV strides on the axiom, firm co-operate to leverage complimentary resources and capabilities they cannot realised internally. On the other hand, CAT posits that, firms that co-operate achieve optimal performance and competitive advantage. This study asserts that firms that network and co-operate improves their resources and capabilities, competitive advantage, and performance.

The rest of the study is framed as Section 2, literature, and framework of the study; Section 3, methodology, results and discussions in Section 4 and conclusion in Section 5.

2. Literature and Framework of the Study

2.1 Linking Firm Co-Operation, Organizational Culture, and Innovation.

There are several bases for firm co-operation either internally or internally. The mutual benefits associated with firm co-operation spur firms to make decisions to either co-operate or not. Firms that lack a resource, the capability to perform an activity or produce a product usually network or co-operate. The co-operation of firms is in various forms, but this study focuses on R&D co-operation, innovation co-operation (excluding R&R) and other business activities co-operation. R&D co-operation involves firms engage in strategic alliances for long term research projects with universities and other public research institutions. Park and Lee (2023) argue that firm horizontal R&D co-operation is effective when there is economic risk and lack of market knowledge regarding the introduction of a new product to the market. Several empirical studies show positive and insignificant impact of R&D co-operation on firm innovation (Žítek & Klímová, 2020; Choi & Choi, 2021). The effect of R&D co-operation on firm innovation has never been in dispute but, the direction and significance of the impact and the type of innovation have been in dispute owing to the discrepancies in the findings over the years. Innovation co-operation includes firms collaborating on innovation joint venture, feasibility of introducing new projects, acquiring patents and licenses and software introduction (Sohag, Chukavina & Samargandi, 2021). This excludes all research and development activities. Innovation activities improve product and process innovation (Madrid-Guijarro, Martin & García-Pérez-de-Lema, 2021) however, Rammer (2023) argues that there is no significant impact on process innovation output when firms co-operate on innovation activities. It suggests that, acquiring external knowledge is not certain for achieving process innovation. Firms also co-operate on other business activities. This form of co-operation is in the domain of sales and distribution, sustainable initiatives, manufacturing, marketing, and promotion. Firms that co-operate experience considerable innovation in marketing, sales, and distribution (Xian & Jiang, 2023). To sum the issues in existing literature, there are varied and inconclusive arguments on the impact of firm co-operation (R&D, innovation activities and other business activities) on innovation. We therefore hypothesized that:

H1a: Firm R&D co-operation improves radical and incremental innovation in the Visegrad region.

H1b: Firm co-operation on innovation activities excluding R&D enhances radical and incremental innovation in the Visegrad region.

H1c: The more firms co-operate on other business activities, the better it is for radical and incremental innovation in the Visegrad region.

Organizational culture defines the shared values, norms, beliefs, standards, leadership, teamwork, and artefacts that is associated with the organization (Srisathan et al., 2020). It influences how people talk, act, and behave in an organization. There is no significant relationship between organizational culture and open innovation performance (Alassaf et al., 2020). Organizational culture may be an improbable but a subtle obstacle to innovation. Some firms have the culture of spending on the training and development of their employees. The purpose is to enhance the skills and capabilities of the employee. While prior literature focuses on using organizational culture as explanatory variable, our study uses it as a moderator. We therefore suggest that:

H2: *Organizational culture positively moderates the relationship between R&D firm co-operation and innovation.*

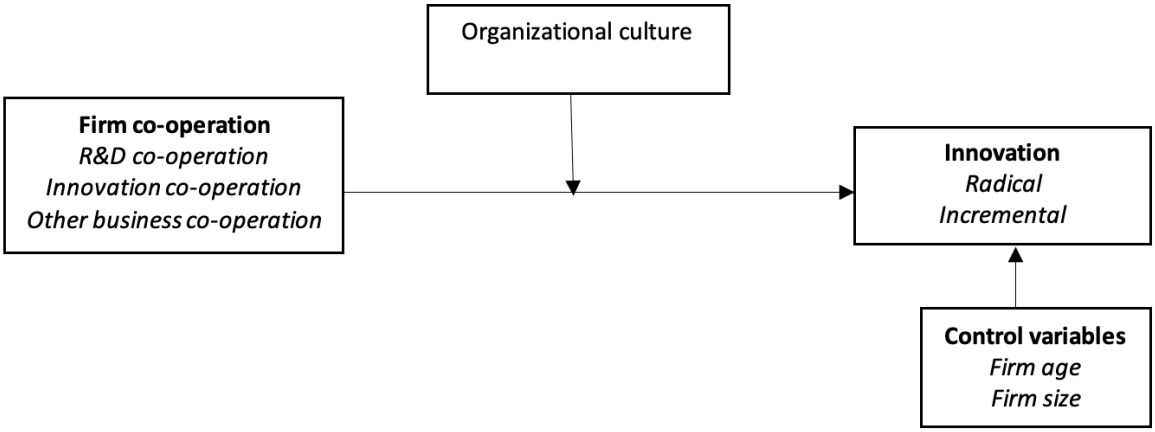

Figure 1: Conceptual framework

3. Methodology

3.1 Data Source and Variables Description

The study used 2018 Community Innovation Survey (CIS) cross-sectional data from the Eurostat database for the analysis. The Eurostat database is credible and reliable site and has been used by several empirical studies. The context of our study in the Visegrad region. It comprises four European countries namely, the Czech Republic, Poland, Hungary, and Slovakia. A total of 31859 firms from these countries participated in the study (Refer to Table 2 for details). According to the European innovation scoreboard 2023, the countries in the Visegrad region fall within emerging and moderate innovators. It is of immense interest to examine the influence of firm co-operation in R&D, innovation activities and other business activities on incremental and radical innovations in the region.

Our independent variable is innovation. Two indicators were used to measure innovation. One is products new to market and new to the firm is used to measure radical innovation while products new to firm only is used as proxy for incremental innovation. We used three indicators to measure firm co-operation. They are firm R&D co-operation, firm innovation co-operation excluding R&D and firm co-operation on other business activities. Expenditure on training and development is the proxy for organizational culture. We controlled for firm age, firm size, and country fixed effects. Firm size is classified into small firms (10-49 employees), medium firms (50-249 employees) and large firms (more than 250 employees). Firm age is coded as firms established in 2016 or later= 1, from 2010-2015 =2 and 2009 or before= 3. All other variables used are dummy in nature. It means they take the value 1 for "Yes" if the activity occurred and 0 for "No" if it did not occur. Refer to Table 1 for the details of variables used including literature sources.

3.2 Methods

We used the OLS regression to assess our hypothesis because it is a base line model for several empirical studies. The OLS model is presented as:

$$Inn\ (Z_1) = \beta_0 + \beta_1\ parameters + firm\ characteristics\lambda + \varepsilon_i \quad [1]$$

$InnZ_1$ represents "1" if the firm introduced a new product and "0" if it did not introduce a new product. β_0 is constant, β_1 parameters, firm characteristics λ is the vector and ε_i is the random error term.

We first assessed the issues of multicollinearity and heteroskedasticity which could be associated with our data and beset our findings. We used Variance Inflation Factor (VIF). The smaller the VIF values the better it is for the model. A VIF value above 10 indicates multicollinearity issues in the variables being studied. The VIF produced and average value of 1.16 indicating that multicollinearity is not an issue with our data. The Breusch-Pagan test for heteroskedasticity showed a P- value of 0.110 for incremental innovation and 0.240 for radical innovation. This insignificant p-values in the BP test implies the likelihood of less or not issues of heteroskedasticity. In the first stage of our analysis, we conducted an OLS regression analysis to examine the impact of firm co-operation (R&D, innovation activity and other business activities) on radical and incremental

innovations. Radical innovation is model 1 and incremental innovation is model 2. In the second stage of our analysis, we did a robustness test using the average marginal effect estimation to check the reliability and validity of the results in Table 5. We introduced expenditure on training and development as an interaction variable to the model in stage 3 of the analysis.

Table 1: Variable description

Variable	Indicators	Data source	Literature source
Dependent variable Innovation- Radical and incremental	Innovation product new to market Innovation product new to firm	CIS 2018	Van Beers & Zand at al., (2021)
Independent variable Firm co-operation	Co-operation on R&D Co-operation on innovation (excludes R&D) Co-operation on other business activities	CIS 2018	Paiva et al., (2020). Nagassi, (2004)
Control variables Firm age Firm size Country	Year of establishment Number of employees Visegrad countries	CIS 2018	Alassaf et al., (2020); Nagassi, (2004)
Moderating variable Organizational culture	Expenditure on staff training	CIS 2018	Alassaf et al., (2020); Srisathan et al., (2020).

Table 2: Firms per country

Country	Number	Percent	Cumulative percent

4. Results and Discussion

Table 4 shows the descriptive statistics of the study. On the average, firms in Visegrad region reported 54.6% radical innovation and 81.5% incremental innovation. They also agree to have had 6.8% R&D co-operation,

7.6% co-operation on innovation (excluding R&D) and 9.8% co-operation on other business activities. Averagely, only 4% of the firms agree to have spent on the training and development of their employees. With a firm size mean of 1.394, it implies that majority the firms in the study were medium firms with 50-249 employees. Most firms involved in the study were established from 2010 to 2015.

The OLS regression analysis results in Table 5 help to evaluate hypothesis H1a, H1b and H1c. There is positive significant effect of R&D co-operation on radical innovation but negative significant effect on incremental innovation. It implies that, there is 10.2% improvement in radical innovation and surprisingly, 1.7% reduction in incremental innovation for every unit of R&D co-operation firms undertake. This partially supports hypothesis H1a. It also confirms the assertion of Choi and Choi (2021) that R&D co-operation has positive and significant impact on innovation although they did not classify the effect on radical and incremental innovations.

Table 4: Summary statistics

Variable	Obs.	Mean	Std. dev.	Min	Max
Co-operation on R&D	29138	0.068	0.251	0	1
Co-operation on other innovation activities (excluding R&D)	29138	0.076	0.265	0	1
Co-operation on other business activities	26110	0.098	0.297	0	1
Firm expenditure on staff training and development	26094	0.004	0.130	0.130	18.283
Firm age	31859	2.728	0.538	1	3
Firm size	31859	1.394	0.648	1	3
Country	31859	1.948	1.059	1	4
Innovation product new to market	31859	0.546	0.233	0	1
Innovation product new to firm	31859	0.815	0.181		01

Own calculations

Again, the results support the argument that R&D co-operation is effective when the economic risk of introducing the new product is high (Park & Lee, 2023). The economic risk associated with radical innovation is higher than incremental innovation. By implication, it is not surprising to find the impact of R&D co-operation on radical innovation stronger and positive in relation to incremental innovation. Firms' co-operations on innovation activities excluding R&D had positive and significant impact on both radical and incremental innovations. This fully supports hypothesis H1b. It confirms existing studies that co-operation on innovation activities enhances product and process innovations (Madrid-Guijarro, Martin & García-Pérez-de-Lema, 2021) even though our finding is on radical and incremental innovations. However, it is contrary to the findings of Rammer (2023) that there is no significant impact on process innovation by firms' co-operating in innovation activities excluding R&D. We partially confirm hypothesis H1c in Table 5 that, firms co-operating on other business activities positively and significantly impact incremental innovation but did not radical innovation. This partially confirms the argument by Xian and Jiang (2023) that firms that co-operate on non-R&D and non-innovative activities such as marketing, sales and distribution promote innovation. We found that this is true for incremental innovation but not radical innovation. To give unbiased results, we controlled for firm age, firm size, and country level effects in all our analyses.

Table 5: OLS regression analysis of the R&D and non- R&D co-operation and innovation

Variables	Model 1 Radical innovation	Model 2 Incremental innovation
Co-operation on R&D	0.102*** (0.006)	-0.017*** (0.005)
Co-operation on other innovation activities (excluding R&D)	0.043*** (0.005)	0.009* (0.004)
Co-operation on other business activities	0.001 (0.005)	0.025*** (0.004)

Adjusted R-sqr.	0.016	0.0037
Obs.	31859	31859

Note: Standard error in parenthesis * p< 0.1; ** p < 0.05; *** p < 0.01

Own calculations

In Table 6, we further conducted robustness test using the average marginal effect estimation to assess the reliability and validity of our results in Table 5. The results confirm that firm co-operation in R&D and innovation activities have significant and positive impact on innovation but insignificant impact on co-operation on other business activities. Thus, for a unit change in R&D co-operation, firms achieve 16.3% improvement in innovation and 8.3% for firm co-operation on innovation activities.

In testing hypothesis H2, we interacted expenditure on staff training and development and firm co-operation on R&D, we found that organizational culture positively and significantly moderates the relationship between R&D co-operation and radical innovation but not incremental innovation. This supports hypothesis H2 but disagrees with Alassaf et al., (2020) that there is no significant relationship between organizational culture and open innovation We reported only the positive results (Radical innovation) on the interaction effect.

Table 6: Robustness test results on the R&D and non- R&D co-operation and innovation using average marginal effect method.

4.1 Discussion

Our first hypothesis H1a sought to examine how firm R&D co-operation improves radical and incremental innovation in the Visegrad region. We confirmed that R&D co-operation enhances radical innovation but surprisingly it retards incremental innovation. This provides an insight into the missing link existing in current literature (Žítek & Klímová, 2020; Choi & Choi, 2021) which mostly focus on R&D co-operation and its impact on general innovation. It is pertinent to state that, firm co-operation in R&D is effective in terms of Radical innovation but not incremental innovation. We also sought to find out the impact of non-R&D innovation on radical and incremental innovations in our hypothesis H1b. This was fully confirmed by our findings that when firms co-operate on innovation activities excluding R&D, is promotes both radical and incremental innovations. We refute Rammer's (2023) are argument that when firms co-operate on innovation activities, it does not necessarily lead to innovation. We extend the understanding in firm co-operation that, policy statements of firms that seek to achieve both radical and incremental innovation should give attention to co-operating on innovation activities excluding R&D with firms of mutual interest that have the resources and capabilities to carry out the co-operation agenda. Furthermore, we assert that, firm co-operation on other business activities excluding R&D and innovation promote only incremental innovation. Such co-operation does not impact on radical innovation. This was confirmed by hypothesis H1c that firm co-operation in other business activities did not have significant impact on radical innovation but was significant on incremental innovation. The essence of assessing the moderation role of organizational culture in the relationship between R&D co-operation was confirmed in hypothesis H2. We proved that, when firms focus on the culture of training and developing their employees and co-operate with other firm on R&D, they promote radical innovation. Firm co-operation is important and costly. It involves great investments. Hence, policy statements on firm co-operation should focus on the kind of co-operation to engage in, the kind of organizational culture to develop because they have a bearing on radical and incremental innovation.

5. Conclusion

The aim of our study is to examine firm co-operation in the determinants of knowledge production function and the impact on innovation. Also, we assessed the moderation role of organizational culture (expenditure on training and development) on the relationship between firm co-operation and innovation. The reason for the purpose of our study is due to the research gap in finding answers to specific firm co-operations and how they impact specific types of innovation. We partially confirmed our first hypothesis that firm R&D co-operation positively and significantly impact on radical innovation but negatively impact on incremental innovation. The second hypothesis was fully supported that firm co-operation on innovation activities excluding R&D positively and significantly impact on both radical and incremental innovations. The third hypothesis was partially confirmed that firm co-operation other business activities excluding R&D and innovation activities positively impact on only incremental innovation and not radical innovation. We confirmed our final hypothesis that an interaction between expenditure on training and development and firm co-operation on R&D positively and significantly impact on radical innovation. Practically, the implications of our findings suggest that firms that aim at achieving radical innovation succeed when they co-operate on R&D.

Because the economic risk in radical innovation requires committed investments policies on R&D and an effective triple helix system. Again, managers of firms that seek to achieve both radical and incremental innovations should have a policy direction towards co-operation on innovation activities. Besides, other business activities co-operation (excluding non-R&D and innovation activities) promotes incremental innovation. Finally, managers of firms that want to succeed with the introduction of a product new to both market and the firm should prioritize the culture of employee training and development as well as co-operating with other firms on R&D. Theoretically, these findings contribute to collaborative advantage theory (CAT), the knowledge production concept (KPF), and the Resource Based View Theory (RBV). From the point of CAT we confirm that when firms are open to co-operation, there is an inflow of new knowledge promotes innovation and the kind of co-operation firms undertake determine the kind of innovation the achieve. We further established that, value of organizational culture in interacting with the determinants of KPF to promote radical innovation in the Visegrad region. From the perspective of RBV, we affirm that new knowledge is a vital resource towards innovation and its acquisition is through various forms of co-operation. Firm co-operation must be done cautiously to achieve the optimal benefit. Regardless of the findings, our study is without limitations. The study focused on only four countries in the Visegard region. Therefore, generalising the findings should be done cautiously as it might not be a true reflection in the European region. Our data is also cross-sectional in nature sourced from the 2018 CIS. The results do not allow for longitudinal assessment over a period. The possibility of endogeneity and cross-sectional dependency issues cannot be ruled out in the data used. We suggest that future studies include all countries in Europe and use panel data for the analysis. We also suggest the that other determinants of KPF should be included in future studies to determine the consistencies and variations in the findings.

Informal Relationships, Digital Competences and Agility in Organizations

Paweł Bańkowski, Yuliia Boiko and Jacek Witkowski
Lublin University of Technology, Lublin, Poland

j.kubaj@pollub.pl
p.bankowski@pollub.pl
j.witkowski@pollub.pl

Abstract: Building interpersonal relationships in organizations plays a very important role and directly affects long-term cooperation with partners. Informal and partnership relations have a particular impact on the agility of the organization, i.e., the ability to immediately respond to changes occurring in the business environment. The aim of this article is to assess the impact of interpersonal relations on the organizational structure and the level of use of digital competencies. According to the literature on the subject, agility in the organization and digital competences contribute to the effective creation and transfer of knowledge. The benefits of implementing an agile structure in an organization also include better management of changing priorities, open cooperation and communication, and greater awareness of the current situation in the organization. The article uses the results of original initial research conducted as part of an inter-university research project entitled "Interorganizational Relations in the Socio-Economic Economy". The research covered relationships in the organization in five areas. The research among the students enrolled in the Master of Business Administration postgraduate program at the Lublin University of Technology was carried out using a quantitative method using a developed survey questionnaire. The analysis of the results confirmed the influence of partnership and informal relations on the agility of the organization and the high level of digital competences implemented. A flexible approach to building relationships enhances the creation of a networked organization. Informal relationships in the organization allow for the building of a team that is more resistant to crisis situations as well as changes in customer needs and sectoral turbulence of the economy. An important aspect of agility is also the high level of using digital competences, which influences the ability to create and transfer knowledge.

Keywords: Interpersonal Relations, Relationships, Agile Structure, Agile Organization, Digital Competences.

1. Introduction

Relationships within organizations serve as the cornerstone for efficient and effective functioning and development. These relationships, as noted by Klimas (2013), encompass both formal and informal aspects, including social and interpersonal connections. The significance of informal relationships is steadily increasing and directly correlates with the agility of an organization—its ability to promptly adapt to changes in the business landscape. Partnership and interaction emerge as pivotal components of cooperation, exerting a direct influence on the organizational structure.

In today's dynamic business landscape, the concept of agility has become paramount for modern organizations in response to the rapid emergence of uncontrollable changes, largely driven by global digitalization. This underscores the imperative of leveraging digital competencies to ensure the accuracy and comprehensiveness of data, as well as facilitate effective communication (Kocot & Kwasek, 2022).

The aim of the work is to examine whether there is a correlation between the type of interpersonal relationships in the organization and the level of use of digital competences of its members, as well as the agility of the organization itself. To achieve this goal, the results of a survey conducted among a group of middle-level managers participating in MBA postgraduate studies will be discussed.

2. Review of the Literature

The role of agility in organizational activities started to be discussed and documented in the 1980s and 1990s by such authors as H. Takeuchi, I. Nonaka, P. T. Kidd, S. L. Goldman, & R. N. Nagel, with increasing scholarly interest in the following decade. Joiner and Josephs (2007) not only focused on defining agile leadership but also mentioned an agile organization, describing it as capable of anticipating and responding to rapidly changing operational conditions. Rafi et al. (2022) and Atkinson et al. (2022) have underscored the significance of this capacity to respond to turbulent environments as the essence of agility. Additionally, these authors emphasize the multifaceted nature of agility, noting its various dimensions.

El Nsour (2021) draws attention to several dimensions of agility, including enterprise, employees, supply chain, customers, and services. Similarly, Silva and Oliveira (2023), in their work discussing research conducted in Brazil,

identify the dominant dimensions of agility in local companies representing Industry 4.0 as leadership, business, markets, strategy, and process.

Devie et al. (2023) contend that an agile organization will focus on its internal culture to support agility, as well as on customers and competitors. However, these authors also observe a research gap regarding the relationship between organizational effectiveness and internal and external changes occurring within the organization.

According to Bernstein (2007), capital is a distinct economic category denoting accumulated resources utilized for implementing and advancing business activities, characterized by the potential for value growth. Regardless of organizational specificity, the human factor holds a pivotal position in organizational structure. Honjo et al. (2022) highlight that enterprises grounded in human capital find it easier to access foreign funds due to being perceived as entities with enhanced creditworthiness. Hasan and Uddin (2022) argue that companies should prioritize retaining talented employees crucial to organizational operations by offering suitable motivational and financial incentives.

Employee relations, along with their interactions with external entities, are frequently viewed as organizational capital (Zhang et al., 2022; Drewniak et al., 2020). Sukarno et al. (2019) regard relational capital as a fundamental component of intellectual capital. Additionally, Ozgun et al. (2022) and Al-Omoush et al. (2020) highlight its favorable impact on organizational agility and enterprise performance.

Interorganizational relationships represent a vital activity for organizations, undertaken to streamline business operations and enhance their competitive positioning in the market (Bańkowski & Rzepka, 2024). The definition of relationships presented in this study was obtained through a literature review undertaken by the author. Another significant aspect concerning intra-organizational relationships is the collaboration between leaders and subordinates. Gren and Ralph (2022) and Reunamäki and Fey (2022) emphasize the necessity of fostering a willingness among individuals to share leadership responsibilities in order to cultivate agile leadership. They also acknowledge that traditional managerial approaches within team settings may impede the implementation of agility within organizations. Das et al. (2023) stress that leaders who prioritize reevaluation and problem examination enhance agility and foster a supportive work environment by demonstrating care for employees' needs and sentiments.

Tyagi et al. (2022) and Trzeciak & Banasik (2022) consider the organization responsible for implementing solutions that determine the effectiveness and commitment of members within agile project teams. A relatively new research avenue explores the impact of familial ties among employees on organizational functioning. Existing literature does not offer a definitive answer regarding how such relationships influence company operations. Ramirez-Solis et al. (2022) discovered, based on research conducted among a cohort of small and medium-sized enterprises in Mexico, that surveyed companies benefit from interactions between managers and the business environment, viewing them as sources of new products and services.

Probst, Raub, and Romhardt (2004) define knowledge as the accumulation of knowledge and skills utilized by individuals to resolve problems. However, while various analyses affirm the fundamental significance of relationships with stakeholders and the business environment for the processes of acquisition, learning, decision-making, and problem-solving in enterprises (AlQuershi et al., 2021; Dar, 2019), the influence of capital on knowledge sharing within these relationships remains a research gap in the literature (Aisyah et al., 2019). As highlighted by Rzepka and Sabat (2022), the efficacy of knowledge utilization is contingent upon employees' receptiveness to external contacts and willingness to embrace innovation.

The problem of the relationship between an organization's agility and its innovativeness is relatively well represented in the literature on the subject. Agility should be understood as the organization's ability to survive in a turbulent environment (Głowacz, 2022), while innovation is defined as the enterprise's ability to create and implement new solutions (Stefaniuk, 2019). Most researchers (e.g., Sjödin et al., 2020; Alamsjah, 2022) represent the view that the impact of agile behavior in organizations on their innovation is positive. However, there are items in the literature that contradict this theory. Annosi et al. (2021), based on research on changes implemented in a large telecommunications company, draw the unexpected conclusion that increasing agility has a negative impact on the ability of local employees to generate new solutions.

The agility of an organization is impacted by a multitude of elements, among which are database management and information technology proficiency (also known as digital competencies). As per the Ministry of Digitization of Poland's definition, digital competencies comprise an integrated amalgamation of knowledge, abilities, and attitudes that are indispensable for efficient operation in a society where digital technologies are integral to

living, learning, and working. Digital capabilities exert both direct and indirect influences on the development of business flexibility and agility, particularly in the context of interactions with external partners (Saputra et al., 2023; Gonçalves et al., 2022).

Wang et al. (2022) have even advocated for the adoption of more advanced technologies, such as artificial intelligence, highlighting their potential to enhance organizational innovation by fostering a greater sense of innovation among management staff. Conversely, Khalil et al. (2023) underscore the significance of large database analysis as a factor positively impacting organizational efficiency, marketing, and organizational innovations. Khalil and Winkler (2023) have proposed a model elucidating how rapid resource acquisition and deployment, experimentation with alternatives, and the emergence of self-organizing business teams contribute to agility.

These activities often intersect with cloud computing, which is viewed as a competitor to the traditional functioning of IT departments within organizations. Deng et al. argue that organizations achieve agility through outsourcing, with IT solutions playing a pivotal role (2021).

Based on the literature review conducted above, the authors of this work conclude that there is a research gap regarding the interdependence between the type of interpersonal relationship and the level of use of digital competences in an organization. The few works in which researchers refer, but not directly, to this issue include the study by Madhavaram et al. (2023), in which the subject of interest is, however, the broader understanding of intellectual capital and its impact on the use of employees' knowledge and abilities for digital development. The text published by Ritala et al. (2021) seems to be slightly more consistent with the topic proposed in this article discussing the beneficial impact of relational capital on the scale of the use of digital technologies. Similarly to the case of digital competences, there is a noticeable need to enrich research in the area of the impact of informal relationships in an organization on its agility.

3. Research Methodology

The authors conducted research as part of the project titled "Interorganizational Relationships in the Socio-Economic Economy," implemented in collaboration between the Lublin University of Technology and the University of Warsaw from October 1, 2023, to September 30, 2024. The research aimed to delve into the essence of interorganizational relationships across five key areas: defining relationships, factors driving and impeding relationships, control over relationships, the role of leadership in establishing relationships, and analyzing the structure and competencies of organizations.

The initial stage of the research project involved conducting pilot studies from December 2023 to January 2024. The primary objective was to gather insights into the functioning of interorganizational relationships within various facets of organizational activities. The research sample comprised middle-level managers who were students of postgraduate studies, specifically the Master of Business Administration program at the Lublin University of Technology.

The study utilized the Paper and Pencil Interview (PAPI) technique, with 47 respondents participating from both the public and private sectors of the economy. An original survey questionnaire, comprising 15 closed questions and information, served as the research tool. Respondents' answers were assessed using a combination of single- and multiple-choice questions, along with a five-point Likert scale for enhanced precision in measurement.

Table 1: Division of Respondents by sex, position held, and type and duration of organization's existence (% of Respondents)

Sex	
Female	38.3%
Male	61.7%
Managerial Position Held	
5 years or less	19.6%
6-10 years	17.4%
11-15 years	23.8%
16 years or more	11.0%
No	28.2%

Type of Organization	
Private	51.1%
Public	42.5%
Other	6.4%
Duration of company's existence	
0-1 year	0.0%
2-5 years	7.1%
6-10 years	7.1%
11 years or more	85.8%

Source: Own study based on research

The analysis of the respondents shows that the respondents were mainly men who had held a managerial position for an average of 11–15 years in an organization that had been operating for at least 11 years. It is worth noting that 51.1% of respondents are members of Generation Y (millennials), whose view is dominant in the presented results. For the purposes of this article, the authors formulated two research hypotheses. Their verification will help achieve the research goal, which is to determine the types of relationships that have a positive impact on the degree of use of digital competencies and agility in the organization.

H1: Informal relationships influence the degree of use of digital competences in the organization.

H2: An organization that is characterized by informal relationships is more likely to have an agile structure.

To verify the above hypotheses, the Mann-Whitney test was used, which allows to identify differences between two populations in the context of a specific variable. The hypothesis will be confirmed when the significance level does not exceed p-value of 5%. When interpreting the results regarding the agile structure, the "I don't know" answer option was treated as the respondent's feeling that the structure in his organization is not agile but cannot be called non-agile.

4. Results

The fragment of research presented below focused on the interaction between the form of relationships existing in the organization, the agility of its structure, and the degree of use of digital competencies. For the purposes of analysis, the forms of relationships were consolidated into two population groups. The authors examined respondents' answers to identify informal, partnership, formal, and bureaucratic business relations.

Table 2: The form of the relationship, the degree of use of digital competencies, and the agile structure in the surveyed organizations

	Informal relationships and partnerships	**Formal and bureaucratic relationships**
The Degree of use of Digital Competencies		
Very Tall	13.8%	5.6%
Tall	41.4%	27.8%
Mediocre	41.4%	55.6%
Short	3.4%	11.1%
Very Low	0.0%	0.0%
Agile Structure in the Organization		
No	13.8%	27.8%
I Don't Know	27.6%	55.6%
Yes	58.6%	16.7%
Form of Relationship		
Formal Relations	27.7%	
Informal Relationships	27.7%	
Partnerships	34.0%	
bureaucratic relationships	10.6%	

Source: Own study based on research

In organizations where the surveyed respondents are employed, all four forms of relationships are identified. Partnership relationships were identified by 34.0% of respondents, while both informal and formal relationships received the same percentage of responses - 27.7%. Bureaucratic relationships were identified by 10.6% of respondents.

Digital competencies have a positive impact on the knowledge creation process within the organization. Respondents from work environments characterized by informal and partnership relationships rated the use of digital competencies in their organization at a medium or high level (41.4% each). In contrast, among respondents working in formal and bureaucratic conditions, 55.6% assessed the level of digital competence utilization in their organization as average. A very high level of digital competence utilization was indicated by 13.8% of respondents from informal and partnership teams, while this figure was 5.6% for respondents in formal and bureaucratic relationships.

Regarding the existence of an agile structure in the organization, differences were identified in the occurrence of agility among enterprises employing the surveyed respondents. Respondents from organizations characterized by informal and partnership relationships most commonly described the structure of their organization as agile (58.6%). In contrast, only 16.7% of respondents from the group with formal and bureaucratic relationships identified an agile structure. Moreover, 55.6% of respondents from this group were unable to identify their organization's structure as agile.

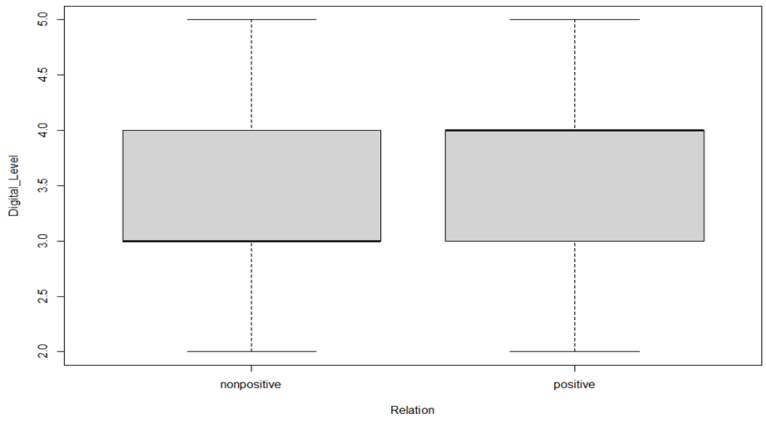

Figure 1:

Source: Own study based on research

The comparison of the degree of use of digital competencies in the studied populations using the Mann-Whitney test resulted in a p-value of 0.0545. This indicates that the level of digitization in both groups is statistically equivalent. Therefore, it suggests that informal relationships do not significantly increase the degree of use of digital competencies.

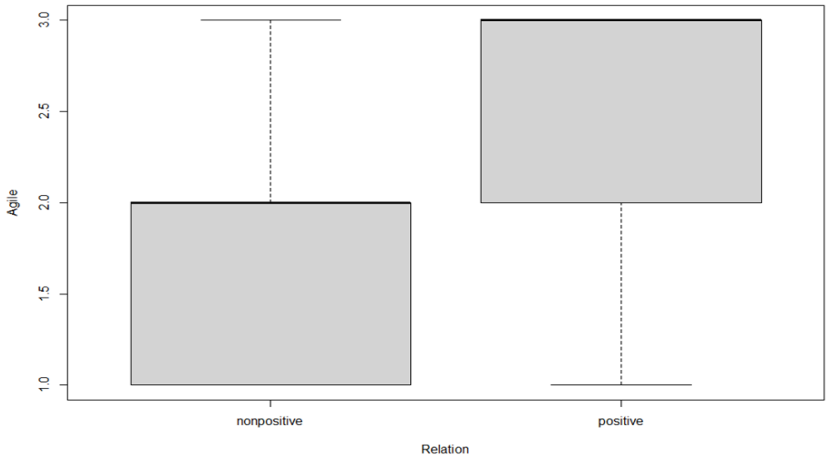

Figure 2:

Source: Own study based on research

The comparison of the presence of an agile structure in the organizations of the surveyed groups of respondents using the Mann-Whitney test yielded a p-value of 0.0051. This result confirms that informal relationships are associated with a more frequent occurrence of an agile structure within the organization.

5. Conclusions and Future Study

Based on the answers received from surveyed people managing various organizations, it was found that these entities usually use the digital competences of their employees to a large extent. At the same time, the statistical tool used in the study did not confirm that in organizations where informal interpersonal relationships dominate, this process is characterized by greater intensity, which means that the first hypothesis (H1) was not positively verified. The obtained results remain in some opposition to what can be read in the works of Madhavaram et al. (2023) and Ritala et al. (2021). In the first case it is concluded that elements of intellectual capital such as commitment, trust and intensity of relationships have a positive impact on software development and innovative capabilities in IT companies, and in the second one, the authors believe that they have at least partially confirmed the truth of the thesis that relational capital supports employees' achievement of goals related to the implementation of the organization's digital strategy.

The second hypothesis (H2), which linked the existence of informal relationships in the group of people employed in the organization with its agility, was confirmed. The conclusions drawn from the analysis remain largely consistent with what was obtained in this respect by other researchers whose publications were cited earlier. This applies in particular to works such as Sukarno et al. (2019), Ozgun et al. (2022) or Al-Omoush et al. (2020). Moreover, the results discussed above correspond to the conclusions of those authors who, focusing on the problem of leadership and its impact on organizational flexibility, quite strongly emphasize in this context the need for openness and departure from more traditional models (Rzepka & Sabat, 2022; Gren & Ralph, 2022; Reunamäki & Fey, 2022)

Analysis of the impact of relationships within the organization on various aspects of its functioning, including the growth and use of digital competences and agility, should be continued. However, examining personal relationships that constitute an intangible asset of every organization may pose some difficulties. In particular, it seems that there is a need to include in the arsenal of cognitive measures these tools that will enable more direct and reliable measurement. As Arszułowicz (2019) notes, this measurement may have a different nature and, therefore, could provide various information of a static or dynamic nature. Attempts are already being made to quantify what is difficult to measure in every organization, and the list of indicators that are potentially usable for the study relational capital is still growing (the set of selected ones is discussed, for example, by Vashishtha (2022)). The scope of knowledge about the possibilities of measuring digital competences is also expanding (e.g. Canina & Orero-Blat, 2021; Tomczyk, 2023) as well as agility (e.g. Yauch, 2011; Lacerda, 2020). This opens new perspectives for a better understanding of how human relationships and the capital based on them affect the knowledge sharing process, because, as Aisyah et al. (2019) writes, currently this phenomenon is still not fully recognized, and it is important both from the point of view of introducing and using digital technologies and organizational flexibility.

An International Comparison of the Sustainability of Knowledge

Andrea Bencsik
Unicersity of Pannonia, Hungary

bencsik.andrea@gtk.uni-pannon.hu

Abstract: Sustainability and organisational knowledge have been of interest to academics for decades, but the long-term sustainability of knowledge within organisations is a less researched area. This study aims to fill gaps in the literature on knowledge sustainability through the views of knowledge management practitioners. It will also provide a generally useful definition of knowledge sustainability. The research was carried out using the Delphi method. A two-round questionnaire survey was carried out involving professionals from 7 continents. The expert groups surveyed were TM experts, Business experts, and Academic staff. In the first round of the survey, 106 respondents expressed their views and ideas on the sustainability of knowledge in a free-text format, which was evaluated using Atlas.ti. In the second round, the statements of the questionnaire, based on a content analysis of the first round of responses, were ranked by experts on a 6-point Likert scale. In this case, 126 responses were received. The ranked statements were evaluated using IBM SPSS 25 statistical program and the validity of our hypotheses was tested. The results confirmed that a trust-based organisational culture, based on the values of sustainability leadership, is a prerequisite for knowledge sustainability. Alignment of the elements of the knowledge management process with organisational objectives is essential for the long-term sustainability of knowledge and the IT tools of the organisation play a dominant role. The comparison of the 3 groups of experts isolated in the study and the opinions by continent did not show any significant differences. As a final summary of the results of the research, a definition of knowledge sustainability was formulated, which provides a new basis for further research into the theory and practice of building sustainable knowledge management systems.

Keywords: Knowledge Management, Sustainable Knowledge, Trust, International Research, Delphi Method

1. Introduction

The problem of knowledge loss has been around for centuries, even millennia, but research on its importance is not a preferred area of research (Massingham 2018; Levallet and Chan 2019). This gap is evident at both theoretical and practical levels. Research on the long-term preservation and sustainability of knowledge is therefore essential. This means that the integration of the knowledge management (TM) process into organisational operations is also a key to the future success of the organisation. A specific set of tools is needed to ensure synergy between organisational knowledge and long-term organisational performance. Sustainable organisational functioning has been a strategic priority for many years. It is a development process or organisational principle that meets the needs of the present without compromising the ability of future generations to meet their own needs (Our Common Future 1988). This definition opens the door to a sufficiently wide range of choices and actions. Thus, the different disciplines and organisational needs determine to a large extent the current actions behind the 'slogans'. The present research does not consider the application of traditional indicator systems but uses their values to develop an option focusing on the transferability and long-term preservation of knowledge.

The research questions were formulated as follows:

- What does the sustainability of knowledge mean for knowledge management experts and researchers?
- What conditions are needed for the long-term sustainability of knowledge?

The research aims to define the definition of knowledge sustainability and to define the organisational conditions for knowledge sustainability. To answer the research questions and to achieve the objective, a practical study was launched using the Delphi method after a literature review. These are presented in the following chapters. The significance of the study is that it (1) fills a gap in the definition of sustainable knowledge, (2) articulates the conditions for sustainable knowledge, (3) provides an international comparison between the views of KM experts, academic researchers and practitioners.

2. Literature Background

2.1 Sustainable Knowledge

According to the resource-based approach, knowledge is a unique internal resource (Freeman *et al.* 2021) that can only bring a competitive advantage if it is used wisely to develop the internal capabilities and competencies that best support the sustainable practices of the organisation. When the market is uneven, competition is at its

peak, profit is dominant, and the strategic position of organizations can be compromised (Gibson *et al.* 2021; Mishra 2019). In such a situation, traditional practices fail to deliver the expected results. Therefore, organizational knowledge becomes a potential resource that can make a pioneering contribution to building the strategic position of organizations (Torres *et al.* 2018). Lopez-Torres *et al.* (2019) in their research have shown how SMEs can adopt knowledge management as an effective strategy to make their operations sustainable. A knowledge culture thus developed is vital for organisations to operate effectively and sustainably (Shujahat *et al.* 2019; Caniglia *et al.* 2021; Glikson and Woolley 2020). Sustainable knowledge and knowledge management go beyond the typical expectations of sustainability in general (such as the preservation of the environment, the necessary use of renewable energy sources, etc.) and think on a scale that seeks not only to create the physical conditions and theoretical possibilities but also to imagine the conditions for an innovative future while achieving social well-being. As is well known, the most critical issue in the knowledge management process is how to solve the problem of sharing knowledge and thus preserving what has become common knowledge. In discussing the sustainability of knowledge, the research logic that characterises sustainability in general is reversed. It is not a question of how knowledge management helps an organisation to operate sustainably. The question is what organisational conditions and operations are needed to preserve and maintain common organisational knowledge in the long term. Phrased in this way, the role of trust in influencing knowledge sharing, capture, collaboration, culture building, etc. becomes clear. These factors call for a holistic approach and a complex way of thinking (Muhammad *et al.* 2020). In summary, to assess knowledge sustainability, it is necessary to go beyond the published knowledge to explore opinions that provide a legitimate basis for a more precise and broader definition and, at the same time, to explore the organisational conditions.

3. Research Methodology

The research represents a new approach and contribution to current knowledge in the field, both in theory and practice. We used both qualitative and quantitative methods, which were conducted using the Delphi method. We conducted a two-round questionnaire survey involving professionals from 7 continents. Respondents were classified into 3 groups: TM experts, business experts, and academic staff. In the first round of the survey, respondents expressed their views and ideas on the sustainability of knowledge in a free-form format. In the second round, the respondents were asked to rank the statements of the questionnaire, based on a content analysis of the first round of responses, on a 6-point Likert scale. The free-form responses of the first round were analysed using Atlas.ti. The statements ranked in the second round were evaluated using IBM SPSS 25 statistical software and then tested for the validity of our hypotheses.

3.1 Delphi Method

The Delphi method is a well-structured visioning method based on expert opinion, which gathers the opinions of experts on a given research problem in at least two rounds. It facilitates the acquisition of a variety of information that can help to provide a more comprehensive understanding of the research topic. Its anonymity and iterative nature ensure the expression of open ideas and opinions and allow for multiple returns to help further refine opinions.

The Delphi technique has four main features:

- anonymity between participants,
- iteration with controlled feedback from the group,
- statistical aggregation of the group's responses
- expert input.

Anonymity allows views to be expressed and changed in private, controlled feedback iteration ensures communication between participants and the sharing of perspectives, statistical aggregation of group responses allows data to be analysed and interpreted, and finally the concept of expert input suggests that all participants are knowledgeable in the area under study (Trevelyan and Robinson 2015).

A large body of research has marked the application of the method and it is often added to the palette of research methodologies in different disciplines (Hirschhorn, 2019). In recent years, it has been used successfully, mainly for research in education and health (de Villiers et al, 2005; Chitu & Pawlowski, 2004; Hsu & Sandford, 2019; Vogel et al, 2019; Chalmers et al, 2019; Varndell et al, 2021; Sablatzky, 2022).

A key part of the Delphi method is to select the right experts to ensure the quality of the results (Paré *et al.* 2013). The target group for our research is a group of experts with a high level of professional experience in the research topic.

The experts in this research are divided into seven panels and two-panel groups. The first-panel group is defined by the main source of opinion of the responding experts. The second group of panels is composed of four panels based on the continent from which the experts' views originate: Europe, America, Asia and the fourth panel is classified as Other. The panels allow the identification of cultural and contextual differences, which can contribute to the reliability and relevance of the research. Experts were selected using the multi-stage approach proposed by Okoli and Pawlowski (2004). A 'knowledge source identification worksheet' was developed to identify the relevant background and skills of the experts. The main selection criterion was the experts' years of experience in knowledge management and their work experience. The questionnaires were sent out online to experts from academic professional societies, websites, professional journals, conference participants, university websites, corporate websites, LinkedIn groups, etc. at the international level. Both rounds of the survey were conducted in approximately 3 months. In the first round, experts were asked to freely express their views on the topic of "**sustainable knowledge as the key to a successful, sustainable future**". The second questionnaire, based on the analytical results of the first round, asked respondents for their value judgements on the statements made, organised around four groups of questions. The second questionnaire followed the procedure of the "ranked" Delphi tests as defined by Schmidt (1997). The statements in the questionnaire were ranked individually and independently using a six-point Likert scale.

Question groups for Questionnaire 2:

- Knowledge sustainability goals and values
- Organisational culture, the role of leadership
- The link between knowledge management and knowledge sustainability
- The link between technological background and knowledge sustainability

3.2 The Sample

Delphi 1 - 1000/106 answers

Respondents:

- TM experts - 38,2%
- Business professional - 28,3%
- Academic sector - 33,5%

7 continents

- Europe - 44,8%
- Asia - 21,9%
- North America - 13.5%
- South America - 10.4%
- Africa - 5.2%
- Australia - 4.2%

Delphi 2 - 1000/126 answers

The characteristics of the first round of respondents are shown in Table 1.

Table 1: Characteristics of Delphi first-round respondents

Features	n	%
The main point of view/source of opinion comes from the following experience:		
• Knowledge management expert	48 persons	38 ,2%
• Individuals working in academia	42 persons	33,5 %
• Company specialist	36 persons	28,3%

Features	n	%
Professional experience in a field related to knowledge management:		
• Less than 5 years	9 persons	7,1 %
• Between 5 and 10 years	21 persons	16,7 %
• More than 10 years	96 persons	76,2 %
Field of qualification:		
• General Business Management / Economics	63 persons	54 %
• Human resource management	58 persons	46 %
Highest level of education:		
• Bachelor training	9 persons	7,2 %
• Master training	62 persons	49 %
• Doctoral studies (PhD.)	55 persons	43,8 %
The continent from which the main point of view/opinion originates:		
• Asia	28 persons	21,9 %
• Africa	7 persons	5,2 %
• North America	17 persons	13,5 %
• South America	13 persons	10,4 %
• Antarctica	0 persons	0 %
• Europe	56 persons	44,8 %
• Australia	5 persons	4,2 %

Source: own editing

Hypotheses

H1. There are significant differences in the way knowledge management experts, academics and business professionals define knowledge sustainability.

H2. There are significant differences between the opinions of experts from different continents.

4. Analysis

Atlas.ti software was used to evaluate the data. The software was used to perform a content analysis based on the first round of expert opinions. The content analysis process consisted of six steps.

- create a new project using the software (name, save location)
- importing replies received
- automatic encryption
- making memos
- list of most common words
- raw data processing

The most common terms are listed and also in the form of a word cloud.

Table 2 shows the most common terms.

Table 2: Delphi first round list of most common terms

Terms	Frequency of occurrence (n)	Frequency of occurrence (%)
Knowledge Management	126 pieces	100%
Organisational processes	112 units	89%
Organisational goals	109 pieces	87%
Corporate (business) strategy	106 units	84%

Terms	Frequency of occurrence (n)	Frequency of occurrence (%)
Competitive advantage (added value, organisational performance)	102 pieces	81%
Long-term thinking	99 pieces	79%
Cooperation (collaboration)	97 units	77%
Organisational culture	94 units	75%
Extremely important/essential/key	93 db	74%
People at the centre	90 pieces	71%
Strategic decisions/decision making	88 pieces	70%
IT solutions (IT, technology)	85 pieces	67%
Skills, competences	83 units	66%
Ethical issues	82 units	65%
A rapidly changing world	79 pieces	63%
Knowledge creation/creation	78 units	62%
Knowledge sharing	78 units	62%
Knowledge management system(s)	75 pieces	60%
Knowledge development/improvement	72 pieces	57%
Knowledge identification	72 pieces	57%
Ownership of knowledge	71 units	56%
Use of knowledge	71 units	56%
Tracking and tracing	67 units	53%
Dissemination	66 pieces	52%
Investment	64 pieces	51%
Communication	63 pieces	50%
Knowledge preservation	59 pieces	47%
Knowledge transfer (handover)	59 pieces	47%
Innovation	57 pieces	45%

Source: own editing

After identifying the most common terms and words, the second phase (questionnaire) was prepared. In this case, starting a new project with the software, the aim was to formulate the groups of questions and the questions to be asked to design the questionnaire, based on the most frequent expressions, words and phrases. The groups of questions and the questions assigned to them are shown in Table 3. After finalisation, the questionnaires were sent again online to the previous target group.

Table 3: Delphi Round 2 question sets and questions

Questions	Description of questions
Knowledge sustainability goals and values	• Organisational goal of knowledge sustainability • Knowledge sustainability as an organisational competitive advantage • Helping to achieve organisational goals • Integration into organisational activities • A vital factor for the 21st century • Making better decisions
The role of organisational culture	• An organisational culture based on trust • Cooperation and shared values between organisational members and management • Implementing the principles of sustainability management • Adequate and continuous training of employees • Ethical issues raised

Questions	Description of questions
The link between knowledge management and knowledge sustainability	• Incorporating elements of the knowledge management process • Continuous, unconditional knowledge sharing between organisational members • Knowledge development/learning renewal • The role of organisational memory • Aligning knowledge management with organisational goals
The link between technological background and knowledge sustainability	• The important role of IT background • Organisational members' trust in technology • Appropriate level of technological background • The role of artificial intelligence • IT solutions as a key role • IT knowledge and skills of organisational members

Source: own editing

The Delphi method and the SPSS program were used to test the hypotheses (to detect differences between expert and national panels).

The Delphi method allows a group of experts to measure consensus. For the second questionnaire, the mean and standard deviation of the responses were examined during the data analysis to understand the heterogeneity or homogeneity of the responses. Next, we focused on measuring the consensus by calculating the median and the interquartile range. In the case where the responses to a query are ordinal, the median can be defined as a measure of central tendency and the interquartile range (IQR) as a measure of dispersion (Hsu and Sandford 2007; Garson, 2014). The interquartile range is a statistical measure used to characterise the dispersion of data. IQR is the range between 25-75 percentile points above and below the median. So IQR represents the middle 50% of the distribution of the data. The interquartile range helps to measure consensus among respondents. In cases where the IQR is relatively small, we can speak of a higher consensus. Conversely, if the IQR is high, it means that opinions are spread over a wider range and there is no consensus. Outlier values are not included in the calculation of IQR and therefore do not bias the result. This allows for a clearer and more objective assessment of the degree of consensus. The use of IQR allows comparisons of consensus between different groups. Following Kittel-Limerick (2005), a value of 2.5 was set to determine consensus. SPSS software was used for this process, with a 5% significance level. The software summarised the results in a table, which allowed us to determine the degree of consensus for each panel group. Due to space limitations, we present as an example in Table 4 the results of the first (knowledge management expert, academic, corporate) and second (European, American, Asian, other continent) panel groups for the six statements related to the first group of questions (Knowledge Sustainability Goals and Values). Following a similar procedure (also analysing the other three groups of questions), we obtained the terms and vocabulary from the experts' opinions which, when summarised, define knowledge sustainability.

Table 4: Results of the first and second-panel groups' responses to the first set of questions.

Knowledge management expert			Individuals working in academia		Company specialist	
Claim	**Median**	**IQR**	**Median**	**IQR**	**Median**	**IQR**
1	5.00	1	4.00	1	5.00	2

In order to verify the validity of the definition, we focused on the questions in the four groups of questions that received the highest scores from the experts. These results are illustrated in Tables (5, 6, 7, 8) below.

Table 5: Knowledge sustainability goals and values

Claims	N	Average	Source
The organisational goal of knowledge sustainability is to increase the added value for stakeholders within the organisation.	126	4,71	1,24
Ensuring knowledge sustainability has become a key source of competitive advantage for organisations in a rapidly changing world.	126	**4,93**	1,01
Knowledge sustainability helps to achieve organisational goals.	126	4,68	1,24
Knowledge sustainability must be embedded in organisational activities.	126	4,92	1,10
In the 21st century, knowledge sustainability is a vital factor for organisations, regardless of the industry they operate in.	126	**5,22**	0,83
The value of knowledge sustainability is used to make better decisions.	126	**5,04**	1,00

Source: own editing

Table 6: Organisational culture and knowledge sustainability

Claims	N	Average	Source
A key to the sustainability of knowledge within an organisation is an organisational culture based on trust, where members of the organisation and its management work together.	126	4,79	1,17
Ensuring the knowledge sustainability cycle depends on the cooperation and shared values of the members of the organisation and its management.	126	**4,94**	1,01
To make knowledge sustainable in the long term, it is necessary to apply the principles of sustainable management.	126	**4,82**	1,09
Appropriate and continuous training of employees is a key element for successful knowledge sustainability.	126	4,66	1,29
Knowledge sustainability within the organisation raises ethical issues (e.g. inappropriate data management, etc.) that need to be addressed.	126	**5,00**	0,88

Table 8: Technological background and knowledge sustainability

Claims	N	Average	Source
The organisation's IT environment plays an important role in making knowledge sustainable within the organisation.	126	4,35	1,20
To ensure the long-term sustainability of knowledge within the organisation, organisational members must have IT knowledge and skills.	126	**4,75**	1,18
IT solutions are more important than other conditions.	126	2,85	1,58
Without artificial intelligence, the sustainability of knowledge cannot be ensured.	126	3,72	1,49
To make knowledge sustainable in the long term, it is necessary to have the right level of technological background.	126	**4,91**	1,14
A vital element of successful knowledge sustainability is the trust that organisational members have in technology.	126	**5,02**	1,05

Source: own editing

A definition of knowledge sustainability, summarised from the above peer review and opinions:

Knowledge sustainability is a vital organisational strategy to make better decisions for ethical and sustainable organisational operations by preserving the value and usefulness of knowledge (tacit and explicit) in the organisation over the long term. It contributes to gaining and maintaining a competitive advantage by continuously updating existing and new knowledge, embedded in organisational activities. At the heart of knowledge sustainability is human capital, the prerequisites for its provision within an organisation:

- An organisational culture based on trust (personal and impersonal), where members and management of the organisation work together in a spirit of sustainable leadership.
- Integrating the elements of the knowledge management process into organisational processes, ensuring a continuous, evolving, knowledge-sharing cycle of knowledge.
- Ensuring a high level of availability of the technological background supporting the knowledge management process, maintaining the stress-free operation of technology, ensuring digital and workplace well-being.

The definition also answers the research questions.

An ANOVA test was performed to test the validity of the two hypotheses. In order to explore the differences in mindset between each panel group, a Post-Hoc analysis was conducted. It allows us to make further detailed comparisons between groups or variables. Within the group of Post-Hoc analyses, we used Tukey's HSD (Honestly Significant Difference) test, which is mainly used to perform multiple comparisons in ANOVA analyses. The result was that there was no significant difference between the panels. Although there were statements with different perspectives in the two panel groups of experts interviewed, overall there were no significant differences.

5. Discussion and Conclusion

The definition of TM confirms that investment in intellectual capital is a key to competitiveness (Zsigmond and Mura 2023). The need to build knowledge management systems and to integrate them into organisational operations is a decades-old business model in Western societies, but a less preferred business model in less successful economies, such as in Central and Eastern Europe (Marquardt *et al.* 2023; Talmo and Bonanomi 2015). The need to build systems is often expressed at the level of management and strategy, but very few firms reach the level of operational implementation. *Organizational* competitiveness and success are inextricably linked to

learning and knowledge, which can be combined into ultimate performance at the organizational level through knowledge management processes (Ayatollahi and Zeraatkar 2019; Škudienė 2021; Abrams *et al.* 2003). In recent years, there has been a lot of research and publications discussing the results of this research on the relationship between knowledge sharing and trust (Darroch 2005; Sankowska 2013; Paliszkiewicz and Koohang 2013; Alsharo *et al.* 2017; Kipkosgei *et al.* 2020; Ayadi *et al*. 2020). Without exception, all confirm that trust influences the occurrence, quality and depth of knowledge sharing, and thus is closely related to the construction and functioning of organizational knowledge management systems. Competitiveness and economic success are interrelated in the so-called "knowledge management". "In this context, competitiveness and economic efficiency are interrelated with 'soft' factors, with a back-and-forth effect. These are long-term factors, focusing on short-term economic indicators can diminish their value, but ignoring them is an untapped opportunity. Knowledge management systems provide organisations with a framework for the long-term preservation of knowledge within a culture of trust (Miller 2019). However, research has not yet reached the point of defining the conditions and practices for the sustainability of necessary and up-to-date knowledge. To formulate an answer, we sought a basis - based on the wisdom of collective thinking - using the Delphi method. The results of a free-form consensus search based on the opinions of international expert groups and their analysis led to a definition of the long-term sustainability of knowledge and the organisational conditions for it. The definition was developed on the basis of expert ratings of the statements of the four groups of questions. The terms of the statements with the highest average score appear in the definition. The results of the consensus search show that the opinions of the expert groups and scientists from the continents on the sustainability of knowledge are converging.

5.1 Research Limitations and Further Possibilities

The limitations of the research are all factors that are specific to questionnaire surveys. First of all, the willingness to respond, which is a problem apparently all over the world. Although the Delphi method combines qualitative and quantitative approaches, at its core, the bias of expert respondents' informal expression of opinion must be taken into account. Professionalism, honesty, reservations about identifiability, possible misinterpretation of questions can be questioned. Despite our best efforts, these factors may affect the outcome. In the future, it would be useful to extend the studies by collecting additional samples. The results obtained, the definition could be further refined by increasing the sample size and/or ensuring representativeness. The inclusion of additional countries from different cultural backgrounds would allow for a more refined comparative analysis and provide an even deeper understanding of the knowledge sustainability practices of organisations and the possible cultural influences in their context.

Abstract: Knowledge Management (KM) and Creativity Management (CM) are increasingly linked to the analysis of healthcare management. The health management of the Covid 19 emergency has amply demonstrated how these two frameworks, which are widely debated in the literature, find practical operational feedback albeit with profound lights and shadows. This study aims to investigate the contributions and threats of KM and CM within the context of local healthcare in order to highlight, using a quantitative methodology, which variables impact healthcare management the most and which variables are negligible. The analysis conducted concerns a sample of 200 healthcare workers from one of the Italian regions that has been most affected by the pandemic and will show how quickly healthcare management has changed in terms of internal procedures and relationships with stakeholders, subverting the paradigm of "rational planning" connected to typical CM variables.

Keywords: Knowledge Management, Creativity, Healthcare Management

1. Introduction

In recent years, the healthcare system has been changed by notable pushes towards the introduction of managerial models (Berardi et. al, 2022; Cepiku et. al, 2021). If we considered the situation a few years after the change process, the result is a made up of positive and negative factors.

The positive factors undoubtedly consist in the fact that we hear more and more about management control, budgeting, reporting and so on, and that after so many words the first concrete applications of these tools are starting to appear. To these positive factors, however, we must add a substantial series of negative factors; we refer in particular to these facts:

- the new management along with its control tools have been interpreted mainly as a method to reduce and cut costs (Boyne, 2001);
- little attention has been paid by management models to the effectiveness and healthcare quality (Di Vincenzo et. al, 2022) ;
- as a consequence of this, the medical component, despite having to play a primary role in the application and use of these tools, has ended up being the great exclusion in many cases (Crosby et. al, 2017).

The limits just mentioned certainly constitute a valid stimulus to reflect and rethink healthcare management models and tools regarding most recent studies regarding creative management in the intelligent management of business processes (Kamara et al., 2002).

Part of the international literature highlights the need to combine traditional models of management and control of business processes with analyses focusing on the quality of the services offered considering the ability of healthcare workers to adapt to social and economic changes (Heeks, 2002 and 2003).

On this topic, the literature has highlighted how the COVID-19 pandemic represented the catalyzing event towards a process of profound rethinking in the management of public health.

While on the one hand the New Public Management has introduced the concept of rational planning (indicator) and achievable (target) objectives, the emergence of extraordinary and often unpredictable events have led the public-healthcare system to review the traditional programming levers by introducing new variables such as unconditional trust towards healthcare workers (trust) and the management of the unexpected on a par with so-called ordinary management (Sternberg et a., 1997).

In this scenario, the ability to adapt and creativity of healthcare workers represents the lever that allows critical issues to be overcome. Creativity and passion are of particular relevance to mission and vision statements. A

simple definition of creativity is the power or ability to invent. We sometimes think of creativity as being a purely artistic quality, but creativity in business is the essence of innovation and progress (Sargiacomo et al., 2021).

Defining passion we intend an intense feeling or conviction. Passion is also associated with intense emotions. This means that a point of view should reflect and communicate something that is relatively novel and unique, and such novelty and uniqueness are the products of creativity and passion (Robinson et. al, 2008).

On this topic, international literature has shown how the management of the COVID-19 health emergency was brilliantly overcome thanks to the creativity and passion of healthcare workers who, through the re-engineering of healthcare action plans (knowledge management in practice) led to the innovation of traditional managerial models.

On these premises, our paper will analyze the changed context of the management of health services through the field analysis of one of the Italian contexts hit by the COVID-19 pandemic event, namely the Abruzzo region. Our same reference context has in fact been the subject of numerous studies on the topic and even the international database "WHO Covid 19" has indexed numerous contributions on this topic. In this regard, as confirmed by the literature, although the Abruzzo population represents only 4% of the Italian population, the impact of the pandemic has literally exhausted the local healthcare system and only the profound dedication and creativity in managing the pandemic has allowed us to react very quickly to the health emergency (Papi et al., 2018).

By applying a quantitative methodology to the context of healthcare in Abruzzo, this work aims to answer the fundamental research question: what is the role of creativity management and knowledge management in the healthcare system?

To answer the research question, we structured the paper as follows: the literature review constitutes the link between Knowledge Management (KM) and Creativity Management (CM); the methodological section will describe the methods and times of the investigation we conducted in order to investigate the strengths and weaknesses of the reference frameworks. Finally, through the analysis of the results we will show the efforts made by the healthcare sector and how the new approach adopted has revolutionized the traditional management of public healthcare management. These conclusions will outline the limitations of our research, the weaknesses of the model adopted and provide ideas for further studies.

2. Literature Review

Creating value is the primary objective of a company and the managerial tools, behaviors and actions of each operator are inspired by this model. For healthcare companies, the value creation model can be valid as long as it is considers the peculiarities that characterize these companies. If creating healthcare value can become the strategic objective of a healthcare company, it is essential, at this point, to evaluate which are the key variables appear to be the paths for creating value.

The old management "tools" such as budgeting and reporting can be enriched from this perspective and constitute an excellent support for all operators, first and foremost for the medical profession, which for various reasons was in the past and still is today more reluctant and less involved in the use of these tools. The value creation model can become the underlying philosophy which inspires all healthcare management tools and can constitute the common language to facilitate meeting, dialogue and comparison of the different professionalities and cultures that coexist within healthcare companies.

In this regard, part of the traditional doctrine identifies the "Knowledge Management Cycle" as the ideal approach to creating healthcare value (figure 1). Knowledge management is commonly defined as the strategic and organized approach aimed at identifying, capturing, storing, organizing and distributing knowledge within an organization. The main objective of this approach is therefore to maximize the use of available intellectual resources, to improve operational efficiency and to promote innovation.

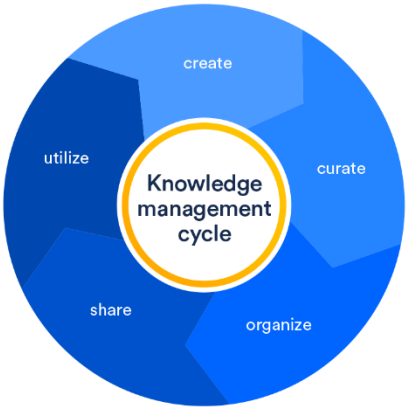

Figure 1: Knowledge Management Cycle (Machlup and Drucker,1978)

The knowledge management approach requires a series of activities to be put into practice: they range from the identification of knowledge to the evaluation and measurement of its effectiveness. Performing these activities perfectly, however, is not necessarily a guarantee of success: knowledge management is truly effective when it is supported by the creation of an organizational culture that promotes knowledge sharing, continuous learning and innovation.

It is therefore not enough to collect and share company knowledge, but it is necessary to convey the message at all levels that knowledge sharing is an essential part of the success of every company activity (Al Ahbabi, 2019; Capolupo et al., 2023). Thanks to knowledge management, the knowledge and skills attributable to this knowledge are not the exclusive relevance of a few, but become accessible to all. Having this fundamental advantage linked to knowledge management , it is also possible to identify other factors that are a direct consequence of:

- Improved productivity - as a strategic and structured approach, knowledge management allows for efficient management of information and, consequently, reduces the time needed to find answers or solve problems, thus supporting the organization's productivity.
- Risk reduction - the collection and sharing of knowledge can also support the identification and effective management of risks, as having access to accurate documentation of crucial information allows you to make informed decisions and potentially prevent, costly mistakes .
- Quality improvement - through the sharing of best practices it is in fact possible to facilitate the continuous improvement of operations and the general quality of its products and services.
- Skills development - the systematic sharing of company knowledge also allows for continuous training and the development of the skills of its collaborators, who can easily access training materials to improve their professional skills.
- Preservation of company know-how - thanks to knowledge management it is possible to share specific knowledge, possessed only by collaborators who carry out a particular activity and which would risk being lost with staff rotation.
- Support for Innovation - it may seem obvious, but it is of fundamental importance to share past experiences and solutions that can stimulate new ideas and innovative approaches.

Therefore, it is clear how knowledge management can significantly contribute to the success and growth of an organization by improving operational efficiency, stimulating innovation and allowing organizations to preserve and transmit the fundamental know-how to carry out their activities (Battiston et al., 2020; Capolupo et al., 2023).

At the same time, this approach is not particularly effective where extraordinary events, for example the COVID-19 pandemic, compromise the natural course of events by jamming the gear of the "Knowledge Management wheel". In these cases, the human capital of corporate organizations represents “The key that unlocks the chain”. As is known, the behaviors of people are characterized by numerous variables including: the predisposition to sacrifice, to teamwork, along with the previously gained experiences.

All things being equal, the literature highlights the creativity of individuals (creativity management theory) as the ability to overcome any corporate critical issues and guarantee the creation of corporate value.The health care

industry needs creativity and innovation to address challenges with quality, safety, cost, and access to care through the development and implementation of new or improved policies, processes, systems, products, technologies, diagnoses and treatments, services, and care delivery methods (Amabile, 1990). In this sense, creativity management is a system of principles, methods, techniques, practices, and instruments for managing employee creativity to get the maximum effect for the organization according to its goals, objectives, employee contingent, and available resources (Amabile; 1996; Ambabile et al., 2014; Al-Husseini, 2024).

Regarding creativity management literature (Patwary et al., 2024; Lubart, 2017) evidence on “the 7C’s the core” create a strong foundation to relate in a more mindful way. More specifically:

- Curiosity: we know that we don’t know everything and that we can’t know everything. When we reconnect with our curious side and practice being open to whatever we find.
- Cognition: By taking the time to explore our thoughts, we can also explore why we perceive, reason and understand in the way we do. As we learn to look at our thoughts, feelings and responses from a more objective point of view, we can begin to see things with greater clarity and understanding and how context can impact our words, actions and decisions;
- Compassion: when we’re compassionate, we decide to accept and engage with ourselves and others with kindness, without judgement, reaction or disengagement. Learning how to engage with ourselves and knowing which strategies we can use to take a gentler approach when times get tough is so important;
- Cultivation: We know learning a new skill or practice can be a messy one, with ups, downs, setbacks and breakthroughs; we get the most out of committing to something when we are able to do so in a consistent but flexible way. Creating meaningful changes can lead to genuinely profound shifts in perspective and behaviour and they take time, practice and patience;
- Celebration: a lot of the time we are so focused on the result, we overlook how far we have come. When we celebrate our achievements, we acknowledge and honour our effort, creating positive feedback loops that keep us motivated when times inevitably become difficult. Learning how to celebrate the journey allows us to experience more joy and gratitude;
- Community: the community is so important in our lives as in community, we find encouragement, accountability, and diversity. Having awareness of our strengths and knowing what we can offer others is so valuable. Being part of a community creates a more compassionate and curious culture where we can foster a sense of openness and kindness together, whilst reducing judgement and increasing tolerance;
- Connection: it’s how we build relationships, understanding and behavior. If we can connect to ourselves, others, and the world around us with understanding and compassion, we can fill the empty spaces in realtionships.

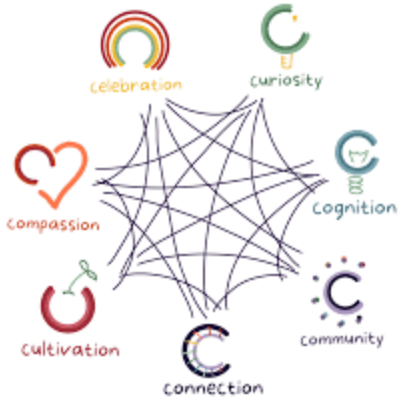

Figure 2: Creativity Management 7C’s (Lubart,2017)

The combination between a knowledge management (KM) and creativity management (CM) approach appears to have been the winning key for overcoming traditional approaches to healthcare management in the period preceding the pandemic emergency. The creation of healthcare value was in fact the final product of a "team game" involving a large series of variables, whose behavior was coordinated and balanced in a synergistic way. In particular, the variables of the model are divided among themselves according to a dual criterion:

- causal, whereby final health state objectives are identified (value for users), and intermediate (or instrumental) objectives aimed at achieving the former, and therefore logically connected to them by a cause/effect relationship that management it must necessarily presuppose.
- temporal, in the sense that the pursuit and realization of value creation requires a balance between actions whose effects will materialize in a short-term time frame, and medium-long term objectives aimed at preparing the conditions to guarantee in the long term the ability to create value. This category includes objectives linked to innovation and skills development projects, research, and the training of resources, the effects of which on the state of health of the population will not be seen immediately, but over a broader time lapse.

The value model thus articulated constitutes a conceptual structure that is no longer static and must not be translated through management support tools and mechanisms.

For this purpose, traditional programming and control "tools" can be profitably used, reviewed and re-calibrated with a view to creating value. This instrumentation has traditionally been based on a very simple logic: it is necessary to plan (first establish which results one intends to achieve) and control the management (then check whether the results being achieved are in line with the expected ones).

In particular, the theory of rational planning (Berardi et. al, 2021; Capolupo et. al, 2023) involves setting objectives and planning commitments and activities, to realize in advance, the possible problems that may be encountered and therefore study the countermeasures and solutions. Subsequently, while management, ascertain whether "things are going as expected", i.e. whether management is taking place in accordance with plans, to promptly realize the need to adopt appropriate corrective measures. Finally, verify in the final analysis whether the actual results corresponded to the planned ones, to "calibrate the aim better" in the development of subsequent programs.

The effort made by healthcare professionals (managers and employees) with respect to this general model we must adapt this formula to the logic of value, filling tools such as the definition of strategic objectives, the budget, reporting with specific contents.

Although COVID-19 has shocked the world and has hit most countries, businesses, and individuals unprepared, this sudden disruption has forced many of them to come up with innovative solutions and improvise, mainly to tackle the health emergency. While the health risks are currently the most frightening and upsetting, the social and economic crisis has vastly “resetted everything” (Berardi et. al, 2021).

3. Methodology

Considering previous literature, we focus our study on the same geographical area that has been investigated by other authors such as Battiston et al. (2021), Marziano et al. (2021) Berardi et al. (2021b, 2022) to provide more details that can contribute to a better understanding regarding how the public policy has affected local authorities. In the period between September 2023 and January 2024 we conducted 190 interviews with public employees from all the 4 main local healthcare districts (ASL), divided into the three macro categories: Deputy Employees (150 interviews), Managers (30), Senior Managers (10). Those four health hubs are the largest in terms of total customers of the Abruzzo Region (296.130 inhabitants in the four municipalities over 1.312 million of total inhabitants of the entire region) and have been largely investigated by Italian literature (Sebastiani et al., 2020; Berardi et al., 2021).

Table 1: Demographic characteristics of the respondents

Employee	**Deputy Employee (150)**		**Managers (30)**		**Senior Managers (10)**	
	Frequency	%	Frequency	%	Frequency	%
Age						
18-30						
31-44	10	6				
45-59	115	76	25	83	10	100
60 - 79	25	18	5	17		

Employee	**Deputy Employee (150)**		**Managers (30)**		**Senior Managers (10)**	
	Frequency	%	Frequency	%	Frequency	%
80+						
Gender						
M	90	60	25	83	8	80
F	60	40	5	17	2	20
Education						
No schooling completed						
Nursery school to 8 year grade						
High School	120	80				
Bachelor or master's Degree	30	20	30		8	80
Phd					2	20

In Table 1 we report the demographic profile of the respondent. Starting from this dataset we extract from interviews our dependent variable (Y) called "Knowledge and Creativity Contribution" computed as the use of new procedures inducted by national policies on digitalization of procedures to achieve smart governance (Vial, 2019). Such a variable was based on prior studies and used a validated single item measure (de Jong & den Hartog, 2010; Mascia &Cicchetti, 2011), by asking them: "how has your creativity influenced the response of your structure to the community needs in terms of healthcare?'.

This measure captured the effectively effort of creativity on KM procedures introduced in the local body with responses on a five-points scale, ranging from 1 (never) to 5 (very frequently). We chose this variable considering the impact that the central government acts (derived to the legislative decree 18/2020) had on the introduction of KM paradigms and logics in the healthcare sector. The dependent variables reconduct to Creativity variables as identified by international literature (Ramirez, 2020) and illustrated in table 2 in coherence with the process phase of the "knowledge management toolkit" (Robinson et al., 2010) measured with a Likert scale 0-5.

Table 2: Research items of the process phase of the C7's items

Process research Items	**Deputy employee**	**Managers**	**Senior Managers**
	Likert scale average	Likert scale average	Likert scale average
Curiosity and cognition	**2**	**4.66**	**4.66**
Community and Connection	**1**	**5**	**5**
Cultivation, Compassion and Celebration	**1**	**3**	**3**

Once the indicators were defined, the following regression model was applied (OLS) to consider all the variables included in the survey (Berardi et. al, 2021). In the equation below, Y represents the dependent variables, *α* represents the constant of the model, β represents the coefficient of the estimation of the variables (independent variables), logxni represents the logarithmic conversion of the variables measured with a Likert scale 0-5 (Table 2), while ε represents the standard error (Berardi et. al, 2022). The logarithmic conversion of some variables has been applied to reconduct the model to a Gaussian distribution. As a result, we build up three different regression models considering the three different clusters of interviews:

a) Deputy employee's C'7s model: YDE= a + βx1 + βlogx2 + βlogx3 + βx4 + βlogx5 + βlogx6 + εi;
b) Manager's C'7s model: YM= a + βx1 + βlogx2 + βlogx3 + βx4 + βlogx5 + βlogx6 + εi;
c) Senior Manager's C'7s model: YSM= a + βx1 + βlogx2 + βlogx3 + βx4 + βlogx5 + βlogx6 + εi;

The combination of the 6 variables which were considered showed no problems related to heteroskedasticity in all the three models (Breusch–Pagan tests results: $\chi 2 = 0.03$; Prob> $\chi 2 = 0.796$) and specificity (Ramsey test results: F (1.45) = 0.78; Prob> F = 0.337), as well as autocorrelation of some variables. Therefore, it was not necessary to proceed through stepwise regression (Shapiro–Wilk test results: pvalue= 0.698).

4. Results

What emerges from the analysis of the results, and answering to rq1, is a misalignment between employees and managers contribution on creativity and digitalization to the creation of public value. As shown in table 3 the YDE model is completely irrelevant for our analysis, as it has shown non-significant results while YM and YSM models reflect exactly the opposite situation.

Table 3: Results of the OLS regression, Source: Authors' own Table (2024)

Item	Regressor	YDE	YM	YSM
Curiosity and cognition	x1	-1,187 (0,245)	3.274 (1.988) *	3.172 (1.978) *
	logx2	0,137 (1,287)	6,846 (1,903) **	6,786 (1,897) **
	logx3	-1,481 (1,377)	8,133 (2,003) ***	7,983 (1,992) ***
Community and Connection	x4	-1,876 (0,345)	4,179 (2,078) *	3,879 (1,578) *
	logx5	-2,385 (2,273)	6,074 (1,738) *	5,874 (1,684) *
Cultivation, Compassion and Celebration	logx6	-3,175 (1.548)	2,507 (1,887) **	2,498 (1,787) **

To better understand the sense of this statical approach we report some extracts from the interviews conducted in the data set. In reference to the research item Community and Cognition, we asked them: "Are the measures adopted in line with the goal of achieve a digital environment?" while the managers just answered with no doubt that they are operating in the right direction, most of the employees specified that: "we are just doing what they asked us to do with absolutely no knowledge about what was going on. We are acting in the old way but with new sophisticated tools and instruments. Honestly, most of us are still having problems on procedures as they had a real lack back knowledge about Information Technologies. We have just received some basic commands and we move one step by step. This aspect had a terrible impact on our productivity because we must help those who are still having a problem after at least two years of the introduction of these new procedures. Moreover, many of us are afraid about the consequences of making an error so we spent a lot of time on re-check all the phases of the single processes. Only the sense of morality and the need to save lives helped us to move on to overcome all the issues".

Another relevant discordant point can be found in the measurement of the outcome or, in other terms, about the impact that the new procedures are having on the benefits for citizens and stakeholders (Bonner, 2023). What emerges from interview is that managers have a more long-range point of view about the outcome on communities:

For the first time in over 30 years of work experience, we have truly served our community. Every day, we found ourselves having to face completely different problems and situations and only our empathy and desire to help others in order to guarantee an efficient service to the community allowed us to overcome the traditional rigidities of the national healthcare system. At times, likely, we also broke some laws but faced with the need to save human lives, common sense prevailed over the rigidity of the procedures".

The extract of interviews, and the analysis we conducted, clearly show that while the managerial area of healthcare local bodies contributes to preserving the creative steam, the employees almost reject innovation, declining all the positive effects that it should have on their daily routine, thus confirming the second paradigm proposed by Rangarajan (2008). This creates a "no return way" in the process of creating public value in terms of user value, value to wide stakeholders or "value to wilder society" and basically let the achievement of public value as you are not in the condition of measure the real outcome on stakeholders, or at least to have no impact on them.

Innovation in the public health systems is taking several forms. For instance, video consultations and online consultations are now becoming regular practice for dealing with patients. This practice is rapidly taking hold in both acute and primary care, although it would have taken years to establish it in ordinary circumstances. Other examples are the test to diagnose breathlessness which has been introduced as soon as the emergency erupted or apps that trace the movement of infected patients and monitor their health condition. This fast transition brings certain risks such as data privacy risks or digital divide due to the limited access to health care of those parts of populations that lack digital connection. This aspect represents just some examples of the contribution of KM and CM that contribute to the rethinking of healthcare management that were emerges throughout the interviews conducted.

5. Conclusions

In this paper we highlighted a grey area still concerns the organizational design solutions related to creativity within the general context of generating new ideas. There is indeed a lack of literature in investigating the contribution of creativity and knowledge management. With this study we explored just one dimension of the policy making process that considers a knowledge management approach, also considering that the data set that we referred to only considers the public bodies organization of just one Italian Region that represent only the 5% of the Italian Population.

On the other hand, we give a first contribution on this topic showing that in a complex organization constituted by employees, managers, and senior managers, the process of creativity is completely different in the three different categories in order to contribute to international debate on KM and CM (Al-Husseini, 2023; Patwary et al., 2024) . The results of the OLS regression are emblematic and confirm that the process of creativity is strictly correlated on different levels and attitudes as supposed by several authors (Rangarajan, 2008; Boyne, 2001; Hood,1991; Amabile, 1996). Moreover, creativity positively affects the creation of value only when there is an alignment between the entire technostructure that gives the possibility to properly measure the impact of the adopted policies and measures.

In our opinion the key element of this study is that no matter where you live, or your income level, healthcare is ripe for change. According to international literature (Saulais et al., 2012), the state of health in the future will be radically better, but only if we create a favorable environment for implementing and adopting health innovations. Innovation within public and private healthcare entities is becoming both mandatory and vital and will be boosted by the creativity and knowledge of healthcare managers.

Knowledge Creation on Costs in the Context of Economic Environment Changes: Perspective of SMEs

Renata Biadacz
Czestochowa University of Technology, Faculty of Management, Poland

renata.biadacz@pcz.pl

Abstract: The increasingly challenging geopolitical situation and the growing frequency of various unpredictable crisis threats make the future uncertain and unstable. On the one hand, the sharp rise in raw material prices and labor costs, supply chain issues, pressures to implement sustainable development principles and non-financial reporting, and the transition to a circular economy model is increasing cost awareness and, consequently, the demand for more detailed cost data. On the other hand, the rapid development of technology and digitization, along with the evolution of Industry 5.0, means that business managers increasingly recognize knowledge as an indispensable element of business management. Knowledge management is an excellent tool for streamlining processes, which each company constructs based on its goals, needs, and capabilities, essential for effective planning and proper organizational functioning. Therefore, enterprises are compelled to continuously self-improve and seek new management methods, including cost management. This article raises a research question concerning how cost knowledge is created in SMEs in the context of changes occurring in the economic environment. The article aims to analyze the use of cost knowledge in managerial decision-making in medium-sized enterprises operating in the Polish SME market. The research methods used to achieve this goal include participant observation, critical analysis, and synthesis. The empirical research was conducted in the form of surveys carried out using CATI/CAWI methods among 400 randomly selected medium-sized enterprises operating in Poland, along with personal interviews. The research results suggest managers should focus on acquiring broader knowledge about incurred costs. Many surveyed enterprises still use traditional cost accounting solutions, providing data necessary solely for reporting purposes. The potential and tools offered by cost accounting are used to a limited extent. This indicates a need to continue and expand the discussion on the usefulness of detailed knowledge about incurred and forecasted costs in decision-making processes. The research findings presented in the article are intended for both researchers and practitioners. The article concludes with practical recommendations for enterprises and future research tasks. It is a continuation of the author's research on the role of cost accounting in managing SMEs in Poland.

Keywords: Industry 5.0, CE, Cost Accounting, SME

1. Introduction

Running a business is associated with significant challenges nowadays. Businesses must adapt to increasingly rapid changes in technology, development, and climate. Just as companies got used to the concept of Industry 4.0 (for more, see Łada, Kozarkiewicz, 2021; Łada 2021; Remlein et al., 2022), there is already a growing vision of further changes dubbed Industry 5.0, which emphasizes harnessing human skills alongside the technological potential of robots and intelligent systems.

The numerous alarming and threatening crisis phenomena that have occurred in the past decade disrupt trade flows and destabilize oli markets and other commodities.

There is an increase in tensions in financial markets and a sharp rise in commodity prices. Growing economic uncertainty, slow economic growth, and rising inflation heighten the risk of business insolvency. This leads to increased uncertainty about the future and the effective operation of companies (Schaltegger, 2020; Becla and Czaja, 2022; Meadows et al., 2022).

In recent years, there has also been increasing pressure to conduct business in line with the concept of sustainable development (Eckert and Kovalevska, 2021; Weizsäcker and Wijkman, 2018). ESG reporting is one of the most frequently addressed issues in managing contemporary enterprises. The amount of scientific research conducted on the popularization of sustainable development, social responsibility, and ESG reporting is impressive and growing yearly (for example Robertson et al., 2023; Arena et al., 2023; Schaltegger et al., 2022; Schaltegger 2020; Tettamanzi et al., 2022; Elalfy et al., 2021; Songini et al., 2021; Kwakye et al., 2018). Additionally, relevant legal regulations are being implemented. European Union (EU) countries have committed to achieving climate neutrality by 2050, fulfilling their obligations arising under the Paris Agreement of 2015. As resources become increasingly depleted, a growing emphasis is on transforming businesses into a circular economy model.

The volatility of the business environment implies new knowledge about environmental instability and the necessity of implementing projects that adapt the company's business strategy to the challenges of the economic environment (Łęgowik-Świącik, 2021).

Knowledge is becoming the driving force behind business development and a key factor in creativity across all areas of life. An increasing number of companies are being forced to seek new management solutions to effectively meet contemporary challenges. Effective management in such an environment requires up-to-date and comprehensive information from various systems, including accounting. Detailed knowledge about incurred costs is becoming increasingly essential. This knowledge enables more effective and rational managerial decisions. Therefore, one of the key aspects of business management is tackling the challenges associated with acquiring and disseminating detailed cost knowledge, which allows for the implementation of necessary changes for efficient operation. This study aims to illustrate the extent to which cost knowledge is utilized in managerial decision-making by medium-sized enterprises in the SME sector operating in Poland.

2. Industry 5.0 - Opportunity or Threat for Businesses?

In 2021, the first comprehensive vision of the 5th Industrial Revolution was created as a report by the European Commission titled "Industry 5.0: Towards a Sustainable, Human-centric, and Resilient European Industry". This report attempts to comprehensively define the concept of Industry 5.0.

In the report, Industry 5.0 is portrayed as an evolutionary step in industry development, with a focus on social and environmental aspects, as well as the integration of advanced technologies with human needs (Di Nardo and Haoxuan, 2021; Longo et al., 2020; Elfar et al., 2021; Jamwal et al., 2021; Xu et al., 2021; Bai et al., 2020).

Industry 5.0 is envisioned as a response to the evolving reality and its challenges. A key element of this approach is the organization's ability to adapt and be flexible to changing conditions. Real-time data analysis allows production systems to adjust to shifting market conditions, eliminating overproduction and reducing costs. It paves the way for personalized production and on-demand manufacturing, contributing to increased competitiveness and sustainable development of enterprises (Yordanova, 2021; Zychowicz, 2023; Kwiek, 2022). Industry 5.0 is a construct that aligns well with the political agenda pursued by the European Union. It combines new technologies and digitization with an environmentally friendly approach, circular economy principles, and the creation of an "ecosystem" of companies and partners.

However, the implementation of Industry 5.0 brings many challenges. One of them is the proper preparation of workers to effectively collaborate with robots and use modern technologies. This requires flexibility from employees, as well as the ability to learn quickly and adapt to new situations. Therefore, investing in training is essential to enable employees to acquire the necessary competencies.

Another challenge is the integration of information and technological systems in manufacturing facilities. Industry 5.0 envisages sophisticated information systems, artificial intelligence, robotics, and the Internet of Things, which must be integrated and operate harmoniously. This requires the involvement of engineers, IT specialists, and automation experts (Saniuk, Grabowska, 2023). As Industry 5.0 involves collecting and processing vast amounts of information, ensuring data security and protection against cyber-attacks is essential. The development of Industry 5.0 also impacts changes in the accounting system. The level of organization of the accounting system in many Polish companies still reflects the limited organizational and financial potential presented at the beginning of their operations and does not evolve despite dynamic development. Therefore, it is necessary to adapt accounting systems to new requirements. Without this, companies will not be able to meet the challenges of the Industry 5.0 era.

3. The Circular Economy (CE)

The concept of the Circular Economy has garnered significant attention over the past few decades. Definitions of the Circular Economy presented in global literature reflect the evolution of its development and implementation (for more details, see Kulczycka and Pędziwiatr, 2019). The Circular Economy has also become one of the main strategic directions for thinking about the development of the European Union since the announcement of the action plan by the European Commission in 2015. Since then, the Commission has issued a series of directives concerning various aspects of the Circular Economy, and in 2020, it published a new, even more ambitious action plan for the Circular Economy. This is a part of the European Green Deal and efforts to achieve climate neutrality and resource efficiency by 2050. The Polish government adopted a Roadmap for the transition to a Circular Economy in 2019, aligning with these efforts.

In global literature and publications of many international organizations, there is also an indication of the role and connection of the Circular Economy with decoupling (separating economic growth from the use of limited

resources through breakthrough technologies). However, this may require radical structural modifications in existing business models and radical organizational changes (Baker et al., 2023; Cano-Rubio et al., 2021).

Nevertheless, there is still a research gap at the micro level regarding the impact of the Circular Economy on financial performance. More and more companies are incorporating circularity principles into their strategies due to regulations and increased societal interest. For companies to succeed in their transition from a linear economy and a take-make-dispose mindset toward a circular economy, it is essential to be able to measure and report progress. The diversity of definitions of the Circular Economy (over 200 definitions according to Kulczycka and Pędziwiatr, 2019) complicates efforts to develop standards and indicators. Due to the diverse definitions, the question of "what to measure?" remains unclear, increasing the risk of choosing different indicators and yielding inconsistent conclusions (Degerstedt and Schaumberger, 2022; Moraga et al., 2019).

Circular Economy models have the potential to create value, reduce costs, generate revenue, support the legitimacy of firms (Park et al., 2010; Tukker, 2015; Urbinati et al., 2017), and provide environmental benefits (Lieder and Rashid, 2016; Moraga et al., 2019; Murray et al., 2017; see also Aureli et al., 2023). However, according to Rodrigue and Picard (2022), managers perceive formal accounting procedures as limiting and seek alternative management accounting systems to meet the needs of a more inclusive and holistic system that can support social and environmental progress.

The transformation of a company's business model into a Circular Economy requires more detailed analytical knowledge regarding the incurred costs. Due to the fact that CE primarily aims to eliminate waste, it involves only two streams: raw materials (inputs) and main and by-product streams. Therefore, it is necessary to value the product streams. According to Uberman's opinion (2019), one of the most reliable methods is the benchmark method. However, the requirement of its reality must be remembered. The fundamental issue in the practical application of benchmarking methods in valuing revenues and production costs of combined products is that they are not aligned with methods used in financial accounting. For this reason, their implementation is only possible when a company has an independent unit responsible for managerial accounting (Uberman, 2019). When redesigning products to be more circular, it is essential to consider budgeting and costs associated with regeneration at the beginning stage of the production process. Cost accounting must include, in addition to direct and indirect costs, overhead costs, delivery and distribution costs, as well as new regeneration costs, to accurately apply cost control and cost determination methods.

It is also necessary to analyze the costs associated with greenhouse gas emissions within the framework of carbon accounting (Kazemian et al., 2022; Burritt et al., 2023; Higashida, 2020). Although it is widely acknowledged that carbon accounting practices are essential for improving corporate sustainability performance, there is little interest in disclosing information externally. Another important aspect emphasized in this regard is the expansion of information beyond the organization to include supply chains. Given that the sustainability of supply chains significantly impacts the sustainable development of products and overall operations, Material Flow Cost Accounting (Burritt and Schaltegger, 2014; Marco-Fondevila et al., 2020) is becoming increasingly important.

4. The Methodology

The primary objective of the research undertaken in this study is to analyze cost awareness and the extent of utilization of cost data in the decision-making process of enterprises in the context of changes occurring in the economic environment. The research focuses on enterprises in the SME sector, which constitutes about 99.8% of all businesses in Poland. Micro, small, and medium-sized enterprises drive the economy, accounting for 43.6% of the national GDP (Gruszkowski, 2023). They are thus a vital element and a key source of economic growth, dynamism, and flexibility. Their operation represents healthy competition and reflects the entrepreneurial spirit of society. Entrepreneurs in this sector typically concentrate on a relatively narrow area of activity, enabling them to contribute to the dynamic development of specific fields. They can develop solutions that large enterprises might overlook during mass production.

The vast majority of SMEs are micro and small enterprises, which face numerous threats and barriers often stemming from their structure and limitations. Most of these businesses use simplified record-keeping forms for tax purposes only, resulting in access to a significantly smaller pool of information to support decision-making processes and limited knowledge about incurred costs. Small enterprises that keep accounting books often limit themselves to recording costs for reporting purposes only. Consequently, the target research group selected for this study comprises medium-sized enterprises employing between 50-250 people. These enterprises typically

maintain accounting books and increasingly go beyond cost reporting to adopt solutions useful in cost management.

The empirical results presented in this study are part of ongoing research conducted by the author since 2018 on the use of pro-quality cost accounting by SMEs operating in Poland.

To achieve this goal, a triangulation of research methods was applied. The theoretical part was conducted based on a critical analysis of the literature. Critical literature analysis is a research method that presents existing theoretical and empirical approaches and demonstrates how to prepare research work aimed at expanding existing knowledge or developing a specific research area.

This allows for the presentation of a new approach to the research objective and indicates the validity and novelty of the adopted solutions. Critical literature analysis should, therefore, be regarded as a synthetic, objective, and reliable summary of a specific theoretical area. The descriptive analysis method was used to describe the research methodology adopted in the studies conducted in this study. The qualitative research method was employed to answer the research question, including a survey and unstructured interviews with practitioners. Conducting survey research is empirical as it enables the analysis and evaluation of the examined phenomena.

The research process involved conducting pilot studies to select the target group of enterprises, developing a survey questionnaire, and implementing the survey research. Following the pilot studies, the target group was identified as SMEs operating in Poland with 50 to 249 employees (medium-sized enterprises). Due to the scope of the survey research, the surveys were directed toward the managerial staff. The survey research was conducted in 2019 and is currently being repeated.

For some time now, unstructured interviews with practitioners have also been conducted regarding the solutions used in cost accounting and the level of interest in contemporary forms of cost accounting. Since last year, to supplement the knowledge about the level of interest of enterprises in the concept of sustainable development and the scope of actions taken in this regard, especially concerning reporting, the surveys and interviews have been expanded to include questions in this area. The interviews are conducted during meetings at scientific conferences, controllers' congresses and by seeking potential speakers at career fairs or on the LinkedIn platform.

5. Results of Empirical Research and Discussion

The survey was conducted on a representative group of 400 medium-sized companies from the manufacturing, services, and manufacturing services sectors. The study had a nationwide scope. An ordinal scale and a dichotomous scale were used in the survey. Therefore, the formula for the structure index was deemed appropriate for determining the minimum sample size. Assuming a 5% margin of error, the minimum sample size was determined to be 385. The obtained sample size of N=400 meets this requirement. The questions used in the questionnaire were verified for quality using Cronbach's alpha. The resulting value of $\alpha = 0.822$ for aggregated data and consistently exceeding 0.700 for individual items indicates that the scales and sequence of questions used are appropriate.

Given the scale used in the study, Wilcoxon signed-rank tests and Mann-Whitney U tests were employed to compare the assessments of individual objectives. The ϕ – Yule coefficient, based on the $\chi 2$ statistic, was used to examine correlations. For the tests applied in the study, a significance level of 0.05 was adopted (see Biadacz 2021, Biadacz 2024).

Due to the research objective pursued in this article, questions regarding the cost accounting solutions used by the examined SME entities and the statements obtained from unstructured interviews are analyzed. In the survey research, one part was dedicated to cost accounting. Three of the surveyed questions were concerned with the cost accounting method for operational activities. Among the 400 surveyed enterprises, 211 (52.75%) use simplified cost accounting, mostly in the form of cost types (chart of accounts 4) (188 respondents). These results are not surprising, as it is a normal trend that has been maintained for years.

Enterprises that indicated cost accounting in the form of cost types (a total of 377 enterprises) were asked to specify how it was expanded to adapt to the needs of the enterprise. The obtained results are summarized in Fig. 1.

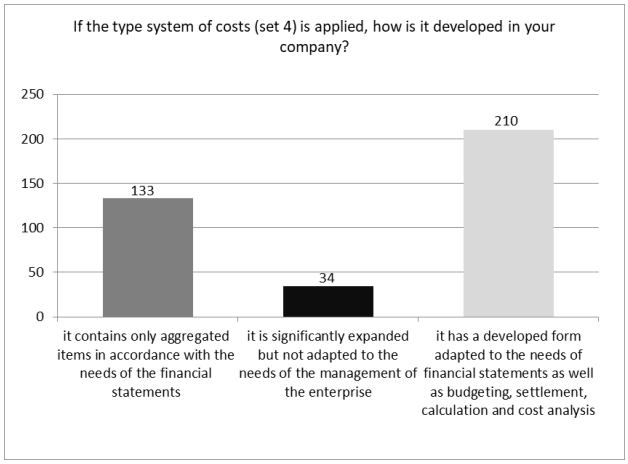

Figure 1: The degree of expansion of the type system of costs in the surveyed enterprise

Note(s): Twenty-three enterprises keep simplified cost accounting only in the costs by functions system (only chart of accounts 5).

Source: own study

Referring to this question, nearly 56% of the surveyed enterprises use an expanded cost type structure adapted for both reporting and managerial purposes, 9.02%, despite having an expanded structure of cost types, do not apply it for managing the enterprise, and 35.28% of the respondents use a cost type structure containing only aggregated items according to the needs of financial reporting. This means that enterprises moderately recognize the need to acquire broader knowledge regarding incurred costs.

The next question referred to the type of cost accounting used. Five of the most commonly applied cost accounting systems in business practice were listed. Respondents were allowed to select more than one solution. The responses are presented in Fig. 2.

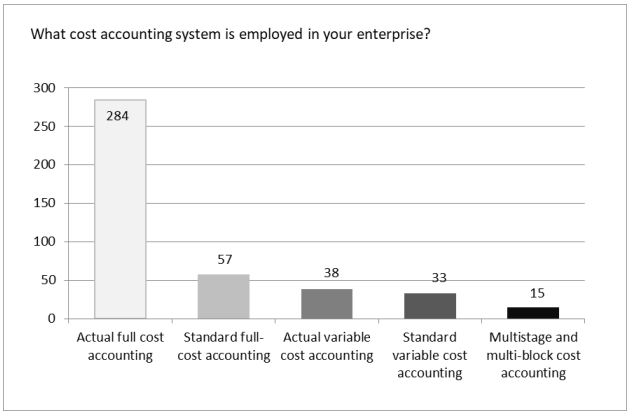

Figure 2: Cost Accounting Systems Used in the Enterprise (400 surveyed enterprises)

Note(s): Respondents could indicate more than one answer

Source: own study

After analyzing the responses to the above question, it is noteworthy that the majority of surveyed firms use the full actual cost accounting system (71%). Although much less commonly chosen, the second most preferred solution is the full standard cost accounting (14.25%). The use of actual variable cost accounting was indicated by 9.5% of respondents, while 8.25% indicated standard variable cost accounting. The multi-block cost accounting system is the least popular among respondents, with only 3.75% using it.

Regarding the method of allocating common costs used in the enterprise, 44% of respondents (176 out of 400 surveyed) indicated that they allocate common costs to departments. A similar number of companies allocates common costs to products/services (112 out of 400 respondents, 28%) as to tasks/projects (103 out of 400 respondents, 25.65%). The complete distribution of responses is presented in Fig. 3.

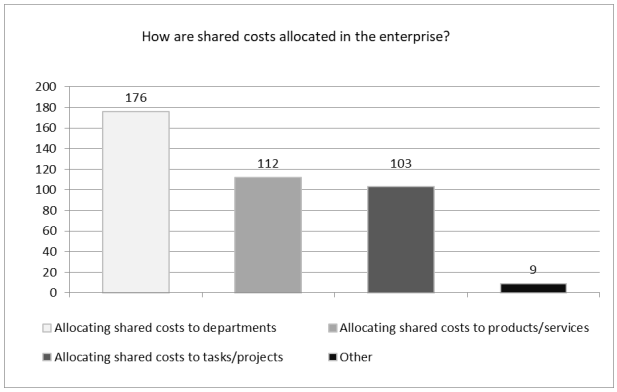

Figure 3: Allocation of shared costs in the enterprise.

Source: own study

One of the important issues for these studies relates to the systems used. In response to the question, "Do you have information systems that allow processing and storing a wide range of data?" as many as 349 respondents answered negatively. Considering the changes occurring in the environment and the perspective of transitioning to a circular economy and adapting enterprises to the Industry 5.0 concept, this cannot be considered a positive phenomenon.

The next question pertains to the calculation of the unit cost of the production of goods (provision of services). In this case, the results obtained are also unsatisfactory, as only 19.25% confirmed that they use cost accounting. A total of 323 respondents answered that they do not prepare calculations for the actual cost of producing products (provision of services). However, the cost of production of a product or provision of a service is an extremely important indicator for enterprises of this profile. It is used for various analyses both at the reporting and decision-making levels. It plays a crucial role in setting prices, managing resources, and business strategies in the enterprise. Knowing the unit cost of producing a product allows for setting competitive selling prices and identifying areas where costs can be reduced without compromising product quality. As a result, companies can improve their profit margins and increase competitiveness in the market. Efficient management of the cost of production of a product/service can positively impact the competitiveness of the company, its long-term stability, and its development. Therefore, different responses would be expected in the above area.

The responses to the question regarding the role of cost accounting in the enterprise can be moderately positive. The full distribution of responses regarding the role of cost accounting is presented in Fig. 4.

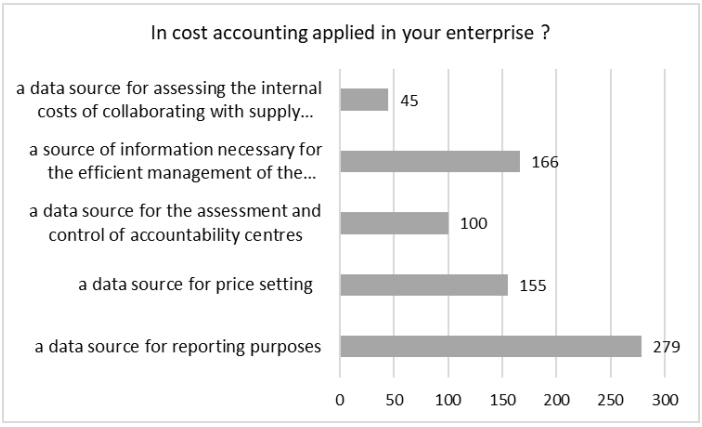

Figure 4: Role of cost accounting in enterprises

Note(s): Respondents could indicate more than one answer

Source: own study

After analyzing the respondents' answers, the following conclusions can be drawn: for 69.70% of respondents, cost accounting serves as a data source for reporting purposes; for 41.5%, it is a source of information necessary for effective enterprise management; for 38.75%, it is a source of data for pricing decisions. Cost accounting is

used by 25% of respondents for assessing and controlling responsibility centers, and by 11.25% for assessing internal costs of cooperation with partners in the supply chain.

These results are consistent with earlier research conducted in this area (Nesterak et al., 2017; Świderska, 2016). This is also confirmed by numerous case studies and publications referring to specific enterprises.

From the conducted research, it emerges that a small percentage of respondents indicate the use of the multi-block contribution margin cost accounting (28%). 72% do not use this solution. The full distribution of obtained responses is presented in Table 1.

Table 1: The use of multi-block cost coverage margin analysis in enterprises.

Is the multi-block cost coverage margin analysis used in the enterprise?	Total 400
A. Yes:	112
a) According to customer segments	24
b) According to product categories/goods/services	81
c) According to sales regions	7
B. No. It is not used	288

Source: own study

Supplementary to the research was a question concerning the application of selected elements of cost accounting. The results are presented in Fig.5. From the respondents' opinions, it appears that various solutions are being used. The majority, about 37.25% of surveyed enterprises, apply gross margin calculation, while 30.5% allocate indirect costs to cost centers. About 23% divide costs within cost centers into fixed and variable, and a similar percentage use planned costs for each center. Significantly fewer respondents identify and monitor the utilization level of production capacity (14.75%) or conduct variance analysis for all cost centers.

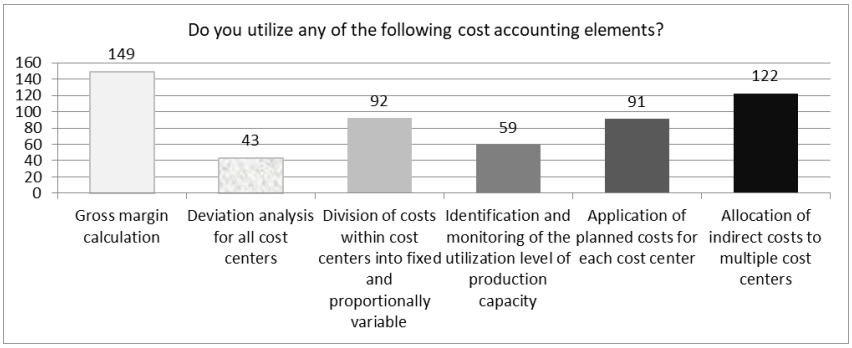

Figure 5: Utilization level of selected cost accounting elements.

Note(s): Respondents could indicate more than one answer

Source: own study

Surprisingly, 394 respondents answered affirmatively to the question of whether the information received from cost accounting is useful for managerial decision-making. This somewhat contradicts the earlier statement that cost accounting is primarily used for reporting purposes, and only 41.5% consider it a source of information necessary for the effective management of the enterprise. Respondents indicated that the data are useful for making both strategic (36%) and operational (47.25%) managerial decisions, as well as for efficient and detailed cost control and precise planning of future actions (both 48.75% of enterprises).

These results indicate that many medium-sized enterprises still use cost accounting only for reporting purposes. This is also confirmed by respondents' opinions from unstructured interviews.

The vast majority of respondents use cost accounting tools to a limited extent to support managerial decision-making. Contemporary variations of cost accounting arouse interest, although, in most cases, companies do not anticipate the possibility of implementing them in the near future. Regarding questions about sustainable development and reporting, only 4 surveyed companies indicated that they had taken action in this area.

6. Conclusion

As indicated by the above considerations, cost accounting should evolve, adapting to current economic, social, and environmental conditions. Unfortunately, this is not the case in a significant portion of the surveyed enterprises. The utilization of cost accounting is insufficient for making managerial decisions in today's volatile and unpredictable economic environment. Most surveyed enterprises rely solely on reporting cost accounting, which often fails to provide accurate information about the costs of resources, products, customers, or partners. Additionally, the calculation of product or service production costs and the utilization of production capacities are not conducted in many cases.

Relying on incomplete or inaccurate cost information results in making misguided decisions. Supporting the implementation of the intended strategy can be contemporary variations of cost accounting, serving as tools for strategic cost management and sustainable managerial accounting. While cost awareness has increased in recent years, interest in advanced cost accounting solutions and cost management is insufficient compared to the demands posed by the contemporary market and legislation. Therefore, it is crucial to raise awareness among the managerial staff of these enterprises about the necessity of implementing new tools adequate to current conditions.

The partial results presented above from the research indicate that selected cost accounting tools are not sufficiently utilized in the practices by medium-sized enterprises operating in Poland. It is therefore recommended that efforts be made to increase cost awareness among the management of these enterprises and convince them to implement new cost accounting solutions. These efforts will contribute to more effective enterprise management and operation in accordance with the principles of sustainable development.

This is essential because all enterprises, sooner or later, will need to adapt to new conditions and meet the challenges brought by the concept of Industry 5.0 and the increasingly emphasized necessity of transitioning to a circular economy model and reporting in this regard in order to survive in the market.

Knowledge Sharing and Protection Mechanisms in Hybrid and Remote Work Settings

Abstract: Organizations can increase their competitive advantage by sharing knowledge. On the other hand, mechanisms are needed to protect this knowledge from leaking. Although there is a growing body research on hybrid and remote working, few studies have looked at the adoption of knowledge protection (KP) mechanisms in these work models. This study seeks to address this gap by analysing KP and knowledge sharing (KS) mechanisms in hybrid and remote work environments in information technology (IT) companies. The research method adopted was qualitative, exploratory, and cross-sectional, with data being collected through twenty semi-structured interviews conducted with professionals working in either hybrid or remote environments in IT companies. Regarding the interviewees' characteristics, the male-female ratio was 60% - 40%, with an average age of 36 years, average time in the same company of 4.5 years, and around 2.5 years in the same position. The content analysis technique was adopted in the data analysis. As there is no standardization of days and times in the hybrid system, KS is hampered by the lack of face-to-face interaction between employees. The KS mechanisms mentioned are training, formal meetings, mentoring, and content available on the organizational intranet or platforms, among others. Not all organizations see KP as being important, and some even allow employees to use their own equipment, which may be potentially damaging for the company. This article presents theoretical contributions, such as the identification of sharing and protection mechanisms used in the hybrid and remote environments, and practical contributions, such as a list of mechanisms that can be used by companies. This research also highlights opportunities for future research, such as the identification and analysis of mechanisms in other segments of the economy, as well as research on the role of organizational culture in protecting knowledge.

Keywords: Knowledge Protection; Knowledge Sharing; Mechanisms; Hybrid; Remote.

1. Introduction

Remote working is widely considered one of the most significant changes in recent times, both for workers and companies (Ganguly *et al*., 2022). It can be defined as a regime whereby employees work from their homes or other locations while connected to their workplace through information technology (IT) (Beno, 2022). Several terms are used in research as synonyms for remote work, including: hybrid work, flexible work, work from home, telecommuting and virtual work. Despite their often interchangeable usage, these terms encapsulate subtle distinctions. For example, hybrid work entails a division of working hours between on-site and remote settings, allowing employees to spend some time physically present in the workplace, with schedules either determined by the individual or the company. In contrast, remote work implies that employees operate entirely outside the confines of the traditional office environment (Beno, 2022). This study aims to explore both hybrid work and remote work in depth.

The rise in the adoption of hybrid or remote working has sparked a surge in research attention towards this subject. Recent studies (Beno, 2022; Yang *et al.,* 2022) have looked into the dynamics of hybrid and remote work, examining both their benefits and drawbacks. Notably, among the identified disadvantages is the challenge of maintaining effective communication among employees and a subsequent decline in knowledge sharing (KS) and innovation, primarily attributed to the prevalence of asynchronous communication methods (Yang *et al.,* 2022).

The growing number workers engaged in hybrid and remote work arrangements has underscored the importance of safeguarding knowledge within these settings (Abbas and Alghail, 2023). Understanding how knowledge protection (KP) mechanisms traditionally utilized in face-to-face work contexts can be adapted by companies to sustain this vital aspect within hybrid or remote work environments, while retaining the benefits of effective KS, and preventing the leakage of knowledge assets, has become a pressing concern for organizations (Beno, 2022).

Despite the growing body of research on remote and hybrid work, a notable gap persists concerning the integration of KP mechanisms within these work models, a topic of significance due to its intrinsic link with effective KS (Singh *et al*., 2021). KP plays a pivotal role in mitigating knowledge leakage, which occurs when a company's proprietary knowledge is inadvertently or deliberately acquired by external parties (Ahlfanger *et al*., 2022).

In light of the aforementioned factors, including the growing significance and prevalence of hybrid and remote work setups within IT companies in Brazil, coupled with the imperative for organizations to safeguard their knowledge assets, this study posits the following research question: **What KP and KS mechanisms are employed by IT companies in hybrid and remote work**?

This study aims to analyse the KP and KS mechanisms in hybrid and remote work environments in IT companies. In addition to this introduction, this article has the following sections: 2) literature review on KS and KP, considering remote and hybrid work arrangements; 3) research methods; 4) analysis and discussion of the results; and 5) conclusions, limitations, and suggestions for future research.

2. Literature Review

2.1 Knowledge Sharing

KS is a key process within Knowledge Management, being distinguished by its capacity to disseminate, transmit, or transfer knowledge among individuals and organizations (Le and Lei, 2018). Consequently, KS emerges as a significant source of competitive advantage for organizations (Chen *et al*., 2018), underlining its pivotal role in fostering innovation and growth. Moreover, the proactive engagement of employees in facilitating KS endeavours is crucial to the sustained development of the company (Fauzi *et al*., 2023).

The departure of specialized and experienced personnel from a company poses an elevated risk of knowledge loss or leakage, potentially compromising its competitive advantage (Joe *et al*., 2013). This risk is particularly pronounced within the realm of IT professionals, given the inherently knowledge-intensive nature of their work (Borges *et al*., 2018).

Yap and Lock (2017) outline various mechanisms aimed at facilitating KS, categorizing them as either technological or non-technological. Their research conducted in Malaysia identified face-to-face interaction, mentoring, and documentation as the preferred mechanisms for KS among professionals.

2.2 Knowledge Protection

KP encompasses "*the array of potential approaches, methods, or tools employed to safeguard not only the tangible results of knowledge exploration but also the knowledge itself*" (Bolisani *et al*., 2013, p. 194). Organizations have to weigh the risks and benefits when determining the nature and scope of their engagement in KS activities (Thalmann *et al.,* 2024). Effective KP mechanisms bolster a company's competitive capabilities within its product market domain, ultimately driving superior sales growth compared to rivals (Nguyen *et al*., 2023).

To safeguard their knowledge assets, organizations must deploy mechanisms capable of averting knowledge leakage and the subsequent erosion of competitive advantage (Guo *et al.,* 2020). Such KP mechanisms typically fall into two categories: formal and informal (Olander *et al*., 2014). Formal mechanisms hinge on legal measures, such as contractual agreements, and may necessitate external resources such as specialized software (Olander *et al*., 2014). Conversely, informal mechanisms rely predominantly on interpersonal relationships and trust, often being favoured by small and medium-sized enterprises with relatively limited resources (Gast *et al*., 2019). Knowledge-intensive enterprises typically adopt a blend of formal and informal mechanisms tailored to their specific needs and contexts (Thallmann *et al*., 2024).

Formal KP mechanisms commonly employed include contracts, non-disclosure agreements (NDAs), and intellectual property safeguards such as copyright, patent registration, and trademarks. However, informal KP mechanisms can be particularly valuable in situations where formal measures like intellectual property protection are not applicable (Olander *et al*., 2011). One prevalent informal method of KP is maintaining secrecy, which involves limiting the number of individuals privy to strategic projects as well as controlling access to specific company facilities or projects (Hurmelinna-Laukkanen and Puumalainen, 2007).

2.3 The Relationship Between KS and KP in Remote and Hybrid Work Settings

A few authors have examined the relationship between KS and KP (Foege *et al*., 2019). This relationship typically exhibits an antagonistic aspect: while companies benefit from KS through enhanced innovation, cost reduction, and increased value of products and services (Gast *et al*., 2019), they also have to ensure against undesirable outcomes such as knowledge leakage and unauthorized appropriation of intellectual property (Ritala *et al*., 2015). Thus, striking a balance between promoting effective communication and protecting valuable knowledge assets remains a critical challenge for organizations.

The sharing of specific knowledge pertaining to innovations, experiences, or confidential information tends to be more restricted and rigorously protected compared to that of more generalized knowledge concerning factories, sectors, or markets (Gast *et al*., 2019). This selective approach inhibits deeper collaboration between companies, as each entity tends to limit the sharing of information to what it deems non-essential.

Remote or hybrid work arrangements introduce novel scenarios wherein employees operate either entirely or on certain days from locations external to the company's physical office space. This necessitates adjustments in the interaction and communication patterns among colleagues and managers. Hybrid and remote work models pose fresh challenges and opportunities for coordinating effective KS within organizations (Kaiser *et al*., 2022).

3. Research Method

To achieve the research objective, a qualitative approach was adopted. The research is characterized as exploratory, being aimed at discovering more about the phenomenon under study to enhance the understanding of underlying issues (Saunders *et al*., 2009). Additionally, the research is classified as cross-sectional, since it focuses on the specific phenomenon at a particular point in time. It encompasses describing the incidence of the phenomenon while elucidating how various factors interrelate across different organizations (Saunders *et al*., 2009).

Data collection was conducted through semi-structured interviews, in accordance with the methodology outlined by Saunders *et al*. (2009). This approach involves utilizing a preliminary script while allowing for the inclusion of additional questions during the interview process, thus increasing the potential to uncover valuable insights pertinent to the research objective (Saunders *et al*., 2009).

The authors drew upon insights from prior studies (Abbas and Alghail, 2023; Beno, 2022; Ganguly *et al*., 2022) to inform the design of the interview questions and their arrangement. The semi-structured interview script was organized into four parts: 1) gathering sociodemographic information about the respondents; 2) exploring their experiences with hybrid and remote work settings; 3) probing into their perspectives KS in the context of those settings; and 4) examining their perceptions regarding KP in those same settings. Following this, the script underwent a rigorous review process, encompassing content validation by two subject matter experts and face validation by a professional possessing the profile of the interviewees. The suggested modifications were duly incorporated into the instrument prior to commencing data collection.

The unit of analysis for this study encompasses the KS and KP practices among employees within information technology companies situated in Brazil. These companies are known for their intensive use of knowledge (Jackowska and Lauring, 2021), with effective communication recognized as a crucial determinant of their success (Ginting, 2020). This specific profile was chosen based on the sector's significant contribution to the Brazilian economy and the identified research gap concerning KP in the context of hybrid and remote work arrangements within IT companies.

The selection of interview participants adhered to the following criteria: a) having engaged in hybrid or remote work for at least 6 months, and b) being IT professionals employed by companies operating in Brazil. Invitations were extended via WhatsApp and email, where the interviewer introduced themselves and outlined the research objective. Data collection occurred during individual interviews, facilitated by Microsoft Teams®. Participants were requested to authorize recording, and subsequently, the interviews were transcribed to streamline the data analysis process. Table 1 provides an overview of the interviewees' characteristics.

Table 1: Characteristics of the interviewees

Work Setting	Code	Position	Gender	Age	Time in the Company	Time in the Position
Remote	E1	Software Engineer	Male	39	17	3
	E6	Software Engineer	Male	28	3	2
	E7	Head of Development	Female	50	4	2
	E11	Developer	Male	28	6	0.5
	E12	Specialist	Male	26	1.5	1
	E14	Product Manager	Male	39	11	3
	E15	Project Manager	Female	45	6	3
	E17	Head of Security	Male	47	2	2
	E19	Project Manager	Female	45	1.5	1.5
	E20	Test Analyst	Female	28	0.1	0.1
Hybrid	E2	Partner	Male	59	13	13
	E3	Director	Male	53	4	1
	E4	Partner	Male	24	1	1
	E5	Partner	Male	34	9	9
	E8	Partner	Male	23	2	2
	E9	Scrum Master	Female	36	0.1	0.1
	E10	HR Manager	Female	33	5	1.5
	E13	HR Manager	Female	35	0.5	0.5
	E16	Support Manager	Male	36	4	4
	E18	Financial Manager	Male	20	1	0.4

The initial phase of data analysis involved the authors reading through the 90 pages of interview transcriptions, during which they identified and emphasized the main ideas extracted from the interviews (Creswell, 2017). Subsequently, MAXQDA® software , designed for qualitative data analysis in academic research, was employed to conduct open and axial coding, allowing for the organization and categorization of data according to emergent themes and patterns.

4. Results and Discussion

4.1 Hybrid and Remote Working

For the employees engaged in hybrid work arrangements, there is no set standard mandating specific days and times for on-site attendance, as expressed by E6: "*I don't have a fixed day, our employment contracts allow us to decide the days we'll be present, right? So it could be Monday and Friday, it could be Tuesday and Thursday, it could be Wednesday and Thursday.*"

None of the remote workers reported a requirement for physical attendance at the company, with some residing in different cities from their workplace. Additionally, certain companies, as mentioned by E13, do not maintain physical office spaces.

The interviewees identified several benefits associated with hybrid and remote work, primarily emphasizing gains in productivity and better time management. Another notable advantage highlighted by the participants is the enhanced security provided by having the online meetings recorded.

The insights from the interviews prompt several considerations: 1) The absence of standardized days and times in hybrid work setups poses challenges for effective KS due to limited face-to-face interactions among employees; 2) In companies where some employees work remotely while others adopt hybrid or on-site arrangements, the situation may be exacerbated. Discrepancies in attendance could result in uneven KS, potentially leaving some individuals poorly informed. Conversely, a unified presence, such as everyone attending the office on the same day, might facilitate smoother KS. When nobody is physically present in the office, KS can be compromised due to a lack of opportunities for interaction. Although physical co-location does not guarantee effective KS, it does foster informal interactions (Hu *et al*., 2023) and contributes to trust-building (Testoni *et al*., 2022), both of underpin effective communication (Ng, 2022).

4.2 Differences in KS Between Hybrid and Remote Working

It is evident that structured processes and incentives for KS, such as training and mentoring, are in place across companies of varying sizes. However, there remains scope for improvement, as expressed by E17: "*More explicit, more documented knowledge exists within the company, but it is still a little immature.*"

Regarding the existence of differences in KS between hybrid or remote environments, three types of responses emerged:

a. KS is better and more effective in a face-to-face environment - 12 interviewees (60%);
b. KS is better in a remote environment - 5 interviewees (25%);
c. There is no difference in KS - 3 interviewees (15%).

Table 2 presents the KS mechanisms cited by the interviewees.

Table 2: KS mechanisms used by the Organisations

Interviewees	Work Setting	KS Mechanisms													Total
		A	B	C	D	E	F	G	H	I	J	K	L	M	
E2	Hybrid	X			X						X	X			4
E3					X				X		X	X	X		5
E4		X							X	X	X	X		X	6
E5		X			X	X		X			X	X	X	X	**8**
E8		X								X	X	X	X		5
E9		X		X	X	X	X			X	X	X		X	**9**
E10		X	X	X	X	X		X	X	X	X	X		X	**11**
E13		X	X	X	X	X		X	X	X	X	X	X	X	**12**
E16						X			X		X	X	X		5
E18						X				X		X		X	4
Total		**7**	2	3	6	6	1	3	5	6	**9**	**10**	5	6	69
E1	Remote	X	X	X	X	X			X			X		X	**8**
E6		X	X	X	X	X			X	X		X		X	**9**
E7		X	X	X	X	X		X		X		X		X	**9**
E11		X			X	X			X	X		X		X	7
E12		X	X		X				X	X		X		X	7
E14		X	X	X	X	X	X		X	X		X		X	**10**
E15		X			X			X	X			X		X	6
E17		X		X	X	X			X	X		X		X	**8**
E19		X	X		X	X	X		X	X		X		X	**9**
E20		X				X				X		X		X	5
Total		**10**	6	5	**9**	**8**	2	2	**8**	**8**	0	**10**	0	**10**	78

Legend: A = Technical Presentations; B = HR Presentations; C = Communities of Practice; D = Project Management; E = Intranet; F = Job Rotation; G = Mentoring; H = Platform; I = Social Networks; J = Face-to-face Meetings; K = Online Meetings; L = Face-to-face Training; M = Online Training.

KS mechanisms were identified, with an observation: in hybrid work settings, face-to-face interactions are predominantly adopted for KS, whereas in remote work settings, a wider array of mechanisms is employed, all of which are non-face-to-face.

Analysis of the interviewee reports reveals the presence of structured processes and incentives for KS across most companies, aligning with findings by Henttonen *et al*. (2016). Commonly mentioned KS mechanisms include online meetings, social networks, platforms, and online training, consistent with observations made by Delfino and Van Der Kolk (2021). While communities of practice, mentoring, and job rotation are recognized as effective mechanisms applicable to both hybrid and remote work, they were less frequently mentioned by the interviewees, possibly due to the additional time required for their adoption.

The number of KS mechanisms reported by the interviewees indicates that the quantity of different mechanisms is nearly identical, irrespective of the work setting.

4.3 Differences in KP Between Hybrid and Remote Working

The interviewees highlighted a variety of KP mechanisms employed in companies, encompassing both formal and informal approaches, as outlined in Table 3. As can be seen, certain mechanisms, such as passwords, are universally present across all cases, and others, like contracts, are employed in almost all instances.

Table 3: KP mechanisms used by the organisations

Interviewees	Work Setting	Formal Mechanisms													Informal Mechanisms		
		A	B	C	D	E	F	G	H	I	J	K	L	Total	M	N	Total
E2	Hybrid				X	X		X		X	X	X		6	X		1
E3				X	X			X	X	X				5	X		1
E4					X			X		X				3	X		1
E5					X			X		X	X			4	X		1

E9			X	X	X		X	X		X	X	X	X	9			0
E10		X	X	X	X		X	X		X	X	X		9		X	1
E13		X	X	X	X		X	X	X	X	X			9		X	1
E16		X	X	X	X			X	X	X	X	X	X	10		X	1
E18			X	X	X		X	X		X			X	7	X		1
Total		**3**	**5**	**6**	**10**	**1**	**4**	**10**	**3**	**10**	**7**	**4**	**3**	**66**	**6**	**3**	**9**
E1	Remote		X	X	X	X	X	X	X	X		X	X	10		X	1
E6			X	X	X	X	X	X	X	X		X	X	10		X	1
E7				X	X		X	X	X	X		X	X	8	X		1
E11			X	X	X	X	X	X	X	X		X	X	10		X	1
E12			X	X	X		X	X		X		X		7		X	1
E14			X	X	X	X	X	X	X	X		X	X	10		X	1
E15			X	X	X	X	X	X	X	X		X	X	10		X	1
E17				X	X		X	X		X			X	6	X	X	2
E19				X	X	X	X	X	X	X		X	X	9			0
E20			X	X			X	X		X				5			0
Total		**0**	**7**	**10**	**9**	**6**	**10**	**10**	**7**	**10**	**0**	**8**	**8**	**85**	**2**	**7**	**9**

Legend: A = Restricted Physical Access; B = Restricted Digital Access; C = Contracts; D = Company devices; E = NDA; F = Policies; G = Passwords; H = Monitoring Software; I = Communication Software; J = Face-to-face Training; K = Online Training; L = VPN; M = Trust; N = Selection Process.

Overall, there appears to be little variation in the types of formal and informal mechanisms employed across companies, although some exceptions exist, particularly regarding strategies implemented when there is a critical need to safeguard specific knowledge assets. For instance, as reported by E13, "*There is contractual clause whereby, depending on the individual's knowledge level, the company pays for them to be retained on the payroll for about 3 months, akin to a quarantine period, even if they are no longer actively engaged in the company's operations, after which they are released.*"

According to the interviewees, the organizations largely rely on formal mechanisms, particularly technical ones such as passwords, digital access restrictions, and monitoring software, to protect their knowledge assets. In terms of informal mechanisms, companies rely on trust in their employees' discretion regarding the non-disclosure of the company's strategic knowledge. Additionally, meticulous attention is given to the selection processes, ensuring that recruited individuals possess the integrity and reliability necessary to safeguard the organization's proprietary information.

The interviewees indicated that their companies have implemented KP initiatives. As expressed by E16: "*So there are a series of mechanisms and processes to ensure KP for different actors involved in the processes*." Moreover, the majority of interviewees noted that there is no distinction between the KP measures implemented for hybrid and remote work setups.

It is evident that not all companies attribute KP the same level of priority. Some organizations permit employees to utilize their personal devices for work purposes, a practice that can pose significant risks to the company and potentially facilitate knowledge leakage, as noted by Abbas and Alghail (2023). Additionally, certain organizations treat KP as a mere procedural formality, limited to the implementation of basic measures such as passwords and access restrictions to specific sections of their platforms. However, they do not prioritize investments in employee training and awareness-raising initiatives regarding the importance of KP.

Although the interviewees may not perceive a difference between hybrid and remote work in terms of KP, disparities in the mechanisms employed do exist. Specifically, the number of KP mechanisms mentioned is 28% greater for remote work environments compared to hybrid setups.

5. Conclusions, Limitations and Future Research

In answering the stated research question, this study provides insights into the mechanisms utilized for KP and KS in IT companies based in Brazil operating remote or hybrid work arrangements. Most of the interviewees claimed that KS mechanisms were part of their daily routine, with online meetings, training sessions, and technical presentations featuring prominently. While few differences in KS mechanisms were reported between hybrid and remote work, most of the interviewees suggested KS was more effective in a face-to-face setting, suggesting that hybrid work, with a planned balance of in-office and remote work, may offer advantages over remote work alone. In terms of KP, a greater emphasis was placed on formal mechanisms such as passwords and communication software. Informal mechanisms, however, were less frequently mentioned, with trust in employees and careful selection processes being the primary focuses for some interviewees.

This study contributes theoretically by identifying the mechanisms employed by companies, as reported by the interviewees, for both KS and KP. It sheds light on the distinctions between remote and hybrid work environments, particularly noting a greater diversity of KP mechanisms in remote work settings. Furthermore, this research provides practical contributions by furnishing a comprehensive list of both KS and KP mechanisms. The recognition by a majority of interviewees that KS is more effective in hybrid work implies that organizations embracing remote work models must proactively motivate employees to engage in effective KS practices.

Several limitations should be acknowledged in this study. Firstly, the surveyed companies are all within the IT sector, and therefore, to a greater or lesser extent, incorporate some type of KP. Additionally, the fact that many the interviewees were still adapting to hybrid or remote working arrangements may introduce variability in perceptions over time and influence their experiences with these work environments.

Indeed, this topic presents several avenues for future research. Firstly, expanding this study to encompass other sectors of the economy. The comparative analysis could shed light on sector-specific nuances in communication, collaboration, and KP practices. Furthermore, future research could focus on the development of a comprehensive framework that integrates KS and KP mechanisms within organizations adopting hybrid or remote work models.

Evaluating Digital Intelligence on Growth Mindset Focus: Q-Methodology Study on Students' Openness

Eszter Bogdány, Krisztina Kiglics and Nóra Obermayer
University of Pannonia, Department of Management, Veszprém, Hungary

bogdany.eszter@gtk.uni-pannon.hu
kiglics.krisztina@uni-pannon.hu
obermayer.nora@gtk.uni-pannon.hu

Abstract: Global competitiveness emphasizes that nations with digitally literate and adaptable populations are likely to be more competitive in the global economy. In the contemporary global landscape, technology plays a pivotal role in economic growth, innovation, and competitiveness. Nations that prioritize the development of digital skills and foster a growth mindset among their populations are better positioned to thrive in the digital age. Moreover as technology continues to evolve, there is a need to understand how individuals integrate and adapt to new digital tools. Another significant aspect is that higher educational institutions can play a crucial role to ensure that graduates are well-prepared to meet the complex requirements of the new digital world. The aim of the research is to explore university students' digital intelligence (DQ) levels from the view of growth mindset. More specifically, understanding how the mindset of students contributes to their openness related to developing the different levels of DQ. The research applied Q-methodology, that allows to capture the diverse perspectives of students, providing a nuanced understanding of their openness to DQ maturity. Different individuals have distinct views on how it relates to a growth mindset, and the strategies they believe are effective for developing digital skills. Findings from this research offer implications for educational policies and curriculum development, ensuring that educational institutions are preparing students for the challenges and opportunities presented by the digital landscape. Moreover it allows educators to tailor teaching methods and curriculum design to enhance students' digital literacy and adaptability. It provides insights into the psychological and behavioral aspects of learning in a digital context. From a theoretical aspect the study contributes to understanding the cognitive processes involved in students' decision-making and attitudes towards different levels of DQ, considering the phenomenon of growth mindset.

Keywords: Digital Intelligence, Growth Mindset, Q-Methodology Study, Students' Openness

1. Introduction

Digital Intelligence (DQ) is crucial for global competitiveness, driving economic success in the digital age (Manasia, Pârvan & Ianos, 2018). Embracing a growth mindset is essential for individuals to adapt to the evolving digital landscape and continuously develop their DQ (Zhang, 2023). DQ encompasses a broad range of digital competencies rooted in universal moral values, empowering individuals to use, control, and innovate with technology (Park & Gentile, 2019). It is a lifelong journey of learning and adaptation, requiring a commitment to continuous improvement (Pornpongtechavanich & Wannapiroon, 2021; Zhang & Farooq, 2021). By investing in digital literacy and skills development, countries can drive sustainable growth, prosperity, and inclusive development (Sharma et al, 2016).

The rationale for exploring university students' DQ from a growth mindset perspective is multifaceted, aiming to enhance learning outcomes, address digital skills gaps, promote lifelong learning habits, prepare students for future success, and optimize educational interventions. Furthermore, the application of Q-methodology in this research could provide a valuable approach by capturing diverse perspectives, exploring subjectivity, identifying contrasting views, and thereby informing educational practice and policy to better support students in acquiring the digital skills needed to thrive in today's digital age.

Therefore, the aim of the research is to explore the diverse perspectives behind students' DQ levels in the context of growth mindset. More specifically, the aim is to investigate different perspective groups regarding how students perceive various elements of DQ in relation to their own developmental aspirations.

The following research question was formulated based on the aim:

RQ1. What are the different perspective groups among university students regarding their beliefs about the potential for growth and improvement in DQ?

This aim aligns well with the principles of growth mindset theory (Dweck, 1999), which emphasizes the importance of effort, perseverance, and a belief in the potential for growth and improvement. By exploring this, the research has the potential to provide a more nuanced understanding of the complex interplay between growth mindset and DQ levels.

This research not only contributes theoretically but also raises awareness among students about essential competencies for successful navigation in the digital realm. Participation offers students insights into areas for improvement, enhancing their understanding of strengths and weaknesses in terms of Digital Intelligence (DQ). It also highlights the significance of achieving higher DQ levels, guiding the design of educational programs tailored to students' developmental needs and expectations in the digital domain. This research covers the conceptualization of DQ and growth mindset, their relationship, and prior studies in higher education (Section 2), followed by methodology explanation (Section 3) and results analysis (Section 4). Finally, it discusses educational implications and future directions (Section 5).

2. Literature Review

2.1 Conceptualization of DQ and Growth Mindset

As the above mentioned definition explains, DQ encompasses a wide range of digital competencies grounded in fundamental moral values. It empowers individuals to effectively utilize, manage, and innovate with technology to drive human progress (Park & Gentile, 2019). The holistic conceptualization of DQ recognizes the importance of equipping individuals with the skills and mindset needed to thrive in an increasingly digital world. According to DQ Institute DQ is characterized as a holistic collection of technical, cognitive, meta-cognitive, and socio-emotional proficiencies deeply rooted in universal moral principles. These proficiencies empower individuals to confront the complexities and capitalize on the advantages presented by digital environments (Park, 2023). The formulation of the DQ framework (developed by DQ Institute) was guided by the transformative impact of technology on our social and professional interactions, prompting the incorporation of cognitive abilities alongside technical skills to effectively navigate interpersonal dynamics, conflicts, and negotiations (Park & Gentile, 2019). This DQ framework encompasses eight key domains, each comprising competencies delineated across three proficiency levels. By categorizing DQ into three maturity levels—digital citizenship, digital creativity, and digital competitiveness—a comprehensive understanding of digital capabilities is facilitated. Aligned with these DQ levels are the delineated eight areas, yielding a total of twenty-four competencies. These areas and competencies facilitate tailored learning experiences that address the immediate relevance of various aspects of individuals' lives (Park & Gentile, 2019). Moreover, the components of DQ according to the definition contain several factors. DQ encompasses various types of competences that individuals need to navigate effectively in a digital environment. This includes knowledge elements (e.g. digital literacy or knowledge about digital security (Dostal et al, 2017)), skills and abilities (e.g. operational, informational, strategic and digital fluency (Cismaru et al, 2018)) and values or attitude elements (e.g. a disposition, a mindset to act (Vuorikari, Kluzer & Punie, 2022)). Moreover, DQ is a complex phenomenon that is based on universal moral values such as honesty, integrity, respect, empathy, and responsibility, and these values serve as guiding principles for ethical behavior and decision-making in digital spaces (Park & Gentile, 2019). DQ equips individuals with the capabilities to address the diverse challenges they encounter in digital life such as cyberbullying, online privacy and security risks, misinformation, digital addiction, and digital divide, among others (Park, 2023). Beyond managing challenges, DQ enables individuals to leverage the myriad opportunities presented by digital technologies such as using digital tools for learning, communication, collaboration and so on (Avci & Adiguzel, 2020). Both DQ and the growth mindset advocate for a holistic approach to personal development, recognizing the interconnectedness of technical, cognitive, and socio-emotional competencies in navigating digital environments.

The concepts of fixed and growth mindset introduced by Dweck (2008) describe variations in individuals' beliefs regarding "the potential for change in fundamental personal attributes like intelligence or abilities, leading to distinct patterns of judgment and response across various tasks and contexts" (Solberg et al., 2020, p. 108). Believing in the potential for growth, adaptability, and the capacity to learn from experiences characterizes a growth mindset, while attributing personal traits to fixed qualities defines a fixed mindset (Dweck, 2008), and these outlooks significantly impact individuals' behaviors and ultimately influence their accomplishments. Masters (2014) demonstrated that a growth mindset correlates with positive learning behaviors among students, while Claro, Paunesku & Dweck (2016) enhances the impact on academic performance and fosters resilience in the face of academic setbacks (Dweck, 2000).

Summarizing the above mentioned concept, we conclude that the holistic conceptualization of DQ emphasizes a wide array of technical, cognitive, and socio-emotional competencies rooted in universal moral values, empowering individuals to navigate digital environments effectively, while the principles of a growth mindset,

which prioritize adaptability and learning from experiences, intersect with DQ, contributing to positive learning behaviors and academic performance among students.

2.2 The Link Between DQ and Growth Mindset, and Prior Researches in Higher Educational Settings

The intersection of DQ and growth mindset is evident in various aspects. Research by Dweck (2000) illustrates how individuals' mindsets, particularly in educational and professional settings, influence their adaptability and willingness to embrace change. The coexistence of physical and cyber space has given rise to a new mindset, particularly among younger generations immersed in digital technologies (Kineshanko & Jugdev, 2018) moreover the exploration of how digital learning contributes to the development of DQ. Santos et al (2017) emphasize the increasing importance of digital competencies in the context of the Fourth Industrial Revolution, highlighting the need for individuals to navigate the digital landscape effectively. Central to this discussion is the notion of being a changemaker in the digital environment, where organizational policies play a crucial role in delineating boundaries between personal, professional, and public communication (Banghart, Etter & Stohl, 2018). The growing demand for DQ, driven by economic imperatives and competitive pressures, underscores the significance of lifelong learning initiatives that address evolving market demands (Curran, Garrett & Puthiyamadam, 2017). However, criticisms have been levied against educational institutions for prioritizing market-driven skills development over holistic personal growth and community-building (Conley & Rauth, 2020; Barnett, 2007).

The research of Loble, Greenaune & Hayes (2017) underscores the importance of students' ability to perceive challenges and failures as opportunities for growth rather than obstacles. Embracing learning as a lifelong journey, with perseverance and a willingness to take intellectual risks, is crucial for success in the evolving digital world. A supportive ecosystem comprising physical and emotional well-being, access to technology, and a growth mindset is essential for effective technology utilization among students (Thomas et al., 2024). This highlights the significance of fostering not only technical skills but also a resilient and adaptable mindset to navigate the complexities of the digital age. Moreover, as advanced technologies reshape the landscape of the workplace, there is a growing demand for individuals, teams, and organizations to embrace adaptability and resilience (Trenerry et al., 2021). Programs and training aimed at cultivating workplace resilience and fostering a mindset shift towards adaptability are essential in the face of ongoing digital disruptions.

Lastly, individual attitudes and mindsets toward job roles and professional development play a crucial role in building resilience during challenging times (Cameron and Brownie, 2010).

This highlights the need for a balanced approach that not only equips individuals with technical skills but also fosters psychological development and creates supportive learning communities. In essence, the convergence of DQ and growth mindset underscores the importance of adaptable, resilient individuals who are capable of thriving in an ever-evolving digital landscape while also nurturing their personal and professional development.

3. Methodology

Q-methodology, renowned for its blend of quantitative and qualitative analyses, is a robust research approach used across various fields to explore competencies and attitudes (Watts & Stenner, 2012). By employing factor analysis, it unveils distinct viewpoints on a topic, as observed in studies spanning nurse education, critical thinking, teacher evaluation, and HRM competency rating (Hensel et al., 2022; Gyenes, 2021; Bogdány, Cserháti, Raffay-Danyi, 2023). While ensuring consistency across samples, its focus on qualitative evidence limits generalizability (Thomas & Baas, 1992). Despite its time-consuming nature, Q-methodology offers valuable insights and aids informed decision-making in higher education settings by aligning curricula with evolving labor market demands (Aldamen et al, 2021). Thus, it serves as a potent tool for identifying and prioritizing competencies crucial for navigating the digital world effectively (Morea, 2022).

The participant selection and recruitment procedures involved targeting higher educational students in their last semester of study. The choice of students in their final semester was deliberate, as this group is poised to transition from academia to the professional world, making their perspectives particularly relevant for understanding developmental aspirations. Participants were selected using purposive sampling, a common approach in Q-methodology (Atwal & Caldwell, 2005), which focuses on selecting individuals who can provide articulate viewpoints on the topic of interest. Specifically, students were chosen based on their ability to articulate their viewpoints on digital quotient (DQ) elements and their relevance to future career aspirations and educational goals. A total of 51 full-time students from the Faculty of Business and Economics were invited

to participate in the survey, of which 46 provided assessable responses (Table 1 present the main characteristics of the sample). This sample size aligns with typical Q-methodology studies, which generally include around 40-60 participants. The rationale for this range is rooted in the methodology's use of inverted factor analysis, which does not aim for generalization to a larger population but rather seeks to identify and analyze distinct viewpoints within a specific group.

Table 1: Sample characteristics

Gender			Age			Age when you started using an electronic device	
	N	Percent		N	Percent		
man	11	23,91%	18 - 20	4	8,70%	Mean	9,91
woman	35	76,09%	21 - 23	33	71,74%	St. Deviation	2,67
Total	46	100,00%	24 - 26	7	15,22%	Median	10
			27 -	2	4,35%		
			Total	46	100,00%		

The survey was administered during a scheduled lesson, facilitating convenient data collection. The survey included elements for ranking DQ elements in the light of developmental aspirations. By focusing on students nearing the completion of their academic programs, the study aimed to capture insights into how these individuals perceive DQ in relation to their future career aspirations and educational goals. By capturing their perspectives during this critical phase, the study provides valuable insights into how students nearing graduation view DQ elements, which can inform educational strategies and career readiness programs.

The following steps of Q-methodology were applied during the research (Table 2).

Table 2: Stages of applied Q-methodology

Stages	Description	Output
Development of concourse	Compilation of Q-sample: compilation of the statements of DQ elements' based on the integration of knowledge, skill, attitude and examples of DQ Institute's DQ Framework and DigComp 2.2 regarding to growth mindset	Q-set: 24 different statements in the light of growth mindset
Selection of P-Sample	Full-time higher educational students in their last semester of study were selected	P-Set: 51 students
The establishment of Q-sorts	Ranking procedure whereby students were asked to rank Q-set according to growth mindset	46 individual Q-sorts
The standard analytical process - Factor analysis	Using PQMethod software Centroid factor analysis, and Varimax Rotation: identifying distinct perspectives, exploring the underlying beliefs or attitudes within each perspective,	3 emergent factor
The interpretation of factors and results	Interpreting the factors, distinguished statements, and Z-score values to gain a deeper understanding of the different perspectives represented in the data. Discussing the implications of findings and how they contribute to the overall understanding of the research topic.	Research proposals, implications

The DQ ranking survey comprised a list of DQ elements derived from several sources. The DQ elements were developed based on established frameworks such as the DQ Institute and DigComp 2.2 (Digital Competence Framework). These frameworks provided comprehensive guidelines and standards for digital competence, encompassing a wide range of knowledge, skills, and attitudes. Each DQ element was accompanied by a coherent definition that clearly delineated its components. Definitions were structured to encompass knowledge, skills, and attitudes, ensuring a holistic understanding of each element. This approach allowed participants to evaluate DQ elements comprehensively and accurately. To provide context and clarity, examples were included for each DQ element. These examples illustrated how the knowledge, skills, and attitudes associated with each element might manifest in real-world scenarios. By incorporating examples, participants were better able to understand the practical implications of each DQ element and make informed judgments during the ranking process.

Participants were asked to rank DQ elements based on the prompt: "I'm willing to look to develop myself in the following areas by the right investment of time and energy...". Participants were instructed to rank the DQ

elements according to their perceived relevance, providing quantitative data on their preferences in DQ development.

Due to the extensive nature of the questionnaire, administered through the Q-methodology ranking method, and the intricate interconnections among DQ elements, completing the survey necessitated careful deliberation. Respondents followed predefined steps outlined by Watts and Strenner (2012), to complete the ranking process, resulting in individual Q-sorts reflecting participants' unique perspectives.

4. Results

After considering the different factor solutions, 3 factors emerged, whereby the average squared residual correlation was 0.036. Table 3 displays the different correlations between factor scores, the number of participants in each group and the reliability of the construct.

Table 3: Correlation between factor scores, the number of participants in each group and reliability

Factors	1	2	3
1	1.0000	0.0855	-0.1412
2	0.0855	1.0000	0.1983
3	-0.1412	0.1983	1.0000
No. of defining variables (participants in the group)	15	14	10
Composite reliability	0.984	0.982	0.976

Drawing from the provided approach, it was found that 7 students remained unclassified, while 39 participants were successfully categorized into distinct groups. The composite reliability of Q-sort items played a pivotal role in determining the reliability of factors. The study identified three discernible factors, each exhibiting composite reliability values ranging from 0.976 to 0.984, signifying a high level of consistency and reliability in the instrument employed, albeit with an emphasis on participants' subjectivity in Q-methodology. The interpretation of emergent factors was guided by the unique sets of perspectives associated with factor scores.

In the subsequent section, emergent factors were interpreted based on the distinctive perspectives of respondents regarding their growth mindset towards DQ elements (as presented in Table 4). Subsequently, significant distinguishing and consensus statements were elucidated.

Table 4: Factor scores with corresponding ranks and significantly distinguishing statements

	Factor 1		Factor 2		Factor 3	
	Z-SCR	Rank	Z-SCR	Rank	Z-SCR	Rank
Digital Citizen Identity	-0.04**	12	-0.82**	20	-1.60**	23
Balanced Use of Technology	1.44	2	0.38**	8	1.68	1
Behavioural Cyber-Risk Management	-1.09*	21	-0.41	18	-0.63	18
Personal Cyber Security Management	-1.11**	22	1.46	4	1.20	4
Digital Empathy	1.26**	5	0.57**	7	-1.33**	21
Digital Footprint Management	-0.77**	17	-1.24**	22	0.51**	9
Media and Information Literacy	1.57	1	-0.13**	11	1.27	3
Privacy Management	-0.10**	14	1.74**	1	0.76**	6

Relationship Management	1.38**	4	0.29**	9	-1.53**	22
Public and Mass Communication	0.55**	8	-1.50*	23	-1.02*	20
Data and AI Literacy	-0.70	16	-0.73	19	1.27**	2
Participatory Rights Management	-0.05	13	-1.15**	21	-0.09	14

Label: (Z-SCR) Z Score Value, (*) P<0.0.5, (**) P<0.01)

Factor_1: This group of respondents emphasizes digital interactions, valuing not only technical proficiency but also social and ethical considerations. They prioritize elements such as Digital Empathy, Self-Awareness and Management, and Relationship Management, indicating a focus on social responsibility and effective communication. Distinguished statements highlight the importance of these elements in fulfilling the respondents' developmental aspirations. The distinguished statements, identified by their Z-score values, further elucidate the importance of certain DQ elements within factor_1. Notably, Digital Empathy, Self-Awareness and Management, Relationship Management, and Public and Mass Communication emerge as particularly salient DQ elements, indicating their alignment with the developmental aspirations of the respondents. Conversely, statements related to aspects such as Organizational Cyber Security Management and Network Security Management exhibit lower Z-score values, suggesting their relatively lower importance in fulfilling the respondents' developmental aspirations within the digital landscape.

Factor_2: Students in this factor prioritize security and responsible digital behavior, as evidenced by their emphasis on elements such as Privacy Management and Personal Cyber Security Management. They also value elements related to social intelligence, such as Digital Empathy and Relationship Management. The distinguished statements further underscore the significance of privacy and security in fulfilling students' developmental aspirations. The distinguished statements further elucidate the significance of certain DQ elements within the respondents' perceptions. Privacy Management, Network Security Management, and Public and Mass Communication emerge as particularly salient DQ elements, indicating their importance in fulfilling students' developmental aspirations. Conversely, elements such as Digital Footprint Management and Content Creation and Computational Literacy exhibit lower Z-score values, suggesting their relatively lower importance within the respondents' perceptions.

Factor_3: This group of students demonstrates a diverse range of competencies and skills related to digital literacy, security, creativity, and social impact. They prioritize elements such as Media and Information Literacy, Data and AI Literacy, and Digital Changemaker Identity, indicating a desire for proficiency in navigating digital content and making a positive impact in the digital realm. Distinguished statements highlight the importance of privacy, data literacy, and social impact in fulfilling students' developmental aspirations. The distinguished statements, identified by their Z-score values, further elucidate the significance of certain DQ elements within the respondents' perceptions. Notably, Privacy Management, Data and AI Literacy, and Digital Changemaker Identity emerge as particularly salient DQ elements, indicating their importance in fulfilling students' developmental aspirations. Conversely, statements related to aspects such as Civic Use of Technology and Relationship Management exhibit lower Z-score values, suggesting their relatively lower importance within the respondents' perceptions.

Answering to the RQ1. (What are the different perspective groups among university students regarding their beliefs about the potential for growth and improvement in DQ?), the findings suggest that students' perceptions of DQ vary based on their developmental aspirations, with some prioritizing social responsibility and effective communication, others focusing on security and responsible digital behavior, and still others valuing proficiency in digital literacy, creativity, and social impact.

5. Discussion

The literature underscores the significance of Digital Intelligence (DQ) in global competitiveness and individual development, with results revealing how individual mindset differences influence various DQ contexts (Manasia, Pârvan & Ianos, 2018; Sharma et al., 2016; Park & Gentile, 2019; Park, 2023). The three factors elucidate diverse perspectives on DQ, reflecting respondents' developmental aspirations ranging from social impact to security to creativity. Understanding these factors informs educational strategies catering to students' varying developmental priorities in the digital age (Park & Gentile, 2019; Park, 2023; Avci & Adiguzel, 2020). Factor 1 prioritizes a balanced approach, emphasizing digital co-creation and social impact, while Factor 2 focuses on security and responsible behavior. Factor 3 encompasses a multifaceted understanding, emphasizing critical thinking, creativity, and ethical considerations, highlighting the complex nature of DQ (Park & Gentile, 2019; Park, 2023). These insights underscore the importance of tailored educational interventions addressing diverse developmental aspirations and priorities in the digital landscape.

By tailoring programs to address specific areas highlighted by factors, such as social responsibility, cybersecurity, and creativity, universities can promote holistic DQ development (Dostal et al, 2017; Park & Gentile, 2019; Park, 2023). Initiatives should focus on enhancing skills in privacy management, content creation, and problem-solving to empower students in digital environments (Zhang, 2023). Practical implications suggest targeting

interventions based on identified proficiency gaps and fostering a culture of lifelong learning (factor_1, factor_2, factor_3). Theoretical contributions lie in integrating DQ with growth mindset, offering insights into how beliefs about growth influence digital skills development, and providing a foundation for further research (Zhang, 2023). This study highlights the importance of tailored educational interventions and the dynamic interplay between DQ and growth mindset, advancing theoretical discourse and informing future research directions.

6. Conclusion

In conclusion, our research findings shed light on the diverse perspectives among university students regarding their beliefs about the potential for growth and improvement in DQ. Factor_1 respondents prioritize digital interactions, emphasizing not only technical proficiency but also social and ethical considerations. Elements such as Digital Empathy, Self-Awareness and Management, and Relationship Management are deemed particularly salient, reflecting a focus on social responsibility and effective communication. Conversely, Factor_2 students prioritize security and responsible digital behavior, with Privacy Management and Personal Cyber Security Management taking precedence. Factor_3 students demonstrate a diverse range of competencies, prioritizing elements such as Media and Information Literacy and Data and AI Literacy, indicative of a desire for proficiency in navigating digital content and making a positive impact in the digital realm.

These findings underscore the importance of considering students' developmental aspirations in understanding their perceptions of DQ and growth mindset. By recognizing these diverse perspectives, educational interventions and policies can be tailored to better support students in acquiring the digital skills needed to thrive in today's digital age. Further research should explore the interplay between growth mindset and DQ to develop more targeted curriculum development strategies and educational interventions aimed at fostering a growth mindset and enhancing DQ maturity among students.

Abstract: Interactions between companies, crucial for economic success and knowledge advancement, involve significant exchanges of information and knowledge beyond mere economic transactions. Understanding how businesses can leverage these knowledge transactions (KTs) with trading partners is vital for both Knowledge Management (KM) research and practice. This entails identifying the knowledge essential for fruitful trading relationships, determining how to derive value from these exchanges, deciding what knowledge should be protected or shared, and developing value-adding strategies for knowledge exchange. To address these questions, this paper critically examines possible theoretical foundations for a KT model. It reviews nine notable KM models to assess the insights they provide (or do not provide) into knowledge exchange mechanisms both within organizations and between trading partners. These models provide some fundamental insights, but also have limitations, especially in addressing the "economic value" of knowledge exchanges. The study highlights the need for a comprehensive and effective KT model that positions knowledge exchanges in trading as a core, value-adding component of economic activities and business strategies. After this preliminary review of existing KM models, it suggests a new KT model, and indicates the need for further development towards a more encompassing approach.

Keywords: Knowledge Management, Knowledge Transaction, KM Models, Prerequisites, Literature Review

1. Introduction

When engaging in trading relationships, trading partners must exchange knowledge in order to augment the economic value of these relationships. This holds significance not only for each specific transaction but also under a broader perspective.

Trading interactions inherently involve substantial exchanges of information and knowledge. Understanding these mechanisms, referred to here as "knowledge transactions" (KT), is crucial (Bolisani, 2010). In this context, fundamental questions arise: What knowledge must companies exchange to establish fruitful trading relationships? How can their value be derived from the exchanged knowledge? By whom? What knowledge should be protected and what should be shared openly? What strategies can increase the value of trading?

Our analysis considers that, in an economic transaction, many KTs can occur, and they are fundamental for the effective conclusion of the economic transaction itself. Therefore, we advocate for a comprehensive and effective KT model that positions these KTs as a fundamental, value-adding components of economic activities. To develop this model, it is imperative to critically analyze the potential theoretical foundations that can be drawn from the KM literature. This critical analysis lays the groundwork for a more comprehensive model that captures the mechanism and economic value of KTs.

The paper proposes a preliminary review of some existing Knowledge Management (KM) models to glean insights and recommendations for the formulation of a new, more comprehensive model. Many useful models have been developed in the KM domain, each offering unique insights into the issue of how knowledge is created, shared, and used within and between organizations. In this study, nine prominent KM models have been selected and their strengths and limitations for modelling the dynamics of KTs in trading relationships have been analyzed. In the last sections, the foundations for an innovative model of KTs are then proposed and discussed.

2. Knowledge Transfer, Exchange, Sharing: Basic Definitions

It is firstly important to consider definitions and terms used in KM to refer to situations similar to the case analyzed here. Terms like knowledge transfer, knowledge exchange, and knowledge sharing generally refer to fundamental mechanisms through which knowledge passes between or across organizations or people. This section outlines their basic definitions and highlights differences and usefulness.

Knowledge Transfer, considering the many definitions proposed in the literature (e.g., Szulanski, 1996; Boyd et al. 2007; Avelino, 2023), can be described as ''the process through which a 'piece of knowledge' is passed from somebody who possesses it in some form to somebody else that is expected to use it in some way'' (Bolisani, 2008). This process depends on a transmission medium and occurs in a framework of rules and mechanisms that influence it. This definition stresses the main elements of this process: the transferred "knowledge item", the knowledge sources (users/receivers), and the channel or medium and enabling framework.

Knowledge exchange refers to the reciprocal transfer of knowledge between individuals, teams, or organizations, where both parties contribute and benefit from the exchange. It involves a complex "economy" of reciprocation and obligation (Konstantinou and Fincham, 2011). Davenport and Prusak (1998) emphasize social context and trust as crucial elements for the effective knowledge exchange, suggesting that knowledge flows best strong relational ties exist between the participants. Also, Wenger's (1998) works on communities of practice outline how social structures facilitate a deeper level of knowledge exchange through shared practices and learning.

Knowledge sharing is often seen as the act of openly distributing knowledge among members of an organization or community. Many authors (Brown and Duguid, 2000; Liu, 2008; Hargadon, 2002), argue that knowledge sharing is fundamentally a social activity, deeply embedded in the informal culture of an organization. Liu (2008, pp-3) defines knowledge sharing as "The process where individuals exchange their (tacit or explicit) knowledge and jointly created new knowledge in a knowing process under certain social contexts that are also constructed out of these activities." This conceptualization underscores the critical role of social interactions in fostering mutual understanding.

To sum up, while these three processes are closely interlinked and these terms have been used interchangeably, each carries its own unique focus and serves distinct purposes. Knowledge transfer is predominantly unidirectional and implies the efficient passage of knowledge from one entity to another, ensuring that the recipient acquires specific insights or skills from a source. Knowledge exchange is inherently bidirectional and reciprocal, crafted around the idea that the two participants both contribute to and benefit from the process. Knowledge sharing expands beyond a dyadic relationship and includes the idea of a more open distribution of knowledge across a network or community, often without any direct expectation of reciprocation.

3. Consideration of "Economic Value" in KM Models

The nine models that we analyze in this section refer, to some extent, to situations where the notions and definitions illustrated in the previous section are relevant. We now briefly examine their core principles, strengths, and limitations to derive suggestions for a new, comprehensive, and effective model that emphasizes the mechanisms and economic value of KTs.

3.1 SECI

Nonaka and Takeuchi's (1995) "Knowledge Spiral Model" is a foundational framework in KM. This model depicts knowledge creation as a dynamic, iterative process within organizations. It categorizes knowledge as being either tacit or explicit and delineates four modes through which knowledge is created and transferred: Socialization, Externalization, Combination, and Internalization (Nonaka and Takeuchi, 1995; Dalkir, 2011, Adesina and Ocholla, 2019).

The model quickly became one of the most popular in KM, and has been applied to diverse contexts (Dalkir, 2011). A key characteristic of the model is its simplicity, facilitating easy comprehension of its core principles and application where there is a need to understand the mechanisms involved in effective exchanges of knowledge between two parties. However, while it effectively delineates the transformations between tacit and explicit knowledge, it overlooks broader considerations such as the integration of these categories of knowledge into decision-making processes. Therefore, the economic value of KM dynamics and the reasons for engagement in knowledge transfer by trading parties are not clearly addressed. Also, some scholars have identified the challenges of applying the model in a variety of situations as well as the non-linear nature of the model(Adesina and Ocholla, 2019; Oztok, 2013; Chai et al., 2011). These critiques underscore the ongoing need for further refinement and adaptation of the SECI model to depict KM implications in interorganizational relationships. Some extended versions, such as Zhang and Huang's (2020), try to incorporate inter-organizational knowledge flows and open innovation principles to better depict the opportunities of knowledge exchanges within and across organizations.

In short, while SECI provides valuable insights into the specific knowledge conversion mechanisms, its applicability as a 'KT model,' as defined in the context of this study, is limited. The model primarily focuses on internal knowledge processes and does not explicitly address the dynamics, value, and motivations of knowledge exchange between two trading partners. In particular, it lacks emphasis on the economic value of these exchanges or their strategic nature and significance.

3.2 Sense-Making

Choo's (1998) Sense-Making Model provides an integrated framework for understanding the use of information within organizations by encapsulating sense-making, knowledge creation, and decision-making. This model presents a comprehensive perspective on how information is processed and transformed into actionable knowledge, factoring in the broader organizational context in which these transformations occur.

The model's strength is its incorporation of a holistic view of information handling, emphasizing the transformational journey from raw data to knowledge and subsequent actions (Choo, 1998; Neto, 2009; Dalkir, 2011; Cristea and Capatina, 2009). However, despite its broad applicability and the insights into organizational knowledge dynamics, its main limitation is the lack of analysis of economic aspects. Its extensive scope, while valuable for understanding internal processes, may also inadvertently gloss over the specific nuances and potential economic value generated through knowledge exchanges between trading entities. This suggests that while Choo's model is instrumental in conceptualizing knowledge processes within organizations, it may require adaptation or extension in order to fully address the complexities and economic implications of inter-organizational trading relationships. Also, this model is a modified and extended Information Science approach and therefore the link to transactions is limited.

3.3 Wiig

This model (Wiig 1993) focuses on the practical aspects of KM, emphasizing knowledge use, building, and maintenance within organizations. It defines a structured approach to KM, emphasizing the systematic management of knowledge assets to improve organizational effectiveness. One of its core strengths lies in its holistic view of KM, encompassing the identification, development, and application of knowledge to support organizational objectives by using a categorization of knowledge into four types—factual, conceptual, procedural, and methodological. Managing these knowledge types can effectively lead to improved organizational performance (Wiig, 1993; Dalkir, 2011; Evans et al., 2014; Cristea and Capatina, 2009). Considered to be a very pragmatic KM model, it seamlessly integrates various KM approaches surpassing the conventional tacit/explicit classification and providing a comprehensive framework adaptable to diverse contexts.

However, while it provides a comprehensive framework for internal KM, its application to the dynamics of relationships (and knowledge interactions) between trading partners is questionable. Firstly, the model primarily addresses KM within the confines of individual organizations and does not explicitly explore the inter-organizational dimensions. Second, the Wiig Model does not explicitly consider the economic aspects of KM. Although it acknowledges the importance of knowledge for competitive advantage, it lacks a detailed exploration of how knowledge exchange between trading partners can lead to the generation of economic value.

3.4 I-Space

The I-Space (Boisot, 1998) model offers a unique framework for understanding the dissemination and utilization of knowledge and basically conceptualizes information or knowledge flow along three dimensions: codification, abstraction, and diffusion. The model is a 3-dimensional framework, which helps in mapping the state and flow of knowledge. Codification refers to the process of converting knowledge into a format that can be easily disseminated. Abstraction involves the removal of contextual details to make knowledge more universally applicable. Finally, diffusion represents the spread of knowledge across a population. The strength of the Boisot model is that it incorporates a theoretical foundation based on social learning. The Social Learning Cycle (SLC) serves to link content, information, and KM in a very effective way - the codification dimension is linked to categorization and classification; the abstraction dimension is linked to knowledge creation, and the diffusion dimension is linked to information access and transfer (Dalkir, 2011; Spinuzzi, 2023; Canals et al, 2008).

Generally, this model sheds light on the complexities of KM particularly in terms of how knowledge is processed, stored, and shared. There is a strong potential of the I-Space model for mapping and managing an organization's knowledge assets and their importance for a learning cycle, which is not directly addressed by other KM models.

One set of limitations relate to the difficulty of applying the model to empirical cases (Spinuzzi, 2023) in real-life workplace situations. First, the underlying theory does not account well for how people use representations synchronically for their mutual learning. Second, it does not adequately bind an analysis case. Thus, it can be applied analogically but not directly for mapping representations in qualitative case studies. Furthermore, similar to the case of other KM models, this model primarily focuses on the properties and flow of knowledge without directly addressing aspects of economic value. Thus, the model, while useful for understanding knowledge dissemination, may not fully capture the strategic and value-related aspects of knowledge interactions in a trading context.

3.5 Von Krogh and Roos

This model (Von Krogh and Roos, 1995) emphasizes the epistemological perspectives and organizational contexts of knowledge creation and sharing. The model distinguishes between individual knowledge and social knowledge through the adoption of an epistemological viewpoint (Dalkir, 2011; Von Krogh and Roos, 1995; Cristea and Capatina, 2009). In the model, knowledge resides in both individuals and their relations, and the human and relational aspects of KM are stressed. By highlighting the importance of social dynamics, such as trust and mutual respect, Von Krogh and Roos offer an approach to understanding how knowledge is cultivated and disseminated within organizations. This perspective is crucial for fostering a collaborative environment.

While deep insights into the internal mechanisms of knowledge creation and sharing are provided, the application of this model to inter-organizational relationships is, again, difficult, especially in trade. In fact, the model does not explicitly address the complexities of KM across organizational boundaries, including issues related to intellectual property, competitive advantage, and the economic value of shared knowledge. It lacks a clear framework for assessing the economic impact of these knowledge transactions on organizational performance and market competitiveness. Again, there is also a lack of concern for linking knowledge to action which is critical both for the knowledge to be 'meaningful' to the organization and to be valuable.

3.6 Intelligent Complex Adaptive System (ICAS)

This model (Bennet and Bennet, 2004) views organizations as complex adaptive systems. Its foundation lies in a recognition of organizations as ecosystems where knowledge flows and evolves through complex interactions among members. It stresses the importance of adaptability, suggesting that the ability to respond to changes and challenges through effective KM is crucial for organizational success (Bennet and Bennet, 2004; Dalkir 2011; Cristea and Căpaţînă, 2009). ICAS systems are based on cybernetics principles, which use communications and control mechanisms as a basis for understanding, describing, and predicting what makes an organization viable. Adaptive systems are comprised of independent interacting agents whose behavior leads to complex adaptation patterns. There is no superior authority controlling agents, and complex system behavior arises because of all the interactions (Cristea and Căpaţînă, 2009, Dalkir, 2011).

The ICAS model provides valuable insights into internal organizational dynamics, but the manner in which it may be applied to inter-organizational relationships is unclear. The model focuses primarily on internal adaptability and learning, with less emphasis on how organizations can manage knowledge exchanges with external entities in order to create economic value and enhance viability. The extension of the principles of adaptability and complex interactions to external partnerships and collaborations, where different organizational cultures, goals, and KM practices should converge, is challenging.

3.7 EFQM Excellence

EFQM Excellence was developed by the European Foundation for Quality Management (EFQM), a not-for-profit membership foundation founded in 1988 in Brussels by fourteen leading European businesses to promote business excellence across the continent. Basically, the EFQM Model is part of a broader framework designed to help organizations improve their performance through a set of principles centered around excellence, including leadership, process, and customer results. It proposes a comprehensive approach to organizational quality, embedding KM in an overall organizational excellence (Bhatt, 2000; Dalkir, 2011; Criado-García, 2020). The EFQM model (Bhatt 2000) examines how KM contributes to achieving organizational objectives. Drawing from traditional models of quality and excellence, this framework establishes robust connections between KM processes and organizational performances, emphasizing the crucial role of knowledge in organizational success. Knowledge is seen as a key strategic resource and the integration of excellence and KM constitutes a dynamic capability for organizations based on continuous improvement, innovation, and learning (Criado-García, 2020).

Whilst the EFQM model provides a robust framework for integrating KM into organizational excellence, its focus on internal processes and outcomes may limit its applicability to the dynamics of knowledge exchange and collaboration among external entities, nor does it explicitly explore the economic value generated through such exchanges or their strategic dimension.

3.8 Inukshuk

The Inukshuk KM model (Girard, 2005) was developed primarily to help Canadian government departments better manage their knowledge. It utilizes the metaphor of Inuit stone landmarks (Inukshuks). Inukshuks serve several functions, including guiding travellers, warning of danger, assisting hunters and marking places of reverence. Inukshucks are used as a metaphior for guiding organizations in knowledge creation, sharing, and utilization in organizations. The model emphasizes the strategic placement of knowledge in an organization, advocating for knowledge to be as visible and usable as are Inukshuk in the Arctic, guiding individuals, and teams effectively towards decision-making and innovation (Dalkir, 2011; Sensuse, 2014). Its primary strength is the simplicity of its metaphor, underscoring the importance of making knowledge accessible and actionable. This approach aids in fostering an environment where knowledge is not just stored but is actively used, an idea also recalled by Davenport and Prusak (1998) who remind us of the necessity how organizations managing what they know.

Like most of the models reviewed, the Inukshuk KM Model offers valuable insights into knowledge accessibility and usability within organizations, but its application to inter-organizational and trading dynamics has limitations. In fact, the model primarily focuses on the internal organization with less emphasis on how knowledge is exchanged, co-created, or valued in inter-organizational contexts. Additionally, the economic value generated through external KT is not explicitly addressed, leaving a gap in understanding how knowledge sharing between partners can lead to mutual benefits and value creation.

3.9 KM Cycle (KMC) (Evans et al., 2014)

This comprehensive KM life-cycle model was developed by Evans, Dalkir, and Bidian (2014) by building on previous models and on Heisig's (2009) analysis of KM frameworks. It has seven non-sequential phases (i.e., identify, store, share, use, learn, improve, and create) and provides a structured approach to understanding the stages through which knowledge is identified, captured, processed, and utilized within organizations. This model emphasizes the iterative nature of KM, where knowledge is continuously developed and refined through cycles of learning and application. The focus on these different activities or processes is important because it helps understand how the cyclical iteration 'improves' the both individual and organizational knowledge. By outlining clear stages in the KM process, the model provides organizations with a roadmap for leveraging their knowledge assets to drive innovation and, potentially, competitive advantage.

Again, the KMC Model offers a robust framework for internal KM processes or cycles, but it primarily addresses KM within the confines of a single organization and does not explicitly explore the dynamics of sharing, co-creating, or monetizing knowledge in inter-organizational contexts. Furthermore, the economic value generated through knowledge exchange between business partners and its impact on market positioning and competitiveness is not directly addressed within the model's framework.

4. Analysis

Table 1 highlights the main pros and cons of the examined models as theoretical foundations for a comprehensive model of KTs. All these models provide important insights into the mechanisms related to the KM processes that involve transfer, exchange, and sharing of knowledge. However, they also have limitations.

On the one hand, they provide useful (and, sometimes, very detailed) insights into the mechanisms which involve knowledge exchanges. Some of them also emphasize the appropriate contexts that favor a fruitable interaction between parties.

On the other hand, they all have two main limitations. The first is they have insufficient applicability to inter-organizational contexts. The second is the general underestimation or complete lack of consideration of the economic value of interactions and exchanges of knowledge. Business organizations do not exchange knowledge just to exchange knowledge but to support economic value generation and, further enhance their strategic position with respect to their competition. Those few models that address this issue do not go beyond a general consideration of the point, providing no detailed analysis.

Based on this critical review and building upon these pros and cons, we argue that a new comprehensive KM is needed to explain how companies exchange knowledge in trading and how this contributes to economic value generation and enhance their strategic positioning, by means of the appropriation, absorption or development of knowledge.

This model should incorporate some key elements.

Inter-Organizational Focus: The new model should explicitly address the mechanisms of knowledge exchange between trading partners, considering the different types of knowledge that can be shared and the platforms or media through which this exchange can occur. Here, there is a need to investigate the nature of the transaction too.

Economic Value Generation: It is essential to integrate concepts from economic theory and value creation frameworks into the model. This integration would provide a foundation for understanding how knowledge exchange contributes to economic outcomes, such as innovation, competitive advantage, and and a variety of strategic objectives.

Table 1: Summary of the examined KM models

KM model	Pros	Cons
SECI	· Structured and foundational framework for understanding knowledge creation and conversion processes · Highlights the importance of tacit knowledge and social interaction · Provides simple and easily comprehensible model for practical applications	· Primarily focuses on internal knowledge processes and does not explicitly address the dynamics, value and motivations of knowledge exchange between trading partners · Lacks emphasis on the economic value of the knowledge exchange in the trading relationships and the implied strategic considerations
Sense-Making	· Offers a holistic perspective in knowledge transformation by considering collective sense-making within organizations · Ideal for Decision-Making Process · Highlights the role of information-seeking and sense-making in knowledge creation	· Lack of prescriptive guidance on how to effectively facilitate sense-making in an inter-organizational context · Limited discussion on the economic implications of the knowledge exchange in trading relationships
Wiig	· Offers a structured approach to managing knowledge assets · Designed Explicitly for Knowledge Building Scenario · Enduring relevance since its inception - remains relevant and widely used in KM practices	· Difficulty in application to dynamics of relationships between trading partners · Does not explicitly explore the economic value of knowledge exchange
I-Space	· Offers a conceptual framework for understanding the dynamics of knowledge as information flows · Emphasizes the role of codification and personalization in KM	· Limited application to inter-organizational relationships · Insufficient framework for economic evaluation of the value generated through knowledge exchange · Difficult empirical application
Von Krogh and Roos	· Emphasizes the importance of social interaction and communities of practice in KM · Emphasizes human and relational aspects of knowledge creation and sharing	· Difficult assessment of economic impact of KTs · Limited application to inter-organizational relationships
Intelligent complex adaptive system (ICAS)	· Relevant to recognize the complexity and dynamism of organizational knowledge based on advanced Intelligent Techniques · Emphasizes adaptability and learning through knowledge exchange	· Complexity in practical application within organizations · lack specificity in addressing knowledge exchange between trading partners. · Limited discussion on the economic value of knowledge exchange
EFQM Excellence	· Best for organizational excellence and performance measurement · Emphasizes the importance of leadership, strategy, and people in KM · Robust framework for integrating KM into organizational excellence	· Primarily focused on internal knowledge processes within organizations, limiting its applicability in a trading partnership · Not directly address the economic consideration of knowledge exchange between trading partners
Inukshuk	· Offers a visual representation of knowledge management processes. · Emphasizes the importance of communication and collaboration in knowledge exchange	· does not directly address the economic value generated through external knowledge transactions · Insufficient framework for economic evaluation
KM Cycle (KMC) *(Evans et al., 2014)*	· Best to demonstrate the holistic view of the knowledge life cycle · Emphasizes the iterative nature of knowledge management processes	· Primarily focused on internal knowledge processes within a single organization. · Lack of exploration of economic value generated by knowledge exchange

Knowledge Disclosure vs. Protection: The model should offer strategies for balancing the disclosure of knowledge with the need to protect proprietary information. This includes mechanisms for establishing trust, negotiating knowledge-sharing agreements, and utilizing intellectual property protections. Also, depending on the nature and characteristics of the knowledge being transferred there may be other requirements.

Adaptability and Contextual Relevance: Given the dynamic nature of trading relationships and market conditions, the model should be adaptable and consider the contextual factors that influence KT. This includes industry-specific challenges, regulatory environments, and cultural differences between trading partners.

Measurement and Evaluation: Finally, the new model should incorporate methods for measuring the impact of KT on economic value and organizational performance. This could include metrics for assessing the quality, relevance, and timeliness of exchanged knowledge, as well as its contribution to achieving strategic objectives.

5. A Model of Knowledge Transaction

This section presents an argument for viewing economic activities from a micro perspective, where a company or an economic player is seen as a system of stocks (wealth such as cash, machinery, real estate, accounts receivable) and flows (expenditures or receipts). Economic value creation is tied to operative activities over time and the accumulation of value in appropriate repositories. The model of knowledge transactions emphasizes the importance of interactions between economic players (e.g., trading) and how the value of assets is influenced through trading and by external conditions, such as market dynamics and trading rules. It introduces the notion that besides the physical exchange of goods/services and money, there is a crucial flow of communications between parties, involving the exchange of messages that allow for the definition of trading conditions and the execution of transfers. This exchange of messages, imbued with valuable knowledge, is essential for trading and underpins the proposed model of KT, highlighting the economic significance of knowledge exchange in the creation of economic value.

In other words, our analysis refers to KTs where knowledge is exchanged during an economic transaction, regardless that the sold goods are products or services. In other words, we have two levels of analysis. One is the classic “economic transaction” of goods, services (or even knowledge in the special case that it is the final product that is sold, for example for a consulting company). The other level is that of “KTs”, i.e. particular exchanges of knowledge that occur during an economic transaction and that have, however, value themselves. We can say that in an economic transaction there are many KTs that occur in parallel and are a value-adding components of economic transactions and, therefore, business strategies.

To sum up, KTs are defined as exchanges of valuable knowledge between traders, occurring multiple times during an economic transaction and being crucial for its execution, to complete economic transactions efficiently and effectively. KTs are differentiated from other communication models used in KM (see above) because they emphasize the economic value of the exchanged knowledge. This approach suggests that knowledge exchange, akin to barter systems, carries inherent economic value and should be analyzed beyond a view of mere data or information transfer ancillary to trade relationships. Knowledge has a role and, therefore, a value in action oriented decision-making. We argue that understanding KTs provides insight into the nature of economic transactions from a new perspective, emphasizing, among other things the cognitive underpinnings of economic activities.

A practical example can help to illustrate the concept of KT, using a simple transaction between a seller and a buyer of a consumer product (Bolisani, 2009), e.g. an item of clothing, a device, some food, or any similar item. Breaking down the interaction into a series of KTs - such as the exchange of information about the availability of that product, then the buyer's preferences, and next the negotiation of the price, etc. - we see that each step involves the exchange of knowledge that has its own economic value, because it influences the decisions and actions of both parties in any of the transaction steps. The example demonstrates that economic transactions are not merely about the physical exchange of goods and money but involve a complex series of KTs, where each piece of exchanged knowledge adds to the overall economic value of the transaction and, in addition, has its own value *per se*, even in the case of incomplete transactions. For example, even when the buyer decides, in the end, that the price of a product is too high in a shop and will not buy it, this is useful learning for the buyers future decisions about where to buy similar products in future. To the seller such knowledge allows the seller to investigate both the impact on price in the buyers purchase decision and other knowledge that may be indirectly conveyed to the buyer through the price signal (e.g. with respect to quality, the social status of the buyers, etc.).

6. Potential Application

A possible example is the analysis of business relationships between companies, specifically within a network of client-supplier relationships. In industries where OEM companies assemble the final products (eg.: automotive, electronics, household appliances, etc.), or in cases where the product is co-designed in the interaction between a client and a supplier, the KT model can be applied to understand the intricate web of knowledge exchanges among firms, including the leading company, local dealers, and final clients, during the development of the new product, its manufacture, and sale (Bolisani, 2010).

The case study presented by Bolisani (2010) highlights the value of KTs in learning from business relationships, capitalizing on exchanged knowledge, and understanding the mechanisms of knowledge exchange during different steps of business relationships and economic transactions. It also points out the challenges that companies must face due to the need for knowledge disclosure on the one hand, as is unavoidable when a component must be co-designed in collaboration between suppliers and customers, and the need for knowledge protection, to avoid leakages and misuse by competitors. The traditional focus on financial transactions is, on the one hand, not sufficient to highlight these implications, while the typical KM models of knowledge exchange, on the other hand, do not stress the value of any element of knowledge that the parties exchange.

7. Conclusion

In synthesizing the strengths and limitations of the KM models discussed in this study, it becomes evident that while each contributes valuable insights into the transformation of knowledge within organizations by means of interactions, exchanges, and sharing, there is a discernible gap in their direct applicability to the economic and strategic aspects of KMs in trading relationships. This gap highlights the need for a model that more directly ties KM practices to economic outcomes in the context of inter-organizational relationships. A new model aimed at addressing these gaps must incorporate a balanced approach to knowledge sharing and protection, facilitate inter-organizational collaboration, and emphasize the measurement and monitoring of KT outcomes to enhance economic activities and business strategies. Such a model would not only advance the theoretical foundations of KM but also offer practical guidelines for leveraging knowledge as a core value-adding component in trading relationships.

In the paper, it is suggested that KTs can play a foundational role in the creation of economic value within the knowledge economy. By focusing on the exchange of knowledge between parties, we also propose a shift in how economic activities are viewed and analyzed, emphasizing the cognitive aspects of trading and the inherent value of knowledge exchange. This perspective opens new avenues for research and analysis in economic and accounting studies, underlining the importance of KTs in understanding the dynamics of the modern economy.

The paper has some limitations. First, it includes a selection of the many models that have been developed in the KM field. Although these models have currency and relevant to the task at hand, our selection is intrinsically subjective. Second, the paper is a preliminary proposal of a new model that still requires refinement and, especially, more robust empirical validation. This can be part of a future research agenda.

Abstract: Business internationalization and globalization naturally led to the need to manage across cultures and develop new competencies for leaders. One of these competencies is cultural intelligence (CQ) that is actually a meta-competence because it incorporates rational, emotional, spiritual, and social intelligence. *Cultural intelligence* expresses the capacity of a leader to understand different cultures and the behavioral types generated by them, and to make decisions able to satisfy multicultural requirements, avoiding intercultural conflicts due especially to different cultural and religious values and principles. Different cultures are characterized by different knowledge dynamics which influence the process of decision making and multicultural leadership. The purpose of this paper is to explore the impact of knowledge dynamics on multicultural leadership, in multicultural business environments, and what is the role of cultural intelligence in this process. Based on the critical literature review we identified the main constructs and connections we have to explore through an investigation based on questionnaires and a statistical analysis using PLS-SEM method. The findings confirmed our initial hypotheses.

Keywords: Knowledge Dynamics, Cultural Intelligence, Social Intelligence, Leadership, Multicultural Leadership

1. Introduction

The increasing dynamics of business internationalization and globalization (Vatamanescu & Mitan, 2024) challenge the leadership competencies within the multicultural environment (Lewis, 2018). Leading across cultures requires a deep understanding of the different value sets of people coming from different cultures to work together in the same company, and making managerial decisions in social contexts with a high potential of conflicts. The new competence required is *cultural intelligence* (CQ), and it can be defined as a capacity to understand different cultures and create a convergence of business interests within a company (Bratianu & Paiuc, 2023; Meyer, 2014). Cultural intelligence is a meta or higher-order intelligence because it is composed of rational, emotional, spiritual, and social intelligence.

Cultural intelligence is impacted by *knowledge dynamics* (KD) understood as a transformation of one form of knowledge (i.e., rational, emotional, spiritual) into another form of knowledge. That relationship is mediated by the decision making that is performed within a multicultural environment (Bratianu et al., 2020; Kahneman, 2011). However, a critical literature review reveals a knowledge gap concerning the influence of knowledge dynamics on multicultural leadership and what are the main constructs involved in this complex process. The purpose of this paper is to explore the connections between knowledge dynamics and multicultural leadership in multicultural business environments and what other variables should be considered in such an analysis. The originality of the present research comes from addressing that knowledge gap and helping managers and leaders working in multicultural business environments to understand the new challenges of the decision making processes.

2. Literature Review

A critical literature review concerning multicultural leadership and the new challenges it faces by comparison with classical management that operates within a monocultural environment reveals the importance of the following constructs: knowledge dynamics, cultural intelligence, and multicultural leadership. The following presentation will focus on the main characteristics of these constructs and on the possible connections between them.

Knowledge dynamics (KD) is a multidimensional concept encompassing variations of knowledge in time and space. Knowledge variation in time is a direct result of learning or unlearning processes at the individual level

(Bereiter, 2002; Cegarra-Navarro & Wensley, 2019; Kolb, 2015; Nonaka & Takeuchi, 1995) or at the organizational levels (Argote, 2013; Cegarra-Navarro, Elridge & Martinez-Martinez, 2010; Nonaka & Takeuchi, 1995, 2019). By extension from knowledge to intangibles, some authors considered the dynamics of intellectual capital (Kianto, 2007; Kianto et al., 2017). In this situation, the dynamics reflect the increase or decrease of the knowledge level from a quantitative point of view. Although there is no measuring system for the quantity of knowledge yet, we can compare the two different states of knowledge before and after a learning or unlearning process, and say which of them is higher. Therefore, it is possible to evaluate a relative variation of the knowledge level instead of an absolute one. At the organizational level, three main processes contribute to the balance of knowledge (Bratianu, 2007; DeLong, 2004): knowledge creation, knowledge acquisition, and knowledge loss. Knowledge dynamics based on the variation of knowledge in space is known metaphorically as *knowledge flow* (Bolisani & Oltramari, 2012; Nissen, 2006; Nonaka, Toyama & Hirotaka, 2008).

From the theory of knowledge fields, knowledge dynamics means *a transformation* of one form of knowledge into another one (Bratianu & Bejinaru, 2020). This transformation process is done continuously within our brain with the final result of making decisions. The classical theory of decision making is based exclusively on rational knowledge and rational intelligence. However, cognitive sciences revealed through many experiments and psychological analyses demonstrated that emotional knowledge and emotional intelligence are very important in decision making (Damasio, 2012; Gladwell, 2005; Goleman, 1995; Hill, 2008). Wise leaders go beyond economic values and consider an enlarged spectrum of values and principles for their thinking and decision making (Kaiser & Martinez, 2023; Nonaka & Takeuchi, 2019; Rocha & Pinheiro, 2021; Zohar & Marshall, 2004). They perform what Aristotle called *phronesis*, or practical wisdom (Aristotle, 1999; Rocha et al., 2021; Shotter & Tsoukas, 2014). Aristotle asserts that *phronesis* is "a state of grasping the truth, involving reason, concerned with action about things that are good or bad for human beings" (Aristotle, 1999, p. 89). In any organization, there is a shared set of values that establishes a certain organizational behavior. That is described in the company's code of ethics. For example, Samsung's ethical code is structured as a "Trinity of Values", that contains the company's management philosophy, core values, and business principles (Song & Lee, 2014, p. 111). "Samsung has set forth core items that were to be followed by all employees as its management principles. The company has 5 overarching principles, 15 detailed principles, and 42 conduct rules that its employees are expected to follow" (Song & Lee, 2014, p. 111). If economic decisions are based mostly on rationality, employees' motivation is based dominantly on emotionality, and their behavior is based on the dynamics between rationality, emotionality, and spirituality. Therefore, their organizational behavior is influenced by knowledge dynamics. It is an independent variable that will be considered in the present research model.

Cultural intelligence (CQ) is a higher-order intelligence because it integrates rational, emotional, spiritual, and social intelligence and becomes significant for people working in multicultural environments, like multicultural companies with employees from different countries (Ang & Van Dyne, 2015; Lewis, 2018; Paiuc, 2021). Understanding the way people from other countries think and behave is essential in creating a supportive working atmosphere in teams and multinational organizations, as well as in competing with products and services on international markets. Rational intelligence (IQ) is the capacity to process efficiently rational knowledge and make the best decisions for a given situation or context (Hawkins & Blakeslee, 2004; Pinker, 2021). As Simon remarks, "intelligence is the work of symbolic systems" (Simon, 1996, p. 23). It is the generic intelligence measured traditionally using IQ tests based on items coming mainly from positive sciences. It is the intelligence developed through formal education in schools and universities and used as a predictor for a successful career. Managers use rational intelligence in making decisions based on economic factors because economic science is based on rational principles like mathematics and physics.

Gardner (1983) introduced the new paradigm of multiple intelligences and opened the way for emotional intelligence and spiritual intelligence. *Emotional intelligence* (EQ) represents the capacity to understand personal emotions and how to work with them. More rigorously, emotional intelligence is defined as: "The capacity to reason about emotions, and of emotions to enhance thinking. It includes the abilities to accurately perceive emotions, to access and generate emotions, so as to assist thought, to understand emotions and emotional knowledge, and to reflectively regulate emotions so as to promote emotional and intellectual growth" (Mayer, Salovey and Caruso, 2004, p. 197). They process emotional knowledge (Goleman, 1995; Mayer, Salovey & Caruso, 2004; Salovey & Mayer, 1990). Emotional intelligence shapes people's motivation and their behavior. It is nonlinear and it manifests faster than rational intelligence in making decisions (Gladwell, 2005; Hill, 2008; Kahneman, 2011). Due to its powerful impact on motivation and behavior, emotional intelligence can be a better predictor for personal success in life and leadership than rational intelligence. *Spiritual intelligence* (SQ) represents the capacity to understand the meaning of life and work, and making decisions in accordance with a

set of well-defined values and principles (Aristotle, 1999; Zohar & Marshal, 2004). As Zohar and Marshall remark, "We know today that human beings are by definition primarily creatures of meaning and value (that is, of 'self-actualization'). We need a sense of meaning and driving purpose in our lives. Without it we become ill or we die" (Zohar & Marshall, 2004, p. 17). Spiritual intelligence is the main ingredient of *phronesis* (Rocha & Pinheiro, 2021; Rocha et al., 2021; Shotter & Tsoukas, 2014). Rational, emotional, and spiritual intelligence are defined at the individual level. When several people work together, the relationships between them become important and that leads to social intelligence (Goleman, 2007). Each of these intelligences may have different levels when people within a team or organization come from different cultures. Therefore, understanding them and leading them toward convergent objectives requires a high level of cultural intelligence.

Multicultural leadership is a complex construct used for leaders of multicultural teams and organizations. The main features of those social contexts are the diversity of education, culture, and thinking models. Leading across cultures requires a high level of cultural intelligence and a balance of knowledge dynamics (Batsa, Abadir & Neubert, 2020; Iskhakova & Ott, 2020; Stahl & Maznevski, 2021). The risk of leading across cultures is the potential conflict between people. The main challenge is to create a set of shared values and a convergent organizational behavior toward achieving the designed objectives.

3. Methodology

The literature review shows a knowledge gap concerning the connections between three main constructs that are characteristic for cross-cultural management: knowledge dynamics, cultural intelligence, and multicultural leadership. Trying to get insight into this complex cross-cultural nexus, we formulate the following research questions (RQ):

RQ: What is the role of knowledge dynamics and cultural intelligence in developing multicultural leadership?

To answer this question we designed a research model containing all three constructs: knowledge dynamics (KD) as an independent variable, cultural intelligence (CQ) as a mediating variable, and multicultural leadership (ML) as a dependent variable. Figure 1 illustrates this research model. The model represents a linear simplification of the nonlinear reality, but it is in accordance with the logic used in designing the quantitative approach based on a questionnaire and statistical analysis using the method of Structural Equations Modeling (SEM). The research model suggests the following hypotheses:

H1: Knowledge dynamics (KD) influences positively multicultural leadership (ML).

H2: Knowledge dynamics (KD) influences positively cultural intelligence (CQ).

H3: Cultural intelligence (CQ) influences positively multicultural leadership (ML).

The construct of KD is measured with three indicators: KD1 – Rational knowledge; KD2 – Emotional knowledge; KD3 – Spiritual knowledge. The mediating construct of CQ is measured with four indicators: CQ1 – Metacognitive cultural intelligence; CQ2 – Cognitive cultural intelligence; CQ3 – Motivational cultural intelligence; CQ4 – Behavioral cultural intelligence. Multicultural leadership is measured using four indicators: ML1 – Administrative skills; ML2 – Interpersonal skills; ML3 – Conceptual skills; ML4 – Multicultural skills. These variables and indicators were defined based on our literature review.

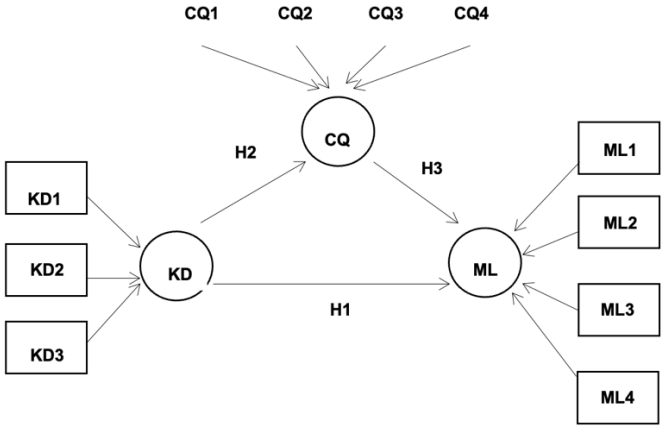

Figure 1: The research model

We designed a questionnaire based on the research model presented in Figure 1 and distributed it online to 396 managers working in multinational companies worldwide. We received 439 answers, out of which we could use 396 valid questionnaires. To establish the sample size we used the standard procedure and data obtained from adequate databases like ILO (2021), STATISTA (2021), and ZIPPIA (2022). The questionnaire has an introductory part where we explain the purpose of the project and guarantee the data confidentiality. Our study reached out to potential participants for the questionnaire through targeted online social media and personal connections such as LinkedIn, Facebook, and email. We used our personal networks of managers working in multinational companies worldwide. Also, we used SurveyMonkey, a worldwide recognized platform for professional online surveys. The valid response recovery rate was 89.14% (396 valid and recorded answers from 439). The demographic statistics show that the respondents can be grouped into three categories: a) males (n=200, 50.5%); b) females (n=188, 47.5%); c) non-binary group (n=8, 2.0%). The educational groups were formed of university graduates (n=164, 41.4%), master graduates (n=157, 39.6%), Ph.D. graduates (n=48, 12.1%), and high school only (n=27, 6.8%). The geographic distribution shows that a number of 47 (11.9%) participants were from Africa, 70 (19.9%) were from Asia, 130 (32.8%) were from Australia, 73 (18.4%) were from Europe, 73 (18.4%) were from North America, and 29 (7.3%) were from South America.

4. Results and Discussions

In the first stage of our analysis, we used IBM SPSS Statistics version 22 software to check the validity of variables, and Cronbach's Alpha's values, for reliability. In the second stage, we used the Partial Least Squares Structural Equation Modeling (PLS-SEM) to test our hypotheses (Hair et al., 2017; Hair et al., 2019). For reliability, we analyzed the factor loading for each item and found that their values were higher than 0.70 (Hair et al., 2019). Therefore, we retain all items for further analysis. All constructs and sub-constructs of the research model met the significant construct reliability threshold of $\alpha > 0.80$.

Our analysis proved that knowledge dynamics has a positive influence on multicultural leadership. Therefore, the hypothesis H1 is validated. Also, knowledge dynamics has a positive influence on cultural intelligence. Therefore, the hypothesis H2 is validated. Furthermore, cultural intelligence has a positive influence on multicultural leadership. Therefore, the hypothesis H3 is validated. In conclusion, all three hypotheses we considered in the present research model are valid, which demonstrates its logical consistency.

The validation of this research model shows that it can be used for further investigations considering more variables and the roles of mediation and moderation. Also, the present research has practical implications for managers and leaders working in multicultural business environments making them aware of the cognitive connections between knowledge dynamics, cultural intelligence, and multicultural leadership. Knowledge dynamics is at the heart of any decision making and thus it is critical for multicultural leadership. The balance between rational, emotional, and spiritual knowledge entering the dynamics varies from one culture to another and therefore leaders should be aware of knowledge dynamics (Bratianu et al., 2020; Bratianu, 2023; Kahneman, 2011). The capacity to understand the potential barriers of cultural diversity and overcome them can be improved through the mediating role of cultural intelligence and the new achievements of neuroscientists (Ang & Van Dyne, 2015; Davidovich & Brunton, 2023; Meyer, 2014). From this perspective, the present research has a

5. Conclusions and Limitations

The present research starts from the new leadership context created by the internalization and globalization of the business processes. Leading teams composed of people coming from different cultures requires a new understanding of how people react to designing and implementing business projects. That difficulty is generated by the different balances between rational, emotional, and spiritual knowledge and intelligence which are specific for different cultures. Knowledge dynamics is the core mechanism in any managerial decision making process and therefore it has a significant influence on multicultural leadership. Also, knowledge dynamics impacts on cultural intelligence, a meta-intelligence that is specific for people living and working in multicultural social contexts. Multicultural intelligence represents the capacity to understand how people from different cultures think and behave. Having different value sets they have different attitudes and behaviors in organizational environments. Multicultural leaders should be capable of anticipating possible working conflicts and finding solutions for mitigation when they appear.

The present research aims at analyzing the influence of knowledge dynamics on multicultural leadership directly and indirectly through the mediation of cultural intelligence. Therefore, we designed a research model

composed of these three main constructs (i.e. knowledge dynamics, cultural intelligence and multicultural leadership) and their relationships. We performed a critical literature review of the literature to extract some ideas from previous similar research and to use them. However, we found that the construct of knowledge dynamics from the thermodynamics perspective was not incorporated in previous studies. Identifying this knowledge gap we designed a questionnaire and a worldwide investigation among the managers working in multicultural business contexts. We collected data from 439 respondents and validated 396 answers. In the first stage of statistical analysis we used IBM SPSS software, and in the second stage we used PLS-SEM software. Findings show that our hypotheses are valid, and therefore we can state that knowledge dynamics influences positively multicultural leadership through the mediating role of cultural intelligence.

The main limitation of the present research comes from the fact that the decision making process of leaders in multicultural companies is a nonlinear process, and we had to consider a simplified linearized model for the purpose of evaluating the interactions between the three constructs (i.e. knowledge dynamics, cultural intelligence, and multicultural leadership). That is in accordance with the logic inherent in the statistical analysis with IBM SPSS and PLS-SEM.

Abstract: This research seeks to identify the state of the art regarding knowledge management practices that have been applied in hospitals with a specific focus on how these practices improve organizational effectiveness, innovation, and performance. Using an integrative review methodology that includes problem identification, strategic literature search, rigorous data evaluation, thematic analysis, and synthetic presentation of results, the research encompassed 19 relevant studies extracted from the Scopus, EBSCOhost, and Scielo platforms. The results demonstrate a predominant use of information technologies, reinforcement of organizational culture, and strengthening of trust and organizational learning. Remarkably, leadership emerged as a critical factor, not only for facilitating the implementation of knowledge management practices but also for actively involving employees in achieving organizational goals. There is also clear demand for substantial increases in investments in training and collaboration technologies to maximize the potential for knowledge creation, retention, and sharing in hospitals.

Keywords: Knowledge Management, Organizational Practices in Hospitals, Organizational Culture and Leadership, Organizational Learning, Health Information Technologies.

1. Introduction

Managing an organization is challenging, especially when it comes to hospitals. Promoting the commitment of a team to the management of human, financial, social, and asset resources with quality, economy, sustainability, and effectiveness requires a differentiated approach to management (Cançado et al., 2020).

Hospitals, regardless of their public or private nature, constitute a business and need to adopt efficient management methods to ensure their permanence (Vilaça & Oliveira, 2008). This need has been partially met by Knowledge Management (KM), whose dissemination of knowledge is crucial in organizational strategy (Colauto & Beuren, 2003). Siddique et al. (2021, p. 04) understand that " knowledge management in a hospital requires well reputable and contributive mechanism, which enriches the main objective of serving humanity and saving a life."

Knowledge Management is considered by Barroso and Gomes (1999) as the ability to identify and map intellectual assets; generate new knowledge to offer market competitive advantages and promote accessibility of large amounts of information by sharing best practices and technology (Barroso & Gomes, 1999). It " improves the competitive advantage and enhances the performance of an organization, its role in the process of innovation and sustainable development cannot be disputed" (Popa et al., 2018, p.555).

Nonaka and Takeuchi (1997, p.01) understand "organizational knowledge creation as the ability of a company to create new knowledge, disseminate it throughout the organization, and incorporate it into products, services, and systems." Knowledge sharing improves services in organizations, elevating them to the status of learning organizations where lessons learned are made available for continuous learning by others (Alajmi et al., 2015; Shateri & Hayat, 2020).

Managers and leaders have already realized that promoting the increase and development of intellectual capital through knowledge management practices is an important action to elevate the company to the knowledge society (Popa et al., 2018).

Knowledge management practices are "the various activities, procedures, techniques and systems which are explicitly intended or utilized for creating and processing knowledge" (Casco, 2000, p. 634). They can provide support to companies in building practical measures to improve their responsiveness, breaking with innovation constraints arising from organizational culture or history (Casco, 2000).

In the health sector, KM has been considered a means to address current challenges such as the introduction of new technologies, the need to provide services to an aging population with chronic diseases, budget cuts, and

the need to redesign the system after the COVID-19 pandemic (Dal Mas et al., 2020). In this sense, the adoption of KM practices can provide health organizations with improved quality of care (Colauto & Beuren, 2003; Shateri & Hayat, 2020). Therefore, hospitals in developing countries are encouraged to develop knowledge management tools to improve hospital performance and practice in the healthcare sector (Shateri & Hayat, 2020), emphasizing KM in patient care rather than information (Tang, 2017a).

However, the application of Knowledge Management practices in hospitals has been very problematic (Alajmi et al., 2015), and the operationalization of knowledge management in different healthcare organizations is not similar, resulting in problems in adapting practices and strategies in healthcare (Siddique et al., 2021).

Considering the specificities and difficulties of applying KM practices in hospitals, this research aims to identify the state of the art regarding knowledge management practices that have been applied in hospitals with a specific focus on how these practices improve organizational effectiveness, innovation, and performance.

2. Method

This research adopts the integrative review method proposed by Whittemore and Knafl (2005), consisting of 5 phases: problem identification, literature search, data evaluation, data analysis, and presentation of results.

2.1 Problem Identification

Considering the importance of KM today and the difficulties in its development in healthcare management, the research question of this review was to investigate how knowledge management practices have been applied in hospital management.

2.2 Literature Search

The data search was conducted in the databases of the Scopus, EBSCOhost, and Scielo platforms, using the search string: Hospital AND Knowledge Management Practice. Ninety-five articles were found, and after applying inclusion criteria and removing duplicates, 41 documents remained for analysis. After analyzing the 41 studies through full-text reading, under the lens of the guiding question of this research and the inclusion and exclusion criteria (Table 01), 19 articles remained for thematic analysis of the data. The process of capturing studies is presented in the flow diagram for integrative reviews, which included searches of databases and registers only, presented in Figure 01.

Table 1: Criteria for inclusion and exclusion of articles.

Inclusion Criteria	Exclusion Criteria
Articles referring to hospital management	Articles not related to the research question
Peer-reviewed articles	Articles published before 2017
Articles published after 2017	

Source: Developed by the authors (2024).

Figure 1: Flow diagram for integrative reviews which included searches of databases and registers only

2.3 Data Evaluation

The articles included in this review were analyzed to identify emerging themes and subthemes. Table 02 presents the list of articles and some of their characteristics.

Table 2: List of articles selected for analysis

Authors	Method	Themes Identified	Conclusions
Ayanbode & Nwagwu , 2021	Quantitative	Technology	The use of collaborative technologies has a direct effect on KM processes and impacts the creation, sharing, transfer and retention of knowledge.
Zhou et al., 2021	Quantitative	Technology Organizational Learning	Improving and promoting the development of intellectual capital through KM practices, associated with technological tools, is an important action to elevate the company in the knowledge society.
Siddique et al., 2021	Quantitative	Technology Organizational culture	KM practices increase efficiency and reduce risks by optimizing resources and providing the development of organizational performance.
Rosário et al., 2021	Qualitative and quantitative	Technology	It is concluded that knowledge management (KM) has become an institution in the health sector.
Ekionea & Fillion , 2021	Qualitative	Organizational Trust	Organizational maturity is achieved when KM processes are effectively managed and applied.
Dal Mas et al., 2020	Qualitative case study	Technology	Institutions must guarantee knowledge translation mechanisms so that it is possible to alleviate differences and provide for the creation and sharing of knowledge.
Shateri et al., 2020	Quantitative	Organizational trust	The results revealed a significant and positive association between perception of organizational support, organizational trust, and knowledge sharing.
Karamitri , et al., 2020	Quantitative	Organizational culture	Leaders must encourage and form a corporate culture beneficial to knowledge sharing and must work on a KM system to enable this sharing in the medical industry.
Gao & Sun, 2020	Evolutionary game theory	Organizational trust	It is necessary to equalize the level of knowledge of groups, increase the degree of trust, reduce the cost of sharing, and increase incentives. Differences in the formation of knowledge between decision makers affect the quality of the process.
Ayatollahi & Zeraatkar , 2020	Qualitative	Technology Organizational culture	Therapy team members should focus on using technology to continually create and share knowledge.
Ouédraogo & Rinfret , 2019	Quantitative	Technology Organizational culture Organizational learning	The organizational determinants for sharing and promoting knowledge management among managers are organizational structure, leadership, organizational culture, organizational climate, technology, training, and performance guidance.
Liu & Li, 2019.	Quantitative survey	Technology Organizational culture Organizational learning	The proposed information system helps to optimize hospital organization, improve knowledge, and increase the quality and efficiency of medical services through learning and knowledge management.
Popa, et al. 2018	Quantitative survey	Technology Organizational culture	Improving and promoting increased development of intellectual capital with KM practices, associated with technological tools, is a relevant action to elevate the company in the knowledge society.

Authors	Method	Themes Identified	Conclusions
Tian et al., 2018	Quantitative and survey	Technology Organizational learning Organizational culture Organizational trust	Companies must implement actions based on promoting participatory leadership, promoting managerial knowledge, sharing, a culture of collaboration and trust, decentralized decision-making, communication, continuing education, and appropriate technologies.
Karamitri et al., 2017	Qualitative	Technology Organizational Learning	Healthcare managers must cultivate a knowledge environment, function as role models, provide the tools for KM, and reward people who act as knowledge brokers.
Bahar , et al., 2017	Qualitative	Organizational culture	The studies analyzed reinforce the relevance of the scientific search to support KM practices in health, as well as using and transforming information into practices that can be socialized to health professionals.
Tang, 2017a	Quantitative	Technology Organizational culture	Technological resources can improve efficiency and performance but may not directly improve finances. IT management capacity and knowledge plays a significant role in improving clinical performance.
Tang, 2017b	Quantitative	Organizational learning	The results of this study indicated a significantly positive correlation between KM, culture, performance, and organizational effectiveness
Alolayyan et al., 2020	Quantitative	Organizational culture of sharing	The better the KM, the greater the organizational effectiveness and organizational culture, as it influences organizational culture and improves the organization's effectiveness.

2.4 Data Analysis

The analysis of the articles eligible for this review was conducted based on thematic analysis by Braun and Clark (2012). Through thematic analysis of the selected studies, themes and subthemes related to the use of KM practices in hospitals and healthcare organizations were identified. The themes and subthemes are presented in Table 03 along with the authors who addressed them.

Table 3: Analysis Themes

Themes	Subthemes	Authors
Information Technology - IT	Improvement of clinical, organizational performance and decision making; *Strengthening knowledge management*	Ayanbode & Nwagwu , 2021; Zhou et al., 2021; Siddique et al., 2021; Rosário et al., 2021; Dal Mas et al., 2020; Ayatollahi & Zeraatkar , 2020; Ouédraogo & Rinfret , 2019; Kartawiguna et al., 2019; Liu & Li, 2019; Popa et al., 2018; Tian et al., 2018; Tang, 2017a.
Culture Organizational	Organizational performance and effectiveness Innovation	Siddique et al., 2021; Karamitri , et al., 2020; Ouédraogo & Rinfret , 2019; Liu & Li, 2019; Popa, et al. 2018; Tian et al., 2018; Bahar , et al., 2017; Tang, 2017a; Alolayyan et al., 2020.

2.5 Presentation of Results

The themes and subthemes displayed in Table 03 are presented and discussed in Section 4.

3. Presentation and Discussion of Results

Based on the analysis of the selected articles, it was identified that the most applied KM practices in hospitals are technology, organizational culture, trust, and organizational learning. Such practices and the impacts of their application are further explained in the following sections.

3.1 Information Technology - IT

In the analyzed articles, it was found that technology is imperative in the development of KM in hospital institutions (Siddique et al., 2021). Its results lead to better clinical and organizational performance, driving the processes of knowledge creation, sharing, and retention, supporting decision-making processes, increasing efficiency, reducing risks, optimizing resources, and leveraging the KM process (Ayatollahi & Zeraatkar, 2020; Siddique et al., 2021; Zhou et al., 2021; Alolayyan et al., 2020; Tang, 2017; Rosário et al., 2021; Dal Mas et al., 2020; Ouédraogo & Rinfret, 2019; Liu & Li, 2019; Popa et al., 2018; Tian et al., 2018). Its impacts are discussed below.

3.1.1 Improvement of Clinical, Organizational Performance, and Decision Making

The use of collaborative technologies has a direct impact on KM processes and indirectly on the creation, sharing, transfer, and retention of knowledge (Ayatollahi & Zeraatkar, 2020). Clinical team members should focus on using technologies that effectively support the process of externalization, combination, and internalization of knowledge, improving the clinical performance of the team and the hospital (Ayatollahi & Zeraatkar, 2020).

A study conducted at the University Hospital in Pakistan pointed out that the intensive use of technological tools in the workplace increases efficiency, reduces risks, optimizes financial resources and revenues, improves organizational performance, and decision-making (Siddique et al., 2021).

The adoption of innovative technologies leads to increased intellectual capital and improvement in organizational performance, promoting market development, better brand reputation, increased organizational value, intellectual capital, and consequently, profits (Zhou et al., 2021).

3.1.2 Strengthening Knowledge Management

Information and communication technologies, when combined, facilitate cross-fertilization of ideas, intuition, skills, and experience for effective personal and collective management, professional development, and efficiency (Ayatollahi & Zeraatkar, 2020).

The study by Alolayyan et al. (2020) in Indonesian hospitals concluded that only organizations that have a constant routine of creating and disseminating new knowledge and technologies, especially in the field of medicine, will succeed.

Governments should focus on improving investments in technology, offering incentives to hospitals or healthcare organizations that have programs to improve their technological capacity, and directing their focus on the competitive advantages provided by KM (Alolayyan et al., 2020; Tang, 2017a).

3.2 Organizational Culture

Different studies have shown that the establishment of an organizational culture of knowledge sharing leads to improved organizational performance and effectiveness, as well as fostering innovation (Tang, 2017b; Alolayyan et al., 2020; Sussan, 2012; Karamitri et al., 2020; Siddique et al., 2021; Ouédraogo & Rinfret, 2019; Liu & Li, 2019; Popa et al., 2018; Tian et al., 2018; Bahar et al., 2017; Tang, 2017a).

3.2.1 Organizational Performance and Effectiveness

The purpose of Knowledge Management is the creation, accumulation, and use of knowledge. For this reason, a good capacity for knowledge creation can contribute to the increase in organizational effectiveness in the health industry (Tang, 2017b, p.1842).

In Abu Dhabi, research identified that KM influences organizational culture and improves organizational effectiveness (Alolayyan et al., 2020). It is necessary, therefore, to strengthen education and integrate channels among employees so that professionals can acquire new knowledge and exchange their skills in a timely manner (Alolayyan et al., 2020).

3.2.2 Innovation

Organizational culture is linked to the development of KM. According to Sussan (2012), the primary condition for a company to create high-quality organizational innovation is to establish a culture and corporate environment of knowledge sharing.

Considering that without innovation organizations do not survive in the market, one of the goals of KM is to contribute to organizations improving their capacities to recognize, manage, and produce successful innovations (Karamitri et al., 2020). To innovate, it is important to establish a culture of knowledge sharing because "people are willing to share information with others as long as they are motivated" (Karamitri et al., 2020; p.09).

The results found in this theme show the importance of organizational culture for Knowledge Management. Organizational culture is a set of norms and values that influence the behavior of members of an organization (Sussan, 2012) and, therefore, affects the sharing behavior of knowledge and information among its members (Allameh et al., 2012). Therefore, KM thrives more strongly in organizations where there is a culture of knowledge sharing (Allameh et al., 2012).

3.3 Organizational Trust

Among the KM practices used in healthcare management, organizational trust was identified as an effective strategy for: 1) achieving a good level of productivity; 2) effectiveness in task development and achievement of organizational objectives; and 3) leveraging knowledge sharing. Additionally, organizational trust is closely related to organizational culture and learning (Ekionea & Fillion, 2021; Shateri et al., 2020; Gao & Sun, 2020; Tian et al., 2018). Its impacts are described below.

3.3.1 Productivity and Task Effectiveness

Trust between leaders and employees is essential for organizational effectiveness (Gao & Sun, 2020). Trust is the result of repeated interactions, where individuals can predict each other's behavior with some certainty, reducing uncertainty in human relationships (Fillion, 2021).

The effectiveness of tasks depends largely on trust between organizational members (Shateri et al., 2020). Trust in colleagues and managers, when high, creates a favorable environment for knowledge sharing, which in turn improves organizational productivity (Gao & Sun, 2020).

3.3.2 Knowledge Sharing

Trust facilitates knowledge sharing between colleagues and supervisors (Ekionea & Fillion, 2021; Shateri et al., 2020; Gao & Sun, 2020). This sharing is essential for improving task performance and achieving organizational goals (Ekionea & Fillion, 2021). Trust increases employees' willingness to share their knowledge, leading to better decision making, increased innovation, and better organizational performance (Gao & Sun, 2020; Shateri et al., 2020).

3.4 Organizational Learning

From the perspective of organizational learning, KM contributes to defining the quality of knowledge and the effectiveness of an organization (Lemay et al., 2012; Pérez López et al., 2004). In general, "organizational learning is the way companies enrich and organize knowledge and the tasks around the activities and the culture and develop effectiveness for improving the competencies of their workforce" (Ekionea & Fillion, 2021, p. 398).

According to the articles in this review, organizational learning relates to culture and the KM process. It encourages knowledge sharing, enhances organizational performance and "intelligence," and increases the effectiveness of the organization and its employees (Zhou et al., 2021; Ouédraogo & Rinfret, 2019; Liu & Li, 2019; Tian et al., 2018; Karamitri et al., 2017; Tang, 2017b). The detailed impact of this KM practice is presented below.

Tian et al. (2018, p.1980) believe that "the creation of a learning climate could reinforce the intention to execute knowledge management and knowledge sharing in an organization and further enhance the continuous progress of the organization."

In the same vein, Liu and Li (2019, p.474) consider that "in an era when intangible assets have become the source of wealth and progress, knowledge management and learning organization may be the missing factors " to improve organizational performance.

Strategically, KM encourages the organization to become "intelligent" and challenges its ways of doing and thinking about things and reinventing itself, thanks to its continuous processes of human and technological learning (Ouédraogo & Rinfret, 2019) provided by knowledge sharing practices.

Furthermore, organizational learning has a significant influence on organizational culture, which is crucial for shaping the sharing culture (Tang, 2017b). For this reason, leaders should encourage a problem-solving culture in the organization based on a willingness for lifelong learning (Chang et al., 2009; Karamitri et al., 2017).

4. Final Considerations

This study investigated the application of knowledge management (KM) practices in hospital administration and healthcare organizations, revealing that technology, organizational culture, trust, and organizational learning are the most prevalent practices. These practices have shown significant improvement in clinical and organizational performance, supporting effective decision-making, increasing efficiency, fostering innovation, and achieving strategic goals. Additionally, there has been continuous improvement in knowledge sharing among healthcare professionals.

The investment in training and learning programs that foster the creation, retention, and sharing of knowledge and the adoption of advanced KM technologies has been identified as a good strategy for hospitals to overcome organizational barriers and promote a culture of continuous learning and innovation.

Furthermore, it has been found that the development of knowledge management in hospitals improves organizational performance and the quality of services provided. The more KM is embedded in the organizational culture, the better the organizational climate, the capacity for innovation, the strategic development of learning, employee satisfaction, organizational learning, and patient care.

Therefore, considering the emerging technological revolution and the continuous need for organizational improvement in the healthcare sector, knowledge management consolidates itself as one of the main pillars for the sustainability of hospitals today and in the future.

5. Future Studies

From the analyzed research, it was possible to identify some practices used and their effects on healthcare organizations, and their limited use in the healthcare industry in general was noticeable. Future research is needed on the development of tools related to the generation, retention, and sharing of knowledge to improve innovation, performance, and patient care.

Studies are also important on each aspect addressed in the data analysis of this review related to organizational sustainability in healthcare and its adaptation in post-Covid-19 hospital routines, a fundamental milestone in health management in current society. Finally, we suggest research on the role and impacts of leadership in the implementation of KM in healthcare organizations.

Acknowledgment to Funding Agency

This work was carried out with the support of the Coordination for the Improvement of Higher Education Personnel (CAPES) – Funding Code 001.

Determinants and Strategies of Knowledge Transfer in Teaching Hospitals

Jolanta Chluska
Częstochowa University of Technology, Częstochowa, Poland

jolanta.chluska@pcz.pl

Abstract: Teaching hospitals are healthcare entities rendering healthcare services to patients. Specialized medical staff not only provide medical services, but also educate future medical staff, conduct clinical research and support the development of medical technologies. The majority of these staff are also research and teaching staff at medical universities. The aim of this article is to identify the determinants of knowledge transfer and the intellectual potential of employees in the relationship between teaching hospitals and medical universities. The inference was made on the basis of the available development strategies of medical universities, including reference to the intellectual potential of employees and the mission of teaching hospitals published on their websites. The following research questions were posed: Is the mission of medical universities consistent with the mission of teaching hospitals? Does the transfer of knowledge and skills of medical staff between a medical university and its teaching hospital contribute to the mission of teaching hospitals? The preliminary findings indicate that the intellectual capital of the scientific-medical staff is of vital importance in the mission of teaching hospitals, which is on a par with the development of the facilities. The analyses were of an expert nature, from the perspective of a statutory auditor and a long-standing researcher of the problems of the functioning of medical entities, namely hospitals. The considerations undertaken in the article are an important voice in the recognition of the determinants for the development of teaching hospitals as entities with intellectual capital useful in solving international health problems. The article is a continuation of the author's research on the development of intellectual capital of employees of teaching hospitals in Poland. The relationship between the findings of the development strategies of medical universities (the founding bodies) and the mission statements of their teaching hospitals confirm their coherence and complementarity.

Keywords: Knowledge Transfer, Intellectual Potential of Hospital Employees, Hospital Management, Knowledge Workers in Hospitals.

1. Introduction

In the era of the knowledge economy, knowledge is the most important asset of an organization. The theoretical and application value of the knowledge of employees is a crucial factor in the development of an economic entity. Learning processes accompany the decision-making and management of the entity, as well as having an impact on the environment. Teaching hospitals are specific economic entities in which human resources, the knowledge and skills of employees, constitute a key asset.

For most teaching hospitals, medical universities are the founding bodies. Medical universities educate future employees, namely, doctors and other medical staff. The place of their education and practical training is the teaching hospitals. The high-level skills of the medical staff are thus shaped by both academic education and practical classes. These relationships indicate the bidirectional nature of knowledge and skills transfer in the relationship between the two entities. When considering a knowledge transfer system, the close relationship between medical universities and teaching hospitals in the area of intellectual capital and human resources, their connections, and interactions must be taken into account. In order to educate future medical staff, their practical experience in patient treatment processes is essential. The reverse relationship can also be considered: the intellectual potential of medical staff is built to a large extent in the educational process. Educational processes accompany medical staff throughout their training and professional work. Lifelong education is embedded in the specifics of the profession and guaranteed by law (Law of 5 December 1996, Article 18).

Knowledge resources, from the point of view of their origins, can be divided into knowledge related to experience (skills), conceptual knowledge (concepts, projects), routine knowledge resources (organizational culture), or systemic knowledge resources (databases, patents, licenses) (Little, Ray, 2005, p.25). There are four basic phases in the knowledge life cycle, such as creation, mobilization, diffusion, and commoditization (Birkinshaw, Sheehan 2002, p.75). For the knowledge transfer process to be effective, all four phases are necessary and, in addition, the process should be continuous and strategic.

2. Essence and Principles of Knowledge Transfer: Literature Review

In an era of rapid technological progress and globalization, knowledge resources, which are a source of competitive advantage, are crucial for the development of a company. For the success of a business entity, knowledge sharing among employees is essential at all levels of collaboration and decision-making..

The concept of knowledge can be discussed based on different approaches and categories. It can be considered as tacit knowledge and explicit knowledge. Tacit knowledge is individual, specific and difficult to formalize. It includes skills, qualifications, and other individual characteristics of its holder. Explicit (accessible) knowledge is formalized by nature and can therefore be transferred between actors using specific tools and forms (Nonaka, Takeuchi 2000, p. 82). Other interesting characterizations of the essence and types of knowledge emphasize its features such as its universal and theoretical nature (episteme), practical and instrumental dimension (techne), "practical wisdom" (phronesis), its non-transferability (sticky knowledge) and the transferability of knowledge between entities, both within and outside the organization (leaky knowledge) (Szyjewski 2003, p.17; Kłusek-Wojciszke, B., Łosiewicz, 2009, p. 140). From the point of view of considerations on knowledge transfer in the health sector, I consider it important to divide knowledge into four categories as follows: know what (facts), know why (principles), know how (skills), know who (context) (Knowledge Management..., 2000, p. 21)."Know what" refers to the knowledge of "facts", "know why" is the knowledge that explains reality, "know how" refers to people's skills, public access to it is limited, "know who" - identifies knowledge holders and describes the extent of knowledge they have (Kłusek-Wojciszke, B., Łosiewicz, 2009, p. 139).

The foundation for the development of an economic entity and the achievement of a competitive advantage is not only the possession of the knowledge, but above all its transfer. Knowledge sharing takes place within the economic entity, but the directions of knowledge transfer may include inter-organizational relations. Proper communication at the entity level is determined by factors such as organizational structure, interpersonal (personnel) relations and organizational culture. These factors can determine both the successes and barriers to knowledge transfer. Among the factors constituting barriers and difficulties in knowledge transfer processes, the following are most often mentioned: the lack of mutual trust, limited perception of knowledge acquisition, the belief that knowledge is assigned to specific groups or positions, different needs and priorities among communication participants, attitudes of uncertainty towards researchers or the value of research, the lack of incentives to participate in communication, excess of various responsibilities, passive forms of knowledge exchange, top-down forms of this exchange, the lack of belief in the capacity and applicability of research knowledge and vice versa (Davenport, Prusak 1998 [after:] Klak M. 2010, p. 82 , Molleman, Fransen2012, p. 160, Gagliardi A. R. et al., 2016, p. 9).

In order to prevent and resolve barriers and difficulties in knowledge sharing, the management of teaching hospitals should establish strategies to deal with them and implement them consistently. Such solutions include the following: creating interpersonal relationships based on trust and cooperation, favouring teamwork among specialists from different disciplines, creating an effective and employee-accepted system of incentives and rewards, and promoting ethical and pro-social attitudes. Selected suggestions for strategies to improve knowledge transfer are presented in Table 1.

Table 1: Suggestions for strategies to improve knowledge transfer in selected publications

Author	Factors for improving knowledge transfer
Eljiz K. et al., 2020	The authors suggest the nine communication methods through which knowledge can be translated: research reports, posters, healthcare industry and academic presentations, peer-reviewed articles, presentations, podcasts, webinars, and infographics.
Wensing M., Grol R., 2019	1. *Researchers and advisors from different disciplines work together in multidisciplinary teams,* 2. *Better recognition of published work,* 3. *Validation of structured approaches,* 4. *Critical evaluation of the effects of implementation programmes,* 5. *Measurement of the results of improvement, transfer, and implementation according to a new generation of measures.*
Gagliardi A. R. et al., 2016	1. Numerous and varied opportunities for interaction, 2. Strong leadership commitment, skills, and experience, 3. Phased approach to developing a common language, achieving success, 4. Support from experts, champions, innovators, 5. Clear and agreed objectives, roles and expectations, 6. Cooperation between researchers and decision-makers, 7. Formalized creation of the brand, structure, and processes.
Wang W., Hou Y., 2015	8. Knowledge sharing is significantly influenced by rewards (hard and soft) and altruism for organizational benefit.
Van Acker F. et al., 2014	1. Trust increases the likelihood of disclosure of accurate information (based on benevolence and competences), 2. Actual knowledge sharing is more frequent in an interpersonal environment than online,

Author	Factors for improving knowledge transfer
	3. Trust in knowledge sharing is higher in an interpersonal environment than in an online environment.

Source: self-compilation based on literature.

In subject-related literature, the boundary between concepts such as data (facts, figures), information (processed data), knowledge (information and people), and wisdom (knowledge, intuition, experience) is sometimes blurred. However, their essence is indicated by attributes, defining their specificity and distinctiveness (complexity, users). (Włodarkiewicz-Klimek, 2016, p. 196)

The term 'knowledge transfer' can therefore be understood and considered at different levels of complexity, from data to information, reaching the goal of wisdom.

Knowledge transfer in the relationship between medical universities and teaching hospitals should be supplemented by additional directions of such transfer: within each entity, from entity to environment, and from environment to entity. Significant enrichment of the knowledge of medical (scientific and medical) staff takes place through their cooperation with the national and international environment. The experience of recent years with the COVID-19 pandemic, its control and prevention, has shown how valuable these relationships are.

3. The Teaching Hospital as a Knowledge Transfer Entity: Methodology of the Research.

The aim of this article is to identify the determinants of knowledge transfer and the intellectual potential of employees in the relationship between teaching hospitals and medical universities. The inference was made based on the available development strategies of medical universities, including reference to the intellectual potential of employees and the mission of teaching hospitals published on their websites.

1. In the research process, the following research questions were posed:
2. Is the mission of medical universities consistent with that of teaching hospitals?
3. Does the transfer of knowledge and skills of medical staff between the medical university and its teaching hospital contribute to the mission of teaching hospitals?

The research process consisted of the following stages:

1. Analysis of legislation on the rules governing teaching hospitals,
2. Recognition of the role of human resources and their intellectual capital in medical universities and teaching hospitals, knowledge building and transfer in these entities (literature review, review of the websites of teaching hospitals and medical universities, synthesis),
3. Compilation and classification of selected data characterizing human resources and the management of these resources, the missions and strategies of medical universities and teaching hospitals,
4. Expert analysis of the relationship of information from sources such as the development strategy of medical universities and teaching hospitals, as well as mission and strategy information materials (websites),
5. Analysis of the conclusions from selected areas of research conducted by the author in previous years on the intellectual capital of hospital employees,
6. Conclusions from the conducted research.

Out of 33 teaching and university hospitals, five teaching hospitals and their founding bodies - medical universities - were selected for analysis. Websites and documents published on them, including mission statements and development strategies were analysed.

The entities for the study were selected while taking into account the possibility of obtaining complete data on documents with a defined mission and strategy of the teaching hospital and its founding body, namely the medical university. In many cases, the development strategy of the medical university was available for analysis, but the teaching hospital established by it did not publish a development strategy, or a formulated mission. The websites of teaching hospitals in the vast majority of cases do not publish activity strategies. Development strategies of teaching hospitals are developed, but they are considered to be classified documents.

Among teaching and university hospitals, 24 of them are on the list of hospitals accredited for the quality of medical services. The list of 187 accredited hospitals is published by the CMJOZ (Centre for Monitoring Quality in Health Care) (List of accredited hospitals, 2024). One of the prerequisites for a hospital to be accredited is to have a strategic plan, while taking into account the fact that the results of the health needs analysis, while also

the need to act on the requirements and financial feasibility of the plan. The strategic plan should include a description of the policy for improving the quality of services provided and this plan should be updated periodically. It is also an important requirement to have a staffing plan and human resource management to carry out tasks such as the following:

1. Implementation of a policy of continuous improvement of staff qualifications,
2. Identification of the educational needs of specific professional groups,
3. Establishment of a training plan for employees, including, among others, quality management,
4. Provision of financial resources for training,
5. Assessment of staff qualifications and professional activity,
6. Employee evaluation,
7. Actions taken on the basis of the conclusions of the staff evaluation (Standards, p. 122).

The CMJOZ periodically assesses the level of implementation of the applicable standards. As the results of the analyses, which are included in the document 'Level of fulfilment of accreditation standards in hospitals in 2022', show, the highest score achieved by a hospital is 96% and the lowest is 42% in terms of the fulfilment of the requirements of accreditation standards. In terms of human resource management, almost 40% of the surveyed accredited hospitals achieved a score of above 90% with regard to meeting the accreditation requirements. The high level of fulfilment of the standards means that the tasks of effective human capital management and human resources are important management areas for these entities. The published results are in the form of a median and are not attributed to specific hospitals. (Levels of fulfilment of standards, pp. 2, 15)

4. Knowledge as a Resource in the Development of the Hospital - Research Findings

Teaching hospitals are distinguished among medical entities not only by the type of specialized health services as an object of activity, but also by their important tasks in the training of medical staff, the performance of teaching, research, consultation, opinion-forming functions, and other tasks assigned by scientific institutions, local government units, or central authorities. Hospitals may carry out economic activities if they do not impede the basic tasks for which they have been established. Such a wide range of activities, educational, research, and scientific tasks is conditioned by a very high level of knowledge and skills of medical staff. Therefore, this group of healthcare entities was chosen as research subjects. Teaching hospitals constitute a knowledge management environment for the intellectual capital (Bose, 2003). Medical universities are also such an environment. Employees of teaching hospitals continuously develop their intellectual potential, which is a long-term activity of strategic importance. The place for the education and continuous training of medical staff is primarily the medical universities. Medical employees are at the same time academics, hence the knowledge they possess is not only developed, but also transferred between different entities.

These strong personal ties justify the link between the missions and strategies of teaching hospitals and their founding bodies, namely, medical universities. The mission of a teaching hospital and its founding medical university was examined, using selected examples. The results of the analyses are presented in Table 2.

Table 2: Teaching hospitals and medical university - missions and strategies

Pos.	Mission of the teaching hospital	Mission of the medical university (the founding body)
		Medical university development strategy
1.	The highest level of treatment, education, research - the constant pursuit of excellence in the field of healthcare	We provide high quality education and research in medical and health sciences. We make a significant contribution to the development of the healthcare system. We are an efficiently managed university whose foundation is people - talented students, excellent teachers, passionate scientists, and professional managers.
Strategic objective 2: Promotion of employee performance and engagement		
Operational objective 1: Development of internal and external recruitment		
Operational objective 2: Promotion of the culture of continuous improvement		
Operational objective 3: Improvement of management competences, leadership, and ability to develop innovative attitudes among employees		
Operational objective 4: Improvement of the teaching staff competences		

Pos.	Mission of the teaching hospital	Mission of the medical university (the founding body)
2.	Our vocation is to treat, educate and conduct research	Creating and strengthening the intellectual capital of the country and the region based on highly qualified medical staff, modern teaching facilities and high-quality educational methods. State-of-the-art pre-graduate and post-graduate medical staff training, combined with the recruitment of new and upskilling of existing academic staff. Raising - nationally and regionally - the level of knowledge, skills, and competences in the field of health sciences.
Strategic objectives 1. Provision of modern and effective education for students in the first and subsequent 6-year teaching cycles 2. Continuous improvement of the quality of education in terms of acquiring the latest medical knowledge, practical professional skills, but also shaping and creating the highest, appropriate ethical and social attitudes 3. Acquisition of new medical staff 4. Upgrade of the skills of existing medical staff 5. Initiating postgraduate training and education 6. Liaising with the medical community and local government in the region		
3.	The highest ethical imperative for us is the welfare of the patient	The mission is to carry out teaching, research, staff development, and health care activities of the highest standards
Strategic objective: Achieving and maintaining a high scientific position in Poland and worldwide Operational objectives: 1. High scientific potential. 2. Systematizing and expanding activities related to the commercialization of knowledge. 3. Development of activities aimed at implementing innovative research projects and conducting commercial scientific research. 4. Development of activities aimed at implementing innovative basic research. 5. Scientific development of staff. 6 Effective management of scientific activities.		
4.	Over 100 years of tradition and modernity in providing the highest quality health services in the care of women, newborns and children.	Our mission is to provide the best education based on innovative medicine and top-level research.
Strategic objectives: Support and development of innovative research and achievement of research university status 2. Strong academic treatment base to ensure effective collaboration in teaching and learning. 3. Modern human capital management - development of staff qualifications and work organization culture		
5.	The mission of the hospital is to provide health services at the highest level and to promote health in conjunction with teaching and scientific research tasks.	Creating a welcoming environment for the academic community, within which high quality modern educational, scientific, and commercial offerings are created
Strategic and operational objectives –Teaching hospital capacity: 1. Using the knowledge and experience of teaching hospital experts in the teaching process a. Maintenance of existing staff resources in teaching units b. Creation of an incentive mechanism to encourage teaching activities among the teaching hospital staff c. Standardization of employment contracts in teaching units by taking clinical and teaching tasks into account d. Supporting the development of the teaching competences of the teaching hospital staff		

Source: Self-study.

The missions of teaching hospitals are dominated by objectives such as:

1. Achieving the highest quality of medical services,
2. Comprehensive implementation of treatment, teaching and development tasks,

3. Comprehensive patient care,
4. Health promotion.

These tasks cannot be fulfilled if there is no medical staff with the right competencies and skills.

Medical universities see the following as their mission:

1. Ensuring that staff are trained to the highest possible standard,
2. Research and development,
3. Building and developing intellectual capital,
4. National and international knowledge development and transfer,
5. Commercialization of educational offerings.

The missions of the teaching hospitals are reflected in the development strategies of the universities. In the refinement of the strategic goals, great emphasis is placed on the education and development of the staff and the development of research. This means that the transfer of knowledge and skills of medical staff between the medical university and the teaching hospital contributes to the mission of teaching hospitals.

The analysis of the missions and strategies of teaching hospitals and their founding bodies - medical universities - indicates a close link and coherence in terms of intellectual capacity development and knowledge transfer. This creates a comprehensive dimension of the knowledge transfer strategy.

5. Discussion on Results and Implications for Practice: Directions of Change for Knowledge Transfer in Teaching Hospitals

The alignment between the strategic goals and missions of teaching hospitals and medical universities identified in the research is a very positive phenomenon. The great importance of this coherence was particularly confirmed in an emergency situation, namely, the COVID-19 pandemic. Medical and scientific staff focused their efforts on containing the pandemic, identifying its causes, combating the effects, while also preventing its spread.

Although millions of patients died during the pandemic, there would certainly have been more victims had it not been for the scientific and research achievements of doctors and scientists. In these difficult, complex and unpredictable times, there will be more crises. The development of knowledge resources and new treatment techniques should be a necessary strategic objective. The existing legal and information environment of teaching hospitals in Poland provides a basis for stating the existence of the intellectual potential of employees and the management of the intellectual capital (Chluska, 2021).

In order to achieve the ambitious strategic goals of teaching hospitals and medical universities, the support and cooperation of the socio-economic environment are needed and these activities should be systemic. An increase in salaries (labour costs) as a motivating factor for improving efficiency and developing goodwill, primarily personal goodwill, results in new opportunities for health services and higher operating revenues. Attention to maintaining and developing the intellectual potential of employees results in an increase in the economic potential of teaching hospitals in the form of increasingly larger contracts for the provision of health services (Chluska 2023).

In order for knowledge resources to develop and for their multi-directional transfer to take place properly, material and financial resources are required. This is confirmed by one of the SWOT analyses of the teaching hospital. The weaknesses included the following: "*the inability to make full use of flexible forms of employment, the lack of a fully integrated IT system, the difficult situation on the labour market - especially the shortage of doctors, which limits the possibility of negotiating rates, the lack of full predictability of the functioning of the new model of health care financing, the increasing costs associated with running the core business, while also the need to invest in modern medical equipment, infrastructure*...".

6. Conclusions and Future Directions

An analysis of the relationship between the two organizationally and scientifically related knowledge entities, namely teaching hospitals and their founding medical universities, showed a consistency in the mission and strategic goals of both entities. Teaching hospitals possess and develop the intellectual capital of their employees, which is confirmed by reliable publicly available data of a financial nature (Chluska 2021, 2022, 2023). In addition to the data indicating the development of knowledge resources in teaching hospitals, the high potential for the development of the intellectual capital is confirmed by the missions and development strategies

of teaching hospitals and their founding bodies, namely, medical universities. Thus, it can be concluded that it was possible to outline the determinants of knowledge transfer and intellectual potential of employees of both entities. The coherence and mutual complementarity of the missions and strategic objectives have, in effect, one main goal –'patient welfare'. The conclusions of the analyses demonstrate that the aim of the article has been achieved and that the research questions posed have been answered.

It remains to be further researched and analysed what the role of health sector legislators should be in terms of stimulating and facilitating the development of the intellectual capacity of teaching hospitals and medical universities as the foundation for healthcare transformation and development strategies, in the face of the challenges of the 21st century. The decision-making processes of both specific teaching hospitals, medical universities and the policies of the health sector as a whole may also provide answers to a number of questions in this regard.

The Utilization of Blockchain Technology in Healthcare Management

Andrzej Chluski
Czestochowa University of Technology, Poland

andrzej.chluski@pcz.pl

Abstract: This paper explores the potential of blockchain technology in healthcare management. It discusses the key features and characteristics of blockchain technology that can enhance management in the healthcare sector, particularly in knowledge management and improving information processing. The paper underlines the potential of blockchain technology to revolutionise healthcare service delivery, presenting new forms of healthcare delivery that are only possible with the cost-effective and efficient use of blockchain technology. The research methods used in the paper include an analysis of selected theoretical studies on blockchain technology and the fundamentals of providing healthcare services, along with the presentation of several case studies. The paper also highlights the practical use of blockchain technology in both large organisations and small niche players serving the global market. The benefits and risks of using blockchain technology in healthcare are also identified.

Keywords: Healthcare Management, Blockchain Technology, Information Processes And Knowledge Management In Healthcare.

1. Introduction

The business activities in the medical sector are based on providing interrelated services to meet human health needs. Medical services include all necessary activities related to prevention, diagnosis of health status, and treatment of specific diseases (Medical service, 2011).

Every human activity requires access to a certain amount of data and its appropriate use. The sources of these data, the methods of processing and using them, and the information processes form what is known as an information system. The information system in the medical industry is very diverse. It is created and used by various stakeholders to meet the needs of a wide range of clients, such as patients (consumers of services), intermediaries in the provision of medical services, and providers of these services, i.e. doctors and other individuals from medical staff working in the respective centres, while also those who finance the provision of medical services (Rainer, Prince, 2021). Patients' needs include a wide range of information, such as information about specific health conditions, methods of diagnosis, treatment, places of services, and opinions about doctors and medical facilities. This information is partly in the form of other patients' views. Healthcare providers need information about different providers and competitors, as well as information about industry trends, the development of medical science, opportunities for further staff training, and planning while also developing the entity (Winter et al., 2023). Blockchain technology is an essential part of modern information technologies. It enables the distributed storage of data and its direct transfer between users, resulting in increased transparency and more secure transactions. Blockchain technologies, when applied to social media to verify the authenticity of patients' opinions and experiences, can significantly aid in their decision-making process related to choosing the right doctor and medical facility. Implementing Blockchain in healthcare can lead to tangible improvements in the management of diagnostic and treatment processes and the financing and administration of medical entities (Upadhyay et al., 2021). Blockchain technology, including the medical industry, can play a significant role in the economy and contribute to its development (Zhang, 2018).

The article aims to explore how blockchain technology can improve healthcare management by enhancing knowledge management and information processing. It examines theoretical and practical case studies highlighting Blockchain's benefits, risks, and practical applications in healthcare services.

The article presents three practical examples of blockchain use in healthcare to supplement the theoretical considerations. Use cases were selected considering the utility of applying Blockchain technology in healthcare for various stakeholders, including patients, medical staff, and service providers, as well as other stakeholders such as insurance companies, public funding bodies, governments, policymakers, and the public. The author intended to present the broadest possible benefits and risks of using Blockchain in healthcare.

Similar studies were conducted by Kurtz et al. (2018), focusing on business models in healthcare utilizing Blockchain technology. Mikula & Jacobsen (2018) analyzed the use of Blockchain technology in managing access to patient medical data. Reda et al. (2020) examined the impact of Blockchain on health supply chain

management. The system of patient appointment booking in healthcare services using Blockchain technology was described by Sumati et al. (2023). A systematic review of the use of Blockchain in healthcare was also conducted by Zang et al. (2018).

2. Blockchain: Distributed Ledger Technology

A blockchain is a chain of blocks (Crosby et al., 2016). Technically, it is a database that functions as a distributed ledger and is accessible to all authorised network users (Chien et al., 2020).

Blockchain technology is a chain of data blocks that store and transmit information about transactions in a network arranged in consecutive data blocks. Each transaction is recorded in this list as a block containing data on its value and time of conclusion. It is an open distributed database with relatively high security ensured using appropriate encryption techniques. Blockchain technology automatically stores data in many different locations. Only a person with private cryptographic keys has the right to edit such records. The keyholder is considered to be the data owner in a blockchain (Odeh et al., 2022).

Blockchain technology is usually associated with virtual currencies, such as Bitcoin. One of the main advantages of these currencies is their independence from state institutions, central banks, etc. The software of the nodes of this network is open and available to any participant. Bitcoin is based on the transfer between accounts using asymmetric cryptography, while all transactions are public and stored in a distributed database. Each transaction in the Bitcoin network is distributed to other nodes and requires confirmation within a time-stamped list of all known transactions, i.e., blockchains. This confirmation is based on mathematical evidence and specific computer operations, otherwise known as *proof of work*.

Another important element of blockchain technology is smart contracts. These are computer programs integrated into network blocks that automatically execute a contract when the specific conditions placed in that contract are met (Crosby et al., 2016). Executing smart contracts using a decentralised cryptographic system enables untrusted parties to conduct transactions securely without using a trusted third party. Smart contracts are most commonly implemented on the Ethereum network. The public Ethereum blockchain was created in 2014 as an open-source project and an alternative to the Bitcoin network. With the introduction of smart contract functionality, applications built on Ethereum can automate selected business transactions without the need for human intervention (from a legal standpoint). The structure of the database, linking all previous to newly added blocks using unique identifiers (hash), makes it impossible to make modifications that are unnoticeable to other users. The result is a database that is considered secure, attack-resilient, and trustworthy.

The most important features of blockchain technology relevant to data management are as follows (Rot, Zygala, 2018):

- security: Blockchain uses cryptography to store data and transactions securely. Each block is protected by mathematical hash functions, making data manipulation and falsification extremely difficult.
- decentralisation: Unlike conventional systems, Blockchain spreads data across multiple nodes, making it more difficult for hackers to attack and alter data.
- transparency: All transactions and operations are visible to network participants, which increases trust in the system and allows processes to be monitored and audited.
- irreversibility: Once the data have been validated and stored on the Blockchain, they cannot be changed or deleted. This guarantees the permanence and immutability of data, which is particularly important for financial transactions and legal documents.
- automation: Smart contracts can automate processes that must be controlled manually. This facilitates management by reducing costs and eliminating intermediaries.

With these features, Blockchain can speed up processes, increase efficiency, reduce costs, and increase trust between business entities.

In the future, more and more blockchain applications can be expected in various sectors of the economy and society, thus allowing further development and innovation in information and communication technology. Gartner (2017) predicts that by 2030, more than 30 per cent of businesses will be using Blockchain as an essential technology for business activity (Antonopoulos, 2017, p. 110).

3. Potential Areas of Application for Blockchain Technology in the Healthcare Sector

Every medical activity requires using well-chosen modern information and communication technologies (ICT). This applies to both patients and healthcare providers. Patients can use the technology to optimise their choice of doctor and place of service, while providers use ICT to develop and better promote their services in the medical market. As an essential element of ICT, blockchain technology can be used in several areas of medical activity, as outlined below.

Improving medical research and knowledge acquisition: Blockchain technology is increasingly used in biomedical research, knowledge acquisition, and medical education, helping protect privacy and maintaining data integrity while sharing and storing data. It is significant for clinical trials mainly because of its unique properties that ensure the safety and invariability of records. Data stored in the Blockchain are protected from unauthorised access, and cryptographic mechanisms guarantee their integrity. As indicated by Nagasubramanian (2018) and Nugent et al. (2016), this significantly increases data reliability obtained during clinical trials. These authors emphasised that smart contracts used in Blockchain can effectively prevent data falsification and the underestimation of undesirable research results, which is critical to maintaining ethical scientific standards.

Blockchain enables data to be securely transferred and shared between various entities without the risk of modification or corruption (Mytis-Gkometh et al., 2017). This is particularly important in large research projects, where collaboration requires a reliable information exchange mechanism. With data transparency and immutability, Blockchain increases confidence in clinical trials. Participants, sponsors, and regulators can verify all the information collected without worrying about its authenticity. With proper implementation and regulation, Blockchain has the potential to revolutionise the medical research sector, leading to significant advances in diagnostics, therapeutics and overall medical knowledge management.

Using blockchain technology helps improve the quality of *monitoring of treatment progress and the overall health status of patients* in the hospital environment. These systems enable secure and uninterrupted real-time tracking of medical data (Griggs et al., 2018). An integral part of such solutions is sensors for health parameters that can be controlled remotely, which aligns with the idea of the Internet of Things (IoT). Processes such as reading, transferring, processing and securing access to sensor data are carried out using blockchain technology (Meisami e. al., 2021). Similarly, results obtained from diagnostic devices used in the hospital can be securely processed and transmitted, for example, to the Electronic Patient Record by using cryptographic methods provided by the Blockchain (Chelladurai, Pandian, 2022).

Identity and privacy: Blockchain technology can be used in applications to help establish the identity of patients. The correct verification of a patient's identity, with the patient's informed consent, enables immediate and secure access by authorised persons to all their medical data at the place of service (Mikula, Jacobsen, 2018). It is a similar case in terms of *the verification of the identity of a doctor* as an employee authorised to access a patient's distributed medical data (within a blockchain database). The benefit of this solution is that an authorised employee of the medical entity (doctor, physiotherapist, radiologist) has immediate access to all the necessary patient's medical data stored in a distributed blockchain database.

Inventory management of medicines and medical supplies: Inventory management in the medical sector is critical due to its large share in the cost of such services. Blockchain technology can improve inventory management and reduce costs by decentralising and reducing the role of intermediaries. Controlling the quality and originality of medicines and other medical supplies is crucial. Medicines, medical supplies, and technical diagnostic equipment must meet stringent requirements for the quality, type, and origin of drugs, diagnostic materials and other auxiliaries. Depending on the procurement procedures and how these funds are distributed, different types of fraud are possible in this area of medical activity. This primarily concerns the purchase of counterfeit medicines and other medical supplies (Reda et al., 2020).

Registration and booking of healthcare services: Blockchain-based solutions can improve the booking and scheduling of services. Medical services, in the vast majority of countries, are provided within a regulated market. The restriction of the free market forces the time rationing of some medical services. This leads to queues of patients being formed while waiting for services. Such queues should be subject to control processes and some optimisation. This relates to the appropriate allocation of patients to the relevant medical entities while considering the option of patient transport. It is also essential, for example, to properly manage cases where a patient opts out of service and does not inform the healthcare provider while remaining on the waiting list. A centralised waiting list based on blockchain technology can reduce this problem (Sumathi et al., 2023).

Medical transport: Blockchain enables efficient real-time processing of medical transport data. Current weaknesses of transport data systems include the need for more connectivity between many medical transport providers and other barriers to transport. This is particularly true of emergency medical transport (Wu, Ho, 2023). Emergency transport resources should be deployed as efficiently as possible (Odeh et al., 2022). Optimisation should not only concern geographical data (the transport to the patient and the destination hospital) but also access to sensitive patient health data. Blockchain allows data collection at all stages of medical transport services. The benefit for the patient is the faster intervention of a doctor with immediate access to all necessary medical data.

Payments: Payments for medical services are made at multiple stages of treatment. The patient's resources finance some medical services. Still, more often than not, a significant part of these services is financed by funds of a public nature (from the state budget or various medical insurance companies). One of the areas for improvement of modern computerised payment systems is multiple data exchanges between different entities and numerous verification steps, which limit the possibility of creating one simple global system. As a decentralised database, blockchain technology can minimise inconveniences by streamlining payment processes while reducing potential errors and fraud.

Opinion-forming social media: Blockchain technology can simplify the creation and use of opinion-forming social media. With blockchain technology, it is possible to create universal online platforms to collect real-time feedback on doctors and medical entities. The opinions can be signed with private cryptographic keys, thus making it much more difficult to falsify views posted on social media.

4. Selected Examples of Practical use of Blockchain Technology in the Management of Medical Activities

4.1 Supporting the Maintenance of the Electronic Patient Record

Any patient-related data entered and processed in the IT system is critical to the patient and the provider. Patient medical data are collected from various healthcare providers. These include the patient's health status, as well as the results of diagnostic tests, methods and course of treatment, outcomes of treatment, etc. They must be accessible and processed independently of their technical implementation and the location where they are created. They should be collected through public resources, such as the Internet, with limited security and access to authorised persons. Essential information about the patient's health and treatment history should be collected to improve the quality and effectiveness of treatment and support lifestyle changes. The most commonly used name is the Electronic Patient Record (EHR).

The International Organisation for Standardisation (ISO) defines an EHR as an electronic repository of patient health data stored and shared securely and made accessible to multiple users with appropriate authorisation levels. It contains historical, current, and predictive information, at least to some extent. The main objective of creating and using EHRs is to improve the quality and efficiency of healthcare delivery by all healthcare providers (ISO/DTR 20514, 2004).

There are several reference models of EHR available in subject-related literature. EHR reference models should be developed so that they ensure the following:

- sharing patient medical data between professionals from different fields of medicine,
- interoperability between healthcare provider organisations, regional and national health system institutions, and, in the future, between supranational organisations,
- interoperability between software developed by different suppliers.

The need to meet the conditions listed above, standardisation, and the object-oriented paradigm approach to programming and data modelling are causing EHR reference models to become increasingly abstract, 'decoupled' from hardware and communication infrastructure, and, therefore, more generic, universal, and flexible. These can be called virtual electronic patient records.

Blockchain technology can significantly facilitate and simplify the practical implementation of EHRs operating according to the proposed reference models.

Computerised systems supporting EHRs have long been developed and implemented in many entities. They use conventional centralised databases maintained in specific computer centres. Administrators also centralise and control access to these data. Blockchain technologies can simplify and automate the allocation of access rights

to these data for medical staff from multiple healthcare providers. The optimal solution would be a distributed blockchain database maintained on a private or public blockchain network (Shahnaz, 2019).

Specialised software companies can provide technological support for the operation of EHRs in medical entities using blockchain technology. Due to the nature of blockchain technology and global access to the Internet, these can be small multi-branch companies. An example of such an entity is Guardtime (Guardtime, 2024).

Guardtime is one of the leaders in implementing blockchain technology in various sectors, including the healthcare sector and healthcare systems. The enterprise uses its proprietary KSI blockchain technology to increase security, transparency, and operational efficiency across multiple applications. Guardtime has been actively researching and developing blockchain protocols and applications for over ten years (Guardtime, 2024) and employs over 120 people (Crunchbase-guardtime, 2024). Outlier Ventures (Outlierventures, 2024) and SCIPA (2024) are the leading investors· Guardtime is working with the Estonian government using blockchain technology to process data in Estonian e-health systems. Their technology allows for the secure management of health records and citizen services that are available online, supporting more than 1,000 different public services (Guardtime-Estonia, 2024).

Furthermore, Guardtime has entered into a contract with a private healthcare provider in the United Arab Emirates. Implementing blockchain technology aims to improve data privacy and security. This project aims to develop a transparent and secure data management system that could serve as a model for other regional medical institutions. Guardtime develops innovative medical data management methods that meet high-security standards and are efficient and compliant with local healthcare data protection regulations.

4.2 Automation of Payment Services and Insurance Claims

Health insurance claims are a broad category of problems and challenges that health systems face worldwide. Most problems concern designing organisational structures and procedures to handle health insurance reasonably and efficiently.

Health insurance is often complex and challenging for the average user to understand. The procedures for making a claim, the documentation required by insurers, and the deadlines for dealing with claims are complex. One of the biggest problems is the high rejection rate of claims. The reasons for rejection vary, including errors in the completion of documents, insufficient evidence of the need for a particular medical service, and the pace of the policy being too low. Delays in the processing and payment claims are another critical problem that can significantly affect their patients' lives and health.

The rising cost of health insurance is a global issue, affecting policies' availability and effectiveness. High premiums can exclude people with lower incomes, increasing inequalities in access to healthcare.

Fraud by healthcare providers and patients is another serious problem for health systems. False claims or prescribing unnecessary medical procedures to obtain insurance money entails significant losses. The incompatibility and complexity of health insurance regulations in different countries can also hinder the effective management and enforcement of claims. Differences in legislation make global insurance operations difficult and require detailed knowledge of local conditions by insurers. Differences in standards of medical care between countries can lead to problems with the recognition of claims, particularly for people receiving healthcare abroad. Furthermore, this can complicate the procedures for verifying and assessing medical needs.

All the problems require nationally and internationally coordinated action to make health insurance systems more user-friendly and cost-effective.

Founded in 2018, MediConCen operates in the insurance technology sector. It has quickly gained local and international recognition for its innovative solutions. This company has used blockchain technology and the latest technological advances to automate insurance claims processes, thus revolutionising the handling of these claims. Through its activities, MediConCen streamlines and significantly changes how claims are managed in the insurance sector (Mediconcen, 2024).

MediConCen has developed an advanced computer system based on Hyperledger Fabric technology (Hyperledger, 2024) (Cachin, 2016), automating medical insurance claims and eliminating the need for paper documentation. This is an excellent example of an application that illustrates how blockchain technology can increase the operational efficiency of insurance companies and healthcare providers while eliminating the need for data reconciliation between the parties.

MediConCen has over 600,000 users in 14 insurance companies and over 900 doctors. In 2021, the company was also recognised in the prestigious Forbes Asia 100 to Watch list (Forbes, 2021), which promotes the most promising startups in the Asia-Pacific region.

Implementing digital signatures via QR codes makes the platform scalable. It enables the integration of insurers and healthcare providers globally without compromising data integrity on providers and claims. This innovation significantly reduces the burden on all involved parties, especially the medical staff, who can focus on more urgent tasks.

MediConCen uses blockchain smart contracts that are triggered automatically when certain conditions contained in the policy are met. This process limits human intervention, allowing a neutral and impartial technology to fulfil the contract's provisions once specific criteria have been met. Furthermore, using the company's proprietary API eliminates the need to submit data in paper form, which is a time-consuming conventional process and is often subject to the risk of forgery.

4.3 Optimising Pharmaceutical Supply Chain Management

The Drug Supply Chain Security Act (DSCSA) (FDA, 2024) was passed by the US Congress in 2013 as part of a larger legislation framework known as the Drug Quality and Security Act (DQSA). The main objective of DSCSA is to increase security in the pharmaceutical supply chain by introducing stricter rules for identifying and tracking pharmaceutical formulations.

The DSCSA requires operators in the medicines supply chain (such as manufacturers, distributors, and pharmacies) to use systems to accurately track medicines' movement at various distribution stages. This system is designed to protect against counterfeiting, theft, and other forms of fraud. Each pharmaceutical product must be equipped with a unique identifier, which allows it to be identified and authenticated at each stage of the supply chain.

Founded in 2016, LedgerDomain specialises in developing blockchain platforms that enable IT systems to operate efficiently in real time. The company is a member of Hyperledger, the Linux Foundation, and the Clinical Supply Blockchain Working Group. In 2019, LedgerDomain and UCLA Health were selected to participate in the DSCSA Pilot Programme to explore and evaluate methods to improve safety and security in the drug supply chain.

As part of this program, UCLA and its solution partner, LedgerDomain, focused on developing a complete system based on the BRUINchain blockchain that would meet all the key objectives of the DSCSA Act for a distributor operating solely based on commercial technology (Chien et al., 2020).

The system developers claim that automated queries to drug manufacturer relational databases implemented using their proprietary BRUINchain technology will reduce the cost of DSCSA compliance to 17 cents per individual drug package. The authors believe that manufacturers adopting an efficient, fully automated computer system based on distributed ledger technology (DLT) can further reduce these costs (Chien et al., 2020).

The interoperability of such a system enables real-time verification without human intervention, which is a critical factor in reducing compliance costs. With 4.2 billion prescriptions dispensed annually in the USA, blockchain technology would reduce the projected cost per unit to 13 cents per unit (saving $183 million per year in labour costs). Still, it would also make incorrect or fraudulent transactions much more difficult. At the same time, it also reduces the need for safety stock and improves the detection and elimination of potentially dangerous drugs from the drug supply chain (Chien et al., 2020).

By working with LedgerDomain, UCLA Health has positively changed its supply chain management for medicines. The appropriate use of blockchain technology can help improve logistics operations in the health sector, which is a significant step forward in combating problems such as drug counterfeiting and other supply issues.

5. Conclusion

Blockchain technology is an innovative tool for improving efficiency and reducing costs. It is a revolutionary concept that offers new possibilities for delivering previously unknown or unfeasible services and creating new innovative business models. New approaches to old problems provide excellent application potential, while the technology's flexibility allows it to be freely adapted to different tasks.

Blockchain technology benefits the healthcare sector by improving data and process management. Some main advantages include the following (Shae et al., 2019) (Reda et al., 2020).:

- Data security: Blockchain technology provides exceptional protection for medical information by cryptographically protecting blocks of data, which is crucial for sensitive patient data.
- Transparency and immutability: Blockchain registers are durable and transparent, thus enabling accurate tracking of medical history and preventing data manipulation.
- Operational efficiency: Blockchain automation of administrative and financial processes can significantly reduce costs and management time while improving the efficiency of health services.
- Information sharing: Blockchain technology facilitates the secure and transparent sharing of data between different medical entities, which supports better diagnosis and treatment planning while also improving the accumulation of medical knowledge and its transfer, i.e. the education of medical staff and patients.
- Reducing fraud: The technology can help reduce fraud and abuse in healthcare by accurately tracking medical products and drugs and automating processing insurance policies and other payments.
- Inventory management: Blockchain technology helps manage inventory efficiently to reduce waste and optimise resources.
- Patient rights: Patients can better control access to their health data, strengthening their privacy and security.

These advantages show how blockchain technology can transform healthcare, making it more secure, efficient, and friendly for providers and patients. Blockchain in healthcare is not just the future; it is a technology already transforming healthcare while benefiting all participants in the healthcare system.

Using blockchain technology in healthcare also involves risks (Kuo, Kim, 2019) (Tsung-Ting 2017). These particular concerns are as follows :

- complex implementation that requires integration with existing systems and the need for collaboration between different actors.
- the lack of uniform regulations in different countries, especially about personal data protection and regulations for medical services in other countries, including various ways of financing healthcare.
- cyber-security risks may relate to the theft, leakage, or manipulation of data stored on the blockchain network (particularly applicable in private blockchain networks controlled by individual organisations that are not adequately distributed).
- performance limitations of public blockchains, which are essential in the medical sector and are characterised by the transfer of large amounts of data and the need to perform most data processing quickly.
- the expected broader automation of processes may affect employment in the medical sector, especially in support and administrative staff. This may require appropriate adaptation measures.

Large companies most often implement innovative blockchain technologies. However, the technology's specifics allow relatively small niche enterprises to participate in the global medical market, for example, in areas where services can be provided partly remotely (Kurtz, 2019).

Data transparency, traceability, immutability, flexible access, trust, privacy, and security are the major problems faced by modern healthcare data management systems. Blockchain is a revolutionary and decentralised modern technology that has the potential to significantly change the way data is processed in the healthcare sector and provide a solution to most of these problems (Odeh et al., 2022).

Future research may concern the application of AI and Blockchain in healthcare. Distributed ledger technologies are databases containing static records of specific data. Smart contracts securely execute certain simple algorithms related to this data. The operation of smart contracts is formalised and precisely defined using relatively simple programming languages. The conditions for "triggering" a smart contract are also strictly specified. The general goal of using smart contracts is the automation of selected processes. In this context, an attractive solution might be using artificial intelligence to expand the scope of this automation (Rai et al., 2023). Utilising AI in mathematically formalised and algorithmic areas is relatively safe, as the outcomes of AI algorithm learning must be mathematically proven.

The article's limitations are as follows. This paper is theoretical rather than experimental, focusing on analysing potential applications of blockchain technology in healthcare management. The research sample consists of

deliberately and subjectively chosen examples by the author to illustrate the discussed concepts. Future research should use quantitative methodologies (e.g., Structural Equation Modeling methods). For this purpose, experiences related to the studies regarding information technology adoption models can be utilised (Zolait, 2012).

Blockchain technology can significantly enhance healthcare management by providing a secure and immutable record of patient data, ensuring data integrity and privacy. Additionally, it can streamline administrative processes, reduce fraud, and improve the efficiency of healthcare supply chains through transparent and traceable transactions. Utilising Blockchain in healthcare management can benefit patients, medical staff, administrators of healthcare facilities, and other stakeholders.

Knowledge Management in Virtual Teams: From the Perspective of Pluralistic Ignorance

Hao-Fan (Joshua) Chumg, Pei-Rong Lu and Min-Jing Li
National Chin-Yi University of Technology, Taichung City, Taiwan

h.chumg@ncut.edu.tw
3B131061@gm.student.ncut.edu.tw
3b131076@gm.student.ncut.edu.tw

Abstract: With the ever-accelerating development of the Taiwanese economy and Information and Communication Technologies (ICTs), the formation and cooperation of virtual teams consisting of inter-departments or inter-organisations is even more critical for Taiwanese enterprises. Notwithstanding, knowledge-sharing behaviours among virtual teams' members seem more to be difficult because of the social influence factors of their short-term cooperation and coordination within such dynamic teams. In light of the above-mentioned crucial facts, this study draws on social influence relevant theories but also adds pluralistic ignorance (which stems from social cognitive bias resulting from behaviour that generally adheres to social norms) as a critical inhibitor or motivator to explore factors affecting knowledge-sharing behaviour through knowledge management systems (KMSs) within virtual teams of the Taiwanese society. Consequently, our predicted findings show that knowledge-sharing behaviour results from a complex interplay of individual psychological motivations, social influences, and the Chinese culture rooted within such virtual teams. The study provides significant insight into the theoretical, practical and cultural implications of KMSs strategies and offers valuable advice for knowledge managers or scholars in Taiwanese society.

Keywords: Virtual Teams, Pluralistic Ignorance, Knowledge Management Systems (Kmss), Social Influence

1. Introduction

With the advent of the knowledge-based economy and the ever-accelerating development of information and communication technologies (ICTs), an increasing number of Taiwanese enterprises are adopting the concept of virtual teams to cope with rapid innovation and shorter product cycles. Notwithstanding, how individuals have the willingness to cooperate, coordinate and even share knowledge with colleagues still lacks enough research studies, especially within virtual teams (Chumg et al., 2022). Pluralistic ignorance, which is one of sociological theories, is a widespread misconception involving two kinds of social cognitive errors. The first is the social comparison error, which is the mistaken belief that other people's behaviours and attitudes are different from our own or that there are deviations from social norms (Prentice & Miller, 1993). The second is accuracy error, which is the false belief that an individual can accurately evaluate the opinions of others (Prentice & Miller, 1993). Halbesleben et al. (2007) pointed out that minority groups may influence pluralistic ignorance or agree with a particular point of view in public to maintain social identity but may hold different opinions in private. Past research shows that pluralistic ignorance can lead to employees' cognition of differences among others in the organisation, suppression of genuine emotions, and change of norms. This, in turn, weakens organisational culture, increases voluntary turnover, or leads to poor group decision-making. Bjerring et al. (2014) pointed out that the critical factors in the formation of multiple ignorances are that the group has an independent view of a specific situation, believes that other group members hold different views, individual behaviour is contrary to personal belief but in line with the view of others, and believes that the behaviour of group members represents personal belief. However, Prentice and Miller (1993) proposed strategies for pluralistic ignorance: agents can adjust private beliefs to approach those supported by group behaviour, promote group beliefs to approach their private beliefs or choose to reject or alienate social groups. In the setting of virtual teams, members composed of different departments or organisations may be unfamiliar with each other, so teams' cooperation and knowledge-sharing behaviours seem more difficult. Finally, this research proposes an integrative model through social influence theory, which combines social norms and critical mass with pluralistic ignorance. We posit that pluralistic ignorance causes changes in social norms and critical mass, affecting the user's knowledge-sharing behaviour within virtual teams in the context of Taiwanese society. This is mainly because, from a socio-cultural perspective, Taiwan is more collectivist than other countries (Sarkar & Huang, 2012). This research aims to improve virtual team members' willingness to share their knowledge within virtual teams in the Taiwanese societal context.

2. Literature Review

2.1 Pluralistic Ignorance

Pluralistic ignorance is a widespread social phenomenon in which a large majority of people in a group privately hold a belief or opinion but mistakenly believe that most others hold the opposite view (Halbesleben & Buckley, 2004). This, in turn, supports ideas or norms that most people may dislike or deny. Research has shown that pluralistic ignorance occurs in a variety of contexts, such as views on race relations (most white Americans support integration, but believe most others support segregation (O'Gorman & Garry, 1976)), drinking norms (college students privately believe that excessive drinking is unwise, but believe that most others support such norms (Prentice & Miller, 1993)) and in the classroom environment (most students are confused about what is being taught, but think that most other students understand it (Miller & McFarland, 1991)). Geiger and Swim (2016) explored the impact of individuals' views on climate change on their willingness to participate in discussions, and the study showed that individuals tend to be hesitant to express their ideas or opinions when they believe that their views or beliefs are in the minority. The phenomenon of pluralistic ignorance can be a barrier to knowledge sharing because people are less willing to share their knowledge or engage in discussions on specific topics if they perceive themselves as in the minority (Prentice & Miller, 1996). Halbesleben et al. (2007) pointed out that multiple ignorances hurt knowledge-sharing behaviour. In an organisational setting, when pluralistic ignorance leads to consistent behaviour among employees or group members, it leads to a decline in the quality of group decision-making. Because employees do not share their genuine opinions in a group decision-making environment, they are more likely to adopt solutions that do not have the support of employees from various groups. For example, Westphal and Bednar (2005) found in their research survey on corporate boards that external board members underestimated other members' concerns about the company's low performance, showing pluralistic ignorance. Specifically, they found that board members tended not to express concerns about the company's poor performance. As a result, minority views supporting the currently ineffective strategy are expressed and treated as majority views. In essence, the minority's views mislead other board members into believing there is more support for the current strategy than there actually is, leading to pluralistic ignorance and ultimately missing opportunities to initiate strategic changes or adjustments. Because Taiwan belongs to a very collective culture (Hofstede, 1997), such behaviour in terms of pluralistic ignorance may play a more critical role in employees' maintaining harmony at work.

2.2 Social Influence

Social norms are norms established by collective action, and individuals often feel uncomfortable when they realise that their attitudes differ from the norms of the social group around them. To address this difference, they tend to adjust their attitudes to conform to social norms (Prentice & Miller, 1993). Social norms are divided into descriptive norms and injunctive norms. Descriptive norms are those that describe typical or normal situations, that is, what most people do, by providing evidence to prove effective actions. Prohibitive (prescriptive) norms are those that specify what constitutes morally approved and disapproved behavior, rules, or beliefs (Cialdini et al., 1990). Thompson et al. (1991) argued that social norms are similar to subjective norms in the Theory of Reasoned Action (TRA). Previous studies on the social psychological aspects of "social norms" include gender norms (Van Grootel et al., 2018), healthy and sustainable eating norms (Moojen et al., 2022), and racial norms (O'Gorman, 1975). Li et al. (2016) investigated the resistance of employees to KMSs in a large petrochemical enterprise in China from the perspective of status quo bias. They found that social norms, loss aversion and transformation cost had a positive impact on KMS resistance willingness. In addition, the relationship between loss aversion, transition cost, social norms and KMS resistance intention is positively moderated by inertia. Companies need to consider these factors when promoting new technologies or systems.

3. Propositions and Research Model

3.1 Social Influences and Knowledge-Sharing Behaviours

Social norms stem from the theory of reasoned action and the theory of planned behaviour, and state that “the attitude of the person who is important to him will affect whether the individual makes the decision” (Ajzen & Fishbein, 1975). Individuals may behave certain behaviours or actions if someone they feel is important to them wants them to do so, even if they do not necessarily agree with those behaviours (Venkatesh & Davis, 2000). Some research studies have validated that social norms positively relate to knowledge-sharing behaviour (Wu et al., 2023; Bock et al., 2005). Hence, this leads us to establish the following proposition.

Proposition 1. Social norms positively relate to their knowledge-sharing behaviour within the virtual teams.

Critical mass can be regarded as a basic factor that triggers group behaviour (Oliver et al., 1985). Initial adopters can create enough motivation in specific interactive media systems to publish valuable information that promotes potential adopters' adoption (Oliver et al., 1985). Critical mass theory has been utilised in the social sciences to offer sophisticated theoretical models for generating collective action. Moreover, critical mass theory is used to analyse the collective behaviour of knowledge sharing in online encyclopedia communities (Zhao et al., 2013). Innovation can only diffuse when it receives support from the critical mass (Rogers, 1983). Therefore, this research considers that when adopters use the KMSs to have more friends (social relations), they perceive that it is more practical and, thus, motivated to contribute their knowledge within virtual teams. Consequently, this leads us to establish the following proposition.

Proposition 2. Critical mass positively relates to their knowledge-sharing behaviour within the virtual teams.

3.2 Social Influence and Pluralistic Ignorance

On the other hand, pluralistic ignorance can arise when social norms are influential but misunderstood. In the context of social norms, people may confuse their views with beliefs they believe others hold, leading to misunderstandings about valid social norms (Perkins et al., 2005; Lewis & Neighbors, 2006). In the field of college students' health behaviours, especially regarding issues such as alcoholism, college students generally mistakenly believe that alcoholism is widely accepted by society, even though it is not (Baugh et al., 2022). Social norms can influence people's cognition of a certain behaviour. At the same time, multiple ignorances may lead people to misunderstand this norm and think that others support a certain behaviour, thus affecting their own behaviour choices.

Proposition 3. The degree to which individuals increase pluralistic ignorance positively relates to their social norms.

Pluralistic ignorance is mainly studied in homogeneous groups in a given environment, e.g., students (Miller & McFarland, 1987; Prentice & Miller, 1993; Baugh et al., 2022), community residents (Moojen et al., 2022), colleagues (Halbesleben et al., 2007), etc., due to the wrong ideas of others, even if most people disagree with this social norm, still in the cycle of misunderstanding and conformity (Berkowitz, 2004). Since Taiwan belongs to a very collective culture (Hofstede, 1997), this pluralistic ignorant behaviour may play a more critical role in employees maintaining work harmony.

Proposition 4. The degree to which individuals increase pluralistic ignorance positively relates to critical mass.

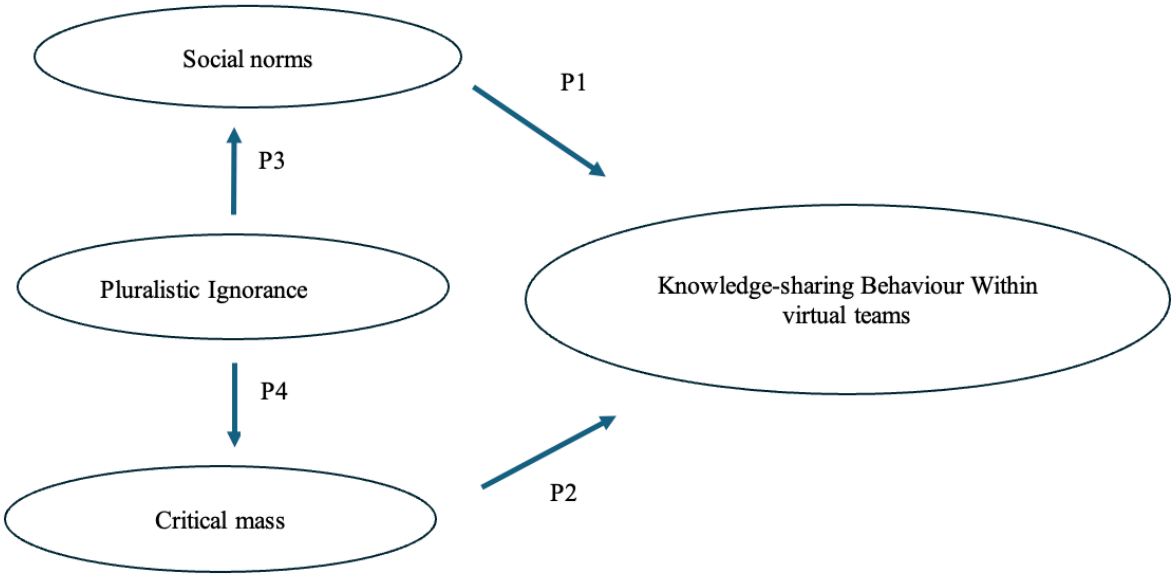

Figure 1: Theoretical model

4. Methodology

In our theoretical model, we have chosen to focus on the behaviour construct rather than intention. While intention is a central component in theories such as the Theory of Reasoned Action (TRA), our decision to emphasise behaviour directly aligns with the specific objectives and context of our study on virtual teams in Taiwanese companies. By focusing on behaviour, we aim to capture observable actions and outcomes within virtual team dynamics, which are particularly relevant for understanding performance, collaboration, and effectiveness in this context. Furthermore, behaviour provides a more concrete and measurable construct, allowing for clearer operationalisation and analysis within our research framework. While the intention may still play a role in shaping behaviour, our model prioritises the direct examination of behaviours exhibited by virtual team members in response to various factors and stimuli. Through this approach, we seek to offer actionable insights applicable to the challenges and opportunities Taiwanese organisations face in managing virtual teams effectively. Having considered the complex and multiple social influences, individual psychology and the context of virtual teams rooted in Taiwanese society may be insufficient to permit a comprehensive understanding of all the complex and abstruse factors affecting knowledge-sharing behaviour within Taiwanese virtual teams; this research will then utilise quantitative equally to analyse the data. Based on the above research model, this study uses a survey method to analyse the behavioural patterns related to knowledge-sharing behaviour within virtual teams of the context of the Taiwanese society. The relevant constructs and items are adapted from prior research, initially developed in English and then translated into Chinese. The translation was validated through a reverse translation process (Brislin, 1980). The questionnaire items were adjusted according to validated scales used in prior literature, with some wording changes. Questions about pluralistic ignorance are sourced from Chumg et al. (2020). Questions about critical mass are drawn from Shen et al. (2013). The social norm is referenced from Shen et al. (2013). Items related to knowledge-sharing behaviour are based on the works of Chumg et al. (2016).

5. Conclusion

These three types of social influences are important antecedents of knowledge-sharing behavior within virtual teams in the context of the Taiwanese society. In this regard, virtual teams' members who in order to maintain the harmony of the team and strengthen the recognition of other members are more likely to develop "common identity" for sharing knowledge within virtual teams. As mentioned above, our predicted results show that critical mass, social norms and pluralistic ignorance affects members' behaviour in terms of knowledge sharing. In this sense, our findings provide additional empirical support for the impact of pluralistic ignorance on knowledge-sharing behaviour particularly within the context of virtual teams in Taiwanese society. This article also explores the potential cultural aspect within the theoretical model, particularly in the context of Taiwanese society. Referencing Hofstede's six dimensions of culture or other relevant cultural frameworks can provide a theoretical basis for understanding cultural influences on virtual team dynamics (Hofstede, 1997). We will also discuss how cultural factors, such as power distance, individualism vs. collectivism, or uncertainty avoidance, may manifest in the behaviour and interactions of virtual team members in Taiwan and highlight any specific Taiwanese cultural aspects that are particularly salient or influential within the context of virtual teams.

3B131061@gm.student.ncut.edu.tw

Abstract: The main objective of this study was to identify and interpret the role of the patent team members' intellectual property claims on knowledge acquisition and innovation performance in the context of today's knowledge-based economy and dramatic ongoing changes (technological and otherwise) in Taiwan, and to survey the Research and Development departments of various universities in Taiwan. To effectively understand and establish a model of patent team knowledge management (KM) and innovation. This study will adopt the qualitative research multiple case study method, with patent team members of universities and colleges in Taiwan as subjects. This study further divides the composition of patent teams into four categories, including national universities, national universities of science and technology, private universities and private universities of science and technology. Using a concurrent combination of quantitative and qualitative approaches, a pragmatist research philosophy was chosen for this research to obtain in-depth analysis and provide comprehensive new insights into the key incentives promoting innovative knowledge-sharing behaviour among university academic staff in Taiwan. The predictive results of this study will provide important theoretical and practical insights into the patent knowledge management strategy and innovation performance of Taiwan universities and colleges, as well as valuable suggestions for patent knowledge managers in the context of Taiwan society.

Keywords: Knowledge Ownership, Knowledge Management, Innovative Performance, Pragmatist Research Philosophy

1. Introduction

The academic community's attention to knowledge sharing stems from the expansion of knowledge management research in the late 20th century when the characteristics of the knowledge economy were obvious. Karahanna (2013) detailed the design scheme of the organisational system suitable for knowledge sharing. Since then, more and more scholars have studied knowledge sharing from different perspectives, and the research field has been expanding from enterprises to social organizations such as government and education. The research on knowledge sharing has gradually become the focus of knowledge management. As for the concept of knowledge sharing is generally regarded as a process of knowledge transfer, interaction and communication, but different researchers have different understanding emphases, and some emphasize the sharing of knowledge between knowledge holders and demanders (Xie et al., 2016). Some emphasize the knowledge exchange and learning process among members of an organization (Senge, 1997), and some emphasize the process of one-party transferring knowledge to the other. The subject scope of knowledge sharing can be both internal and cross-organizational (Lee et al., 2016). Regarding the process of knowledge sharing, Nonaka et al. (2000) put forward the SECI model based on the four parts of knowledge socialisation, externalisation, combination and internalisation based on summarizing knowledge management, knowledge sharing and innovation. Szulanski (2000) proposed a five-stage model from the knowledge transfer perspective, including acquisition, communication, application, reception and assimilation. As for the factors that influence knowledge sharing, many scholars at home and abroad have studied them from different perspectives. Simmoni (1999), Coleman and Casselman (2016) argue that knowledge ambiguity affects knowledge sharing due to the reticence, complexity and specificity of knowledge. Regarding organisational characteristics, the salary system, incentive system, organisational atmosphere and organisational culture impact knowledge sharing (Serenko & Bontis, 2016). Individual characteristics, individual personality, self-realisation, sense of self-worth embodiment, attitude, organisational identity, and status competition motivation impact knowledge sharing (Kim, et al., 2019).

The scope of research in knowledge management at home and abroad is getting broader and wider, and remarkable achievements have been made. Various discussions and empirical studies have different concerns and perspectives, as well as different theoretical frameworks and research questions. However, judging from the current research perspective and scope, the current research on patent knowledge ownership still has considerable room for expansion. The comprehensive interdisciplinary perspective of knowledge sharing has yet to be expanded, and the comprehensive influencing factors of patent knowledge ownership have yet to be analysed. More comprehensive and specific. Research on universities as knowledge-intensive organisations

needs to be strengthened from the perspective of knowledge ownership of patents. In particular, most domestic research on the knowledge management of university teachers or scholars mainly conducts theoretical discussions, and research on the knowledge ownership mechanism of university teachers' patents is insufficient, especially since there is a lack of research on issues related to patent ownership among cross-regional university teachers, which points out the space and direction for this research.

2. Literature Review

2.1 Research on Knowledge Sharing Among University Academics

Learning and practising through teaching, practice and research, and enhancing innovation through collaboration with businesses and institutions, universities are generally viewed as knowledge-intensive and knowledge-creative entities that play a vital role in the dissemination and sharing of knowledge (Patel & Ragsdell, 2011; Fullwood et al., 2013; Ramayah et al., 2014). Therefore, the research on knowledge sharing of university teachers is an important part of knowledge sharing research. Regarding the importance of knowledge sharing among university teachers, scholars communicate with each other and share knowledge, and effective knowledge management is considered to be a key factor in the success of higher education (Fullwood et al., 2013; Fullwood & Rowley, 2017), this factor is particularly significant in research universities (Goddard, 1998). Tan (2015) believes that knowledge sharing and research collaboration among scholars are fertile soil for knowledge innovation and foster new knowledge for the academic community. Therefore, encouraging important behaviours, such as frequent knowledge sharing, cannot be ignored in academia. For example, in the relevant programs of government departments (such as the special research plan of the Ministry of Science and Technology, the teaching practice plan of the Ministry of Education, etc.), most teachers in research universities choose to cooperate with others to provide each other with the research knowledge and work experience accumulated over the years, so as to complete academic work jointly. Therefore, academic personnel working in universities, especially research universities, through the sharing of knowledge among each other, carry out collaborative research, thereby creating new theories and ideas and establishing new research principles. Unfortunately, many institutions, including research universities, do not seem to realize the importance of knowledge management, and the implementation of knowledge management programs within institutions is still hampered by a lack of enthusiasm and initiative (Tan, 2015). Therefore, universities should focus on increasing the importance of knowledge management to understand the preparation of universities to maintain a knowledge-based society, including the sharing of quality resources, expertise, research work and collaboration, so as to achieve good development (Jandaghi et al., 2014). In the past, influential factors and ways of promoting knowledge sharing among university teachers have attracted much attention, such as the willingness to share knowledge. Osterloh and Frey (2000) pointed out that knowledge-sharing behaviour among scholars is closely related to the motivation behind it. Donate and Canales (2012) believe that the market mechanism will not improve the enthusiasm of university scholars for knowledge sharing. On the contrary, these scholars will be encouraged to retain and hide their own knowledge or research results. Therefore, intrinsic motivation is the key factor affecting the transfer and sharing of implicit knowledge by university scholars, while external motivation has no expected impact on knowledge-sharing behaviours of organizational members (Fullwood et al., 2013; Fullwood & Rowley, 2017). Many researchers have also paid special attention to social network factors. Relevant studies believe that teachers' knowledge-sharing behaviour is affected by job titles, scientific research collaboration networks, friendship relationship networks, team affiliations, etc.

2.2 Research on Patent Knowledge Management and Knowledge Ownership of Organisational Members

According to the World Intellectual Property Organization (WIPO), intellectual property can be primarily divided into the following types: patents, trademarks, trade secrets, geographical indications, and industrial designs (WIPO, 2021). Concerning the importance of intellectual property knowledge management, for scholars, how to effectively manage and share knowledge, practice, and protect intellectual property is a topic worth attention. However, constrained by various factors such as school encouragement, awareness of intellectual property knowledge, innovation and novelty of research and development outcomes, the presence of technology transfer centers, university attributes, etc., many institutions, including research universities, do not seem to realize the importance of intellectual property knowledge management, leading to limitations in the implementation of intellectual property knowledge management programs (AR et al., 2021). Effective patent knowledge management is even more crucial for scholars in research universities within intellectual property. Research

universities need to enhance scholars' emphasis on patent knowledge management. Besides understanding the academic contributions of scholars in science and technology to the socio-economic aspects, sharing high-quality resources, expertise, research outcomes, and industrial collaboration can further disseminate laboratory research results through incubation centres and research institutions. In the realm of patent knowledge management, many scholars analyse from a technical perspective, such as countries, inventors, applicants, citations, etc., to gauge the extent of knowledge diffusion (Kayal & Waters, 1999; Sun et al., 2008; Hall & Helmers, 2013; Song et al., 2018). Some scholars also use social network analysis as a substitute for patent citation analysis to understand the diffusion of knowledge across different institutions and countries (Hsieh & Wang, 2009) and utilize multidimensional network analysis of patents to evaluate the impact of network structure and government funding on knowledge diffusion networks (Jiang et al., 2013). In studies on organizational and individual patent ownership, scholars have examined factors at the organizational, individual, and patent levels and their respective relationships with academic patents, indicating that for academic inventions, the value of the patent itself appears unrelated to choices in patent ownership (e.g., whether a university owns it) (van Burg et al., 2021). Furthermore, there is a positive correlation between the proactiveness of intellectual property ownership and the success of university-industry cooperation (UIC) projects when companies implement robust shared governance (Gretsch et al., 2020). In research on patent knowledge ownership, scholars suggest that companies can strategically disclose their inventions based on internal knowledge, demonstrating their ownership of knowledge (Dornelles, 2020).

3. The Overall Framework and Contextual Development of This Research

This research will utilise a concurrent combination of quantitative and qualitative approaches to obtain an in-depth analysis and provide comprehensive new insights into the key incentives promoting innovative knowledge-sharing behaviour among university academic staff in Taiwan. The predictive results of this study will provide important theoretical and practical insights into the patent knowledge management strategy and innovation performance of Taiwan universities and colleges, as well as valuable suggestions for patent knowledge managers in the context of Taiwan society.

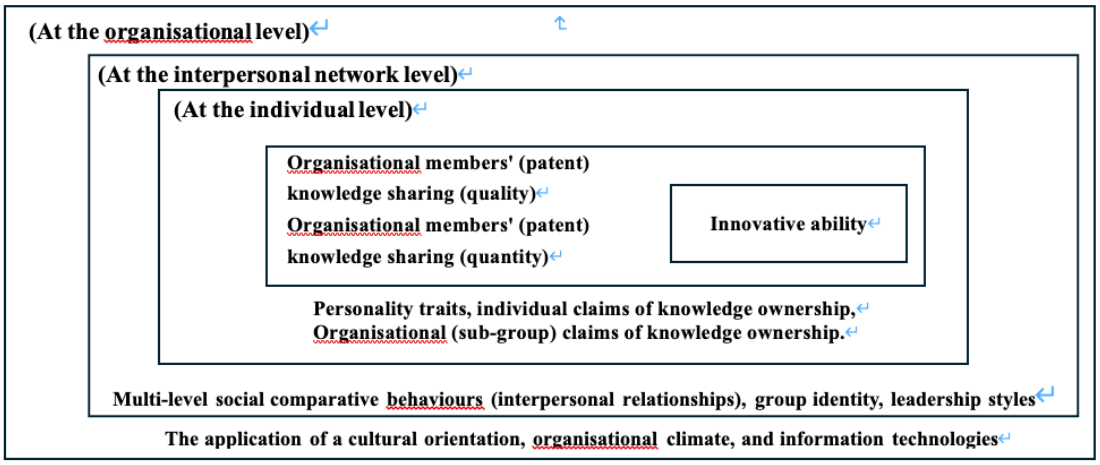

Figure 1: The application of the concept of organisational behavior (based on different historical backgrounds and social contexts) in this study.

This research aims to reveal the "black box" of the relationship between academic staff's traditional cultural orientation and their knowledge-sharing behaviour at the individual level. Research key points include: ① Introducing knowledge ownership to deduce the general mechanism of employee innovative behaviour; ② Analysing the potential "interaction" relationship between different traditional cultures and social network variables and different innovation motivations; ③ Using the "values → motivation → behavioural tendency model "(VMB) examines the mediating effect of different innovation motivations between different traditional cultural variables and employee innovative behaviour; ④ based on the first three points, construct a path model of the individual-level employee traditional cultural orientation on employee innovative behaviour, and Empirically test whether the impact of cultural orientation on innovative behaviour is mediated by different innovation motivations to produce a "masking effect".

Building upon the analysis results of the previous research content, this study delves deeper into the complex causal relationships among knowledge-sharing behaviour, interpersonal (relationship) networks, organizational culture, and organizational innovation capability of academic staff in Taiwan. This project is grounded in organizational behaviour research, integrating psychology (micro-level knowledge-sharing behaviour through ICTs), social psychology (mid-level), organizational systems, and anthropology (macro-level) to explore. Combining research breadth and depth, it explores a cross-layer collaborative mechanism model.

This research aims to explore whether the impact direction and magnitude of the innovative knowledge-sharing behaviour of academic staff at Taiwanese universities will be subject to the interference (moderation) of social comparison situational variables. Key research points include: ① Determining the heterogeneous effects of individual knowledge-sharing behaviours due to multi-level social comparison behaviours; ② Determining the heterogeneous effects of cultural social contexts in Taiwan's different regions (academic universities, industry-oriented universities) on knowledge-sharing behaviours in contrasting scenarios (high innovation demand atmosphere vs. low innovation demand atmosphere, cooperative atmosphere vs. autonomous atmosphere); ③ Determining the heterogeneous effects of culture on knowledge-sharing behaviours in contrasting scenarios (high-performance pressure vs. low-performance pressure).

4. Ongoing Research

This research aims to complete the transformation from theoretical research to practical application. Based on the previous theoretical research, this research will ultimately be based on Taiwan's unique cultural values and ideologies, focusing on the dual cultural subject of "individuals - other team members" and focusing on multiple groups of comparative innovation scenarios from the perspective of personal intrinsic motivation, Organisational workplace networks, organisational culture, organisational structure and other areas propose governance strategies that are suitable for promoting innovatively knowledge-sharing behaviour among university academic staffs in Taiwan. At the same time, this research will also provide theoretical references and a basis for decision-making for creating a cultural system and environment conducive to the national innovation-driven development strategy at the macro level. Finally, the full article containing the entire work is expected to be finished by August 2024.

Abstract: Organizations, particularly those that are knowledge-intensive, such as educational institutions, increasingly recognize the importance of managing knowledge sharing (KS). Consequently, KS in universities is an emerging research area as the transfer of knowledge from universities to the socio-economic environment is growing in importance. This study investigates the relationship between the communication departments and KS in two Brazilian universities. To this end, fifteen interviews were conducted with institution managers, communicators, researchers, and stakeholders involved in KS projects. The interviews were transcribed and subjected to content analysis. The key findings suggest that while communication departments play a vital role in transferring knowledge to various stakeholders, they could be further leveraged. Challenges identified include the complexity of university ecosystems, academic language barriers, and the reluctance of researchers to provide access to the knowledge they generate. Students are identified as the primary recipients of university knowledge, followed by public/political bodies and companies. However, society at large is perceived as the most distant stakeholder. According to the interviewees, the involvement of communication departments in knowledge transfer hinges on the visibility of the projects they undertake. Limitations in this process include restricted access to researchers, limited understanding of the strategic role of the communication department and resource constraints. The research paves the way for more in-depth investigations into the integration of communication departments in the university environment, as well as the construction of more assertive guidelines for the work of communication departments, to enable all the stakeholders, including society in general to make the most of the knowledge generated by the HEIs.

Keywords: Knowledge Transfer; Knowledge Sharing; Corporate Communication; Stakeholders

1. Introduction

Higher education institutions (HEIs) face increasing demands to foster knowledge sharing (KS) with society (Benneworth, Pinheiro, & Barrioluengo, 2016). Nevertheless, elucidating how KS can be optimized remains a challenge, especially in the context of contemporary trends such as globalization, digitalization, and mediatization (Seiffert-Brockmann *et al*., 2021). Moreover, the complex nature of HEIs poses obstacles to effectively engaging diverse audiences and broader society (Benneworth, Pinheiro, & Barrioluengo, 2016).

Managing KS in HEIs has emerged as a research agenda yet to be fully explored (Al-Kurdi *et al*., 2018). HEIs are expected to lead in knowledge generation and application, so that their wealth of knowledge can be shared within the regions around them (Dal Buono & Fortezza, 2017). Despite possessing the expertise, communication departments in HEIs have thus far underutilized their potential contribution to the KS process (Cidade & Oliveira, 2023). In light of this, the study aims to address the following research questions:

Q1. In HEIs, what are the biggest challenges to KS with their different stakeholders?

Q2. Regarding KS, which are the closest and most distant stakeholders to the HEIs?

Q3. What is the biggest difficulty facing HEI communication departments in this scenario?

Based on these inquiries, this research endeavours to enrich the understanding of the role of Organizational Communication (OC) in facilitating dialogue between HEIs and their stakeholders. Additionally, the study seeks to provide a scholarly contribution by pinpointing gaps in KS within HEIs and the challenges OC encounters in this context. Moreover, it proposes to formulate recommendations for future research with the aim of enhancing the role of the communication departments of HEIs in the realm of knowledge sharing.

Following this introduction, the article is organized as follows: Section 2 introduces the key concepts underpinning the discussion. Section 3 outlines the adopted methodological procedures. Section 4 presents the analysis and discussion of the results. Finally, Section 5 encompasses the conclusion, limitations, and suggestions for future research.

2. Literature Review

2.1 Knowledge Sharing: HEIs and Their Stakeholders

Efficient knowledge management within organizations necessitates prioritizing KS (Wang *et al*., 2014). Recognizing that the mere creation and acquisition of knowledge are often insufficient, it is imperative for organizations to ensure the dissemination of that knowledge among individuals to maximize its benefit. Knowledge can be either tacit, residing within individuals' minds and thus relatively challenging to convey, or explicit, being documented in materials such as manuals, rules, and procedures (Nonaka, 1994). The benefits of KS are seen in various forms, including innovation and the development of novel products, processes, and departments (Tseng, 2010), along with enhanced operational efficiency (Ahmad & Karim, 2019).

Numerous studies have emphasized the need for organizations to disseminate the knowledge they generate to address contemporary challenges and benefit their ecosystems (Al-Kurdi, El-Haddadeh, & Eldabi, 2018; Benneworth, Pinheiro, & Barrioluengo, 2016; Dal Buono & Fortezza, 2017; Wereda & Wozniak, 2018). A recent literature review by Leonitou *et al.* (2020) underscores academia's central role as a stakeholder in studies focusing on enhancing innovation management and fostering entrepreneurship. This prominence is attributed to the fact HEIs are acknowledged as key hubs for knowledge sharing and dissemination (Al-Kurdi, El-Haddadeh, & Eldabi, 2020), thereby constituting a shared heritage within their communities (Dal Buono & Fortezza, 2017).

Beyond educational settings, knowledge and its dissemination among stakeholders have garnered attention from organizations. For instance, Wereda and Wozniak (2018) examined a cohort of Polish companies experiencing a decline in market value, concluding that insufficient KS with stakeholders, due to ineffective communication, was a determinant factor in their situation. Additionally, Leonidou *et al*. (2020) synthesized a framework, drawing from an extensive literature review, that delineates various stakeholders influencing organizational innovation and entrepreneurship. Furthermore, another study found effective stakeholder management entails processes such as identifying and understanding needs, managing expectations, monitoring activities, and the continual review of these processes (Bourne, 2009).

2.2 Organizational Communication

Since the 1990s, communication departments have progressively gained visibility and significance within organizational frameworks (Riel, 1995). In recent years, these departments have evolved to encompass more strategic functions (Koehler & Zerfass, 2019), overseeing processes that ultimately address stakeholder relationships, including image crisis management, internal communication, employee engagement, Corporate Social Responsibility (CSR) reporting, and various digital channels (Brockhaus & Zerfass, 2022).

According to Barker (2013), communication is characterized as a strategic process involving the exchange of messages via information knowledge management, fostering mutual understanding and beneficial relationships between an organization and its stakeholders. Within the scope of this article, organizational communication also encompasses specialized areas within organizations responsible for managing communication processes, staffed by professionals with distinct expertise and practices. Wereda and Wozniak (2018) assert that efficient communication is indispensable for generating new and valuable knowledge and collaborating effectively with other partners.

Recent research highlighting the gap in communication functions hindering knowledge dissemination from HEIs to society is scarce. Miklosik, Evans, and Hlavaty (2023) examined online channels available to HEI audiences, discovering that knowledge communicated through these channels correlates with factors such as institutional longevity and type (public or private), among others. They note that while universities are expected to disseminate knowledge, the manner in which knowledge is communicated beyond HEIs remains largely unexplored in academic studies. Torres, Ziviani, and Silva (2012) proposed a competency mapping initiative at the Federal University of Minas Gerais to establish a catalogue of experts or dissemination guide, aiming to enhance the KS in the University.

This study acknowledges the significant role of communication departments in knowledge management, recognizing that knowledge must be effectively transferred to be fully explored, a process achievable only through communication (Grigorsescu, Lupu, & Zink, 2014).

3. Research Method

3.1 Classification

This study adopts a positivist philosophy, aiming to understand reality independently, objectively, and ontologically (Saunders, Lewis, & Thornhill, 2019, p. 130). Data collection involved semi-structured interviews with managers and researchers holding management positions at two HEIs in southern Brazil. An inductive approach was employed, beginning with specific questions and expanding to more general inquiries, providing clearer insights into the research topic (Saunders, Lewis, & Thornhill, 2019), potentially yielding novel information (Hair *et al*., 2005). Prior to the interview stage, the semi-structured script was reviewed by two scholars and was pilot-tested with a professional from an HEI.

3.2 Data Collection

Data were collected during individual exploratory interviews held between October 2023 and February 2024. The semi-structured interview script consists of three parts: 1) challenges encountered in KS between HEIs and their stakeholders; 2) regarding KS, identification of stakeholders more closely and distantly associated with the HEIs; and 3) assessment of the significance and potential constraints faced by communication departments in facilitating KS.

The interviews involved eight university researcher-managers, along with seven managers, four of whom were affiliated with the communication departments and three from various sectors of the university, namely planning, governance, and a technology park. Each interview lasted an average of 29 minutes, and all sessions were transcribed and subjected to content analysis.

Interviewees were initially contacted via email, and the interviews were conducted via videoconference. Saturation, as recommended by Saunders *et al*. (2019), was employed to determine the appropriate number of interviews. According to Guest *et al*. (2006), in homogeneous groups, saturation is typically achieved with around 12 interviews. In this study, saturation was reached after the eleventh interview, as no new ideas emerged in the subsequent four interviews.

3.3 Data Analysis

The data were meticulously analysed following each interview, facilitating the identification of saturation, while the content analysis was applied as proposed by Bardin (2009). This method encompasses systematic procedures for content description, employing both qualitative and quantitative indicators, as advocated by Bardin (2009) and Krippendorff (1980). Initial open coding involved the dissection of data based on its contextual interpretation, succeeded by axial coding, wherein these open codes were grouped into coherent categories, enabling cross-interview comparisons. These codes were derived directly from the speeches provided by the interviewees. One researcher conducted the interviews, while two researchers concurrently scrutinized the acquired data. Any variances detected in their respective analyses were thoroughly discussed until a consensus was reached, thus affirming the reliability of the findings, in alignment with the criteria outlined by Krippendorff (1980).

The data were analysed both collectively, as a single group, and with a distinction made between researcher-managers (8) and other managers (7). This approach was done to discern potential differences in the understanding of knowledge transfer among those who not only hold leadership positions but also actively manage their own research.

4. Analysis and Discussion of the Results

4.1 Challenges to be Overcome

The analysis revealed several significant challenges that HEIs must address to enhance the efficiency of KS with their diverse stakeholders. Among these challenges, two aspects emerged with great frequency: the application of knowledge and the academic language.

Within the category of ‘application of knowledge’, all viewpoints highlighting the disparity between researchers’ interests and societal problems were considered. For instance, as one researcher-manager explained, “*the biggest challenge is that the scientific research and the real problems are not the same thing*.” Another

interviewee emphasized, "*the challenge is to make the knowledge produced at the HEI relevant and have a significant impact on society*."

In the category of 'academic language', interviewees underscored the challenge of translating knowledge into a format understandable by society. One interviewee articulated, "*We need to find mechanisms that make the knowledge produced more accessible to the general public.*" Notably, researcher-managers predominated in this category, likely due to their recognition of the specialized language inherent in research, which may alienate those outside the academic realm. Reflecting this, a researcher-manager remarked, "*the communication department can contribute because researchers don't know how to do this.*" Similarly, another interviewee from the same group emphasized, "*with the appropriate language, the communication department can facilitate transfer of knowledge to society.*" It is a barrier to the demand mentioned by Benneworth, Pinheiro and Barrioluengo (2016), which is to foster knowledge sharing with society.

In addition to the aforementioned categories, two others emerged consistently in the discourse of various interviewees: the 'complexity of the university ecosystem' and 'the reluctance of researchers to provide access to the knowledge they generate'. Concerning the complexity of the ecosystem, it is pertinent to note that this study was conducted at two large universities situated in different cities in southern Brazil, both with extensive physical infrastructures, offering undergraduate, graduate, and extension programs in hybrid face-to-face and distance learning formats. An interviewee highlighted the presence of "*fiefdoms*" within the university, which hinder communication among internal areas. Another interviewee questioned, "*we encourage everything to be considered. But when everything is important, what is the priority?*"

Concerning the category 'the reluctance of researchers to provide access to the knowledge they generate', three references were made in the interviews, all from non-research managers. In this context, interviewees emphasized that "*researchers need to communicate more about their work beyond their bubble*" and noted that "*… while knowledge transfer actually occurs, it is often diffuse, scattered, and unrecognized*".

Two challenges were separately emphasized by two different interviewees. One pertains to the disparity in the perception of time and speed between academia and society. The other highlighted challenge concerns the complete absence of KS, with communication efforts primarily focused on university marketing initiatives aimed at attracting students. The table below summarises the challenges and their respective incidence rates. The number of challenges exceeds 15, as some interviewees mentioned multiple challenges even when asked to identify 'the most significant one'.

Table 1: Summary of the highlighted KS challenges and the incidence with which they were mentioned

Application of the knowledge produced/understanding the demands of society	8
Academic language	8
Complexity/size of the university ecosystem	4
Reluctance of researchers to provide access to the knowledge they generate	3
Speed and sense of urgency	1
There is no focus on KS	1

Notably the two most frequently mentioned challenges revolve around interactions with stakeholders, underscoring the significance of external engagement. Conversely, the remaining challenges predominantly concern internal university matters.

4.2 Stakeholders

When asked about the closest and most distant stakeholders regarding KS, interviewees provided a comprehensive list. Notably, the HEI students were identified as the closest stakeholders by 10 out of the 15 interviewees. Subsequently, mention was made of companies with which the HEIs maintain relationships, particularly through technology parks and research institutes. Other stakeholders mentioned were, in order of frequency: governments and other entities - e.g. the education ministry, councils, unions, and trade associations and: the internal university community and political leaders.

In the list of more distant stakeholders, the interviewees mentioned "*companies that have never had a relationship with the university.*" The industrial sector was noted as having the least engagement with HEIs. Additionally, the surrounding community and society were mentioned in a general manner. However, specific mentions included former students, high school students (potential future students), third-sector organizations, supply chain partners, companies and entities from municipalities geographically distant from the universities. It is important to note that both universities where the research was conducted are situated in large urban centres, with one being located in the state capital. The illustration below provides a representative overview of interviewees' perceptions of stakeholder proximity. Notably, there was no significant distinction between the responses of managers and researcher-managers in these questions.

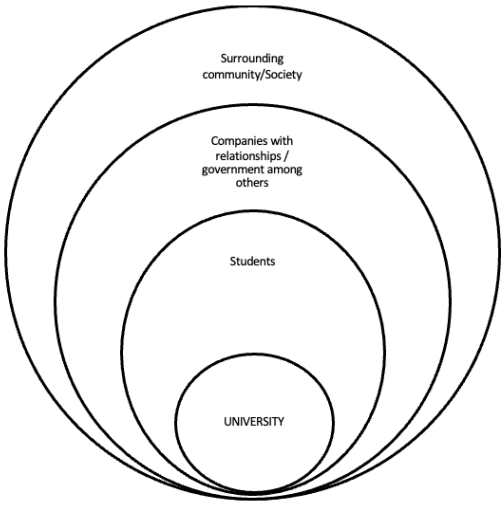

Figure 1: HEIs and their main stakeholders

4.3 Overcoming Limitations and Becoming Strategic

The research evaluated interviewee's perceptions of how communication departments contribute to the process of HEIs sharing knowledge with their stakeholders. Predominantly, the responses underscored a tactical/operational role for the communication departments, primarily focused on transmitting or converting knowledge. Specifically, 12 interviewees, including both the researcher-managers and managers, emphasized these tactical/operational aspects. Conversely, strategic actions were highlighted by only three - one manager and two researcher-managers.

The statement "*The communication department uses technical knowledge to make the university a relevant source*" reinforces the operational dimension of communication. Another interviewee highlighted: "*the communication department helps to map and organize content so that it can be used in different ways for the university, packaged for different stakeholders*". Additionally, five interviewees emphasized the marketing function of communication, being aimed solely at attracting new students to the HEIs: "*almost nothing to do with the transfer of knowledge, because it is very focused on capturing students*".

The perception of communication as a tacit/operational means or channel is evident in the following expressions: "*transposition of abstract knowledge,"* "*transferring in a correct way,"* "*translating what we do for the lay community*," and "*opening channels and establishing relationships with the traditional press."* Consequently, communication is perceived as a purely operational sector, lacking a strategic vision of its potential impact. The few managers (3) who mentioned strategic communication used expressions such as "*strategic role*" and "*being strategic,*" highlighting not only the function of translation or channel selection but also envisioning the communication department as being fully capable of "*engaging with diverse actors in a complex system."* When asked if the communication department play a greater role in the dissemination of knowledge from the HEIs to society, all the interviewees (15) answered affirmatively. Some supplemented their responses with phrases like "*very*," "*yes, if it is connected to management*," and "*there's definitely space to contribute more*."

Finally, the interviewees were asked about the most significant limitations hindering the effective contribution of communication departments. Equally, among both managers and researcher-managers, the most frequently mentioned limitation (8) was "*understanding the strategic role of communication.*" In this regard, most

interviewees emphasized that recognition rests primarily with the institution itself and its managers. Only one interviewee suggested that communication professionals themselves need to "*understand themselves as being strategic.*" Additionally, one interviewee noted that "*universities, as a whole, are very poorly managed, and in this regard (the communication department) it is no different."*

As a second limitation of communication departments in contributing to KS, scarcity of resources was cited (7). These resources encompass not only financial allocations for operations but also the shortage of suitably qualified staff. One argument put forth was that "*the communication department is primarily focused on areas with potential economic and financial impacts on the university*." It was also noted that *"communication professionals require highly specialized knowledge, necessitating a well-prepared communication team capable of handling substantial production volume."* In this context, interviewees emphasized the necessity for "*institutional investment decisions*" to ensure that communication departments have adequate resources and personnel with the requisite qualifications to fulfil their strategic function effectively.

The third most frequently cited limitation (6) was "*access to researchers*." Interestingly, this concern was raised by more researcher-managers (5) than managers (1), indicating recognition of their own constraints. Comments such as "*we need researchers to be trained to be attentive to communication*," "*scientists need to pay attention to the dissemination aspect*," and "*there needs to be greater dialogue between the research sectors and the contribution of the communication department*" reflect this sentiment.

Occasionally, other limitations were mentioned. They are: "*difficulty measuring results*", "*understanding the academic world and developing greater proximity*", "*lack of interest of parties outside the university"* and "*content being distributed through diverse channels*". In this sense, an interviewee mentioned that the communication department needs to be "*divided into sections"*, which would be a limitation. Below is a table with the limiting factors and their incidence during the interviews.

Table 2: Factors limiting the contribution of communication departments towards KS and their frequency

Limitation	Frequency
Understanding the strategic role of communication	8
Limited resources	7
Access to researchers	6
Difficulty measuring results, understanding the academic world and developing greater proximity, lack of interest of parties outside the university, *content being distributed through diverse channels*	1

Source: authors, 2024.

It should be noted that the total count of responses exceeds the number of interviewees, as some cited more than one limitation, even when asked to identify the most significant one. These factors probably are the reason that communication departments in HEIs are underutilized considering KS process as mentioned by Cidade and Oliveira (2023).

Despite possessing the expertise, communication departments in HEIs have thus far underutilized their potential contribution to the KS process (Cidade & Oliveira, 2023).

5. Conclusion, Limitations, and Future Research

According to the interviewees' perceptions, the communication department plays a crucial role in facilitating KS between HEIs and their various stakeholders, and could further enhance that contribution. However, despite its importance, this role is not widely recognized as strategic. Instead, they primarily view it as tactical/operational, focusing on determining dissemination methods. Consequently, most interviewees see the involvement of communication departments in the transfer process as contingent on the visibility it provides to developed projects. Only three interviewees highlighted a strategic role for communication in this process, indicating a potential gap in recognizing the broader impact and potential of communication departments within HEIs.

The majority of interviewees perceive several challenges that need to be addressed for KS to occur more intensely. These challenges include the complexity of the university ecosystem, the barrier of academic language, and the reluctance of researchers to share the knowledge they generate. Notably, academic language is particularly emphasized by the researcher-managers, highlighting the communication difficulties faced by

scientific researchers. The primary stakeholder with whom HEIs share the most knowledge is identified as the student body, followed by public/political bodies, companies, and society at large. However, it is noted that the general public, defined as society, is seen as the most distant from the knowledge produced by HEIs.

The most significant limitations hindering communication departments from making a greater contribution to the KS process include challenges related to understanding the strategic role of communication, time constraints, the limited number of professionals involved, their level of experience, and access to researchers. These factors collectively impede the communication department's ability to play a more impactful role in facilitating KS within HEIs.

This study paves the way for more in-depth investigations into the integration of communication departments within the university environment, as well as the construction of more assertive guidelines for the work of communication departments, to enable all the stakeholders, including society in general to make the most of the knowledge generated by the HEIs.

This study has successfully achieved its objectives. Firstly, it identified the primary challenges in the KS process of the HEIs in relation to their stakeholders, as perceived by the interviewed managers. Additionally, it delineated which stakeholders are considered closer and which are perceived as more distant in terms of KS. Furthermore, the study effectively mapped out the difficulties that must be overcome to alter this scenario. Overall, the study has provided valuable insights into the complexities of KS within HEIs and has laid the groundwork for addressing those challenges.

This research presents theoretical and practical contributions. As a theoretical contribution, the following stand out: 1) the identification of the challenges to KS with different stakeholders in HEIs; 2) the closest and most distant stakeholders to the HEIs; and, 3) the difficulty facing HEIs communication departments in this scenario. As a practical contribution, one can mention: 1) knowing the challenges, the dean can direct efforts to mitigate the disparity between researchers' interests and societal problems that were considered; and, 2) the HEIs understanding the strategic role of communication, can solve the problem of limited resources in this sector; a closer relationship between researchers and professionals in the communication department can be an alternative to leveraging the KS among HEIs and society.

This study has two limitations. Firstly, the interviews were conducted with managers from only two universities, thus reflecting the reality of those specific contexts. The research could be expanded to include other institutions, which may reveal different challenges and limitations. Secondly, interviews alone were used to understand how communication departments can contribute to KS in HEIs. Employing other data collection methods could enrich the analysis of this issue. For instance, a quantitative survey could increase the number of respondents and potentially uncover additional insights, while also opening avenues for exploring other research questions related to the topic.

Abstract: This study aims to explore the intersection of Knowledge Engineering, Management, and Media (KEMM) in enhancing innovation and competitive potential within Knowledge-Intensive Organizations (KIOs). The objective is to understand how these fields interact to optimize the management and dissemination of knowledge in the context of the Knowledge Society (KS). A qualitative methodology is employed, using a scoping review to assess interrelated phenomena and map existing literature. This approach involves an exploratory bibliographic strategy and an interpretative analysis to identify key concepts, theories, and gaps in knowledge. The results indicate that effective integration of KEMM significantly improves decision-making, organizational performance, and innovation. The cultural differences in knowledge management models are highlighted, contrasting the American focus on technology with the Japanese emphasis on socialization. It also underscores the need for balancing technological advancements with human skills to foster a sustainable and innovative organizational environment. In the discussion, the paper emphasizes the critical role of KEMM in navigating the complexities of a BANI world (brittle, anxious, non-linear, and incomprehensible) by enhancing resilience and adaptability among workers. The integration of emerging technologies such as AI, machine learning, and digital platforms is shown to facilitate knowledge sharing and collaborative innovation. The conclusion stresses the importance of a holistic approach to KEMM, suggesting that future research should focus on practical applications in real-world scenarios, including education and organizational learning. By leveraging KEMM, organizations can develop more effective business models and contribute to the creation of Human, Intelligent, and Sustainable Cities. This study provides a foundation for further investigations into the synergistic relationships between Engineering, Management, and Media in the knowledge-based economy.

Keywords: Knowledge Engineering. Knowledge Management. Knowledge Media. Knowledge Society.

1. Introduction

Knowledge is the driving force behind innovation, propelling progress at personal, community, and global levels (Kaźmierczak, 2017). The advent of Knowledge Society (KS) signifies the fusion of technological advancement with social development through creative and experiential education (Stehr, 2015). This society transcends mere information access, emphasizing the attribution of meaning and continual redefinition of achievements amidst complex interrelationships (Muños, Bohórquez, & Díaz, 2022).

The COVID-19 pandemic accelerated the characteristics of the Knowledge Society, reshaping the corporate landscape and emphasizing resilience and adaptability among workers. The concept of a BANI world (brittle, anxious, non-linear, and incomprehensible) underscores the need for flexible approaches to navigate complexities (De Godoy & Ribas Filho, 2021). Behavioral skills like resilience, empathy, and adaptability gained prominence, with organizational knowledge management and leadership playing pivotal roles in facilitating adaptation and fostering continuous learning (Nataliia & Olena, 2023).

In KS, knowledge acts as both an intangible asset and a co-production factor, with interdisciplinary approaches at the intersection of Knowledge Engineering (KE), Knowledge Management (KMa), and Knowledge Media (KMe) playing its own roles in driving innovation, enhancing decision-making, and optimizing organizational performance (Burgin, 2016).

The interplay among these areas is vital for effectively utilizing and disseminating intangible assets within organizations and society. Understanding the integration and synergy among Engineering, Management, and Knowledge Media is essential for effectively governing and leveraging intangible assets in Knowledge-Intensive Organizations (Zieba, 2021).

Hence, this work aims to explore how Knowledge Engineering, Management, and Media (KEMM) intersect and support each other in fostering innovative and competitive potential, particularly for Knowledge Intensive Organizations (KIOs), also proposing a research agenda in these areas.

2. Theoretical Background

2.1 Knowledge Engineering, Management and Media

The fields of Knowledge Engineering, Management, and Media focus on the effective management and utilization of knowledge within systems (organizations, communities, ecosystems, etc.). This interdisciplinary field combines principles of science and technology to improve the acquisition, storage, processing, and sharing of knowledge, as well as collaboration and innovation (Schreiber, 2000; Pacheco, 2007).

KMa enables organizations to leverage their intellectual capital and gain a competitive edge, involving the systematic collection, organization, and dissemination of knowledge to facilitate decision-making, problem-solving, and innovation (Vieira, 2020). Effective knowledge management practices can improve organizational performance, increase employee productivity, and promote a culture of continuous learning (De Carvalho, Ponciano & Bianchi, 2021).

Knowledge modeling and associated technological aspects, such as Knowledge Management Support Systems, are subjects of study in Knowledge Engineering, which is concerned with the development of systems that enable the capture, storage, processing, and retrieval of knowledge (Kendal & Creen, 2004).

Knowledge Media emerges from the convergence of computing, telecommunications, cognitive sciences, and learning sciences, focusing on the communication, dissemination, and sharing of knowledge, including digital platforms, social networks, and communication technologies, providing channels for interaction and learning within organizations (Muller & De Souza, 2020).

By interfacing these three areas, KIO represents a new organizational paradigm in the Knowledge Society, and the areas of Media, Management, and Knowledge Engineering are fundamental to their success and operation. These areas, as evidenced by the work of authors such as Günther and Cunha (2022), Bignetti (2002), and Nadai and Calado (2006), are complementary in terms of people, processes and technology, defining together the essence of KIOs in contemporary business environments.

2.2 Knowledge Society and Knowledge Intensive Organizations

The term "Knowledge-Intensive Organizations" (KIOs) refers to companies that rely heavily on knowledge for producing and offering products and services. These organizations are characterized by a strong base of intellectual skills among employees and effective knowledge management practices (Nadai & Calado, 2006).

To thrive, KIOs must constantly redefine boundaries and adopt new collaboration paradigms, such as business networks and innovation ecosystems. In this context, Knowledge Engineering Management and Media (KEMM) play a crucial role, enabling responsiveness to changing demands and opportunities. Investing in knowledge-based technologies and infrastructures is essential for maintaining competitiveness (Rossetti et al., 2008).

Macedo and Souza (2023) emphasize balancing technological and human aspects within KIOs. Promoting an environment that fosters technological growth while valuing employees' skills is key to long-term success. Operational workers should be granted autonomy, making them primary holders of practical knowledge, while managers provide guidance without imposing strict monitoring. A horizontal structure with low bureaucracy allows greater flexibility and effective communication. Saiti and Stefou (2020) note that flexible networks, open communication, and visionary leaders enhance employee satisfaction and innovation.

KIOs focus on customer experience, directing changes to improve service and deliver personalized products. They also face the challenge of leading in sustainable development, as sustainability practices drive innovation (De la Torre & Berbegal-Mirabent, 2020). These practices can be adopted internally to enhance operations and externally through collaborations with suppliers, extending positive impacts beyond the organization.

3. Methodology

In this study, a qualitative methodology is implemented, using a scoping review to assess the interrelated phenomena in the domain of Knowledge Engineering, Management, and Media. The adopted research strategy includes a bibliographic exploratory approach, intended to elucidate the object of study, and an interpretative methodology (Creswell, 2014). Qualitative research is particularly relevant when detailed exploration of complex nature topics or phenomena is required. This type of study refrains from using statistical methods, allowing for direct observations and interpretation of data.

The purpose of a scoping review is to map existing literature on a specific topic to identify key concepts, theories, sources, and gaps in knowledge. This type of review is particularly useful for emerging, complex research topics or those that have not yet been subject to comprehensive reviews. According to Munn et al. (2018), a scoping review undergoes five stages: identification of the research question; identification of relevant studies; selection of studies; data extraction; and presentation of results.

Following the five mentioned stages, this study aims to examine the interaction between Knowledge Engineering, Management, and Media, especially in the context of Knowledge-Intensive Organizations.

4. Results and Discussion

Regarding Knowledge Management models, there is a notable distinction between American and Japanese approaches, with the former focused on information technology and the latter centered on people and socialization. These divergences can be traced back to the Fordist (American) and Toyotist (Japanese) production models (Paula & Paes, 2022). The roots of these distinctions lie in cultural aspects, where Japan perceives key concepts differently (Mendehall & Oddou, 1986):

- Dualism: In the West, dualism, exemplified by concepts like good and bad, is often seen as a conflict zone, with the aim to eliminate one in favor of the other. However, for the Japanese, both coexist harmoniously, without the possibility of nullifying one for the other. This perspective results in different approaches to facing challenges, conducting negotiations, and perceiving company values.
- Contextuality: While in the West, the search for a sense of belonging often involves internal reflection before interacting with society, Eastern philosophy seeks its purpose in the external context. Easterners strive to fit into society and understand how they can contribute to the environment they are in. This promotes greater flexibility and a less individualistic mindset when facing challenges or diverse environments.
- Principle of flow: The idea that nothing is permanent, including organizational contexts, implies that there can be no rigid and immutable norms. As a result, members' obligations regarding the context are unlimited, and their responsibilities are ambiguous, guiding their actions according to the specific context. This perspective contributes to KM practices such as high loyalty, low turnover, and implicit control systems.
- Holism: Unlike the West, where analyzing the parts often precedes understanding the whole, Easterners approach information and contexts from a holistic view. They start the process intuitively before conducting a rational analysis of the parts. In organizations, this approach implies that managers must keep their teams connected to the company's mission to promote effectiveness and efficiency, stimulating the development of creative and innovative potential.
- Intuitive bias: Due to the understanding of the complexity of contexts and emphasis on the global view, Easterners do not seek total control and absolute understanding of the involved parts. They are not strictly focused on the analytical use of words nor overly rely on logical consistency. When the analytical process fails to solve challenges, they return to the whole, reflecting the true reality.

Eastern mental models have influenced widely-used Knowledge Management (KMa) models, aligning with traits needed in the BANI world. Nonaka and Takeuchi's (2008) SECI model highlights the bidirectional conversion between tacit and explicit knowledge as a competitive advantage. Macedo and Souza (2023) showed that this complementarity fosters innovation and adaptability but is hard to implement in cultures lacking knowledge sharing.

Davenport and Prusak (1998) categorized knowledge as tacit and explicit, aiming to enhance accessibility via structured systems, though it may downplay culture's role. Wiig's (1999) approach integrates knowledge management with strategy, focusing on processes and learning, needing cultural commitment. Choo's (1998) model prioritizes information management before knowledge management, improving efficiency but potentially limiting knowledge creation.

Effective knowledge management in KIOs requires aligning with Engineering and Media areas to avoid knowledge loss, using various approaches based on organizational context.

Examples of knowledge attributes in People, Processes, and Technologies.		
Axis	**Attribute**	**Description**
People	Knowledge managers	Individuals designated to oversee knowledge management within the organization, responsible for defining strategies, guidelines, and processes to optimize the creation, sharing, and application of knowledge.
	Communities of practices	Formal or informal groups of professionals who share common interests and expertise, providing a collaborative environment for the exchange of knowledge, experiences, and best practices.
	Training and communications	Training activities and communication programs aimed at developing knowledge management skills, promoting awareness of the importance of sharing and collaboration.
	Measurement and reward system	Establishment of metrics and indicators to assess the effectiveness of knowledge management practices, as well as the implementation of incentives and rewards to encourage engagement and contribution.
	Knowledge sharing culture	Promotion of an organizational culture that values and prioritizes knowledge sharing, encouraging collaboration, continuous, active, and lifelong learning, and collective creation.
	Knowledge consultants	Specialized professionals, usually external to the organization, designated to provide guidance, insights, and support in the application and dissemination of knowledge in organizational projects and activities.
Processes	Knowledge capture and reuse	Processes and procedures for identifying, capturing, and documenting knowledge generated in projects or past experiences, making it available for future use.
	Collaboration	Establishment of workflows and platforms that facilitate collaborative interaction between teams and individuals, promoting active exchange of information and ideas.
	Selection of good practices	Identification and promotion of best practices and lessons learned within the organization, aiming to optimize processes and future results.
	Content management	Efficient organization, storage, and categorization of documents and relevant information, making access and retrieval of knowledge more effective.
	Metrics and e reports	Establishment of performance indicators and generation of reports to assess the effectiveness of knowledge management activities, identify areas for improvement, and support decision-making.
	Change management	Implementation of strategies to manage organizational transitions resulting from the adoption of new knowledge management practices, ensuring a smooth transition and effective adoption.
Technology	Interface and user experience	Development of intuitive and user-friendly interfaces for knowledge management tools and platforms, aiming for ease of use and adoption by users.
	Community portals	Creation of online spaces where employees can gather, share information, participate in discussions, and access resources related to knowledge.
	Knowledge repositories	Establishment of centralized storage systems for documents, records, and information, facilitating quick and organized access to knowledge.
	Search, storage and support	Implementation of advanced search functionalities, indexing, and categorization to quickly locate relevant information, as well as providing efficient technical support.
	Collaboration spaces	Creation of digital environments that allow asynchronous or real-time collaboration, sharing of documents and ideas, promoting accessible interaction among members.

When establishing a knowledge ecosystem in KIOs, an environment is created that promotes the flow of knowledge among individuals, teams, and departments (Shaba et al., 2023). This ecosystem embraces the

integration of various knowledge management practices, technologies, and platforms to encourage continuous collaboration, sharing, and innovation. Leveraging emerging technologies such as artificial intelligence, machine learning, the metaverse, among others, can enhance the discovery, extraction, and application of knowledge in KIOs (Wang, Pauleen & Taskin, 2022). Indeed, digital transformation contributes in the long term to the value creation process (Di Vaio et al., 2021).

The interaction of these areas, illustrated in Figure 1, is also strongly influenced by digital transformation, which redefines the operations, value delivery, and interactions of KIOs with stakeholders (Erceg & Zoranović, 2022). This transformation encompasses the digitization, automation, and optimization of knowledge management processes, resulting in enhanced efficiency, agility, and innovation. Furthermore, it enables the adoption of emerging technologies such as blockchain and the Internet of Things to strengthen knowledge sharing, security, and traceability (Frozza, de Lima & da Costa, 2023).

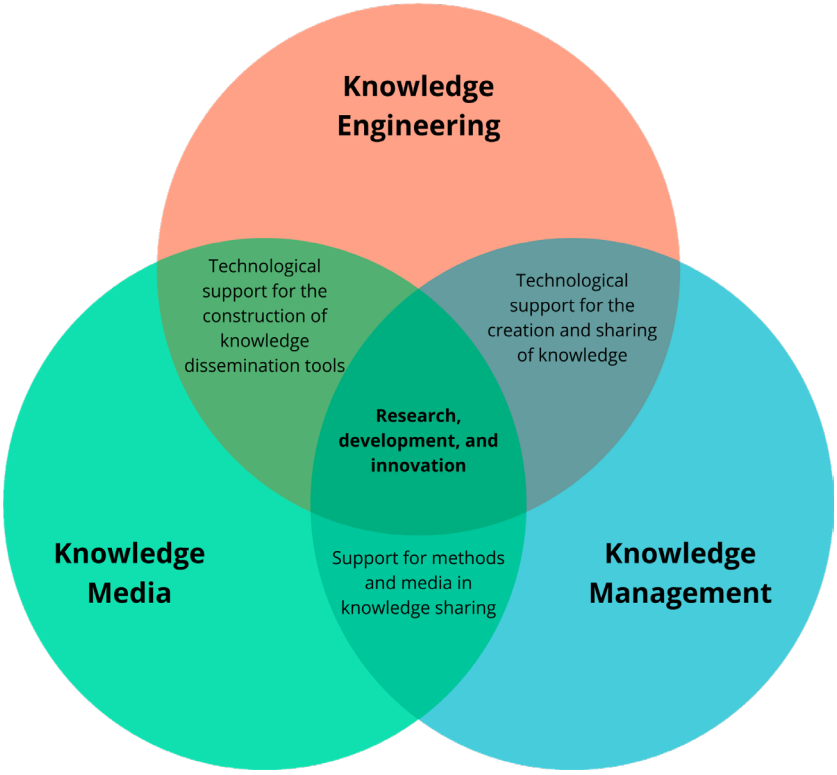

Figure 1: Interrelation between the areas of focus. Source: Adapted from Pacheco (2007).

In Knowledge-Intensive Organizations (KIOs), innovation thrives through KEMM by capturing, organizing, and disseminating knowledge assets. These areas provide infrastructure, methodologies, and tools to foster innovative ideas. Emerging technologies like augmented and virtual reality enhance this process by enabling immersive knowledge sharing and interactive collaboration (Wang, Pauleen & Taskin, 2022).

Humans, as co-creators, attribute meanings to reality through language and communication (Briggle & Christians, 2017). In the knowledge-based economy, Knowledge Management (KM) recognizes knowledge as a competitive advantage (Burgin, 2016). Knowledge Media and interdisciplinary approaches are crucial for understanding complexity. Online collaboration tools and social media enhance knowledge dissemination and problem-solving. Technologies like ontologies, Natural Language Processing (NLP), and Machine Learning (ML) aid in organizing and managing knowledge from diverse sources.

Engineering, KM, and Media extend beyond organizations, impacting broader contexts like Innovation Ecosystems and Smart, Human, and Sustainable Cities (Almeida, Doneda, & Da Costa, 2018). Amid challenges like information overload and AI, distinguishing "information" from "knowledge" in KEMM is vital. Expanding "cognition" emphasizes cognitive beings' roles in knowledge processes (Santos & Sousa, 2010).

Effective KEMM practices are crucial for KIO innovation and success, relying on the triad of People, Processes, and Technologies, with emphasis on "People".

4.1 The Central Role of People

The writers perceive that at the heart of any successful KEMM implementation is the human element. People are the primary drivers of knowledge creation, sharing, and utilization. They bring diverse perspectives, creativity, and expertise, which are indispensable for fostering innovation. Therefore, building a culture that values and promotes continuous learning, collaboration, and knowledge sharing is fundamental. This involves not only providing the necessary tools and technologies but also creating an environment where individuals feel empowered and motivated to contribute.

4.2 Building a Knowledge-Centric Culture

The authors believe that cultivating a strong organizational culture centered around knowledge is vital. This culture should emphasize values such as trust, openness, and mutual respect. By fostering a culture that encourages experimentation and tolerates failure as a learning process, organizations can create a safe space for innovation. Leaders play a crucial role in this regard by modeling knowledge-sharing behaviors, recognizing and rewarding contributions, and providing opportunities for professional development.

4.3 Integrating Processes and Technologies with Human Factors

While processes and technologies are essential components of KEMM, the authors perceive that their effectiveness is significantly enhanced when integrated with human factors. Processes should be designed to be user-friendly and supportive of the ways people naturally work and collaborate. Similarly, technologies should be selected and implemented with a focus on how they can best support human interactions and knowledge workflows. For instance, leveraging collaborative platforms and tools such as Microsoft Teams, Slack, and Trello, which facilitate real-time communication and seamless knowledge exchange, can greatly enhance productivity and innovation.

4.4 Creating an Enabling Environment

It was concluded that creating an enabling environment that supports KEMM practices is crucial. This includes not only the physical and digital workspaces but also the organizational policies and structures. An environment that promotes flexibility, autonomy, and cross-functional collaboration can significantly boost the effectiveness of KEMM initiatives. Moreover, aligning these initiatives with the broader strategic goals of the organization ensures that knowledge management efforts are purposeful and impactful.

4.5 The Synergistic Relationship of People, Processes, and Technologies

The authors believe that the synergistic relationship between people, processes, and technologies is what ultimately drives the success of KEMM practices. Each element of this triad supports and enhances the others, creating a holistic system that promotes continuous improvement and innovation. For example, well-designed processes and advanced technologies can facilitate knowledge capture and dissemination, but it is the people who apply this knowledge in creative and meaningful ways to solve problems and drive progress.

By focusing on the human element and building a culture and environment that supports KEMM practices, organizations can harness the full potential of their knowledge assets. The authors perceive that this approach not only enhances organizational performance and competitiveness but also contributes to the personal and professional growth of individuals, leading to a more engaged and innovative workforce.

5. Research agenda

In a world of knowledge creation and innovation, the authors perceive that working with interdisciplinary knowledge and the merging of different technologies are key factors influencing the main research areas. Drawing from the seminal works of Bernardi and Diamantini (1932) to recent discussions by Freire et al. (2021), the writers concluded that the intersection of multiple disciplines and the convergence of diverse technological domains foster new opportunities for collaborative research endeavors. The research agenda, with detailed topics following, seeks to explore the synergistic relationships between different disciplines, such as Engineering, Management, and Media, within the context of interdisciplinarity and technological convergence. By examining the ways in which these disciplines intersect and complement each other, the authors believe researchers can uncover novel insights and approaches to address complex societal challenges and technological advancements.

5.1 Sustainability and Social Responsibility

The imperative of sustainability and social responsibility permeates contemporary discourse, driving scholarly inquiries into the ethical, environmental, and socio-economic dimensions of human activities. As articulated by the Instituto Brasileiro de Governança Corporativa (IBGC, 2021) and the Brazilian Court of Audit (TCU, 2014, 2020), governance principles underscore the importance of responsible decision-making and accountability in corporate and public sectors. This topic aims to investigate how KEMM intersect in promoting sustainable practices, fostering social inclusion, and addressing pressing environmental concerns. By exploring innovative approaches to sustainability and social responsibility, researchers can contribute to the development of strategies that reconcile economic growth with environmental stewardship and social equity.

5.2 Governance and Ethics

The discourse on governance and ethics occupies a central position in contemporary discussions, reflecting growing concerns about transparency, accountability, and ethical conduct in organizational practices. Building upon the definitions provided by the Information Systems Audit and Control Association (ISACA, 2012) and the Brazilian Court of Audit (TCU, 2014, 2020), a research agenda covering governance themes seeks to examine the intricate relationship between governance, ethics, and organizational performance. By investigating how Engineering, Management and Media intersect in shaping governance structures and ethical frameworks, researchers can advance our understanding of the principles that underpin responsible decision-making and stakeholder engagement.

5.3 Digital Inclusion and Accessibility

The digital revolution has ushered in unprecedented opportunities for connectivity, innovation, and access to information. However, disparities in digital access and literacy persist, posing challenges to achieving universal inclusion and accessibility. In line with the discussions by ABBUD (2017) and Al-Ruithe et al. (2018), this research agenda aims to explore the intersection of Engineering, Management, and Media in promoting digital inclusion and accessibility. By examining strategies to bridge the digital divide, foster digital literacy, and ensure equitable access to digital resources, researchers can contribute to creating more inclusive and accessible societies.

5.4 Digital Transformation and its Impacts

The advent of digital technologies has precipitated a paradigm shift in various spheres of human endeavor, from business and governance to media and communication. As highlighted by TCU (2020) and Freire et al. (2021), digital transformation encompasses far-reaching implications for organizational structures, processes, and relationships. This research agenda seeks to investigate the multifaceted impacts of digital transformation on Engineering, Management, and Media domains. By analyzing the challenges and opportunities posed by digital disruption, researchers can inform strategies for navigating and harnessing the transformative power of digital technologies in diverse contexts.

6. Conclusion

Collecting data in these organizations is challenging due to their complex activities. However, constant efforts in data explanation and process improvement stimulate innovation.

Knowledge is complex and dynamic, influenced by social, cultural, and organizational contexts. Managing it requires understanding epistemological assumptions and embracing complexity for effective strategies (Bento, 2020).

Exploring interactions between Knowledge Engineering, Management, and Media within KIOs highlights their importance in the Knowledge Society. This study opens room for further reflection and future perspectives.

Future research should focus on practical applications of these concepts in real-world scenarios within KIOs. Strategies valuing knowledge as a co-production factor, new governance systems, and technologies like Virtual Reality, Augmented Reality, Metaverses, and AI can drive significant innovations.

Studying how KEMM can create comprehensive innovation ecosystems is crucial. Viewing knowledge as a shared resource ("commons") can lead to effective business models and support Human, Intelligent, and Sustainable Cities. Additionally, exploring KEMM's role in education and organizational learning is essential for

promoting agile learning and knowledge updates.

KEMM transcends organizational boundaries, applicable to governments and ecosystems. Understanding its role in driving collaboration, innovation, and knowledge dissemination is key to addressing global challenges.

This study encourages future investigations to enhance understanding and practical application of KEMM.

Abstract: Projects are considered to be temporary organisations (Lundin & Söderholm, 1995), so the non-permanent nature of the projects makes it even more important for the organisations to put a significant emphasis on knowledge sharing (KS). This paper aims to present an overview of the KS concept in project management (PM) by involving selected top journals of this research field. Furthermore, to create a KS theory map introducing subject areas related to KS concept with their relationships. Scopus database was used as a source and articles published in four journals (Q1 and Q2 ranked) were chosen: International Journal of Project Management, Project Management Journal, and International Journal of Managing Projects in Business; International Journal on Information Systems and Project Management. Our primary search resulted in 49 records over a 20-year time-period (2003-2022). 'Knowledge sharing' was applied as our primary search-word and the document type was limited only to 'articles', and regarding language, source type and article 'English' 'journal' 'articles' were applied as filters concerning the database. Systematic literature review (SLR) was conducted based on the steps of Okoli (2015) and was visualized by a PRISMA flow chart. The final sample included 36 articles based on a three-criteria selection process. Descriptive analysis was conducted on this sample, and it was also content analysed based on multiple aspects. The main subject areas related to KS concept resulted in a theory map, which visualizes influencing and influenced factors of KS based on the analysis of the past 20 years' articles from the selected top PM journals. The analysis revealed the overlaps and interrelationship amongst the influencing factors, which enables us to group them. These findings are useful for PM academics to place their current and future research in this KS theory map, or to identify possible gaps in the literature in this field. By being aware of the complex nature of KS, practitioners could make more focused decisions to foster the KS mechanisms in their projects.

Keywords: Knowledge Sharing, Project Management, Systematic Literature Review

1. Introduction

Searching for journal articles in English about knowledge sharing (in the title, abstract or keywords) in the Scopus database within the 17 journals listing "knowledge" in their names, but without any limitation regarding the year of publication or the subject area, the results showed that the number of articles is above 1.200 records (1.284). This draws attention on the relevance of knowledge sharing (KS) in journals related to knowledge. However, focusing on the KS concept by involving selected top project management journals could show a completely different picture.

Since the mid 1990's there was a growing attention in the scientific community towards the temporary forms of working constellations focusing on a special result, namely towards the projects, which were defined as temporary organisations (Lundin and Schöderholm, 1995; Söderlund, 2004; Beaume et al. 2009). The temporary nature of this endeavours together with the fact that projects consider a unique, complex, one-time task within the organisation, called significant attention towards KS regarding projects. It could be important at personal, project or organisational level as well. In the organisational context KS is of high importance since it involves transforming knowledge into a usable form for others, facilitating innovation or growth within organization (e.g., Ipe, 2003; Tsai et al. 2014). It is also recognized as essential for both large companies and SMEs, emphasizing its strategic significance across different organizational sizes (e.g., Wang and Noe, 2010; Anand et al. 2021). While the critical role of knowledge sharing in enhancing project performance is well-recognized, there remains a notable research gap in exploring those factors which have an influence on KS and which are influenced by it in project management context.

This paper could be connected to those research initiatives which try to combine the two scientific fields, namely knowledge management and project management (Brookes et al., 2006; Gomes et al. 2008) to understand the challenges of knowledge management, and more specifically KS, in projects (temporary organisations).

Despite the increasing number of publications, "*it is difficult to systematically synthesize, interpret, and apply the knowledge about knowledge sharing to project management (and other fields*)" (Ramaprasad and Prakash, 2009, p.1). Our investigation revealed that no systematic literature reviews have been conducted previously based on the database of high-quality project management journals, specifically focusing on the concept of KS

and its relationship with PM. Thus, this paper aims to present an overview of the KS concept in project management by involving selected top journals of this research area, and to create a KS theory map. The primary focus of the study is directly on KS activities, processes, models and mechanisms while articles which mention this in an inherent manner are excluded.

The paper starts with the introduction of the related theoretical background focusing on a brief overview of project management and KS. Research methodology part introduces the description and the steps of the applied systematic literature review. Results are introduced in two sections; the first part includes the descriptive analysis of the sample, while the content analysis focuses on the identified, related subject areas. Before the conclusion, the limitations and the further research areas are listed.

2. Theoretical Background

2.1 Knowledge Sharing

KS can be considered an important element of knowledge management practices (Meher et al. 2024). In terms of definitions of KS, it is mainly described as an activity during which information or other important content is shared (Bartol and Srivastava, 2002; Möller and Svahn, 2004; Li, 2010). However, Ipe (2003) sees KS between individuals as a process in which knowledge is transformed into a form that other individuals can understand, accept and use. Furthermore, KS can be realized not only through written correspondence or personal communication, but also by establishing relationships with others, or by capturing, documenting, or organizing knowledge for others (Cummings 2004; Pulakos et al. 2003). KS can be considered important for any team (e.g. project team), group or organization, as it focuses on individual, group, social, organizational, and technological cohesion (Nguyen, 2020). Previous studies have shown that KS has become a fundamental driver of innovation and growth within large organizations (e.g. Tsai et al. 2014; Wang and Noe, 2010). At the same time, the strategic importance of KS in the SME context has also been revealed by previous studies (Anand et al. 2021). This shows that KS can be interpreted at various levels and could be investigated in case of different organizational size. Knowledge sharing models are frameworks that help understand and analyse the factors influencing the effective dissemination of knowledge within an organization. These models consider elements such as organizational culture, communication channels, technological support, and individual motivations and barriers (e.g., Lin, 2007; Wang and Noe, 2010).

2.2 Knowledge Sharing and Projects (Temporary Organizations)

Lundin and Schöderholm (1995) described projects as temporary organisations within a permanent organisation. Because of the temporary nature of projects, KS has a special significance on different levels; amongst individuals within the project team, and amongst projects within the client organisation.

Ramaprasad and Prakash (2009) prepared the ontology of KS in project management focusing on the following aspects: (1) KS fostering methods, (2) KS fostering factors (e.g. individual, organizational, societal), (3) KS fostering functions (e.g. facilitators, barriers), (4) knowledge types (e.g. problem recognition, formulation, analysis, solution, prevention), and (5) the KS methods (e.g. orally, in writing).

Project knowledge can be shared through various KS mechanisms, and inter-project KS behaviours are influenced by various organizational features (e.g. organizational culture) (Wiewiora et al. 2013; Wiewiora et al. 2014). Focusing on the individual level, e.g on the leadership style, shared leadership through KS can enhance the success of projects (Imam and Zaheer, 2021). On the other hand, trust in the context of projects is also a widely researched topic and several contradictory results have been found (Buvik and Tvedt, 2017)

After the short theoretical background focusing on a brief overview of project management and KS, the paper continues with the applied systematic literature review regarding the KS concept in project management by involving selected top journals.

3. Research Methodology of the Literature Research (SLR)

Booth et al. (2012) distinguishes six forms of academic reviews: the literature review, the critical review, the integrative review, the mapping review/systematic map and the mixed studies review/ mixed methods. Templier and Paré (2015) only creates two forms; reviews which serve as background for an empirical study aiming to provide the theoretical context, and there are the stand alone reviews which could have the following purposes: describe, test, extend, and critique. Our review belongs to the combination of the literature and the mapping

review, and to the stand alone descriptive category. Four phases and eight steps of a successful systematic literature review (SL) are distinguished: PLANNING - (1) identify the purpose, (2) draft protocol and train the team, SELECTION – (3) apply practical screen, (4) search for literature, EXTACTION (5) extract data, (6) appraise quality, EXECUTION (7) synthesize studies, (8) write the review (Okoli, 2015; Okoli and Schabam, 2010).

The Scimago Journal & Country ranking page's (https://www.scimagojr.com/) publications database served as a starting point for the journal selection. The newest list available was the 2022 publication list at the time of our research (as of January 2024). The following filtering criteria was specified to narrow down the publication database: only journals were involved in our review, the word "project" had to be a part of the journal title, the journal had to fall into the SJR (SCImago Journal Rank) Best Quartile (Q1 and Q2), and the category of the journal had to belong to Business and International Management or Management of Technology and Innovation or Strategy and Management within the subject area of Business, Management and Accounting. As a result of our screening, 4 journal remained in the focus of our investigation:

- International Journal of Project Management (Q1, Elsevier UK, H index: 167, Published since: 1983-),
- Project Management Journal (Q1, Sage USA, H index: 55, Published since: 1998-),
- International Journal of Managing Projects in Business (Q2, Emerald UK, H index: 43, Published since: 2008-)
- International Journal of Information Systems and Project Management (Q2, UMinho Editoria Portugal, H index: 20, Published since: 2013-)[1].

Limited to the 4 selected professional project management journals, the process of selecting articles dealing with 'knowledge sharing' was also prepared on the Scopus database. The search for the term "*knowledge sharing*" was conducted in the title, abstract and keywords for each journal separately, and we limited the selection of articles in each journal to English journal articles (language, source type, article). Our primary screening resulted in 49 records (18 papers in IJPM, 12 papers in PMJ, 15 papers in IJMPB and 4 papers in IJISPM) over a 20-year time-period (2003-2022).

After checking the results of the primary search, one record was excluded because the search words ('knowledge sharing') could not be found in the title/abstract/keywords, that modified the number of records to 48.

Several authors emphasized the importance of the rigor of the search process (Booth et al., 2012, Vom Brocke et al., 2009), so we applied a selection criteria , based on which our primary sample was narrow down to the final sample (Table 2). In line with the originally defined research aim the following selection criteria was formed (Table 2).

Table 1: The selection criteria of journal articles (own compilation)

Selection criteria		Description of the selection criteria
Closely related to the research aim		Focus is on KS. Focus is on phenomenon which is influenced by KS. Focus is on phenomenon which influences/has an effect on KS. Focus is on KS appearing at certain project type. Focus is on KS appearing at certain organizational levels.
Moderately related to the research aim	After revision remaining in the final sample	Focus is on sharing uncertain information. Focus is on tangible KS mechanism. KS is introduced as part of a complex KM model.
	After revision excluded from the final sample	KS does not appear as a concrete process or method, just in general in agile environment. KS does not appear as a concrete process or method, just in general in software development environment.

[1] *Based on the journal homepages: https://www.sciencedirect.com/journal/international-journal-of-project-management, https://journals.sagepub.com/home/pmx, https://www.emerald.com/insight/publication/issn/1753-8378, https://www.sciencesphere.org/ijispm/*

Selection criteria	Description of the selection criteria
Not related to the research aim	Focus is not directly on KS and papers investigate this phenomenon in an inherent manner: Focus is on knowledge base building (KS is mentioned related to the implication) Focus is on balanced sharing with protection or knowledge hiding. Focus is on knowledge exchange. Focus is on the advances of the community of practice. Focus is on information and communication design. Focus is on knowledge transfer.

Based on the primary selection criteria (closely related to the research aim) 33 records were immediately selected to the final sample. Then, we categorized 5 records after the analysis to be moderately related to the research aims. These records were revised based on an extended criteria list and 2 records were removed out of the 5 from the sample. As a result, the final sample consisted of 36 records (14 papers in IJPM, 11 papers in PMJ, 10 papers in IJMPB and 1 paper in IJISPM).

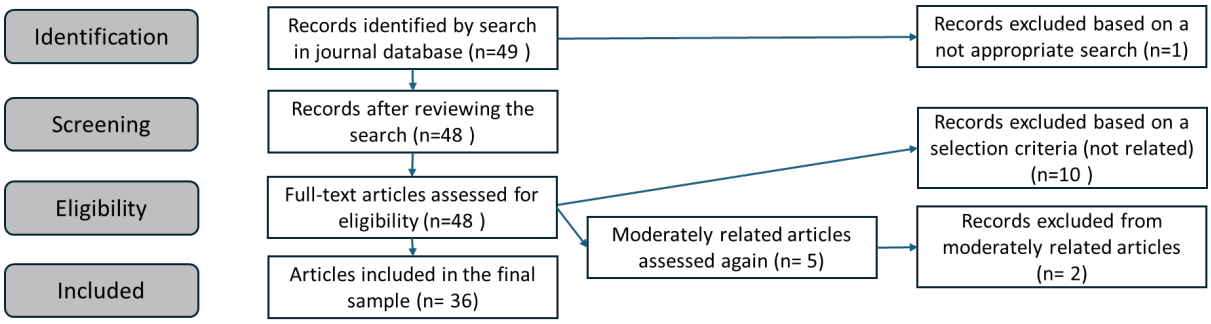

Figure 1: PRISMA flow chart of journal article selection (own compilation based on Gallagher et al., 2016, p.4)

4. Results

4.1 Descriptive Analysis

The earliest (3) articles in the literature selection were published in 2003, all in International Journal of Project Management. Comparing the two investigated decades we could see that there is a significant increase in the number of publications in this topic regarding the second decade: 8 articles between 2003 and 2012, 28 article from year 2013. The largest number of relevant papers, in the period under review, appeared in the year 2021 and 2022 immediately after the breakout of the pandemic with 5-5 articles. The popularity of the topic has increased in recent years, which highlight of investigating the background of this phenomenon (Table 3)

Table 2: Statistics based on publication interval (own compilation)

Year of publication	2003-2007	2008-2012	2013-2017	2018-2022
No. of publication	4	4	15	13

In the Q1 ranked journals altogether 25 articles were published in the investigated topic, compared to the 11 in the two Q2 ranked ones. Based on this, it could be claimed that this topic still belongs to the relevant research areas of the project management profession.

The most common author composition form was the two-author format with 15 records of the sample. Only five out of the 36 investigated papers were submitted by an individual author, so 31 was prepared in bigger or smaller research groups (3 authors in 8 cases, 4 authors in 6 cases, and 5 authors in 2 cases).

As of 9th January 2023, altogether 2066 citations were recorded in the Scopus database regarding the articles of our final sample. There were six articles with more than 100 citations. All of them were published in IJPM (Q1 ranked journal) between 2003 and 2014 by multi-author groups (Table 4).

Table 3: TOP6 most cited papers (own compilation)

Authors	Year	No of citations

Koskinen, Pihlanto, Vanharanta	2003	283
Park, Lee	2014	228
Fernie, Green, Weller, Newcombe	2003	198
Liebowitz, Megbolugbe	2003	147
Wiewiora, Trigunarsyah, Murphy, Coffey	2013	140
Pemsel, Wiewiora	2013	132

The final sample consists of one SLR, two theoretical papers, nine case studies, the remaining presents results of qualitative (nine records) and quantitative studies (15 records).

4.2 Content Analysis

During our content analysis, the articles were reviewed with a special focus on the theoretical design of the research and the research findings. After a thorough reading of the articles, we collected those factors that the authors mentioned in their works due to their connection with KS.

KS is a complex phenomenon so revealing the exact relationship with other subject areas could be a difficult task, so we grouped the identified factors into two categories; those which have an effect on KS and those which are influenced by KS. Based on that our research resulted in a KS theory map.

4.2.1 Factors Having an Effect on the Knowledge Sharing in Project Management

In our research the identified subject areas are usually independent variables which have an impact on KS and only a few of them are mediating variables. Altogether three significant subject areas have emerged: (1) leadership, (2) trust and (3) organizational culture.

(1) Leadership related subject area

Four articles highlighted different forms of leadership which are contributing to KS. These are as follows: servant (article in our sample: #4, see Appendix 1.), shared (#28), ethical (#34) and knowledge leadership (#8) More articles focus on the project manager's KS attitude (#21). One article highlights that knowledge leadership could contribute to KS through social capital (#8). Social capital as an important factor was also mentioned in other two articles (#9, #22). It could be seen that many researchers draw a direct link between the project manager's leadership and KS within the project team. (e.g. Imam and Zaheer, 2021; Pemsel and Wiewiora, 2013)

(2) Trust related subject area

Trust was the most frequently appearing factor in the analysed articles. Its contribution to KS was highlighted five times by itself (#5, #25, #26, #29, #33) and three times together with other factors (#24, #27, #32), from which language (#24, # 27) appeared twice. Trust, security and informal collaboration are forming a milieux, which enables KS (#27), and psychological safety was also mentioned as a factor in an article (#36). Together with trust the interpersonal relation as a factor (#24) is also described. Motivation was mentioned together with trust (#24) and the role of motivation was also highlighted in another article (#35). (e.g. Buvik and Tvedt, 2017; Park and Lee, 2014)

(3) Organizational culture related subject area

Organisational culture and organisational cultural characteristics were mentioned in four articles (#1, #3, #19, #29) as a contributing / enabling factor of KS. The cultural values' effect on the formal and especially on the informal KS practices are highlighted. One article used the competing values framework (#29) to underpin how different organisational culture types are supporting KS mechanisms (e.g Mueller, 2015; Wiewiora et al., 2013).

4.2.2 Factors Being Influenced by Knowledge Sharing in Project Management

The literature treats the impact of KS on project team performance as a kind of evidence, which is underpinned by the fact that significantly less journal articles of the giving sample are dealing with the dependent variables which are influenced by KS. Eight articles were identified out of the final sample which investigated the KS's effects on another factor (dependent variable); two of them connected KS to the project success, one to the success and quality of the project portfolio and two to the project team performance. Although leadership is

usually an input factor of KS, but one article of the sample introduced KS's contribution (as an enabling factor) to distributed leadership through supporting the decision-making process within the project team. The quality of the project partnership and uncertainty management were both mentioned once.

So based on the final sample analysis it could be said that there is a significantly bigger interest in the scientific community towards those factors which influence KS than on those which are its output factors.

4.2.3 Knowledge Sharing Theory Map (in project management) and Discussion

Our content analysis resulted in a KS theory map introducing the main subject areas related to KS concept and their interrelationships, and our results were depicted on the following visual map (Figure 2).

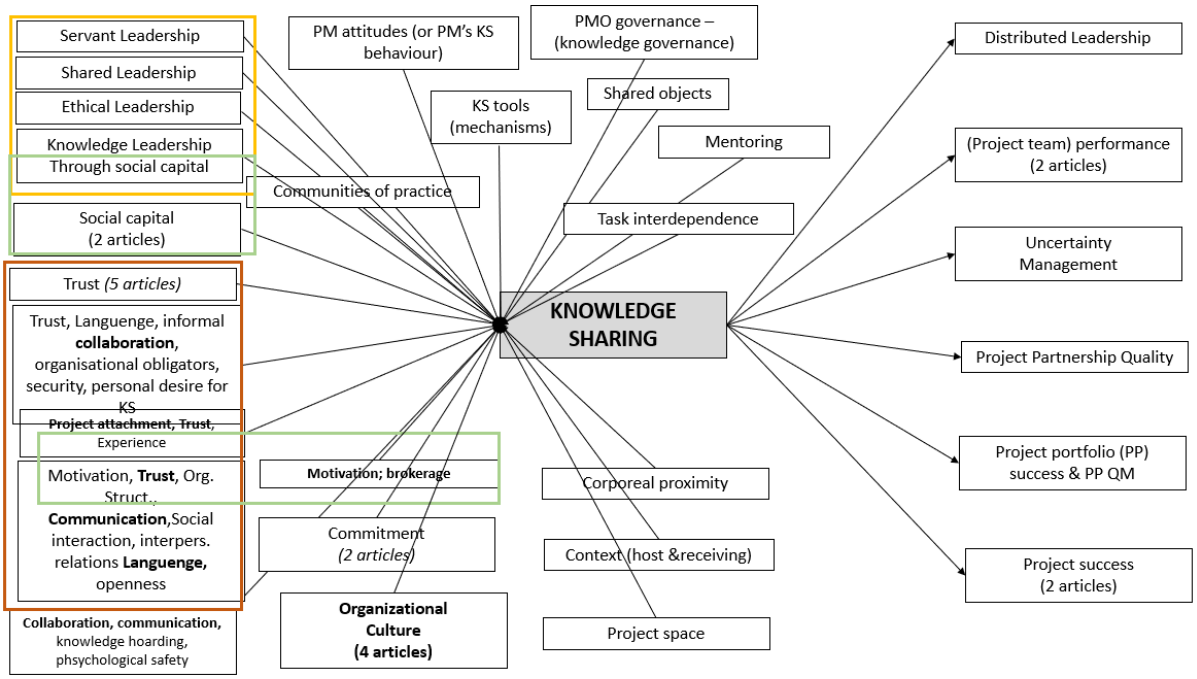

Figure 2: Knowledge Sharing Theory Map (own compilation)

Previous systematic literature reviews covered publications not only on KS but also involved innovation from 1973 to 2017 based on articles from the Scopus and Web of Science databases (Castaneda and Cuellar, 2020). While others focused on the SME context and involved knowledge transfer as well besides KS and investigated article between 1998 and 2018 based on the Scopus database (Anand et al. 2021). In project context, the number of SLR based publications in this topic is quite limited, although Zahedi et al. (2016) in their study were focusing on the challenges and practices of KS and they identified six themes connected to this topic: management, team structure, work processes/ practices, team cognition, social attributes, and technology.

5. Limitations and Further Research

The quality of the present study's methodology was ensured through the deliberate selection of high-ranking journals, confined to those classified within the top tiers of academic quality (Q1 and Q2 rankings). Consequently, there exists a tendency for publications within the scope of this study to experience delays. Conversely, forthcoming topics are frequently found in online articles or presented at conferences. Hence, to mitigate this limitation of the study in future research endeavours, it is advisable to broaden the database filter to include conference proceedings.

Expanding the sample size is of high importance, given that the current study only encompasses a 20-year timeframe (2003-2022), while publications both predate 2003 and extend beyond 2022.

This article primarily delves into elucidating the relationships between factors influencing KS. However, it is important to explore the interplay among these influencing factors further. Moreover, it may prove beneficial to categorize both influencing and influenced factors according to pertinent theoretical frameworks.

6. Conclusion

This paper aimed to provide an overview of the KS concept in project management covering the last two decades (2003-2022) focusing directly on KS activities, processes, models, and mechanisms. For the systematic literature review four top (Q1- and Q2-ranked) journals of project management were selected, and our final sample was narrowed down to 36 records based on our predefined selection criteria. After the conducted descriptive and content analysis, it can be highlighted that authors of the top PM journals have basically put more emphasis on examining the factors that promote and contribute to KS, and significantly less attention has been paid to the factors that are influenced by KS.

Based on the identified factors, three main subject areas were identified (leadership, trust, and organizational culture) which were most mentioned in the articles as factors having an influence on KS. Although there is a much smaller number of sample elements in the case of those factors, which are influenced by KS, but project success and the performance of the project team can be observed here as recurring subject areas. Our findings highlighted the most important subject areas and the KS theory map could serve as a guidance for future research to find the possible connections between related topics or to identify potential new research gaps.

Abstract: The question on how to finance innovation activities of countries has taken a center stage in economic policy discussions in countries and among regional bodies. Such discussions require a policy direction to present alternative ways of financing innovation activities at lower cost in the face of dwindling resource available to countries and regional bodies for innovation activities. One important way of dealing with this challenge is to invest the limited resources in countries and sectors with the potential of higher knowledge spillover to benefit other countries and sectors. In this study therefore, we investigate to determine the knowledge spillover hotspot countries in Europe and how they affect neighbouring country's innovation performance. For the purposes of policy to improve innovation performance in Europe, the knowledge spillover hotspot countries will guide European regional bodies to concentrate innovation investments in countries with the potential of high knowledge spillovers for the benefit of other countries. The study specifically investigated R&D spillover and explicit knowledge spillover hotspots in the manufacturing sectors of Europe and their effects. Data for the study is unstructured and sourced from the World bank with the longest spans being 2005 to 2020 and shortest being 2013 to 2017. In all, nine countries were sampled based on data availability for the study. These countries include Poland, Germany, Slovakia, Slovenia, Lithuania, Belgium, France, Spain and Czech Republic. The study employed panel data analysis. Based on the Hausman test, fixed effect model was chosen as against random effect model. The results of the study show that after controlling for institutional and economic factors and ensuring robustness against heteroskedasticity and autocorrelation R&D spillover hotspots in Europe include Germany and Slovakia whereas explicit knowledge spillover hotspots are Poland, Slovenia, Lithuania and France. The results of the study have shown that the relationship between knowledge spillover from the hotspot countries and surrounding country's innovation varies. For some of the hotspots, the relationship is linear whilst in others the relationship is nonlinear. The study also confirm that explicit knowledge is more susceptible to Knowledge spillover.

Keywords: Spillover, Innovation, Knowledge, Hotspot, R&D

1. Introduction

The choices firms and countries make in improving innovation activities and performance will usually come at great cost. This is probably because resources for innovation activities are continually becoming difficult to come by. Generally, countries and firms have relied on several sources to finance innovation activities which have come at great cost (Valencia-Arias et al., 2024; Yılmaz, Bıyıklı, & Demir, 2023). In the innovation literature, knowledge spillover has become an important source through which firms and countries can improve their innovation activities and performance. Knowledge spillover, unlike knowledge transfer, which is a cross party collaboration and compensation, this involves external benefit derived from another agents' investment in knowledge creation (Ko & Liu, 2015). Knowledge spillover has therefore become an important source of input for most firms and countries in their knowledge creation activities. Policy responses to the need to improve innovation and productivity of firms have centered on a hand full of policy tools such as tax credits, subsidies, and R&D expenditures. These tools, even though, have been largely effective, come with their attendant limitation of cost. A large majority of countries and firms have made gains from knowledge spillover. Such spillovers have occurred even where no formal collaborative arrangements have been made between firms and between countries to transfer knowledge (Agarwal, Audretsch, & Sarkar, 2010). These R&D gains come in free without any compensation to the originator of the knowledge and may therefore serve as a cheaper source of input for innovation. It is a long-held view that Knowledge spillover is an important source of innovation performance, however, the literature also recognises the importance of capacity of firms and countries to absorb and utilize these free flowing knowledge to enhance innovation performance (Xie, Zou, & Qi, 2018). Empirical studies, even though, have acknowledged the important role of Knowledge spillover, the benefits of firms and countries relying on such externalities as an important source of R&D input for innovation have not been fully explored. It is rather the case that empirical studies have linked knowledge spillover to firms' productivity mainly (Audretsch & Belitski, 2020) and not innovation.

The European region remains one of the regions with high innovation performance disparities among countries (Dobrotă, Marcu, Siminică, & Nețoiu, 2019). Other studies have explored how innovation lagging countries could

rely on neighbouring countries with high innovation performance as a way of reducing these disparities (Noni, Orsi, & Belussi, 2018). To find alternative, cheaper, and reliable strategies of financing innovation activities of lagging countries, knowledge spillover from knowledge rich countries cannot be overlooked. An important way to address these innovation challenges is to rely on knowledge spillover from knowledge rich countries to less endowed countries. However, identifying the knowledge spillover hotspots as a source of innovation input remains obscured from prior literature. In this study therefore, we aim to identify the knowledge spillover hotspots in Europe to support knowledge innovation activities in the European region.

2. Theoretical Review

This section of the study presents a review of the literature on R&D and explicit knowledge spillover and how these externalities affect innovation performance.

2.1 Knowledge Spillover

Ordinarily firms and countries expend their own resources in the creation of innovation. However, in the creation of innovation some firms and countries are unable to fully appropriate the gains of their innovation activities. The part of the innovation that is not appropriated by the originator feeds into some other agents' knowledge production function as an input in the form of knowledge spillover. Prior literature has explained that inter-firms/country knowledge flow defines knowledge spillover (Bernal, Carree, & Lokshin, 2022). The literature on knowledge spillover splits knowledge spillover into tacit and explicit, depending on the type of knowledge involved (Bernal, Carree, & Lokshin, 2022). The literature on innovation distinguishes between tacit and explicit knowledge and the literature is reviewed along these lines. The literature on knowledge spillover distinguishes between knowledge spillover and a closely related concept, knowledge transfer. Knowledge transfer is the flow of knowledge from an originator of innovation to the intended economic agents (Scarra & Piccaluga, 2022) whereas knowledge spillover is an externality and therefore an unintended flow of knowledge resources from an originator of knowledge to another economic agent without a commensurate compensation (Henderson, 2007). The latter is the focus of this study and is given further attention in this study.

2.2 R&D and Explicit Knowledge Spillover

Knowledge spillover has been well documented in the innovation literature. In the formulation of growth models, knowledge spillover is considered an important determinant (Henderson, 2007; Romer, 1990). Knowledge spillover has been known to be influenced by several factors that either enhance the flow or reduce the flow of knowledge. The distribition of knowledge spillover poles is not even as it is based on the presence of certain essential factors. In the literature, authors have found for example that knowledge spillover has a distance decay (Lucas & Rossi-Hansberg, 2002; Ciccone & Hall, 1996) suggesting that spatial distance between the knowledge source and neighbouring areas determine whether or not the source of the knowledge will be a source of knowledge spillover. In a study by Jasimuddin, Li and Perdikis, (2015), the authors showed that colocation is important to knowledge spillover. It is also known that firms that are colocated bring something more than just proximity. In a study conducted by Cohen and Levinthal (1990), colocation was used rather as proxy for technology relatedness. The authors revealed that knowledge spillover is partly explained by the extent which the firms involved are related. Knowledge spillover is therefore a function of the relationship between the source of innovation and the potential beneficiary of knowledge spillover. Other studies have also focused on the role played by absorptive capacity in knowledge spillover. In a study by Zhao, Jiang, and Wang, (2019), the authors showed that the relationship between knowledge spillover and green economy is positively moderated by absorbtive capacity of the receiver. The authors explained that spillover knowledge is directed at enterprises which can use their absorptive capacity to digest and use the advance technologies. In some instances potential beneficiaries of neighbouring knowledge have not shown interest in adopting available technologies.

The type of knowledge has been observed as an important variable in determining knowledge spillover. In the knowledge spillover literature, two main types of knowledge is discussed, tacit knowledge and explicit knowledge. Tacit knowledge has been considered as task oriented know how embedded in the operational routine of firms and their network (Nahapiet & Ghoshal). Authors such as Lam (2000) and Acs, et al (2009) showed that these characteristics of tacit knowledge makes it more difficult for knowledge spillover relative to explicit knowledge. This is in contrast with explicit knowledge which is codified and detached from the originator of the knowledge and therefore makes spillover relatively easier through oral explanations and written works

(Fu, 2012). Studies on knowledge spillover emphasises the ease with which knowledge can be appropirated is a hindrance to knowledge spillover. Considering the nature of these types of knowledge, tacit knowledge which is attached to the originator of knowledge and the detached explicit knowledge transitted by word of mouth and written works, it is argued that explicit knowledge is more suceptible to knowledge spillover relative to tacit knowledge (Xiang, Cai, Lam, & Pei, 2013). The literature on knowledge spillover has an indepth account on the measurement and flow of explicit knowledge. Even though explicit knowledge is recognised as knowledge that is easy to diffuse relative to tacit knowledge, its measurement has proven to be daunting. Principally, explicit knowledge has been measured by patent citation (Gomes-Casseres, Hagedoorn, & Jaffe, 2006; MacGarvie, 2005; Hu & Jaffe, 2003; Jaffe, Trajtenberg, & Henderson, 1993). Because explicit knowledge is transmited using orderly and formal language (Polanyi, 1966), it lends itself well to spillovers (Fallah & Ibrahim, 2004). Based on the position of the prior literature, the following hypothesis is postulated for testing:

H: There is a significant explict knowledge spillover among European countries

In a study conducted to assess managerial knowledge spillover through the diffusion of managerial practices, Fu (2012) showed that managerial knowledge is both explicit and tacit in nature. Fu (2012) showed that such knowledge geographically bound and the effect of the spillover is greater at the clusters and managerial system level. In this study, apart from explicit knowledge, we also review literature on R&D spillover. R&D of firms are investments into both tacit and explicit knowledge creation activities. We therefore expect R&D spillover to retain the traits of both tacit and explicit knowledge spillover. A study by Spithoven and Merlevede (2023) assessed the productivity impact of R&D and FDI spillovers. The findings showed that R&D spillover is a significant contributer of productivity. In other studies, findings have shown that cross border R&D spillover have contributed to innovation performance in neighbouring countries. For example in a study conducted by Coe and Helpman (1995), the authors showed that foreign R&D has been important in improving the domestic productivity. In a related study, the Coe, Helpman and Hoffmaister (2009) confirmed the findings of Coe and Helpman (1995) even after controlling for institutional factors and human capital. R&D spillover has also been observed to be a function of volume of trade flows. In a study by (Keller, 2004) it was revealed that international R&D spillover is a function of international trade volume. The colocation of countries and trade among countries is therefore a condition nevessary for international R&D spillover. Based on the prior literature thefore, we postulate the following hypothesis for testing:

H: There is a significant R&D spillover among European countries

3. Methodology

In this study was sought to determine the knowledge spillover hotspot countries in Europe. The sampled countries for the study are based on data availability. Nine European countries including Poland, Slovakia, Slovenia, Lithunia, France, Spain, Germany, Belgium and France form the study sample based on data availability. Data for the study is sourced from the World Bank spanning 2005 to 2020. The data sourced includes data on variables such as value addition in the manufacturing sectors as a measure of innovation output. The study also sourced data on R&D in the manufacturing sectors of the respective countries. The study also sourced data on economic and institutional factors. The economic variables include variables such as trade openness, GDP per capita and labour force participation rate. Data on institutional factors include rule of law, political stability, broadband internet subscription, globalization index and property right index. Dependent variable is value addition in the manufacturing sector of the sampled countries. This variable is a measure of innovation. This agrees with prior literature which have generally used value addition or variant of value addition such as productivity and other innovation outcomes (Audretsch & Belitski, 2020). Value addition is also considered as an independent variable and as a measure of explicit variable. This should not be confusing as the dependent variable (value addition) of one country is regressed on explicit knowledge (value addition) of other countries. *see equation 1.* R&D of countries is measured R&D intensity of countries which is a proportion of R&D to the country's GDP.

To ensure that our estimate of spillover is unbiased control variables are introduced. These control variables are the economic and institutional factors.

The estimation technique for the study is multiple regression analysis. This is consistent with studies on knowledge spillover (Audretsch & Belitski, 2020; Nonic, Orsi, & Belussi, 2018; Coe, Helpman, & Hoffmaister, 2009). The study models the equation to determine the countries that are spillover hotspots.

$$lvman_{it} = \beta_1 lMR\&D_{jt} + \beta_2 lMR\&D_{it} + \beta_3 Con_{it} + \alpha_0 + U_{it} \quad (1)$$

Equation 1 presents a model for R&D knowledge spillover between countries. The dependent variable is the logarithmic transformation of value addition in the manufacturing sector of countries. Country is represented by the subscrit *i* whilst *t* is the time dimension of the variables. β are the regression coefficients, $lMR\&D$ is the logarithmic transformation of R&D expenditure of the manufacturing sector of spillover country where the subscript is *jt* and beneficiary country if the subscript is *it*. Con represents vector of control variables which are economic and institutional factors. α_0 is the individual effect which at this point may or may not be correlated with the explanatory variables depending on the outcome Hausman test. *U* is the random error term.

$$lvman_{it} = \beta_1 lvman_{jt} + \beta_2 lMR\&D_{it} + \beta_3 Con_{it} + \alpha_0 + U_{it} \quad (2)$$

In equation 2 the study seek to model explicit knowledge spillover between countries in Europe. The explanation of the model remains the same as equation 1 with the exception that the first right hand side variable is the explicit knowledge of spillover countries. The variables of interest in estimating knowledge spillover in equation 1 and 2 are $lMR\&D_{jt}$ and $lvman_{jt}$respectively. These are the spatial lag variables that measure the effect of one country's innovation activities on other countries innovation output. Knowledge spillover must necessarily have a positive effect on innovation of the beneficiary country or sector (Noni, Orsi, & Belussi, 2018). The criteria for determination of knowledge spillover in equation 1 and 2 is that β_1 must be positive and significant. If the Hausman test suggests a correlation between the explanatory variables and the individual effect (X, α) = 0 then a fixed effect model where the individual effect becomes a parameter to be estimated used. On the other hand where the Hausman test shows no correlation between explanatory variables and the individual effect (X, α) $\neq 0$ a random effect model is used where the random error term then becomes Ϣ = $\alpha_0 + U_{it}$.

3.1 Robustness Checks

In the study, we have implemented several strategies to improve the robustness of the study results. The use of panel data and analysis techniques improves the robustness of the result. With panel data we combine both cross sectional and time series. This is more informative as it allows the study to follow behaviour of the variables over time. The panel data analysis technique also allowed us to account for the individual effect of the data structure which is critical to ensure efficiency of the model. In this study also we use robust standard error to ensure that the model is robust against heteroskedasticity and autocorrelation.

4. Results and Discussions

In this study, we investigate knowledge spillover among selected countries in Europe. The results present analysis on knowledge spillover from countries with focus on tacit, explicit and R&D. In this section of the study, we present results on R&D spillover among selected European countries.

In Table 2 we present results on R&D spillover among manufacturing sectors of nine selected European countries. The results present two variants of analysis, fixed effect and random effect. Both models confirm our hypothesis that there is R&D spillover in the manufacturing sector of countries. In the fixed effect model Germany and Poland have R&D spillover but R&D spillover from Slovakia exhibits a quadratic effect with an inverted U-shaped relationship. In Slovakia increasing R&D intensity increases R&D spillover but beyond a minimum level of R&D intensity the effect of R&D knowledge spillover is negative. There is no R&D spillover from Slovenia, Lithuania, Belgium, France Spain and Czech Republic. On the contrary the random effect analysis proves that the only country that is a source of R&D spillover is Germany. All other countries are not R&D spillover hotspots.

Hausman test in Table 3 is employed in selecting between the fixed effect and the random effect model under the null hypothesis that random effect is the efficient model. The Chi square test results shows a significant chi square statistic. The null is therefore rejected for the alternative hypothesis that the fixed effect model is the ideal estimation technique. The fixed effect model from Table 3 has a total variability of 57.7% which decomposes into a within effect variability of 76.13% and between effect variability of 49.1%.

Table 4 presents robust fixed effect analysis with robust standard errors. These standard errors are robust against heteroskedasticity and autocorrelation. The results confirm the hypothesis that R&D spillovers occur between manufacturing firms in the sampled European countries. Specifically, R&D spillover Germany and Slovakia but none other from the study sample is a knowledge spillover hotspot.

In Table 5 we present the results on explicit knowledge spillover among nine sampled European countries. Model 1 in Table 5 presents the fixed effect model (within effect). The results of the study confirm the hypothesis that explicit knowledge spillover occurs among countries. Our findings show that explicit knowledge spillover from

Poland and Slovenia and France are a quadratic U-shaped relationship. The positive and significant explicit knowledge spillover from Spain is an indication that Spain is a knowledge spillover hotspot. Countries such as Germany Slovakia, Belgium and Czech Republic show no evidence of being explicit knowledge hotspot. As a variant of the fixed effect model, the random effect GLS model in Table 5 shows a similar result that confirms the hypothesis that intercountry explicit knowledge spillover in the manufacturing sector of the sample countries.

The results show that Poland, Slovenia, and France show an inverted U-shaped relationship indicating that these are spillover hotspots but after a maximum level explicit knowledge is reached, explicit knowledge falls leading to a fall in value addition. Lithuania and Spain also showed evidence of being spillover hotspot. Germany, Slovakia, Belgium, and Czech Republic showed no signs of being a knowledge spillover hotspot.

Table 6: Hausman Test

****P<0.01, **P<0.05, *P< 0.1. All variables in the logarithm transformation*

The choice between the fixed effect model and the random effect model is determined by the Hausman test. The test is conducted under the hypothesis that the random effect estimate is more efficient. The Chi Square test shows that the test is significant. This rejects the random effect estimates in favour of the fixed effect model as shown in Table 6.

From Table 7 below value added in the manufacturing sectors of Poland, France and Slovenia are significant and are polynomial in degree 2. This indicates that these are knowledge spillover hotspots. However, the quadratic relationship observed indicates that the size of the explicit knowledge matters. An excessively high explicit knowledge spillover reduces knowledge spillover to neighbouring countries. At lower levels of explicit knowledge, the effect of knowledge spillover from Poland, Slovenia and France are high. The study results also show a positive and significant coefficient for explicit knowledge coefficient for Lithuania. This is an indication that Lithuania is a knowledge spillover hotspot.

The results from Table 7 also shows however, that coefficients of explicit knowledge spillover for countries such as Slovakia, Czech Republic, Spain Germany and Belgium are either not significant, negative or U shaped. These indicate the absence of evidence to suggest these countries are knowledge spillover hotspots.

5. Discussions

The findings of the study confirm the position of the literature that R&D spillover has been a major contributor to productivity. Whereas in the study by Spithoven and Merlevede (2023) the authors showed that knowledge spillover contributes to improving productivity of firms, the findings of the current study shows likewise that

there is international R&D spillover to some domestic economies. It is worth mentioning that even though there is evidence that most of the countries are R&D spillover pole in agreement with the position of the literature, there are some exception to this expectation. Countries that are not Knowledge spillover pole could be explained by the reason that the conditions for such knowledge spillover are not present. Henderson (2007) and Romer (1990) highlighted the important precursors for knowledge spillover such as proxity, relatedness of technology among others. Countries that could not be identified as R&D spillover poles most likely lack the determining factors. Considering the closeness of these countries one would expect that, the argument that proximity is a determinant of knowledge spillover (Jasimuddin, Li and Perdikis, 2015) will apply. However, the important point to note here is that colocation as explained by Cohen and Levinthal (1990) is not just an issue of proximity but also relatedness of technology. The study also shows that generally international R&D spillover is more improtant than any other factor in explaining value addition in the manufacturing sectors of the selected European countries. This could suggest the possibility that knowledge among these countries are related or the proximity among the countries has made these countries more reliant on themselves for innovation inputs. It may be expected that the closer countries are the higher international R&D spillover will be. However, the findings of the study showing only two R&D spillover hotspot, Germany and Slovakia may be enough to disprove that. What may be accounting for this can include limited trade relationship among the countries. As Keller (2004) has shown the volume of trade among the countries is important for knowledge spillover. Absorptive capacity of countries could also be a determinant of R&D spillover hotspot. It is noteworthy to state that the results of the study shows that Slovakia R&D intensity exhibit a quadratic (inverted U shaped) relationship with value addition in neighbouring countries. This could point to the role of absorptive capacity of neighbouring countries to the spillover. At lower levels of R&D intensity in Slovakia, neighbouring countries are ready to take on knowledge from Slovakia after a maximum level any extra R&D spillover is not absorbed by the neighbouring countries.

The study's confirmation that there is significant explicit knowledge spillover among European countries is in line with what the literature suggests (Spithoven & Merlevede, 2023). Explicit knowledge, according to Fallah and Ibrahim (2004) are easily transmitted because of its codifies nature. It is important to state however, that findings of the study also confirms that in the absence of the essential factors knowledledge spillover does not occur. It is also striking in the study findings is that countries that are R&D spillover spillover poles such as Poland and Slovakia showed no evidence of being an explicit knowledge spillover poles. This is an indication that the various types of knowledge may behave differently. Countries in contiguity as has been revealed have shown no sign explicit knowledge spillover. This casts doubts on the colocation assumption (Jasimuddin, Li & Perdikis, 2015) for knowledge spillover. What is also important with study findings worth mentioning is that in most of the explicit knowledge spillover hot spots an extremely volume of explicit knowledge reduces knowledge spillover. We interpret that to mean the lack to absorptive capacity on the part of beneficiary countries. This may explain why some large economies with a very vibrant R&D and explicit knowledge sector may not be knowledge spillover hot spot. This is in agreement with Zhao, Jiang, and Wang (2019) who showed a positive moderating effect of absorptive capacity in the relationship between knowledge spillover and green economy. The findings of this study will therefore mean that countries could be doing well with the R&D and explicit knowledge but the extent to which there will be knowledge spillover depends on factors including the absorptive capacity of the receiver. Major economies with large R&D and explicit knowledge which have not proven to be knowledge spillover hot spot could be explained by the fact that perhaps their neighbouring countries do not have the required absorptive capacity to take up the floating knowledge.

6. Conclusions

In this study we have investigated the knowledge spillover hotspots in Europe. Specifically, the study focused on R&D and explicit knowledge spillover hotspots in Europe. The main results reported by large portion of the prior literature are confirmed by the findings of the current study. The study findings are robust, taking into consideration heterogeneity of the different countries, heteroskedasticity and autocorrelation, we conclude that knowledge spillover hotspots in Europe differ based on the type of knowledge considered. After controlling for economic and institutional factors, the fixed effect model showed that R&D spillover hotspot countries in Europe include Poland, Slovenia, Lithuania, France, and Spain. Germany, Slovakia, Czech Republic, and Belgium fell short of being classified as knowledge spillover hotspot. To further ensure robustness to deal with the possibility of autocorrelation and heteroskedasticity, the results showed that Germany and Slovakia are the only countries that show evidence of R&D spillover hotspot. In the case of explicit spillover, the study concludes that Poland, Slovenia, Lithuania, France and Spain show evidence of being knowledge spillover hotspots. This allows

us to make the conclusion in agreement with the position of the prior literature that explicit knowledge by their nature are more susceptible to spillovers.

It is also concluded that knowledge spillover hotspot countries in Europe have contributed to innovation performance of their neighbour.The study also concludes that knowledge spillover is generally not linear for most knowledge spillover hotspots. Knowledge spillover from Slovakia, Slovenia, and France have an inverted U-shaped relationship whereas it is linear for countries such as Germany and Lithuania. In the case of Germany and Lithuania the size of R&D and Explicit knowledge has proportionally the same effect on knowledge spillover. However, the study, based on its findings conclude that in the case of knowledge spillover hotspot countries such as Slovakia, Slovenia and France knowledge spillovers are influenced by the volume of knowledge. We further conclude that above a certain minimum level of knowledge, knowledge spillover begins to reduce which can be interpreted as absorptive capacity constraints in the receiving countries. The implication of the study to European countries is that knowledge sharing among these countries has the potential of reducing the cost of R&D and innovation activities.

Shaping the Knowledge Worker Through a *T-Shaped Skills Profile* Framework

Hendrik Jan de Weerd, Yasmina Khadir and Pascale Peters
Nyenrode Business University, Breukelen, The Netherlands

rikdeweerd@gmail.com
y.kpoggi@nyenrode.nl
p.peters@nyenrode.nl

Abstract: The paper revisits the concept of knowledge workers using the lens of a *T-shaped skills profile*. This framework combines breadth and depth of a worker's knowledge with their skill durability. The T-shaped skill profile represents an individual who combines deep expertise in a field (the vertical bar of the T) with a broad understanding across multiple disciplines (the horizontal bar). This metaphor emphasizes the balance between specialized knowledge and not specialized one. To enhance this approach, a time dimension accounting for the perishability of skills, is integrated. Indeed, the unprecedented changes the last Covid-19 pandemic have brought about in work habits and culture seem to forecast the working habits of the future. Changes, such as a less work-centric behavior and higher flexibility demands, necessitate a better understanding these knowledge workers. 10 interviews have been conducted with knowledge workers from various organizations and sectors. Results show an original inverted pyramid T-shaped skills profile featuring a time dimension following this pattern: (i) Contextual level – Semi durable skills and knowledge; (ii) Foundational level – durable skills and knowledge; (iii) Specialist level – Perishable skills and knowledge. New insights on the nature of these knowledge workers are also provided. This paper contributes to theory by bridging two interesting concepts: the traditional eclectic approach to knowledge workers and the T-shaped skill profile. This research provides valuable insights to managers, supporting the development of effective policies and structures to retain and motivate these specialized employees.

Keywords: Knowledge Workers; T-Shaped Skills Profile; Skill Depth; Skill Breadth.

1. Introduction

Understanding the competencies of workers in terms of breadth, depth and their potential for innovation has been an ongoing problem in organizations (AlEssa and Durugbo, 2022; Birkinshaw et al, 2020). This is particularly the case for knowledge workers (KWrs) who add significant value to organizations' mission (Kaur, Gupa, Singh et al, 2019; Newell, 2015; Drucker, 1959, 1999). Millar et al (2017) argue that leading KWrs requires different leadership structures recognizing that these workers present different identities (Sveningson and Alvesson, 2003). Additionally, the level of knowledge depth (or expertise) and knowledge breadth (or general business knowledge) vary among workers. Understanding this peculiarity is conditional to organizational creativity (Mannucci and Yong, 2018) and thus innovation. As knowledge workers' skills are perishable (Arbesman, 2012), aligning these with corporate objectives calls for a strategic approach that harness the potential of the workforce (Muzam, 2023). Echoing Peter Drucker's (1959) prophetic statement which declares that leading KWrs will be the greatest management challenge of the 21st century, Issahaka and Lines (2021) note that scant progress has been made in addressing this issue. Instead, scholarly discourse has often consisted of normative and fragmented propositions. A better understanding of these workers in terms of knowledge depth and knowledge breadth, and the relevance of their skills along a time continuum, is a possible avenue that this study examines through the T-shaped skills profile. The time dimension or skill perishability factor is paramount within the current economic landscape (Harris and Spencer, 2019; Bansal, Reinecke, Suddaby et al, 2022).

Extant literature acknowledges the fuzzy character of the knowledge worker and the challenges in 'defining it' (Alvesson, 2001; Surawski, 2019). For example, Davenport (2005) conceptualizes the knowledge worker from an individual point of view (e.g., having a high degree of education) while Surawski (2019) argues that KWrs are specialists that require trust to achieve specific goals. Drucker (1994) is concerned by KWrs at work where they primarily use knowledge and information to complete their tasks. Following a study on the nature of knowledge work, Pyöriä (2005) concludes that the existing literature lacks a satisfactory definition capable of encompassing all dimensions of knowledge work.

To address this issue recent studies have highlighted the potential a framework such as the T-shaped skills profile promises. The T-shaped skills profile is a framework that supports a representation of individuals' skills breadth and depth (Heikkinen, 2018; Saukkonen and Kreus, 2022). The horizontal bar to the T encompasses broad competencies that allow knowledge workers to integrate knowledge across multiple domains. The vertical segment signifies depth in a specific domain or expertise area. It represents specialized skills and knowledge that make workers specialists in their fields. Finally, a third dimension is considered: time. This dimension is expressed by the skill durability model introduced by IBM and discusses skills in terms of durability (Malik, 2020).

This paper aims to contribute to the discussion on knowledge workers management and leadership within an increasingly complex work environment. More specifically, the focus is on KWrs' evolving skills, capabilities, want and needs. To gain deeper insights on the unique attributes of these workers and their engagement with organizational requirements, T-

shaped skills profile is implemented. This research seeks to examine how knowledge workers evolving organizational and personal dimensions are understood through the T-shaped skills profile. The following three sub-research questions facilitate the study:

1. How do knowledge workers engage with the organization they work for?
2. What are knowledge workers' generic/durable capabilities and their contextual/semi-durable capabilities?
3. What are knowledge workers' specialistic/perishable capabilities?

The following sections present a conceptual framework and summarize the research method. This is followed by a discussion of the results, culminating in a final framework with corresponding explanations. The paper concludes with a discussion and conclusion section.

2. Conceptual Framework

2.1 Knowledge Workers

Introduced in 1959 by Drucker, the concept of KWr remains highly relevant in today's organizational landscape (e.g., Muzam, 2023; Issahaka and Lines, 2021). Although no consensus has been reached in literature regarding their definition, numerous attempts have been made to delineate KWrs. Davenport (2005) challenged Drucker's (1959) original definition, emphasizing that KWrs' work is characterized by "thinking for a living" rather than merely knowing more about their job compared to other people in the organization. Kidd (1994) highlighted the non-routine nature of KWrs' work, where they create their own processes, necessitating experiential learning. More recently, Surawski (2019) refined the definition, portraying KWrs as individual engaged in cognitive tasks demanding a broad knowledge base, complex problem-solving skills, and autonomy. Surawski (2019) also echoes Drucker's perspective, emphasizing the shift toward specialization, expertise, and the need for novel management paradigms to enhance productivity. However, Waizenegger et al (2020) extended the term KWrs to include remote workers leveraging information technology during the pandemic, aligning with Davenport's (2005) view. This juxtaposition of definitions has contributed to confusion in the field over the past two decades.

Drucker (1959) was among the pioneering management scholars to anticipate the rise of these forward-thinking specialists. KWrs demand effective leadership while simultaneously navigating self-management. Subsequently, Davenport (2005) acknowledged workers who consistently interact with knowledge within an environment profoundly impacted by the surge in information technology. This scenario necessitates novel management approaches. In Drucker's (1999) view, the term KWr highlights the transition from traditional labor to intellectual work. He further emphasized the critical role of KWrs' productivity in the global economy, already foreshadowing the contextual challenges organizations must address. An empirical study conducted by Zhan et al (2013) describes these continually evolving circumstances surrounding KWrs, circumstances driven by technological advancements and the necessity for their skill updates. Despite the numerous scholarly contributions attempting to 'define' the KWrs' context, both Pyöriä (2005) and Surawski (2019) noted that there is (still) a lack of a structured framework that fully encapsulates the roles and attributes of KWrs within changing economies.

2.2 The T-Shaped Skills Profile Development

Originally introduced by David Guest in 1991, the T-shaped skills profile was developed to address organizations' need for talented workers amidst the 1990s' economic and technological turmoil in the U.S. Prominent industry figures like Tim Brown, Chief Executive Officer of IDEO, have endorsed this T-shaped skills profile, viewing it as essential for fostering innovation and interdisciplinary collaboration (Hansen, 2011). The T-shaped skill sprofile is a framework or model that helps delineate workers' skills in term of expertise or knowledge depth and general knowledge or knowledge breadth. This framework also gained popularity among scholars and is used to discuss the multidisciplinary nature of academic research networks and their 'T-shapedness' (Turner et al, 2019). In his PhD dissertation, Heikkinen (2018) explored the concept of T-shaped professionals to understand the knowledge Finnish students should acquire to remain relevant at work in the future. His work highlighted the importance of equipping knowledge workers with the ability to navigate diverse contexts and collaborate effectively across disciplines.

Despite the many promises the T-shaped skills profile holds, its descriptive and fragmented nature, coupled with a top-down perspective, falls short of capturing the dynamics of the modern workplace (Heikkinen, 2018). The model oversimplifies the multifaceted skills needed today and overlooks context as a crucial influence factor. In response, alternative solutions (i.e., different skill profile shapes) have been proposed (e.g., Elayan, Hayajneh, Abdellatif et al, 2022). The T-shaped skills profile continues to be a focal point in discussions about professional competency, highlighting the importance of both deep domain-specific expertise and broad interdisciplinary knowledge. Addressing these limitations, Saukkonen and Kreus (2023) introduced the T2-model. This framework conceptualizes individuals as possessing depth in a specific domain (the vertical

line of the T) complemented by breadth across various disciplines (the horizontal line). This horizontal dimension is vital for fostering collaboration, cross-disciplinary understanding, and adaptability in dynamic work environments. Overall, the framework shows that the ideal KWr shows an ability to integrate business expertise with technological skills, balancing both technical and social components within a broader system (Figure 1)

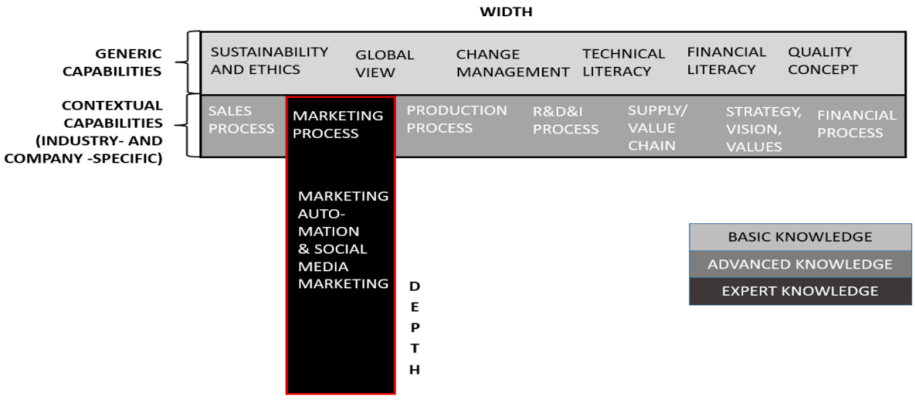

Figure 1: T2-shape skills profile for a digital marketing lead (From Saukkonen, and Kreus, 2022, p. 1039)

2.3 The Perishability Factor

Drucker (1999) emphasized the significance of continuous learning and teaching within one's field of expertise as a key contributor to a knowledge worker's productivity. Considering evolving job market demands and the constant need for fresh skills in the workplace, employees must continually enhance their capabilities (Muzam et al., 2023). Harris and Spencer (2019) recognize the changing employment landscape and stress the need for employees to re-skill and develop. The authors added that this situation has led companies to broaden and innovate their learning resources and modify their approaches to workplace strategy. This prompted organizations to make the integration of new learning systems a rapidly expanding area in Human Resources investment. In addition, humans can forget knowledge (Baddeley, 2013), tendency that becomes problematic conspires with the increasing pace of change. This predicament forces an acknowledgement of the idea of 'skill perishability' when attempting to visualize KWrs. The skill profile categorization proposed by IBM offers a clear framework that aligns well with the T2-model developed by Saukkonen and Kreus (2022). Skill perishability also presents a fit with Drucker (1985) who stated that what individuals have learned by age 21 will begin to become obsolete five to ten years later and will have to be replaced or at least, refurbished by new learning, new skills, and new knowledge.

This study adopts the following approach conceptualized within the T2-model:

i. Durable skills last for more than 7.5 years. This group of skills includes more foundational skills such as design thinking, project management practices, effective communication, and leadership. These skills can be positioned in the horizontal bar of the T shape.
ii. Semi-durable skills last between 2.5 to 7.5 years. This category often includes frameworks that form the base for field-specific technologies, processes, and tools. These skills can be positioned in the horizontal bar, below the top line of the T shape.
iii. Perishable skills last less than 2.5 years. These skills include specific technology skills frequently updated, organization-specific policies, tools, and specialized processes. These skills can be positioned in the vertical bar of the T shape.

3. Method

This study strives to understand KWrs' lived experiences in working situations. These are viewed as dynamic, shaped through interactions within their evolving professional environments. The subjective and context-dependent nature of these experiences calls for qualitative research (Creswell and Creswell, 2023). A semi-structured interview was designed to capture the nuanced and varied experiences of 10 KWrs based in The Netherlands, aged between 30 to 55 years old. The respondents were identified within the researchers' personal network. The interview guide structure was inspired from the T2-model from Saukkonen and Kreus (2023). To facilitate the conversation and obtain rich data, interviewees were asked to describe a positive experience in managing a project and a negative one. Following the description of the positive project, the researchers stimulated a conversation around broad generic skills, contextual skills and expert skills, making sure to cover all dimensions of the T2-model.

Data analysis followed Brooks and King's (2014) thematic analysis method, moving from an open, exploratory phase to focused categories centered on the KWrs' perspective, but within the categories of the T2-model Brooks and King's (2014) method supports the use of a preliminary framework to analyze the date. In this instance, the T2-model was used only during the selective coding stage to develop the final template that encapsulates foundational, contextual and expert skills respectively. Beyond Brook and King's (2014) recommendation, researchers identified patterns in respondents' responses that supported the use of a framework such as the T2-model. In discussing their most rewarding career projects or periods, respondents consistently shared the following insights. In the following order, respondents:

1. Perceived competence growth, fostered through collaborative knowledge/skill acquisition, which was crucial for task performance.
2. Internalized corporate objectives aligned with their own values, morals, and ambitions.
3. Gained adequate autonomy over resources, authority, and strategic/tactical information over time.
4. Exhibited pride, commitment, and drive within a context of entrepreneurial management (as described by Drucker in 1985).
5. Focused their tactical decisions on preserving value and future development, balancing innovation with risk mitigation.
6. Engaged in in-situ development of essential expertise (referred to as "the T's tip") via experimentation and collaboration.
7. Believed that management trust was rooted in the worker's track record and their effective ability to create value.

These seven patterns reveal a tri-level framework, delineating an evolving profile and visual representation of the KWr. This approach supports then the use of framework as a guiding structure for making sense of the data. In the final coding stage, the identified codes were refined into major themes, providing contrasts with established academic models. The T2 model by Saukkonen and Kreus (2023) was employed to categorize the findings into foundational, contextual, and specialist skill levels.

4. Results

The results of this study are provided hereafter, summarized in Figure 2. The elongation of the contextual level (the pointy part of the figure) challenges the traditional proportions of the T2-model or the original T-shaped skills profile. This research results propose a modified visualization as an inverted triangle, which more accurately represents the skill distribution and acquisition in contemporary knowledge workers (Figure 2). The items of this figure are explained hereafter.

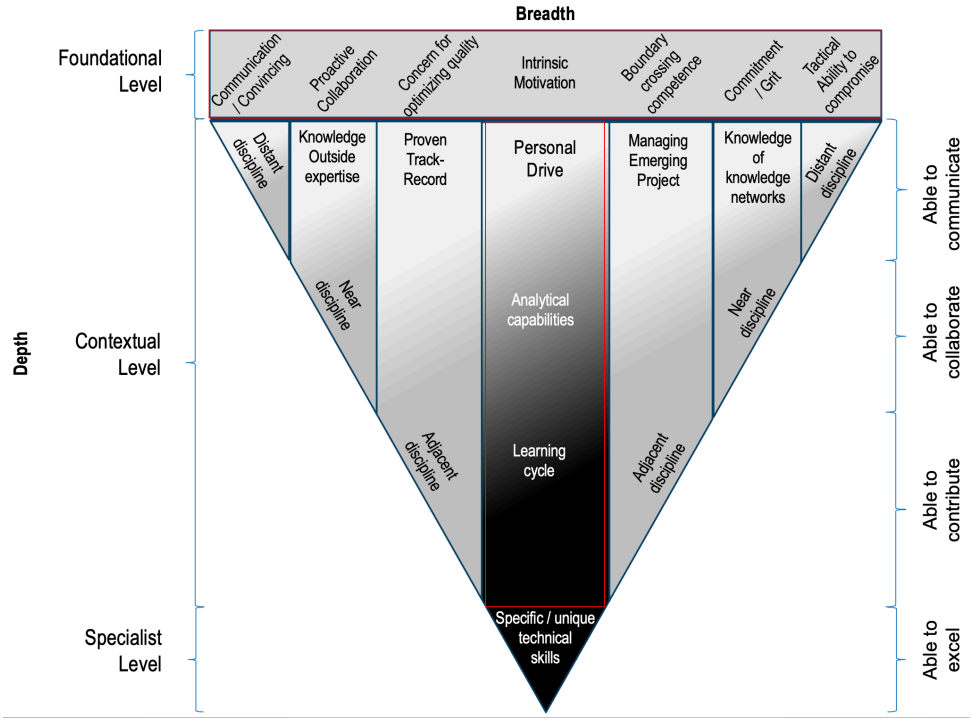

Figure 2: Modified T-shaped skills as inverted triangle illustrating contemporary knowledge workers

4.1 The Foundational Level

The Foundational Level (Durable Skills and Knowledge) encompasses a variety of essential and distinct skills and traits that contribute to the economic relevance of KWrs within an organization. The different dimensions composing this level are presented hereafter.

Communication and Convincing Skills: KWrs skillfully combine persuasive communication with their deep professional expertise to drive progress in collaborative projects and initiatives. A cancer research laboratory specialist aptly likened the process of seeking approval to "a bit like a game"—a strategic challenge to make it appealing to management. KWrs navigate the delicate balance between substance and influence, ensuring that their ideas resonate and propel organizational success.

Proactive Collaboration: Respondents shared that active engagement and collaboration characterize their interactions. They engage in a dynamic exchange of advice, embodying both learning and teaching principles, as emphasized by Drucker (1985; 1999). These KWrs adeptly navigate organizational hierarchies, leveraging informal networks, and harnessing the collective strengths of diverse teams. Hence, KWrs thrive in an ecosystem of shared knowledge, where their interactions foster growth, innovation, and collective success.

Concern for Optimizing Productivity and Quality. KWrs take proactive steps to enhance both their personal productivity and the organizational output within their functional domain. This proactive behavior is triggered by a combination of sufficient knowledge and genuine concern. Drucker (1959; 1999) and Kidd (1994) support this perspective, which diverges from Davenport (2005). In essence, when KWrs possess the right knowledge and care deeply about their work, they become catalysts for positive change, challenging the status quo and driving progress in their organizations.

Intrinsic motivation. In line with Drucker's (1959; 1999) management theory lies a counterpoint to external management as a mean of behavior control or motivation. The empirical evidence resonates with self-determination theory (Ryan and Deci, 2000), underscoring that autonomy, competence and relatedness are conditional to KWrs. It does not matter whether the emphasis lies on group affiliation or individual self-actualization as mentioned by a defense infrastructure specialist.

Boundary-Crossing Competence: In line with Heikkinen (2018) and Saukkonen and Kreus (2022), results show that KWrs rely on a unique capacity to bridge disciplinary and organizational divides, enabling seamless adaptation and knowledge integration across diverse domains.

Commitment/Grit: KWrs exhibit *grit*. They proactively orchestrate their deep involvement and demonstrate a willingness to endure discomfort in pursuit of their goals. Their unwavering dedication is evident through phrases like "have to," "committed," "our motto," and "stand for."

Ability to compromise: KWrs exhibit a strategic behavior that prioritizes immediate tangible value, while intentionally deferring uncertain aspects for future iterations. Rather than rigidly pursuing an "all or nothing" approach, KWrs strategically balance short-term impact with long-term adaptability and growth.

Davenport's (2005) emphasis on the analytical aspects of knowledge workers within a repetitive context differs significantly from the findings, which underscore the importance of non-routine work and intrinsic motivation.

4.2 The Contextual Level

The Contextual Level (Semi-durable Skills and Knowledge) plays a pivotal role in KWrs' productivity and innovation capabilities intricately tied to specific organizational contexts. The different dimensions composing this level are presented hereafter.

Knowledge Beyond Expertise: KWrs need to possess a nuanced understanding of adjacent fields to ensure high-quality and effective service delivery. This multidisciplinary approach not only broadens their expertise but also enhances their capacity to explore, analyze, and hypothesize. Importantly, this horizontal expansion of skills challenges the conventional T-shaped model, emphasizing the value of a wider knowledge base. Within this multidimensional perspective, KWrs connect insights across domains, fostering innovation, and breaking down silos within organizations.

Proven Track Record: Knowledge work inherently involves novelty, and some skills must be acquired on-the-fly. Whether KWrs receive the necessary support and autonomy hinges on the established level of trust, which is influenced by their demonstrated success and the promise of future reciprocity.

Personal Drive: A significant finding in this study is that the concept of drive resides within the contextual layer. It can be best understood as an innate ability to stay motivated, which becomes evident when not hindered by context-dependent organizational elements. This perspective aligns with Entrepreneurial Management, as defined by Drucker (1985), which highlights the essential conditions for fostering innovation as positive and sustaining factors. Additionally, Herzberg's (1968)

list of Hygiene factors in the Two-Factor theory outlines what must be in place within a work context to sustain an employee's drive. Furthermore, respondents explained that the emotional connection between work and the situation at hand is shaped by a delicate interplay of pride and shame.

Managing emergent project Skills: Unlike traditional project management, where projects are meticulously planned and executed, respondents had to face a different challenge: managing the emergence of projects. This aspect, although it may appear to align with Davenport (2005), spotlights the non-routine nature of KWrs' work. It is not about adhering to routine project management protocols; rather, it is about cultivating innovation momentum and seizing opportunities as they arise. Results show that KWrs thrive in the dynamic interplay of creativity, adaptability, and forward-thinking.

Knowledge of Knowledge Networks: KWrs leverage networks for productivity, placing tacit knowledge and interpersonal connections above rigid formal organizational structures. This underscores the significance of informal relationships and personal initiative in navigating complex organizations. As an Information and Technology architect puts it, success often hinges on "knowing the right people who do know."

4.3 The Specialist Level

The Specialist Level, symbolized by the vertical bar of the T-shaped skills profile, centers on the most perishable and defining aspect of a KWrs' profile: specialist skills and knowledge. As Drucker (1999) described, KWrs are experts in their respective fields, inherently making them specialists. Their specialized expertise is pivotal for high-value productivity within organizations. The following codes emerged from the study.

Analytical Capability: Consistently, respondents exhibit robust analytical skills within their specialized domains. These skills are essential for comprehending complex challenges and driving continuous improvement in respondents' specific work areas.

Learning Cycle: Respondents explained that they manage their own dynamic learning cycle, leveraging their network for knowledge assimilation, setting up experiments, and actively seeking feedback. This process emphasizes Drucker's (1999) view on the necessity of continuous learning and teaching in knowledge work.

Creation of Business Functionality: Respondents play an ever-expanding role in innovating and enhancing corporate value propositions. They frequently lead the charge in creating new services or improving existing ones. When the complexity of a business function surpasses a certain threshold, optimization becomes achievable primarily through the expertise and insights of KWrs. Their ability to navigate intricate challenges and drive strategic improvements is pivotal for organizational success.

Specific / Unique Technical Knowledge: Contrary to the conventional understanding of specialization (Heikkinen, 2018), our findings reveal that respondents often combine multiple skills to create unique value. This creatively combined expertise poses staffing challenges and underscores the nuanced nature of respondent's specialization. This is the case both for a deep expertise in a single niche and a blend of skills that create unique capabilities driving business innovation.

5. Discussion and Conclusion

This study attempts to shed more light on the opaque concept of KWrs using a T-shaped skills profile. The ambiguity surrounding the broad use of the KWr label within the working environment has hindered progress in research in this field. After Davenport's (2005) seminal publication, subsequent research has often resorted to short-lived lists and descriptions of niche situations (e.g., Surawski, 2019). This research shows for the first time a structured and holistic vision through the T-shaped skill profile that makes a KWr a special type of employee.

Data underscores the value of boundary crossing skills (Hansen, 2011) but finds that these and their adjacent skills go dormant without the drive to apply them. While Heikkinen (2018) focuses on educating students about boundary crossing, this study delves deeper in this phenomenon and explores the contextual requirements for effective utilization of skills. The impact of organizational context on KWrs is transformative. The T-shaped skill profile has evolved into an inverted triangle (Figure 2). Contrary to the belief that specialization equates to expertise in a single niche, our study reveals that unique value often arises from a combination of skills as suggested by Saukkonen and Kreus (2022). Interviewees, while not top experts in any single skill, occupy their own crossroads, deriving value from the intersection of multiple abilities. Their unique value was derived from an intersection of several skills, of which the core to their discipline took centerstage.

A second original finding is that this study delves into the intricate components of specialist-level expertise or skill depth identified in the data as *analytical capability, specific technical knowledge, and self-management of their learning cycle, oriented towards the creation of new business functionality*. Moreover, the dynamic underpinning how these skills become

relevant or qualify a worker as a knowledge worker, is revealed. The most valuable, specialized, and perishable skillset—the one forming the tip of the inverted triangle—is cultivated during KWrs' *quests*. Skills from adjacent disciplines are not merely accessed indirectly but are actively assimilated to a significant extent. The learning cycle of a KWr seems to move their skills and knowledge set laterally as well, it is not restricted to vertical motion. A significant finding highlights that KWrs undertake a quest, actively seeking to broaden their knowledge beyond existing boundaries. This insight aligns with Kidd's (1994) perspective on non-routine, analytical knowledge work. Similarly, Drucker's approach emphasizes that KWrs possess deeper job-related expertise compared to others in the organization. As a result, the KWr label specifically pertains to those actively involved in knowledge work as described in this study. Moreover, it is important to observe that KWrs do not proactively engage with their organizations unless the fundamental conditions that stimulate motivation (or drive), are present. It is essential for employees within a business function to be empowered to communicate, collaborate, and contribute to the corporate strategy. However, the responsibility ultimately lies with the KWrs to surpass this baseline by fostering innovation and optimization. Indeed, data shows that leader's micromanagement is counterproductive. This study presents two main limitations. (i) Data is extracted from a small number of respondents (n=10) (ii) solely based in The Netherlands. Further research should be conducted in different settings and with a greater number of respondents. Research can also focus in turn on different dimensions of the framework and identify, for example, what should foundational skills composed of.

Abstract: Domestic, sexual, and gender-based abuse (DSGBA) is a complex societal issue with implications for individuals, families, and communities. According to the World Health Organisation, violence remains a pervasive problem, affecting one in three women globally. Addressing this complex issue requires the coordinated efforts of all agencies involved in the intervention and prevention of DSGBA. Despite shared goals, these agencies predominantly operate independently, resulting in the development of their own knowledge bases. Recognising the negative implications of agencies developing isolated knowledge bases for service users and society, this Action Research study adopts an integrated knowledge translation approach to investigate the knowledge production and transfer processes among multi-agency practitioners and academics engaged in the DSGBA field. The study introduces a virtual community of practice (vCoP) as a dynamic knowledge management system, aiming to evaluate its effectiveness in facilitating knowledge translation and bridging the research-to-practice gap. Employing a mixed-methods approach, the study combines quantitative and qualitative measures to explore knowledge transfer dynamics. Surveys, focus groups, interviews, user metrics, and content analysis provide a comprehensive understanding of community participation and interaction within a vCoP. Beyond traditional analysis methods, this study incorporates natural language processing techniques to uncover patterns, themes, and sentiments, facilitating the knowledge translation process. By extracting and translating insights from the vCoP discussion forums, the research aims to produce actionable resources such as best practices, academic papers, and policy guidelines, bridging the research-to-practice gap. The study aims to contribute a framework for implementing multi-agency vCoP, offering insights that could be adapted and applied in similar contexts. In addition, it seeks to address knowledge production and translation issues by fostering improved collaboration between academia and practitioners. The enhanced understanding of knowledge transfer dynamics within the DSGBA vCoP has the potential to influence positive change in decision-making processes and best practices, leading to more effective interventions and services combatting DSGBA.

Keywords: Virtual Community of Practice, Knowledge Translation, Evidence-Based Practice, Interprofessional Collaboration

1. Introduction

Gender-based violence encompasses physical, sexual, and psychological forms, impacting individuals irrespective of age, gender, culture, or socio-economic background, rendering it a critical public health issue (Greville et al., 2023). The World Health Organisation (WHO) reports that globally, one in three women experiences physical or sexual violence in their lifetime, highlighting the pervasive nature of gender-based violence (WHO, 2018). Recent studies by Women's Aid reveal ongoing issues, with one in five young women and one in eleven young men experiencing intimate partner abuse in Ireland (Womens Aid, 2021). Evaluating the economic cost of domestic, sexual, and gender-based abuse (DSGBA), Forde and Duvvury (2021) estimated a woman's journey to safety in Ireland at €113,475, equating to an annual economic cost of €2.7 billion. Ireland has responded to DSGBA through legislative measures, including the Criminal Law (Sexual Offences) Act 2017 and the Domestic Violence Act 2018, in addition to ratifying the Istanbul Convention in 2019 and implementing its third national DSGBA strategy called *Zero Tolerance* (DoJ, 2022). Despite legal advancements, a victim's journey to safety in Ireland remains non-linear (Safe Ireland, 2023). The fragmented DSGBA landscape and the lack of cohesive knowledge translation may also highlight a potential research-to-practice gap (DoJ, 2022).

The effective management of knowledge is central to navigating the complex multi-agency DSGBA landscape. According to Venkatraman and Venkatraman (2018), knowledge management involves generating, capturing, storing, and disseminating knowledge for competitive advantage. Knowledge management systems, often leveraging information technology, are crucial in supporting knowledge-sharing and transfer activities (Nezafati et al., 2023). This knowledge management focus requires a knowledge translation (KT) approach, an iterative process concerned with putting research knowledge into practice to bridge the research-to-practice gap (Leggat et al., 2021). WHO (2023) defines KT as "the synthesis, exchange, and application of knowledge by relevant stakeholders to accelerate the benefits of global and local innovation in strengthening health systems and improving people's health". The Canadian Institutes of Health Research (CIHR) identified two categories of knowledge translation, integrated knowledge translation (iKT) and end-of-funding knowledge translation (CIHR, 2019). iKT focuses on knowledge production by involving knowledge consumers in identifying research gaps,

data collection, analysis, dissemination, implementation, and reflection (Leggat et al., 2021). In contrast, end-of-funding KT addresses knowledge transfer problems (Bowen and Graham, 2013).

Communities of Practice (CoP) and virtual Communities of Practice (vCoP) have emerged as effective mechanisms for knowledge management and inter-agency collaboration (Habash, 2019). vCoP evolved from traditional CoP, leveraging collaborative technologies for member engagement (Sims, 2018). Rooted in situational learning theory, CoP emphasise that learning occurs in social groups through collaborative participation and relationships (Lave and Wenger, 1991). Wenger-Trayner and Wenger-Trayner (2015) define a CoP as a group of people who share an interest in a domain of human endeavour and engage in the process of collective learning that creates bonds between them. CoP and vCoP are distinct from other learning environments in three elements: domain, community, and practice (Wenger, McDermott and Snyder, 2002). vCoP foster learning anytime and anywhere as they transcend geographical boundaries (Greville et al., 2023), and their global reach introduces diverse perspectives (Michaelides, Tickle and Morton, 2010). Cost-effective and resourceful, vCoP share rich media resources and may prevent professional isolation (Ford et al., 2015). However, challenges arise in maintaining personal connections and engagement, necessitating a balanced and structured approach to their setup and management (Valenti and Sutton, 2020).

A review of the literature highlights vCoP as a tool for evidence-based practice (EBP) (O'Brien and Richey, 2010) and evidence-informed practice (EIP) (Rolls et al., 2016). EBP values research and practical experience, although it prioritises scientific evidence in decision-making (O'Brien and Richey, 2010). Evidence supports vCoP effectiveness for EBP within clinical settings as a cost-effective solution to improve the quality of care (Sahay et al., 2022), standardise best practices (Chu et al., 2021), or implement research-based interventions (O'Brien and Richey, 2010). However, EBP implementation faces challenges due to cultural, resource, professional, organisational, or geographical factors (Linkewich et al., 2022). Valaitis et al. (2011) suggest that vCoP can be a valued resource for occupations with limited professionals. Noting that vCoP should be designed around practical issues to enhance collaboration, Graaf and Ratliff (2018) argue that EIP is more applicable to community-based human service professionals. EIP is an iterative process incorporating evidence, expertise, resources, and preferences (Kumah et al., 2019). While vCoP can support EIP, knowledge brokers are crucial for successful implementation (Hajisoteriou, Karousiou and Angelides, 2018). Knowledge brokers are nominated individuals who aim to bridge the gap between research and practice by facilitating connections between knowledge consumers and producers. Their responsibilities include promoting knowledge sharing, building links between research findings and practical applications, and summarising relevant research (Hennessy et al., 2013).

O'Brien and Richey (2010) highlight vCoP as an effective mechanism for resource development, facilitating the generation of educational materials and best practice guidelines. These resources are designed for dissemination within the professional community, aiding knowledge transfer, decision-making, and practice standardisation. An illustration of the application of vCoP for resource development can be found in the Elements of Success in Family Planning Programme vCoP, hosted on the WHO Gateway (Richey and Salem, 2008). This vCoP demonstrates a structured approach through collaborative efforts, resulting in tailored resources for family planning programme managers. According to O'Brien and Richey (2010), the model's success lies in task allocation, defined timelines, and focused discussion forums.

vCoP also serve as an effective platform for professional development, enabling collaborative learning (Hajisoteriou, Karousiou and Angelides, 2018). O'Brien and Richey (2010) also emphasise the global role of vCoP in professional development, demonstrated by the Global Alliance for Nursing and Midwifery (GANM) on the WHO Gateway. GANM used their vCoP to disseminate an educational module on cervical cancer detection, targeting regions with limited resources. Hajisoteriou, Karousiou and Angelides (2018) advocate for collaborative projects and reflective practices within vCoP to support professional development. Nguyen et al. (2019) note that vCoP serve as a platform to support innovation, as observed with HOBE+, a community dedicated to innovating primary care in Spain. HOBE+ (1627 members) yielded 48 submissions with 133 ideas, 23 of which were approved for implementation. Success is attributed to a structured framework, active facilitators, clear objectives, and two working groups focused on idea management and innovation (Abos Mendizabal, Nuño Solinís and Zaballa González, 2013).

Critical success factors for achieving an effective vCoP were identified from the literature. One key factor is knowledge-sharing behaviour (KSB), which involves the willingness, attitude, and actions towards sharing knowledge (Tan and Ramayah, 2018). However, fostering a willingness to share knowledge remains a consistent challenge in vCoP (Hernández-Soto, Gutiérrez-Ortega and Rubia-Avi, 2021). Various motivational factors influencing knowledge-sharing intention were identified, and these are categorised into individual cognition,

interpersonal interaction, and organisational effort (Cheung, Lee and Lee, 2013). Hernández-Soto, Gutiérrez-Ortega and Rubia-Avi (2021) extend this classification, highlighting personal factors, particularly pro-community and altruistic behaviour, as precursors to knowledge sharing. The complexity of knowledge-sharing dynamics in vCoP highlights the importance of considering individual motivations and community dynamics for sustained engagement and collaboration (Haas et al., 2020).

Trust is a critical factor in shaping community engagement within vCoP, influencing knowledge-sharing behaviour and member participation (Hennekam et al., 2020). Social cognitive theory (SCT) outlines a three-stage trust development process: economy-based, information-based, and identification-based, that impacts personal factors and behaviour. Hsu et al. (2007) explain that this sequential trust process is situationally dependent and not progressively smooth, emphasising the substantial impact of identification-based trust on KSB, which is attributed to emotional investment. Sharratt and Usoro (2003) categorise trust into integrity, benevolence, and competence and support its impact on KSB, but acknowledge that integrity trust holds greater significance for knowledge-sharing intention. The absence of face-to-face contact in vCoP poses challenges to trust development (Lev-On and Adler, 2013), impacting social presence and sense of belonging (Ikioda et al., 2013). However, the findings from these studies may be influenced by characteristics, such as age, attitude, and profession, as some professions may use technology more for day-to-day tasks than others.

Ford et al. (2015) highlight the importance of knowledge brokers in fostering community engagement in vCoP, and Haas et al. (2020) stress the critical role of facilitators in providing administrative support, encouraging community engagement, and ensuring value to members. Facilitators prove valuable in bridging gaps in multidisciplinary or geographically dispersed vCoP by facilitating effective communication (Greville et al., 2023). Lin (2017) adds that facilitators, leading by example, significantly influence community engagement, underscoring the need for a balanced approach between facilitator-led initiatives and organic community activities.

Evaluation is vital for assessing the value and performance of vCoP and understanding online user behaviour. Evans and Mathur (2005) found that online surveys aid demographic exploration or member feedback collection within vCoP. They offer benefits such as low cost, convenience, reach, and quick execution. However, limitations arise from potentially low response rates attributed to the inundation of emails and perceived time efficiency. Cook-Craig and Sabah (2009) used online surveys on the Israeli Social Worker Gateway vCoP, achieving a 33.67% response rate. However, the study lacked in-depth trend analysis or correlations among variables. Semi-structured interviews offer qualitative insights into participants' perceptions or experiences in a vCoP. Lev-On and Adler (2013) used them to gauge members' perceptions in the same Israeli community. However, challenges in quantifying engagement levels emerged, impacting the study's depth. Website analytics are crucial for understanding community engagement within vCoP (Cook-Craig and Sabah, 2009). Metrics include the number of logins, forum interactions, and downloads to provide insights on vCoP performance and user behaviour. Cook-Craig and Sabah (2009) evaluated website analytics, revealing insights into lurker participation. However, the analysis lacked granularity, such as explaining user surges and addressing these aspects would have provided more significant insights.

The literature underscores the integration of EBP and EIP within vCoP. However, a gap exists in assessing the adoption of EBP versus EIP among vCoP member segments, hindering understanding of their differential uses. Moreover, the practical application of knowledge acquired within vCoP lacks evaluation, impeding assessment of its real-world impact. vCoP primarily focus on discussion forums, neglecting diverse content formats such as webinars. Furthermore, a standardised approach to data mining and limited information on data cleansing and exploratory data analysis impede thorough analysis, yielding generic findings. The literature also lacks evaluations of multi-agency vCoP for knowledge translation in the non-profit sector. Furthermore, Action Research (AR) use in evaluating multi-agency vCoP for knowledge translation is underexplored. These gaps call for comprehensive assessments in vCoP studies, warranting an AR study to evaluate a multi-agency vCoP for knowledge translation in the DSGBA field. This study is being conducted in collaboration with Haven Horizons, an Irish non-profit group that advocates for inter-agency collaboration to bridge the research-to-practice gap and support the intervention and prevention of DSGBA.

2. Research Design

The study employs an AR methodology, a collaborative research approach that involves the researcher at every stage of the process. Central to AR is the cyclic process of action and reflection, distinct from traditional research

methodologies, as it promotes the acquisition of tacit knowledge through critical reflection (Masters, 1995). The study adopts a five-stage cyclical AR process adapted from Susman and Evered (1978), as shown in Figure 1.

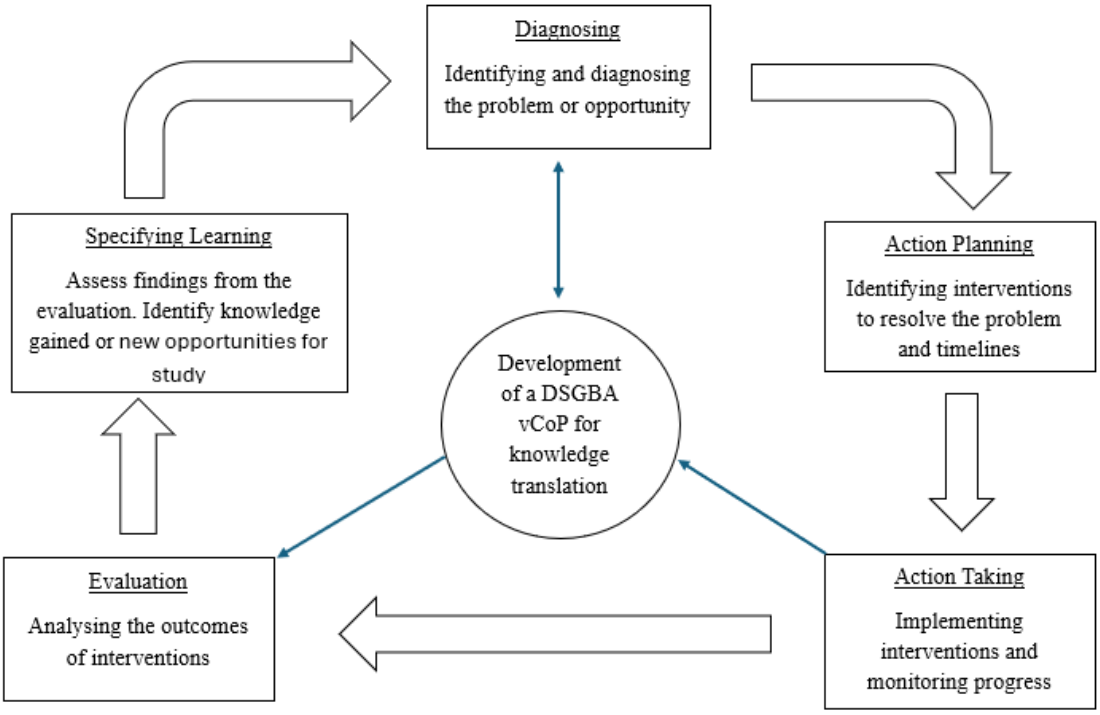

Figure 1: Five-Stage Action Research Model

The first phase of the AR process, diagnosing, focuses on identifying the problem, which then serves as the research focus. For this study, the literature review served as a mechanism for determining the barriers and motivations of using a vCoP to facilitate knowledge translation among professionals in the DSGBA field. The findings formed the basis for developing a conceptual framework (see Figure 2), which informed the research objectives, questions, and subsequent action-planning and action-taking stages.

The next stage of the AR process, action planning, involves identifying, developing, and scheduling interventions to address the problems identified in the diagnosing phase. Knowledge brokers and Haven Horizons are involved in the planning phase, outlining a quarterly roadmap of activities to support community engagement. The action-taking phase focuses on implementing the planned interventions and monitoring progress. This includes conducting focus groups with knowledge brokers, launching the DSGBA vCoP, developing a database of relevant contacts, and issuing marketing campaigns to attract members. Applying an iKT approach, the DSGBA vCoP membership will comprise multi-agency practitioners and academics to support bridging the gap between research and practice, aligning with EBP and EIP. Discussion forums and webinars will be initiated to foster engagement, and resources will be designed to support knowledge sharing. Furthermore, natural language processing (NLP) techniques such as aspect-based sentiment analysis (ABSA) and topic modelling will be implemented to extract insights from vCoP discussions. Topic modelling uses statistical methods to determine the frequency of words within the text to identify topic patterns (Murshed et al., 2023). Topic analysis aims to identify hidden topics to improve knowledge production and transfer issues, while ABSA serves as a tool to gain deeper insight into emotions towards entities or topics (Nazir et al., 2020). ABSA is a robust tool for analysing discussion forum content and evaluating the application of knowledge acquired within the vCoP. The observed patterns will help to understand the vCoP efficacy in bridging the research-to-practice gap and use of EBP or EIP. Data extracted from the topic analysis and ABSA will support the evaluation phase of the AR cycle.

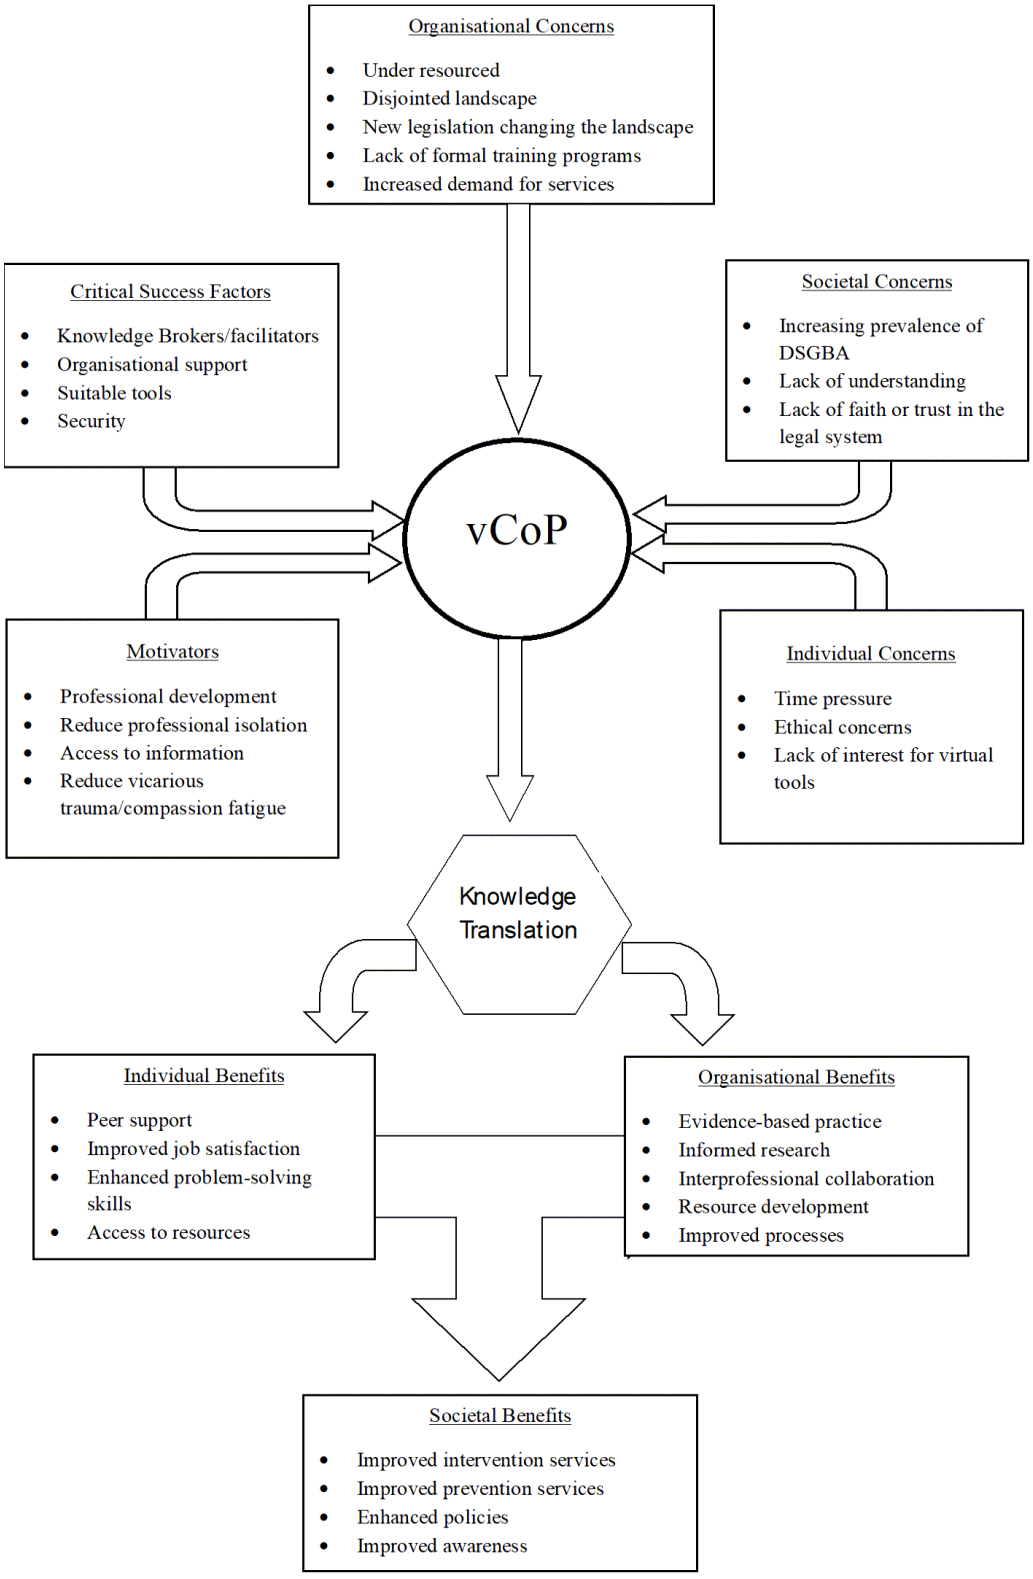

Figure 2: Conceptual Model

Evaluation of interventions is important to determine their effectiveness. Quarterly online surveys will be conducted to gather member feedback and monitor trends, supplemented by user statistics. The specifying learning phase assesses the findings from the evaluation phase to identify knowledge and contribute to theory development. To maintain research rigour, Corcoran and Duane (2017) recommend using a reflective diary to document methods, interventions, observations, and experiences throughout the research process. Reflective

journaling is used in this study to ensure research rigour and embrace the reflective practice. In summary, this study uses an AR methodology to enhance understanding and practice in the DSGBA field while contributing to scholarly dissemination and accredited academic programme development through diagnosing, action planning, action taking, evaluation, and specifying learning phases.

3. Implementation and Initial Findings

In preparation for the launch of the DSGBA vCoP, project documentation was developed to streamline project organisation, task coordination, and communication with Haven Horizons as part of the action-taking phase. This included creating a platform requirements document outlining essential features, integration requirements, and the aims and objectives of the DSGBA vCoP. Additionally, comprehensive documentation was generated to establish thematic areas, inquiry protocols, and content frameworks for conducting focus groups, interviews, and online surveys to gather feedback from community members and knowledge brokers. Creating a contact database was necessary to facilitate user engagement within the DSGBA vCoP. This involved identifying suitable organisations and job roles and manually extracting contact details from websites and digital documents. The resulting database included 320 direct contacts spanning diverse professions, such as solicitors, academics, and support services. A ten-week marketing plan was devised to assist Haven Horizons in post-launch promotional activities for DSGBA vCoP membership acquisition. This plan included social media postings, general newsletter content, and personalised email invitations.

Several platforms were evaluated to identify one that aligned with project requirements and budget. Heartbeat emerged as the preferred choice due to its functionality, user-friendly interface, and cost-effectiveness. Heartbeat is a platform for online communities that has an easy-to-use interface that lets people build and run their communities (Olayiwola, 2023). An FAQ document on Heartbeat features was developed to support Haven Horizons onboarding. Knowledge brokers from various professional backgrounds were recruited in collaboration with Haven Horizons to ensure representation across domains. An email campaign was launched to 38 individuals in September 2023, resulting in 26 acceptances by December 2023. Focus groups were then organised with vCoP knowledge brokers to discuss the motivators and barriers to knowledge sharing and inter-agency collaboration in the DSGBA field. Three focus groups were organised across March and April 2024 with 19 participants, detailed in Figure 3.

		Years of Experience					
Role	**Total Numbers**	0-4	5-10	11-15	16-20	21-30	31-40
Academic	3		2			1	
Practitioner	10	4	1	1	1	2	1
Lived Experience	6	3	1	1	1		
	19	7	4	2	2	3	1

Figure 3: Focus Group Participant Overview

The researcher facilitated the focus group sessions, and recordings were transcribed for NVivo thematic analysis. Findings revealed key insights regarding inter-agency collaboration. Participants identified staff turnover as a significant challenge, leading to disruptions in collaboration efforts, causing continuity issues and requiring time for new members to integrate into DSGBA networks. The absence of clear policies and procedures hindered collaboration efforts, with reliance on individual initiative rather than institutional support. Workload pressures also constrained participants' ability to engage in collaborative initiatives. Despite these challenges, participants recognised the value of inter-agency collaboration in facilitating knowledge-sharing and learning from diverse practices. The absence of standardised services across regions underscored the importance of sharing best practices and developing a common language within the vCoP. Strategies such as local networks and resource development were identified as effective means of supporting collaboration and addressing service gaps. Furthermore, academic participants viewed the vCoP as a platform for extracting information for academic pursuits. In contrast, practitioners and individuals with lived experiences emphasised the importance of peer learning, knowledge exchange, and the development of a common language across the agencies. The virtual nature of the vCoP was perceived as advantageous, offering accessibility and opportunities for relationship-building across diverse stakeholders. However, sustained engagement was viewed as contingent upon participants perceiving tangible benefits, whether in the form of resources, knowledge acquisition, or networking opportunities. DSGBA vCoP members are expected to experience enhanced collaboration,

knowledge-sharing, and networking opportunities, which will ultimately improve service delivery and professional development.

4. Summary

Gender-based violence remains a pressing global issue, persistently prevalent in Ireland. The Irish Zero Tolerance strategy underscores the necessity of an inter-agency approach to combat DSGBA. Effective knowledge management is important in this complex environment to facilitate seamless knowledge sharing among stakeholders. A review of the literature suggests that a vCoP holds the potential for knowledge translation among DSGBA professionals and agencies. By providing a platform for practitioners and academics to connect and collaborate without geographical, political, or financial barriers, the vCoP fosters interaction, discussion, mutual learning, and the application of research in real-world settings. This aids in bridging the gap between research and practice, fostering a collaborative environment conducive to interprofessional cooperation in combating DSGBA. However, building trust through online communities remains a significant challenge. In addition, the literature identifies research gaps, particularly in understanding knowledge translation dynamics within non-profit vCoP. An Action Research approach is used to establish a multi-agency DSGBA vCoP as a knowledge management system to address these gaps. This methodology, complemented by sentiment analysis techniques, aims to provide insights into knowledge translation processes within the vCoP. The outcomes may include the development of a framework for managing vCoP in multi-agency settings and contributions to understanding knowledge translation dynamics using NLP techniques.

Abstract: In 2020, the International Accounting Standards Board (IASB) published the Discussion Paper (DP)/2020/1 - *Business Combinations - Disclosures, Goodwill and Impairment*, to receive contributions on more useful disclosures about business combinations, bringing the issue of the subsequent measurement of goodwill back into the discussion. When analysing the comment letters from preparers by sector of activity, in some sectors (Automotive, Banking, Luxury Goods, Household Appliances, Energy and Technology) no preparer prefers the impairment-only model, which suggests that perhaps, in these industries, this model is not appropriate. Some respondents say that the pace of change in technology, customer preference, competition in the market and substitute products, among others, contribute to the loss of value of goodwill acquired over time and that it is systematically replaced by internally generated goodwill (D'Orey and Carvalho, 2023). This study aims to identify the main criticisms of goodwill accounting and to analyse the influence of the sector of activity and level of business digitalisation on the subsequent measurement of goodwill. To this end, semi-structured interviews were conducted with Portuguese preparers, auditors and financial analysts. The study makes it possible to compare the perception of Portuguese stakeholders on the subsequent measurement of goodwill and to understand whether the sector of activity and the level of digitalisation of the business influence the subsequent measurement of goodwill, a pioneering aspect in goodwill research. This study contributes to the debate on the subsequent measurement of goodwill, identifying new practical and conceptual arguments adjusted to current business models, highly influenced by digital transformation, in a legal context that is still very little explored, as is the case in Portugal.

Keywords: Goodwill; Impairment; Amortisation; Subsequent Measurement; Activity Sector; Digitalisation

1. Introduction

According to IFRS 3 - *Business Combinations*, goodwill represents the excess of the purchase price over the fair value of the identifiable net assets in a business combination. A company can generate goodwill internally or acquire it during a business combination. However, only the acquired goodwill is recognised in the acquirer's balance sheet and internally generated goodwill is not recognised as an asset.

The subsequent measurement of goodwill is a topic that has generated successive discussions over time, due to its complex nature and the important impact it has on financial statements and decision-making. In 2020, the IASB published DP/2020/1, to gather input on more useful disclosures about business combinations, bringing the controversial issue of impairment testing versus goodwill amortisation back into the discussion.

As mentioned by the IASB (2020a) in the DP, some of the stakeholders' concerns about goodwill relate to the fact that investors don't get enough information about acquisitions and their subsequent performance, and that goodwill impairment losses are recognised at low values and too late.

Therefore, this study aims to identify the main criticisms of goodwill accounting, based on semi-structured interviews with Portuguese experts, and to analyse whether the sectors of activity and the level of business digitalisation influence the subsequent measurement of goodwill, a pioneering aspect in goodwill research.

In order to contribute to the debate around the measurement of goodwill and to meet the IASB's call (IASB, 2020a) for new proposals and arguments on how to account for goodwill, we carried out this research through interviews, to obtain an overview of the perception of Portuguese stakeholders on the measurement of goodwill, thus allowing a more in-depth look at the subject under analysis.

The study is organised as follows. After this first section of the introduction, section 2 presents the theoretical basis of the research. Section 3 explains the methodology used to conduct and analyse the interviews. Section 4 presents and analyses the results of the interviews and section 5 presents the main conclusions of the study.

2. Background

2.1 Accounting for Goodwill

According to IFRS 3, companies must test goodwill for impairment annually, but stakeholders have differing opinions on the effectiveness of this test (D'Orey and Carvalho, 2023). In March 2024, the IASB published for public comment the Exposure Draft (ED) - *Business Combinations -Disclosures, Goodwill and Impairment*. The ED contains proposed amendments to IFRS 3 and IAS 36 - *Impairment of Assets*, suggesting improvements to the disclosure of information on company acquisitions.

Although some parties have suggested reintroducing the amortisation of goodwill (D'Orey and Carvalho, 2023), the IASB has chosen to maintain the impairment-only approach, as there is no clear evidence that amortisation would significantly improve the information provided to investors (IASB, 2020a). The IASB also tried to define a more effective impairment test but concluded there is no suitable and economically viable alternative to the current test. The new disclosure requirements are expected to provide investors with relevant information on the performance of acquisitions.

2.2 Literature Review

2.2.1 Main Criticisms of Goodwill Measurement

The main criticisms of the initial measurement of goodwill emphasise its subjectivity and potential manipulation by management, allowing its value to be overestimated (Hamberg et al., 2010; Li et al., 2017). Thus, the strategic allocation of the cost of an acquisition favours goodwill over other assets subject to depreciation (Bugeja and Loyeung, 2015; Zhang and Zhang, 2017). Linsmeier et al. (2020) identify three components of goodwill - expected synergies, going concern value and overpayment - the latter being associated with a greater risk of future impairment losses. Due to the heterogeneity of these components, it is difficult to apply a single appropriate treatment to all entities.

Goodwill impairment tests are complex and costly, favouring the untimely recognition of losses (Noland et al., 2013; Plotnikov and Plotnikova, 2019), which undermines investors' perception of companies' financial health (André et al., 2017; Ashmarina et al., 2020; Gray et al., 2016; Noland et al., 2013).

Timely recognition of goodwill impairment losses is crucial for the relevance of financial statements. However, the literature shows that the recognition of these losses is not timely, leading to inflated goodwill values (Bepari and Mollik, 2017; Li and Sloan, 2017; Pechlivanidis et al., 2022).

2.2.2 The Subsequent Measurement of Goodwill for Preparers, Auditors and Financial Analysts

Agency theory predicts that managers will use write-offs of unverifiable assets in financial reports to maximise advantages (Ramanna and Watts, 2012). Additional studies emphasise that cultural aspects affect the application of controversial accounting standards (André et al., 2016; Mazzi et al., 2017), with the Chief Financial Officer (CFO) and management being able to account for write-offs taking into account, not only financial and economic conditions, but also their individual, business and cultural interests and the characteristics of the external auditor (Ferramosca and Allegrini, 2021).

Thus, preparers tend to take advantage of the flexibility allowed in the subsequent measurement of goodwill, either to overestimate or anticipate a goodwill impairment loss or to increase results when they are close to the limit for avoiding impairment. Despite the importance of impairment tests to ensure the timely recognition of losses and accounting conservatism (Amiraslani et al., 2013; Roychowdhury and Martin, 2013), their application requires the use of estimates, assumptions and unverifiable cash flow projections, making

assessment by auditors and regulators difficult (Hayn and Hughes, 2006; Hilton and O'Brien, 2009; Li and Sloan, 2017; Ramanna and Watts, 2012). There are therefore auditors reporting that goodwill impairment losses are not always recorded, although it would be appropriate to do so (Saastamoinen et al., 2020).

The disclosure of the assumptions used in impairment tests also varies widely (Amiraslani et al., 2013). Consequently, the role of auditors in ensuring the objectivity and transparency of impairment tests is more pronounced, being one of the areas in which professional scepticism is most evident (Chambers and Finger, 2011), referenced in the inspection reports of the Public Company Accounting Oversight Board (PCAOB) as an audit deficiency (Ayres et al., 2019).

Given that goodwill impairment tests are comparable to a company's valuation, transparency in the respective disclosures is very useful to analysts, reducing the divergence between them and managers (Andreicovici et al., 2019). However, studies show that analysts tend to ignore goodwill and impairment losses in their valuation models and rarely use the information disclosed about goodwill to adjust their projections of future cash flows (Cascino et al., 2021; Durocher et al., 2022; Schatt et al., 2016). This is because the inconsistent application of IAS 36 and the generic nature of the associated disclosures does not result in quality information to assess the performance of each acquisition and verify whether the expected synergies have been achieved (Andreicovici et al., 2019; Durocher et al., 2022). There are, however, other analysts who use information on goodwill and impairment losses, despite being disappointed with the quality of those disclosures (Silvola et al., 2024).

2.2.3 Influence of Activity Sectors and Business Digitalisation on the Subsequent Measurement of Goodwill

Economic sectors with high growth and innovation rates can face unique challenges in assessing goodwill, due to rapid technological obsolescence and changing consumer preferences (Bugeja and Gallery, 2006; Gray et al., 2016; Plotnikov and Plotnikova, 2019).

Digital technologies have transformed industries (Dal Mas et al., 2020), introducing "Industry 4.0" or the "smart factory" (Lasi et al., 2014). Digital platforms have created a new "business ecosystem" (Presch et al., 2020), with digital infrastructures such as data analysis, cloud computing and 3D printing accelerating their expansion (Huang et al., 2017). The digital transformation has affected the creation, delivery and capture of value in almost every sector, giving rise to new business models such as frugal innovation and the circular economy (Vaska et al., 2021). The widespread use of digital technologies and the efficient use of information increase productivity, reduce costs and increase efficiency, generating a multiplier effect for economic development (Ullberg et al., 2021).

The subjectivity inherent in the measurement of goodwill often involves estimates and judgements, which can lead to significant variations in reported values between similar companies (Gray et al., 2016; Noland et al., 2013). This subjectivity is especially problematic in the current context, with the development of the digital economy offering the opportunity to expand the factors that influence the formation of goodwill (Tiesheva and Smyrnov, 2023). These authors demonstrate a lack of public understanding of digital goodwill, despite the evident paradigmatic changes in the formation of company value in the digital economy.

The digitalisation of business has a growing impact on goodwill through both digital transformation and the valuation of digital intangibles. Companies that invest significantly in technology and digitalisation tend to have higher goodwill values, reflecting expectations of future economic benefits derived from their digital capabilities (Plotnikov and Plotnikova, 2019; Yang et al., 2024). However, recognising digital intangible assets, such as software and online platforms, can complicate the measurement of goodwill, requiring new valuation and impairment methods (Ashmarina et al., 2020) to better reflect the value of digital assets (Tiesheva and Smyrnov, 2023).

3. Methodology and Sample

This study aims to identify the main criticisms of goodwill accounting and to analyse the influence of the sector of activity and the level of business digitalisation on the subsequent measurement of goodwill, from the perspective of different Portuguese stakeholders, a pioneering aspect in goodwill research.

To this end, the following research questions were defined:

1. What are stakeholders' perceptions of the subsequent measurement of goodwill and why?
2. Does the sector of activity influence the subsequent measurement of goodwill and why?
3. Does the level of business digitalisation influence the subsequent measurement of goodwill and why?

For this purpose, twelve individual semi-structured interviews (Ruslin et al., 2022) were carried out with Portuguese stakeholders who have extensive knowledge of goodwill in their respective areas of expertise, namely: four auditors from Big-4 and two auditors from large non-Big-4 audit firms; four preparers of IFRS financial statements (three from EURONEXT-LISBON listed companies and one from an unlisted company); and 2 financial analysts. The interview script was prepared based on the DP of the IASB and the literature review.

The interviews were conducted between 12/3/2024 and 23/5/2024, in person or online, and lasted a total of 1,170 minutes. All the interviews were recorded, with the prior authorisation of the interviewees, and then transcribed into a content analysis grid.

When selecting the individuals in the sample, it was considered a fundamental requirement that the interviewees had extensive professional experience in their current role, guaranteeing their mastery of the subject under study, which in itself is highly complex and subject to successive regulatory changes. The auditors interviewed (A1, A2, A3, A4, A5 and A6) are partners in their firms and have between 23 and 30 years of professional experience. The preparers (PA, PB, PC and PD) also have between 24 and 26 years of experience and are responsible for the financial reporting of companies with significant goodwill on their balance sheets. Finally, the financial analysts (AA and AB) have between 21 and 30 years of professional experience as credit analysts for large companies, working for two large Portuguese banks.

4. Analysis and Discussion of Results

4.1 Stakeholders' Perception of the Subsequent Measurement of Goodwill

4.1.1 Criticism of the Current Model for Subsequent Measurement of Goodwill

The preparers of the financial statements pointed out several criticisms of the current goodwill measurement model, based on impairment-only. According to the preparer PA, the subsequent measurement of goodwill involves complex judgements due to the difficulty of predicting the future of the business and frequent internal restructuring. PD emphasised the great speed of change, which makes it uncertain whether the objectives and synergies expected when acquiring a business will remain relevant over time. Impairment tests are considered to be highly subjective, making it difficult to assess cash-generating units, especially when businesses are integrated differently than initially anticipated (PC and PD).

Another criticism of the impairment-only model is that goodwill impairment losses are irreversible, which can lead to the late accounting of these losses in the hope of a future improvement in business performance. The preparers were unanimous in stating that goodwill impairment losses are not recorded in a timely manner, adding PB that the impairment-only model does not balance income and expenses in the same economic period.

The complexity of impairment tests and the sophistication of valuation models are highlighted by auditors, especially those in favour of amortisation, arguing that the tests are based on subjective future projections, susceptible to earnings management (A2, A3, A4, A6). Managers prefer impairment-only because of its discretion, while technical preparers prefer amortisation because it is less subjective, resulting in information asymmetries (A3).

The pessimistic or optimistic culture of management impacts the estimation of future cash flows, more than the discount rate itself. Optimistic managements tend to set ambitious budgets, while prudent managements prefer conservative forecasts, generating different results, particularly in sensitivity analyses and impairment tests for the same company (A2).

The definition of cash-generating units (CGUs) for allocating goodwill is also critical. Especially in fast-moving sectors, business changes can detach the goodwill initially attributed to a CGU from that unit's current products, even though it continues to generate profits (A2, A4).

The irreversibility of goodwill impairment losses is also criticised, because recognising a loss implies admitting recognising such losses, and their accounting is postponed, even though business synergies dissipate over time, not justifying the perpetuation of goodwill (A2, A4).

The auditors report that, in terms of disclosures, the tendency is to disclose as little as possible, with A4 stating, "*When we ask a listed company to increase its disclosures, they compare it to the benchmark. If other companies don't disclose, they don't either, especially when compared to Portuguese and European listed*

companies in the same sector." Auditor A2 emphasises: "*Increasing disclosures can exacerbate the problem, as unverifiable information can lead managers to provide inaccurate data, introducing more noise and compromising the reliability of financial information*."

The financial analysts interviewed, with experience in companies using the IFRS (impairment-only model) and Portuguese standards (amortisation of goodwill), have different opinions on the importance of goodwill. For AB, the importance depends on the weight of goodwill in the entity's equity, while for AA it depends on the weight of goodwill in the company's total assets, equity and financial autonomy.

Analysts tend to exclude goodwill from their analyses because they consider it to be an asset of questionable realisation. According to AB, the exclusion is made to assess the company's ability to meet its obligations assuming no realisation of goodwill. AA, on the other hand, analyses operating flows before depreciation to avoid distortions and tests extreme scenarios, such as the total exclusion of goodwill, to understand the impact in adverse situations.

Both analysts criticised the insufficient disclosures in the impairment-only model. AB pointed out the lack of clarity and indicators in the information disclosed and highlighted the manipulation and delays in recording impairment losses. For AA, the accounting of impairment losses reflects flaws in the projections, suggesting unexpected events that require investigation.

4.1.2 Preference for the Subsequent Goodwill Measurement Model

Financial preparers and auditors have varying opinions on the subsequent measurement model for goodwill, with criticism of the impairment-only model and diverse preferences for amortisation followed by impairment testing.

Three preparers (PA, PB, PD) prefer the amortisation model, followed by impairment tests, when necessary, while another (PC) prefers the impairment-only model. PB, in favour of amortisation, argues that the goodwill initially recorded may no longer reflect reality due to market changes, but the tendency is to delay recognition of impairment, so he is always wary of high goodwill values on the balance sheet.

PC, on the other hand, defends impairment-only, stating that this model reflects the market valuation of the business, unlike amortisation, which distances the group's book value from its market valuation. Therefore, managers look at the market price to determine the need to recognise impairment.

PA and PD support amortisation because it allows for a balance between income and expenses, making it easier to match the return obtained with the amortisation of the amount overpaid and avoiding the perpetuation of goodwill. For PA, even in successful businesses, after 20 years goodwill no longer makes sense as an asset.

Among the auditors, three (A2, A3, A4) prefer amortisation followed by impairment tests, two (A1, A5) prefer the impairment-only model and one (A6) suggests that it should be a choice of accounting policy. Proponents of impairment-only consider this model to be conceptually more robust, adequately capturing the initial value and eventual loss of goodwill, and that goodwill can increase in value. They also criticise the arbitrary definition of the useful life in the amortisation model.

The auditors in favour of amortisation (A2, A4) believe that this model is more appropriate, as the useful life of goodwill can be defined based on an economic rationale captured during the PPA, or by the expected period of realisation of the synergies acquired. They suggest that amortisation should reflect the expectation of future profits, unlike impairment-only, where internally generated goodwill can protect acquired goodwill against impairment. A4 disagrees with setting a maximum period for amortisation but points out that it is unlikely to last more than 10 years.

A6, which defends the choice of accounting policy, suggests keeping the impairment-only model with more disclosures and considering amortisation as an alternative method. It considers impairment an event and amortisation a fact based on expectations and argues that goodwill should be removed from the balance sheet through impairment losses or amortisation.

The financial analysts interviewed did not express a specific preference as to the subsequent measurement model for goodwill, emphasising the importance of having access to the client's calculations and assumptions in order to carry out an accurate assessment of goodwill.

4.2 Influence of the Sector of Activity on the Subsequent Measurement of Goodwill

When asked about the influence of the sector of activity on the subsequent measurement of goodwill, the preparer PA mentioned that a different measurement model may make sense for specific cases, such as concessions with a defined useful life. PB pointed out that technological business models, which change rapidly, may need a different approach compared to more traditional and stable businesses. PD believes that comparability would be compromised if there were more than one measurement model, although he recognises that the characteristics of the activity sector should influence the definition of the useful life of goodwill. Thus, sectors that become obsolete quickly and need constant innovation should assign shorter useful lives to goodwill.

Auditor A4 pointed out that there are sectors of activity in which the speed with which they evolve and change can make it more difficult to carry out impairment tests. He compared sectors such as paper, which change little, with sectors such as telecommunications, which evolve rapidly. As A1 points out, these changes "*affect the ability to maintain the business with the original assumptions of profitability and synergies*".

Despite A3's preference for amortisation in traditional business models, he finds no theoretical justification for there being separate models by sector, not least because the large groups are multi-sectoral.

Interviewee A6 takes the opposite view, arguing that in certain more technological sectors, the existence of a single model for the subsequent measurement of goodwill seems misaligned with the number of existing business models, not least because "*there are activity sectors that are more exposed to technological disruption, market discontinuity and consumer and generational preferences*".

As for financial analysts, AA emphasised the importance of understanding the type of activity of the entity in order to measure goodwill. For AB, the financial analysis is carried out regardless the sector, always considering the different goodwill measurement models used between companies and competitors, to avoid bias in the analysis.

4.3 Influence of the Level of Business Digitalisation on the Subsequent Measurement of Goodwill

When asked about the influence of the business digitalisation level on the subsequent measurement of goodwill, the PA preparer pointed out that the speed and dynamics of change in businesses make long-term projections difficult, with five-year plans being replaced by three-year plans and rolling forecasts. PC emphasised that in more digital businesses with fewer physical assets, it can be more difficult to separate goodwill from other intangible assets.

With increasing digitalisation and the reduction in the useful life of business models, the preparers agree that goodwill tends to lose value more quickly, underlining PA that rapid change in business increases subjectivity and uncertainty in financial projections, and PD that the speed of change in digital businesses can shorten the useful life attributed to acquisitions in these sectors.

New customer habits and behaviours also influence how goodwill is consumed or integrated into the business. PB emphasised that in technological areas, products and services evolve over time, increasing the value and substance of the original goodwill with internally generated goodwill. Hence his preference for the amortisation model, as it assigns a cost to each financial year, like companies that grow organically and cannot recognise internally generated goodwill.

From the auditors' perspective, most digital businesses change rapidly, increasing the complexity of the subsequent measurement of goodwill. A1 and A5 considered that, in technology businesses, there are business models based on employees and others on organisational platforms and processes, with different expectations of identifiable assets. A4 emphasised that in sectors intensive in technological innovation, it is difficult to sustain the impairment test, since "*it is complicated to say that the goodwill you are testing today is the same 5 years later.*"

Auditors in favour of the amortisation model also consider that new customer habits influence how goodwill loses value. A2 emphasised that rapid change reduces the life cycle of goodwill, reinforcing the need for amortisation. A3 argues that non-amortisation presupposes non-existent perpetuity in businesses, which change completely in five years. A4 also emphasised that technological innovations, such as artificial intelligence, change business models, making it difficult to apply traditional impairment tests and to separate acquired and internally generated goodwill.

Financial analysts also admit the impact of digitalisation on financial analyses, highlighting the need for tangible guarantees in banking. They believe that banks need to project pessimistic scenarios and that the intangible assets of digital businesses are insufficient as guarantees because they don't create liquidity quickly. AB also emphasised that the rapid change in customer habits could lead to goodwill acquired years ago being replaced by new goodwill.

5. Final Considerations

The debate on the subsequent measurement of goodwill, which is clear from the analysis of the interviews, reveals significant criticism of both models (amortisation versus impairment tests). Common concerns include subjectivity, complexity and the impact on the comparability of financial statements.

As most of the preparers and auditors interviewed pointed out, goodwill is more related to the future than to the company's history and is a subjective judgement and difficult to predict. It is therefore essential to assess the quality of the business project, the management team, the market in which the company operates and macroeconomic factors because the future is being audited.

Some auditors consider that, conceptually, the impairment-only model is perfect, but in practice it is very difficult to apply due to the great inherent subjectivity in the projection of future cash flows resulting from management estimates and associated assumptions, internal reorganisations and reallocations of goodwill, as well as the fact that acquired goodwill is being protected against impairment due to internally generated goodwill.

Therefore, both measurement models have pros and cons for the interviewees. While the amortisation model has the advantages of simplicity of application and predictability, determining the useful life can be challenging and provide useful information insofar as it manages to capture the period of realisation of the synergies expected from the concentration. Advocates of the impairment model consider that it provides a more accurate reflection of a company's economic condition, despite its inherent subjectivity and potential for earnings management. These perceptions highlight the need for a balanced approach that addresses the shortcomings and virtues of both models in order to improve the reliability and comparability of financial reports.

The nature of this asset is closely linked to what the business is and what it is, or was, intended, to achieve with that acquisition. So, the influence of the activity sector and level of business digitalisation on the subsequent measurement of goodwill is also highlighted. Technology sectors and more digital businesses, with rapid changes and shorter useful lives of business models, present additional challenges for the measurement of goodwill. Growing digitalisation and new customer habits increase subjectivity and uncertainty in financial projections, suggesting the need for measurement models that reflect the dynamic reality of these sectors.

In short, the subsequent measurement of goodwill continues to be a debated topic, with different needs depending on the sector of activity and the level of business digitalisation. The search for a model that balances subjectivity and objectivity, and that offers transparency and reliability in financial information, remains a central challenge for the stakeholders involved.

The main limitation of this study is that the data was collected through interviews, which means that the results cannot be extrapolated. However, the results of this study could serve as a basis for future research, namely, to carry out a questionnaire aimed at a wider sample of stakeholders. Extending the research to include stakeholders from different countries could provide a global perspective and allow for international comparisons of goodwill measurement practices.

Acknowledgements

We would like to thank all the interviewees for generously sharing their knowledge, gained over several years of intense professional experience, without which this study would not have been possible.

Knowledge Graphs in Information Retrieval

Jakub Dutkiewicz and Czesław Jędrzejek
Poznań University of Technology, Poznań, Poland

jakub.dutkiewicz@put.poznan.pl
czeslaw.jedrzejek@put.poznan.pl

Abstract: This paper introduces an information retrieval model that leverages knowledge graphs, specifically tailored for Clinical Trials. In these scenarios, the document in question takes the form of a semi-structured clinical trial, containing details about enrolled patients, descriptions of experiments and procedures conducted during the trial, relevant diseases, and specific enrollment criteria. While the document retains a semi-structured format, the majority of the information is expressed in natural language. Queries in this context consist of specific patient characteristics, such as disease type, genetic information, and demographic data. The primary aim of this paper is to develop and utilize a knowledge graph capable of storing this information, including links to external resources like the Disease Ontology. We propose an Object-Relational model, which is then transformed into a knowledge graph. This graph is subsequently employed to identify semantic connections between concepts present in the clinical trials and those in the queries. These connections are then utilized to formulate a retrieval model for each aspect of the query. To achieve this, we design a relevance formula that incorporates weights to account for ontological relationships between concepts. We evaluate the effectiveness of our model by comparing the results with manual annotations.

Keywords: Knowledge Extraction, Knowledge Modeling, TREC Clinical Trials Track

1. Introduction

Information Retrieval(IR) deals with searching and evaluating information from document repositories. Given a set of documents and a list of queries, the task is to return a list of documents sorted by the relevance of each document to the given query. TREC-PM (Roberts, et. Al 2017, 2020) was (and is in a TREC-CT version) a biomedical track, which evaluates the systems performing the IR tasks on a specific set of documents (clinical trials) and queries called topics. The TREC PM in 2017-2018 in total and partially in 2019 was dedicated to oncology related topics. The set of clinical trials originates from clinicaltrials.gov. In this paper we use the snapshot which was used in the The relative narrowness of content facilitates a use of a knowledge based model. The organizers of the TREC-PM track provide a manual, along with a meticulously crafted set of annotations, and an outline to guide annotators. In this paper, our goal is to automate this process. Specifically, we aim to automatically identify relevant entities within both clinical trials and the topics. We propose that carefully chosen relevant links can serve as the foundation for an exceptionally accurate Clinical Trial retrieval system. This paper presents a detailed description of our Knowledge Graph model, along with the publication of the generated graph. Additionally, we provide a code repository containing key components of the implementation, including the object-relational model of the data, a set of functions for populating the database, and functions for generating the knowledge graph. We utilize the data stored within the database in order to find entity links to external Disease Ontology as well as to our hand-crafted set of data. This indirectly enhances the information retrieval quality. We also provide an ad-hoc retrieval model, which utilizes the entity links.

2. Related Work

The concept of employing knowledge graphs in Information Retrieval is succinctly outlined in a survey (Reinanda et al, 2020). Specifically, the notion of directly utilizing knowledge graphs for Document Retrieval is expounded upon in section 4.1. Our perspective resonates with the authors of the survey, who assert that effectively leveraging entity annotations and text in tandem to enhance ad-hoc document retrieval remains a challenge yet to be fully addressed. This challenge serves as a primary motivation for our research endeavors. Within the survey, the authors cite two papers that exemplify the utilization of knowledge graphs in this particular task. Both papers make use of the Knowledge Graphs for query expansion. Authors of the first paper mentioned in the survey (Dalton et el, 2014) introduce the idea of knowledge base links to the Information Retrieval model. We expand on the idea by employing only a specific subset of the knowledge base entities, which corresponds to the query domain. We also make use of dedicated external knowledge sources, such as the Disease Ontology (Schmirl et al, 2018). In our research queries are structured, hence specific parts of the query are linked to various external knowledge sources - mentions in a field dedicated for diseases are linked to the disease entities, mentions in a gene field are linked to the gene entities. Second paper mentioned in the survey (Xiong and Callan, 2015) exploits entity links in the process of query expansion. The terms in the query are linked to various

Freebase entities. Each linked entity is a basis for a query expansion. The expansion is done via a general Freebase description of an entity. This approach is different to ours as it doesn't exploit entity linking in the documents.

Information retrieval techniques are frequently employed in knowledge management (Rezgui, 2006). This is due to the connection between natural language and knowledge models—concepts are articulated using specific phrases that are part of both the knowledge model vocabularies and natural language. Ontology serves as a fundamental formal mechanism to link concepts from knowledge models to their natural language expressions. (Munir and Anjum, 2018) discuss effective methods for retrieving information from a formal ontology. However, this approach has limitations, as converting extensive natural language resources into a formal framework requires highly complex and detailed algorithms. A successful attempt at creating a Clinical Trials Knowledge Base (CTKB) for clinical trials resources was undertaken by (Chen, 2020). This work uses data provided by publicly available Aggregate Content of Clinical Trials (AACT) and focuses on the full description of each clinical trial. (Jayaram et al., 2015) propose an approach for querying the knowledge model. By analyzing their work, one can clearly deduce that information retrieval engineering should focus on key, elementary concepts, rather than graph nodes with extensive textual information. Consequently, we propose a cost-effective approach that incorporates the key low-level concepts into the model. In our work, the documents are interpreted as knowledge model entities. We make use of the natural language descriptions within Clinical Trials and link the documents to existing concepts in external ontologies. The knowledge graph in this work focuses on all aspects of the document retrieval process: documents (clinical trials), document entity links, queries (topics) and query entity links. (Otegi et al., 2015) propose an alternative approach, using concept relatedness for information retrieval. Unlike our method, they employ ad-hoc query expansion, linking documents to external resources each time a search is performed. We believe it is more effective to index all relevant concepts before the information retrieval process. In our opinion, a knowledge model-based approach allows for the creation of an environment where AI methods can be utilized in an explainable manner (Pascal et al., 2020).

3. Object-Relational Representation of a Clinical Trial

The dataset utilized for this research comprises a snapshot of clinical trials sourced from clinicaltrials.gov. We use the particular snapshots of the data, used by the human annotators. In this research, the trials were initially converted into an Object-Relational model using a dedicated Django application. This model comprises 21 object-oriented classes put into 25 relations. In addition to clinical trials, the model encompasses TREC PM topics, Entity Links to external ontologies, and hand-crafted resources such as lists of drugs and genes. These resources provide sufficient terminology to construct a T-Box ontology tailored specifically for this subset of clinical trials and queries.

Let's explore the primary sections of the model. The ***clinicaltrial*** relation is intended for storing data related to Clinical Trial documents. Clinical Trials may include various additional fields, such as lists of ***keywords***, ***conditions***, or ***outcomes*** they are associated with. The ***entity*** relation includes links to external ontologies, particularly the Disease Ontology. The ***gene*** and ***drug*** relations are designed to house hand-crafted data concerning drugs and genes relevant to TREC topics. Entities, drugs, and genes are linked to clinical trials through three connecting relations: ***entitylink***, ***druglink***, and ***genelink***. These relations establish associations between specific entities, drugs, or genes and the respective clinical trials in which they are referenced or utilized. Information regarding Information Retrieval queries is stored within the ***topic*** relation. Each instance of a ***rating*** relation pertains to a specific topic and a Clinical Trial. Details regarding matching genes and diseases (and indirectly drugs) are stored within the ***conditionannotation*** and ***geneannotation*** relations. These relations contain data on the associations between conditions, genes, and diseases referenced within the clinical trials and mentioned in a given topic.

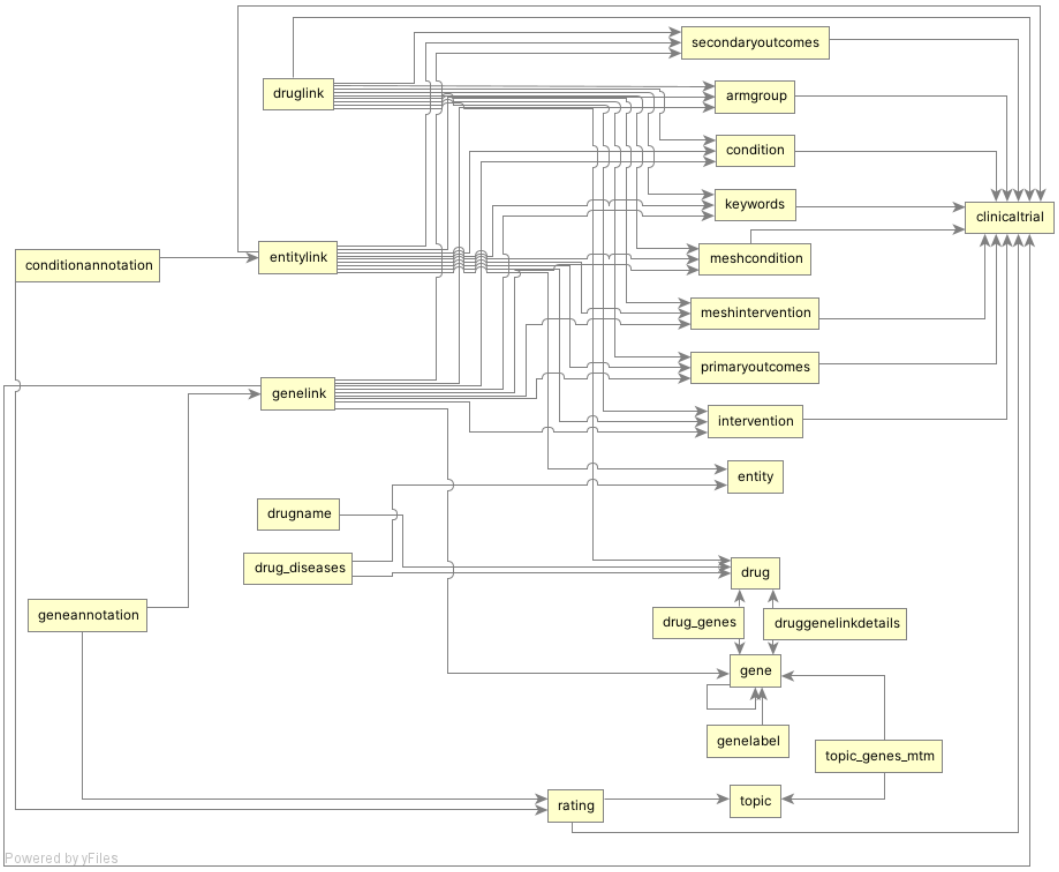

Figure 1: Relational model of the data.

4. Knowledge Model for a Clinical Trial

In this section, we examine different components of the Knowledge Model. We specifically address various **entities** and the *relationships* that exist between them. We propose a simple model for describing a clinical trial, where each document within the database is instantiated as an example of this class. Similarly, we outline a model for topic description. The connection between Clinical Trials and Topics is established through links to external resources or a manually curated vocabulary.

4.1 Clinical Trial Model

The focal points of the graph are the **Clinical Trial Documents**. Each document consists of a set of fields of a **Clinical Trial Document Part** type. As this is a knowledge graph, the vast majority of the data is stored as the individuals. Each individual consists of a set Data Properties, for which every **Clinical Trial** has exactly one value. The **Clinical Trial** model is depicted in Fig. 2 and Fig. 3. The first figure illustrates all of the Clinical Trial document properties. A model of **Clinical Trial Document Parts** in the second figure is depicted on the latter figure. Such parts are modeled as Object Properties, this is due to the fact the documents can be related to more than one such part. The second figure illustrates only two document part types, however in fact the graph incorporates Mesh Terms, descriptions of the Arm Groups, Keywords, Interventions and Outcomes in a similar manner. The data we used to create a graph consists of 18883 unique clinical trials.

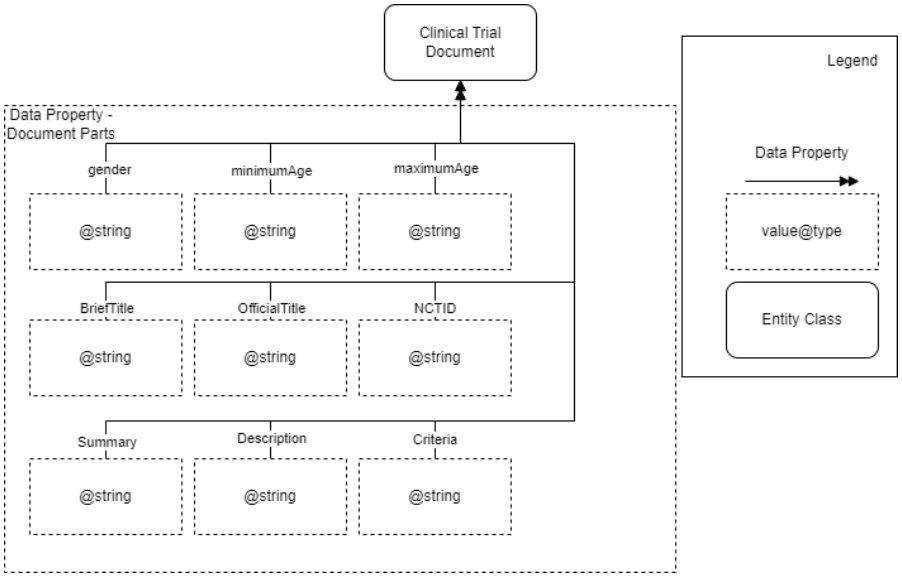

Figure 2: The clinical trial model with a list of document parts, which appear only once in the trial.

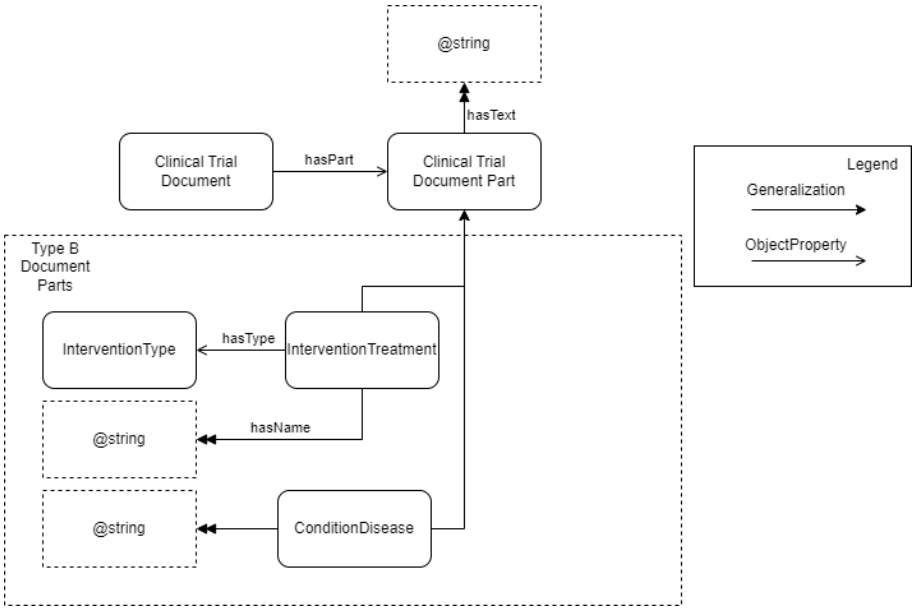

Figure 3: The clinical trial model with sample document parts, which can appear more than once in the trial.

4.2 External Terminology

This research encompasses three types of external terminology: a collection of phrases utilized to represent Disease, Drug, and Gene concepts. It's important to note that frequently, existing ontological resources prioritize proper topology and relational properties of the described classes, while overlooking the aspect of a rich and extensive vocabulary. This oversight is particularly crucial in Entity Linking, and indirectly affects Information Retrieval when utilizing such resources.

For disease-related vocabulary, we rely on Disease Ontology. This standardized ontology offers consistent, reusable, and sustainable descriptions of human diseases. Considered a core ontology, it features external links to many popular resources such as MeSH, ICD, NCI's thesaurus, SNOMED, and OMIM. We extensively utilize the *label* and *hasExactSynonym* annotation properties to model the vocabulary knowledge of concepts. Efforts are made to manually expand this knowledge to accommodate the language used in clinical trials for referring to disease concepts. The concepts described in the Disease Ontology are integrated into our model using the *entityLink* object property. This property has a domain of Clinical Trial Documents and Clinical Trial Document Parts, and a range of the flat Entity class, essentially serving as a reference to the Disease Ontology. While this relation may seem somewhat redundant as the link could directly refer to an external class, it proves convenient

in practical applications where we utilize only a portion of the external resource. The Entity class functions as a hyper reference, facilitating streamlined access to relevant disease-related concepts within our model depicted on Fig. 3.

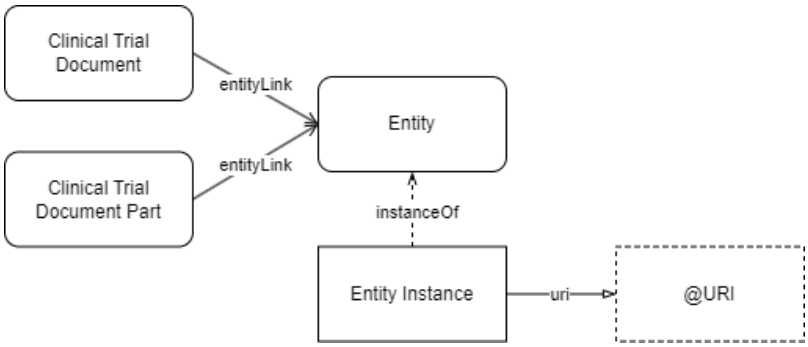

Figure 3: Entity Linking Knowledge Model

The vocabulary for **Gene** and **Drug** entities is hand-crafted. Both genes and drugs are stored in the ontological T-Box. The information stored in the Knowledge Model does not refer to specific instances of neither Drugs nor Genes. **Clinical Trials Documents** relate to the concepts via **GeneLinks** and **DrugLinks**. The model for hand-crafted vocabulary is presented on Fig. 4.

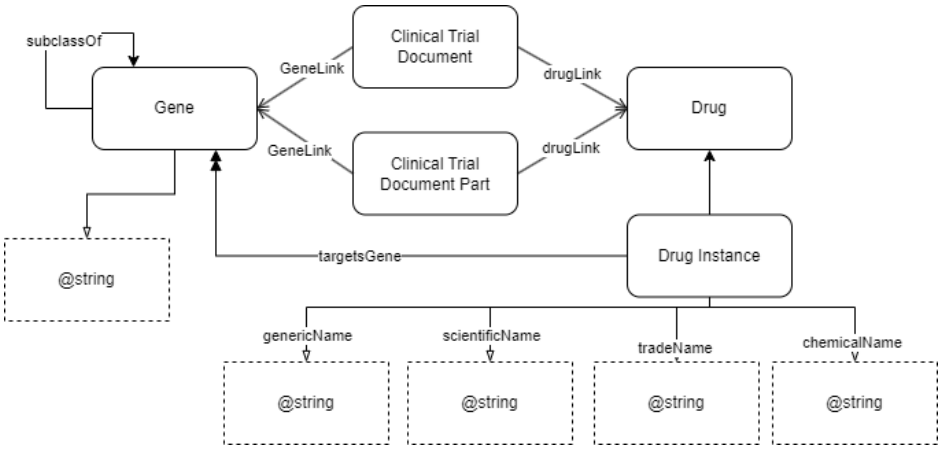

Figure 4: Gene and Drug Knowledge Model

4.3 Topic and Rating Model

In the knowledge graph, each TREC **Topic** is associated with a single disease, a list of genes, patients' demographics, and a single textual field for more information. Each **Topic** is linked via EntityLink with a **CrossReferenceEntity** and via a **GeneLink** with a set of Gene entities. The demographic description and the additional information are stored as a Data Properties. This structure facilitates efficient organization and retrieval of information related to TREC topics within the knowledge graph.

Rating encompasses information about the relevance between a given **Topic** and a **Clinical Trial Document**. There are two versions of the relevance assessments, the one delivered by TREC organizers and one calculated with use of this knowledge model. The fifth section of this work covers the details on obtaining the relevance score.

5. Using the Graph in Information Retrieval

In this section we describe the processes of using the Knowledge Graph for direct information retrieval. We provide description of annotation process, which we want to recreate.

5.1 TREC Annotation Guidelines

We implement our retrieval system according to the guidelines for annotators provided by the TREC organizers. There are several steps in the annotation process. The first step is ought to determine whether the clinical trial

is related to precision medicine. Here the organizers provide a list of steps, which after detailed evaluation seems vague. Document is related to Precision Medicine if: it is related to humans, involves any form of cancer, focuses on treatment or prognosis of cancer and contains any mention of a genes from the relevant topic. This seems not obvious as the PM property, in our eyes should not be decided in correlation with the formulated query. On top of that we find some annotations, which deem the documents as related to the Precision Medicine and annotate all of the genes as missing. We assume that this intermediate step should not be interpreted very directly, as it uses specific vocabulary – mention of a gene could not be interpreted as a relation to any given gene. In fact, we refrain from its complete evaluation. We intend to work on this step of the evaluation, as it is particularly important for the total evaluation. In this stead we focus on the analysis of clinical trial treatment type.

If a document passes the first phase – is annotated as relevant to precision medicine – it enters the second phase. In the second phase annotator is supposed to determine whether the document is relevant to a given query. It comes in three parts: determining appropriate category for a Disease part of a query (Exact, More General, More Specific and Not Disease), appropriate category for a Gene part of a query (Exact, Missing Variant, Different Variant, Missing Gene) and assessing the score for demographic criteria. We assume that the patient described in the query should be eligible for the trial, as it is expressed in eligibility criteria.

5.2 Treatment Evaluation

The first item in the TREC guidelines underscores the importance of documents in the field of precision medicine. This requirement prompts an analysis of the treatment type, which constitutes the focal point of the clinical trial.

Definition of “treatment” in TREC PM/clinical trials is the most difficult among the clinical trials’ concepts. In the wide sense “treatment” encompasses: diagnosis, treatment, and prevention. In general, Screening tests are not “treatment”, because they are primarily used for early detection of disease or risk factors whereas diagnostic tests are used to establish the presence or absence of disease. Medical “treatment” should be differentiated from clinical research.

Clinical research is characterized by (*Clinical Research Versus Medical Treatment*, access 2024):

1. Generally designed and intended to benefit future patients.
2. Involves periodic and systematic assessment of patient data.
3. Tests products and procedures of unproven benefit to the patient.

Medical “treatment” is characterized by:

1. Generally designed and intended to benefit future patients.
2. Address the needs of individual patients.
3. Intended to benefit the individual patient.
4. Requires real-time decisions.
5. Based on as-needed patient assessment.

This analysis encompasses the following fields within a clinical trial: **Intervention/Treatment** and **Study Type**. A single **Clinical Trial** document has one **Study Type**. This is represented with *hasStudyTypeAssignment* object property. **Clinical Trial** is capable of encompassing several **Intervention/Treatment** fields. There are four distinct **Study Types:** Interventional, Observational, Expanded Access and Observational (Patient Registry). The knowledge model for the study types is represented on Fig. 5. The knowledge model is implemented with the owlready2 library, which does not support class punning, which would be very useful in this case. We use a similar model, in which we create a single instance for each of the study type classes, which represents the respective class.

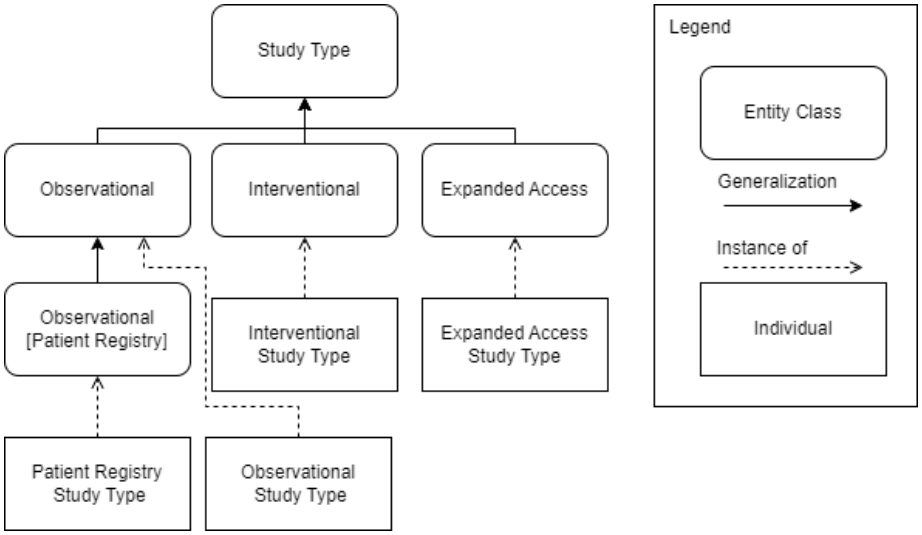

Figure 5: Study Type knowledge model

The **Intervention/Treatment** field comprises two sections: a type and a description. Here we analyze a set of types. There are a total of 8 distinct Intervention/Treatment types: Drug, Procedure, Other, Biological, Behavioral, Genetic, Radiation, Device.

The scoring depends on what weight we ascribe to each of the treatment types> If a Drug name appears in a document (alone or with other types) the score has value 1. For observational study type the score is 0.

For 2017-2019 years (2019 only cancer related topics) the total number of evaluated document is 41444 (15481 labeled by TREC as Human PM, and 25963 Not PM). We can directly compare TREC Human PM cases with our score.

When each of the 8 distinct Intervention/Treatment types: Drug, Procedure, Other, Biological, Behavioral, Genetic, Radiation, Device is equal 0 (corresponding to non-intervention types, mostly observational we get 1255 cases (1144 cases for only observational type). There are 2218 cases where a Drug is absent but there might be other non-zero types. Using our method we get 1615 non-treatment cases for TREC Human PM. This amounts to a 10.4% discrepancy with TREC in the treatment Human PM category. For the Not PM category the direct comparison with TREC is not possible (because a possible cause: disease, gene, treatment and demography are not separated). This will be the goal of future analysis.

5.3 Demography Evaluation

Demographic evaluation follows a straightforward process. Both TREC topics and clinical trials adhere to standardized demographic information. In TREC topics, demographic information is represented using a specific format: NN-TIMEUNIT-years-old gender. Here, NN denotes the numerical quantity of the age property, while TIMEUNIT indicates the unit of time used. To manage this format, we utilize a regular expression interpreter. If the TIMEUNIT is anything other than "year," we interpret the specified age as zero. The TREC topics cover only two genders: male and female.

Each Clinical Trial includes properties such as minimum age, maximum age, and gender, represented as text strings following a standardized format. If any of these properties are unspecified, we assume that every patient meets the relevant demographic criteria. The outcome of the evaluation is binary. If a particular topic describes a patient who does not fall within the specified criteria range outlined in the trial, the trial is considered irrelevant to that topic. Conversely, if the patient described in the topic fits within the specified criteria range, the demography criterion is deemed fulfilled. Table 1 presents the agreement between our system and human annotators on the Demography assessment.

Table 1: Annotation agreement between human TREC annotators and our automated system on the demography assesment.

Annotation\Demography score	0	1
Excludes	371	370
Not Discussed	21	651
Matches	67	8 319

5.4 Disease and Gene Evaluation

Another aspect of the relevance between a given query and a clinical trial is assessed by considering the number of relevant entity links. Each topic is associated with a single assigned entity from the Disease Ontology and can have up to three Gene links.

In the Clinical Trial, various entity links are present: disease links, gene links, and drug links. Each link is annotated with the part of the document it originates from. We posit that a higher number of links in a document, which either match the topic's disease link, match one of the topic's gene links, or are drug links for drugs targeting one of the genes within the topic, indicate greater relevance between the topic and the document. Conversely, we hypothesize that links within the document that do not match the topic links may lower the relevance score.

We also consider the source of the links within the document. Links originating in the title (or in the condition/disease field for diseases) of the clinical trial are deemed more important than those from other parts of the document. Additionally, we utilize the taxonomic properties of the ontology. Diseases found in the trial that are more specific than the one mentioned in the title are considered fully relevant. Conversely, diseases that are more general are treated as partially relevant and contribute to the total score with partial impact. If there are any disease links in the title of the document, the disease part of the relevance score is calculated as follows:

$$rel_{disease} = \frac{\#disease_{rel,title} + \#disease_{rel,condition} + 0.5\#disease_{part-rel,title} + 0.5\#disease_{part-rel,condition}}{\#disease_{rel,title} + \#disease_{rel,condition} + \#disease_{part-rel,title} + \#disease_{part-rel,condition} + \#disease_{non-rel,title} + \#disease_{non-rel,condition}}$$

If there are no diseases mentioned in the title, we rely on other parts of the document. In this scenario, we operate under the assumption that if the ratio between relevant and non-relevant diseases appearing in the same document is sufficiently high, the document is relevant. Therefore, the relevance score should be adjusted using a non-linear, sigmoid-shaped function:

$$rel_{disease} = \sigma(w_0 \cdot \frac{w_1 \cdot \#disease_{rel,other} + w_2 \cdot \#disease_{part-rel,other}}{1 + w_3 \cdot \#disease_{non-rel,other}} - b)$$

The parameters are selected manually after investigating the shape of the relevance function with synthetic data. Empirically assigned values are as follows: w0=3, w1=1, w2=0.5, w3=1, b=3. Moreover, the gene relevance score incorporates information on the number of relevant drugs mentioned in the document. However, it's important to note that genes are not searched in the condition field. The coefficient d represents the number of mentioned relevant drugs in the entire clinical trial:

$$rel_{gene} = \sqrt[d+1]{\frac{\#gene_{rel,title} + 0.5\#gene_{part-rel,title}}{\#gene_{rel,title} + \#gene_{part-rel,title} + \#gene_{non-rel,title}}}$$

Similarly, if there are no genes in the title, the gene score is given by:

$$rel_{gene} = \sqrt[d+1]{\sigma(w_0 \cdot \frac{w_1 \cdot \#gene_{rel,other} + w_2 \cdot \#gene_{part-rel,other}}{1 + w_3 \cdot \#gene_{non-rel,other}} - b)}$$

We use the same parameter values as for the disease score.To complete the relevance assessment between a document and a topic, we need to implement a total score, which should be calculated as the multiplication of the component relevances.

Table 2: Annotation agreement between human TREC annotators and our automated system on the disease assesment.

Annotation\Disease Score	0.25 > Score	0.25 <= Score < 0.5	0.5 <= Score < 0.75	Score >= 0.75
Not Disease	5 025	57	60	44
More General	2 271	250	273	156
More Specific	236	129	260	1 969
Exact	450	272	646	3 364

Table 3: Annotation agreement between human TREC annotators and our automated system on the gene assesment.

Annotation\Gene Score	0.25 > Score	0.25 <= Score < 0.5	0.5 <= Score < 0.75	Score >= 0.75
Missing Gene	5838	289	123	132
Different Variant	329	143	126	537
Missing Variant	1 336	341	400	710
Exact	1 882	734	834	1 949

6. Conclusions

In this work, we combine a knowledge graph-based approach with information retrieval for clinical trial documents. We make this knowledge graph publicly available, along with the object-relational model and graph creation code (https://github.com/dudenzz/ClinicalTrialsKGBasedIR). For convenience, we also publish a database filled with data. We compare our results with TREC annotations for individual concepts within the Human PM category. In contrast to (Otegi et al. 2015), who use concept relatedness and ad-hoc query expansion for information retrieval, we advocate for indexing relevant concepts prior to retrieval, believing this to be a more efficient approach. Additionally, our strategy supports the creation of an environment where AI methods can be employed in an explainable manner, a perspective also shared by Jayaram et al. (2015), who emphasize focusing on key, elementary concepts over graph nodes with extensive textual information. Our incorporates these key concepts into the model. In this work, we compare the outputs of our automated retrieval system, which is based on the knowledge graph, with hand-crafted annotations. We have shown that such a system can implement simple retrieval models. The proposed models appear to partially align with annotators' assessments; however, we refrain from a comparative analysis of retrieval quality at this point. Our major concern, which we leave to future work, is the formal and strict definition of a non-PM clinical trial. We aim to address this issue so we can ultimately compute and evaluate final relevance scores.

Exploring Perceptions of Benefits and Challenges Associated with Cryptocurrencies: A Demographic Analysis among University Students in Poland

Monika Eisenbardt[1] and Tomasz Eisenbardt[2]
[1]University of Economics in Katowice, Poland
[2]University of Warsaw, Poland

monika.eisenbardt@ue.katowice.pl
teisenbardt@wz.uw.edu.pl

Abstract: This study investigates the differences in perceptions of benefits and challenges associated with cryptocurrencies among diverse demographic cohorts. We focus on gender, field of study, and prior experience as key demographic factors influencing perceptions. Data were collected from 679 university students in Poland using a survey questionnaire. The findings reveal disparities in perceptions based on gender, with males perceiving more benefits and females encountering more challenges. Additionally, regardless of academic background, students tend to perceive the benefits and challenges similarly. Moreover, prior experience with cryptocurrencies significantly influences perceptions, with experienced students perceiving more benefits and fewer challenges compared to their inexperienced counterparts. Our study contributes to the literature by highlighting the importance of considering personal characteristics in understanding perceptions of cryptocurrencies and provides insights for policymakers, regulators, and industry stakeholders to develop targeted strategies for addressing concerns, enhancing adoption, and mitigating risks associated with cryptocurrencies.

Keywords: Cryptocurrencies Perception, Students Opinion, Gender Differences, Field of Study-Related Differences, Prior Experience.

1. Introduction

Numerous studies have delved into cryptocurrencies, often emphasizing economic aspects such as national regulations, taxation, and monetary policies (Benigno et al., 2022; Marthinsen and Gordon, 2022; Raza et al., 2023). While some researchers concentrate on domestic approaches, their focus tends to be primarily economic (Alvarez et al., 2022; Cifuentes, 2019; Li et al., 2023). Many papers center solely on Bitcoin, given its widespread recognition (Alvarez et al., 2022; Köchling et al., 2020; Mzoughi et al., 2022; Nouir and Hamida, 2023). In contrast, our paper adopts an interdisciplinary perspective, treating cryptocurrencies as a multifaceted phenomenon beyond mere economics.

This paper seeks to address a significant research gap by examining how personal characteristics influence the perception of benefits and challenges associated with cryptocurrencies. While numerous studies have delved into various aspects of cryptocurrencies, including economic factors and regulatory frameworks, few have systematically investigated the role of personal characteristics in shaping individuals' opinions and perspectives on cryptocurrencies. Existing literature predominantly focuses on gender-related issues (Jora and Nandal, 2020; Nyhus et al., 2024; Sudzina, Dobes, and Pavlicek, 2023). In our paper, we concentrate on three complementary factors: gender, field of study, and prior experience. Thus, our study aims to provide a deeper understanding of how gender, academic background, and field experience influence individuals' perceptions in this rapidly evolving field of cryptocurrencies.

We purposefully selected our sample for this research by targeting young individuals, specifically university students. This demographic is notably engaged with emerging technologies and solutions in the market, exemplified by the growing interest in cryptocurrencies (Gogus and Saygın, 2019; Szymkowiak et al., 2021). Furthermore, our observations from teaching experiences indicate a rising number of students with cryptocurrency experience. They actively seek to expand their understanding of this topic through various sources, both technological and conventional, driven by two primary motivations: (1) viewing cryptocurrencies as a form of entertainment and leisure activity, and (2) exploring the potential for financial gain.

The structure of the paper is as follows: we begin by presenting the research questions and hypotheses, followed by an outline of the research methodology. Subsequently, we present and analyze the results, leading to a comprehensive discussion. Finally, the paper concludes with a summary of findings, discussion on limitations, and suggestions for future research directions.

2. Benefits and Challenges Facing Cryptocurrencies – the Literature Review

Cryptocurrencies represent a complex and interdisciplinary field, drawing on principles from economics, computer science, cryptography, and finance. Despite its relatively recent emergence, this domain is experiencing rapid growth and evolution, marked by ongoing technological advancements, regulatory developments, and shifts in market dynamics. Challenges such as the enigma surrounding BTC's creator, the absence of a central authority, volatility, intricacy, and legal entanglements contrast with the undeniable advantages, including the unrestricted, anonymous, and swift movement of capital. Notably, instances of cryptocurrencies being exploited for illicit activities, exemplified by the Silk Road case, have been conspicuous. Furthermore, concerns about the environmental repercussions of cryptocurrency operations have emerged due to the escalating energy demands of mining endeavors. The substantial downturn in the cryptocurrency market in 2022 serves as a stark reminder of the risks entailed in cryptocurrency investment (CoinMarketCap, 2024).

The genesis of cryptocurrencies is intricately linked with the emergence of Bitcoin (BTC) in the late 2008 and early 2009 period (Nakamoto, 2009). Facilitated by technologies such as the Distributed Ledger concept, Blockchain technology, cryptography, and peer-to-peer networks, cryptocurrency trading has burgeoned, providing digital alternatives to conventional currencies. The proliferation of cryptocurrencies has been exponential, with the cryptocurrency market assuming a prominence that cannot be disregarded (CoinMarketCap, 2024; Phillips and Graves, 2021).

The volume of literature on cryptocurrencies is extensive. Numerous authors discuss the benefits and disadvantages of cryptocurrencies. Decentralization is one of the prominent benefits highlighted in the literature. Chenguel (2021), Lee (2019), Narayanan et al. (2016), delve into the concept of decentralization, emphasizing its significance in the cryptocurrency realm. Another advantage frequently mentioned in the literature is the lower transaction fees associated with cryptocurrencies. Frankenfield (2023), Tambe and Jain (2023), and Hileman and Rauchs (2017) contribute to the discourse surrounding the economic benefits of cryptocurrencies. Security emerges as a crucial aspect of cryptocurrencies, attracting attention from scholars such as Thul (2021), Zimprich (2019), Lewis (2018), Narayanan et al. (2016), Burniske, and Tatar (2017), Bonneau et al. (2016), as well as Vigna and Casey (2015). These authors emphasize the robust security measures inherent in cryptocurrency systems. Privacy and anonymity are additional advantages frequently explored in the literature. Lewis (2018), Antonopoulos (2017), Burniske and Tatar (2017), Vigna and Casey (2015) shed light on the privacy features of cryptocurrencies, highlighting their importance in preserving user anonymity. Furthermore, the literature also emphasizes the speed of transactions facilitated by cryptocurrencies. Frankenfield (2023), Tambe and Jain (2023), and Hileman and Rauchs (2017) discuss the efficiency of cryptocurrency transactions, underscoring their rapid processing capabilities.

On the other hand one can list the challenges related to the cryptocurrency market. Volatility and risk management emerge as significant challenges in the literature. Almeida and Cruz Gonçalves (2022), Al Guindy (2021), Peng et al. (2018), Baur, Dirk, and Dimpfl (2018), Klein et al. (2018), and Katsiampa (2017) delve into the volatility of cryptocurrency markets and the associated risks, emphasizing the need for effective risk management strategies to mitigate financial losses and ensure market stability. The lack of regulation represents another pressing challenge discussed in the literature (Chenguel, 2021; Lee, 2019; Song, Chen, and Wang, 2023; Kim et al.,2022; Dordal, 2018; Hardy and Norgaard, 2016; Böhme et al., 2015). They explored the regulatory uncertainties surrounding cryptocurrencies, highlighting the absence of clear regulatory frameworks and the resulting legal and compliance challenges faced by market participants and investors. Security risks pose a significant challenge to the cryptocurrency, attracting attention from scholars such as Weichbroth et al. (2023), Yu et al. (2022), Zaghloul et al. (2020), and Zimprich (2019). These authors analyze various security threats, including hacking attacks, fraud, and vulnerabilities in cryptocurrency protocols, underscoring the importance of robust security measures to safeguard digital assets and protect investors. Environmental impact emerges as a constantly growing concern associated with cryptocurrency mining activities. De Vries (2018), Hileman and Rauchs (2017), Peck (2017), Stoll, Klaaßen, and Gallersdörfer (2019), Wendl, Doan, and Sassen (2023), and Vranken (2017) investigate the environmental implications of cryptocurrency mining, particularly the significant energy consumption and carbon footprint associated with proof-of-work consensus mechanisms. Limited acceptance represents a challenge to the mainstream adoption of cryptocurrencies, as discussed by Bajpai (2023), Eisenbardt and Eisenbardt (2023), and LLC (2021). These authors explore the factors contributing to the limited acceptance of cryptocurrencies in various sectors and highlight the barriers to their broader integration into traditional financial systems and everyday transactions.

In summary, the literature review reveals a comprehensive examination of the benefits and challenges facing cryptocurrencies. Figure 1 presents a conceptual model illustrating the benefits (B) and challenges (C) discussed by scholars in the field. This model serves as the foundation for our subsequent analyses. It integrates two demographic variables, specifically gender and field of study, along with students' prior experience.

Code	Benefits		Fields of analyses		Challenges	Code
B1	[Low transaction costs]				[No issuer]	C1
B2	[Fast transactions]				[Lack of control and independence]	C2
B3	[No issuer]				[Unstable exchange rate]	C3
B4	[Lack of control and independence]		*Gender*		[Interest from the black market]	C4
B5	[Resilience to crises]		*Field of study*		[Network security aspects]	C5
B6	[Mining]		*Prior experience*		[Increasing energy consumption]	C6
B7	[Limited supply]				[Not widely accepted]	C7
B8	[Decentralization]				[Instability]	C8
B9	[Transparency]				[Storage necessity]	C9
B10	[Immutability]				[Risk of loss]	C10
B11	[Easy storage]				[Legislative gap]	C11

Figure 1: The conceptual model of benefits (B) and challenges (C) of cryptocurrencies

3. Research Methodology

3.1 Research Purpose, Questions, and Hypotheses

The primary objective of this paper is to address principal research question: What are the differences in perceptions of benefits and challenges associated with cryptocurrencies among diverse demographic cohorts? The demographic factors examined encompass gender and field of study, alongside respondents' prior experience. To achieve this aim, the study addresses the following research questions:

RQ1: What is the perception of benefits and challenges associated with cryptocurrencies in students' opinion?

RQ2: What are the differences between males and females in their perception of cryptocurrencies' benefits and challenges?

RQ3: What are the differences among students based on their field of study in their perception of cryptocurrencies' benefits and challenges?

RQ4: What are the differences among students based on their prior experience in their perception of cryptocurrencies' benefits and challenges?

To explore above research questions, three hypotheses were formulated:

H1: There are statistically significant differences between males and females in their perception of cryptocurrencies' benefits and challenges.

H2: There are statistically significant differences among students based on their field of study in their perception of cryptocurrencies' benefits and challenges.

H3: There are statistically significant differences among students based on their prior experience in their perception of cryptocurrencies' benefits and challenges.

3.2 Research Procedure

The research undertaken in this paper is part of a broader study aimed at gathering students' opinions and experiences with cryptocurrencies. To address the primary research objective, tackle specific research questions, and test the formulated hypotheses, a quantitative research approach was employed, involving the administration of a questionnaire survey. The research process unfolded through the following phases:

(1) Survey Questionnaire Development: The questionnaire, prepared in Polish, aimed to collect students' opinions on cryptocurrencies, particularly focusing on evaluating the benefits and challenges associated with them. It was created using LimeSurvey software and consisted of five parts. The first part included questions about students' experiences with cryptocurrencies, while the second part explored the sources of information and knowledge about cryptocurrencies that students utilized. The third part was dedicated to students' opinions on the benefits and challenges of cryptocurrencies. The subsequent section aimed to gauge students' beliefs about the future of cryptocurrencies as a mainstream and widely accepted form of payment. Finally, demographic characteristics of the respondents were collected at the end of the questionnaire (Table 1). In this paper, our focus is on the third part of the questionnaire, where respondents were asked to evaluate the following issues: 1. Assess the benefits associated with cryptocurrencies. 2. Assess the challenges and risks associated with cryptocurrencies. A 5-point Likert scale was used for evaluation, with response options ranging from (1) definitely disagree to (5) definitely agree.

(2) Data Collection Process: A pilot survey was conducted in October 2021 to ensure the questionnaire's validity and methodological soundness. Data collection took place from November 2021 to February 2022, with a deliberate selection of university students as the target population. Specifically, the focus was on Generation Z, comprising 679 respondents, which accounted for 87.3% of the final sample (see Table 1). Gender, field of study, and prior students' experience were considered in order to capture students' perspectives on the benefits and challenges of cryptocurrencies across different academic disciplines.

Table 1: Demographics of the research sample

Variable	Categories	Number of respondents	Percentage
Age/ generation	Z: 1995-2009	679	100%
Gender	females	413	53.1%
	males	365	46.9%
Field of study	social sciences	445	65.5%
	exact sciences	190	28%
	humanities	19	2.8%
	natural and medical sciences	25	3.7%
Prior experience	yes	200	29.5%
	no	479	70.5%

(3). Data analysis. To address the research questions and test the research hypotheses, statistical analyses were conducted. Firstly, descriptive statistics such as mean, median (MDN), first quartile (Q1), mode, third quartile (Q3), standard deviation (SDV), skewness (SK), and coefficient of kurtosis (CK) were computed. Secondly, the Mann-Whitney U test was employed to either confirm or reject the hypotheses. These tests were chosen due to their non-parametric nature, which does not require assumptions about the distribution of the data (verified through the Shapiro-Wilk test with $\alpha = 0.05$). The statistical analyses were performed using Statistica package.

4. Results

4.1 Analysis of Benefits and Challenges in the Opinion of Generation Z

To answer the RQ1, the frequency procedures were employed and the results are presented in Table 2.

Table 2: Descriptive statistics for benefits and challenges of cryptocurrencies

Variable	Mean	MDN	Mode	Q1	Q3	SDV	SK	CK
B1	3.57	4	5	3	5	1.22	-0.51	-0.64
B2	3.98	4	5	3	5	1.13	-0.99	0.18
B3	3.24	3	3	3	4	1.15	-0.11	-0.60
B4	3.55	4	5	3	5	1.29	-0.47	-0.85
B5	3.39	3	5	3	5	1.30	-0.35	-0.93
B6	2.91	3	3	2	4	1.18	0.04	-0.71
B7	3.74	4	5	3	5	1.16	-0.69	-0.27

Variable	Mean	MDN	Mode	Q1	Q3	SDV	SK	CK
B8	3.47	3	3	3	4	1.08	-0.24	-0.49
B9	3.44	3	3	3	4	1.07	-0.15	-0.58
B10	3.17	3	3	2	4	1.25	-0.21	-0.86
B11	3.97	4	5	3	5	1.10	-0.93	0.17
C1	2.71	3	3	2	3	1.13	0.18	-0.51
C2	3.05	3	3	2	4	1.34	-0.05	-1.12
C3	3.72	4	5	3	5	1.20	-0.62	-0.53
C4	3.71	4	5	3	5	1.23	-0.65	-0.52
C5	3.63	4	3	3	5	1.16	-0.49	-0.54
C6	3.53	4	3	3	5	1.19	-0.40	-0.69
C7	3.50	3	3	3	5	1.20	-0.32	-0.81
C8	3.69	4	5	3	5	1.13	-0.52	-0.49
C9	2.76	3	3	2	3	1.16	0.08	-0.72
C10	3.71	4	5	3	5	1.20	-0.62	-0.56
C11	3.32	3	3	3	4	1.13	-0.19	-0.48

The results presented in Table 2 shows that, in the scope of the average value, the benefits students perceive as the most important are B2 [Fast transactions], B11 [Easy storage], and B7 [Limited supply] whereas B6 [Mining] they evaluate as the less important one. In case of challenges, the crucial are C3 [Unstable exchange rate], C4 [Interest from the black market], and C10 [Risk of loss], whereas C1 [No issuer] is the less important in their opinion. It is advisable to stress that the results presented in Table 1 embrace all students' opinions regardless of their characteristics. Thus it was decided to perform detailed analyses for respective groups of students. This approach could bring the wider perspective the problem analyzed.

4.2 Benefits and Challenges of Cryptocurrencies for Males and Females

To test hypothesis **H1** and answer **RQ2**, since the authors used convenient samples in the study, the Mann-Whitney U test was employed to determine whether the H1 is supported by empirical data. The test results presented in Table 3 show that there are significant differences (the *p*-value is lower than 0.05) between students opinion and their gender for benefits in case of B3, B4, B5, B7, and B8 and C1, C2, C4, C5, C9, C10, and C11 in case of challenges. Hence hypothesis H1 is supported in the study.

Table 3: The Mann-Whitney U test results as to for gender comparison

Benefits	Z	*p*-value	Challenges	Z	*p*-value
B1	-0.109	0.914	C1	-3.000	0.003
B2	-0.683	0.494	C2	-4.014	0.000
B3	2.310	0.021	C3	-0.059	0.953
B4	3.992	0.000	C4	-2.484	0.013
B5	-2.788	0.005	C5	-3.228	0.001
B6	-1.944	0.052	C6	0.688	0.491
B7	2.227	0.026	C7	-0.332	0.740
B8	6.376	0.000	C8	0.286	0.775
B9	1.526	0.127	C9	-3.315	0.001
B10	-1.718	0.086	C10	-3.757	0.000
B11	-0.272	0.786	C11	-2.748	0.006

Taking into account the test results presented in Table 3 it was decided to show the broader picture of the problem analyzed using frequency procedures. The results are presented in Figure 2. They embrace statistically significant variables only.

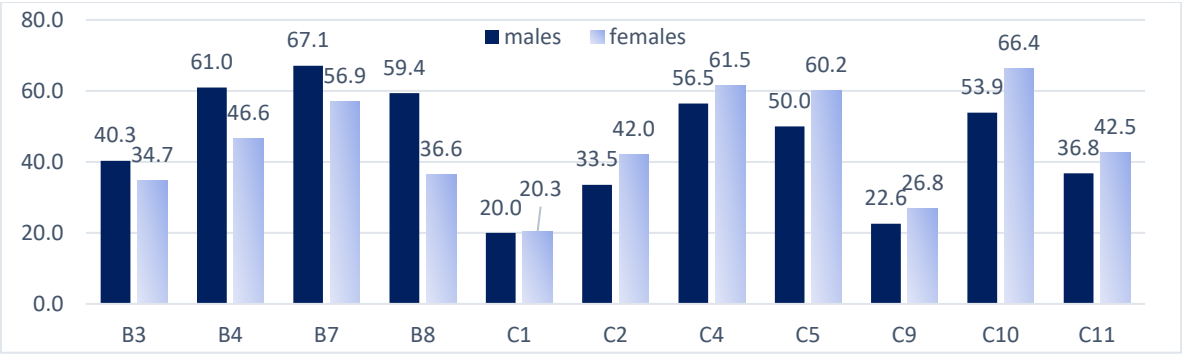

Figure 2: The benefits (B) and challenges (C) in males and females opinion [% values]

The results presented in Figure 2 show that males tend to perceive more benefits associated with cryptocurrencies compared to females. The most notable gender gap is observed in B8 [Decentralization], with males showing a 22.8% higher inclination towards the benefits. Conversely, females appear to encounter more challenges than males. Particularly C10 [Risk of loss] stands out, indicating that females perceive it as a greater risk compared to males.

4.3 Benefits and Challenges of Cryptocurrencies for Students – Fields of Studies Perspective

To test **H2** hypothesis and answer **RQ3**, the Mann-Whitney U test was employed for students representing two distinct fields, i.e. social sciences and exact sciences. We have limited the results to these two groups of students as they represent the majority of the sample. The results are presented in Table 4.

Table 4: The Mann-Whitney U test results as to fields of study

Benefits	Z	*p*-value	Challenges	Z	*p*-value
B1	1.729	0.084	C1	0.151	0.880
B2	1.590	0.112	C2	0.735	0.462
B3	1.625	0.104	C3	-0.434	0.665
B4	0.490	0.624	C4	0.848	0.396
B5	0.613	0.540	C5	1.345	0.179
B6	0.071	0.944	C6	-0.508	0.612
B7	-1.785	0.074	C7	2.060	0.039
B8	-0.878	0.380	C8	0.153	0.878
B9	-0.350	0.726	C9	0.889	0.374
B10	-1.914	0.056	C10	0.478	0.632
B11	-0.095	0.924	C11	0.918	0.358

The test results presented in Table 4 show that only for C7 [Not widely accepted] the *p*-value is lower than 0.05. It means that there were statistically significant differences in students opinions for this one variable exclusively. Thus, hypothesis H2 is rejected.

4.4 Benefits and Challenges of Cryptocurrencies – Students' Prior Experience Perspective

To assess hypothesis H3, the results of the Mann-Whitney U test are presented in Table 5, revealing significant differences (p-values below 0.05) between students with and without prior experience. Specifically, these differences are observed for 8 out of the total 11 benefits and 6 out of the total 11 challenges. Therefore, hypothesis H3 is supported by the findings of this study.

Table 5: The Mann-Whitney U test results

Benefits	Z	*p*-value	Challenges	Z	*p*-value
B1	2.56651	0.010273	C1	-4.12426	0.000037
B2	3.33058	0.000867	C2	-4.97030	0.000001
B3	5.03646	0.000000	C3	-0.16647	0.867790
B4	5.11063	0.000000	C4	-0.97912	0.327520
B5	-1.09409	0.273918	C5	-0.80210	0.422494
B6	-0.12156	0.903248	C6	1.97373	0.048413
B7	2.14409	0.032026	C7	0.22460	0.822294
B8	6.19076	0.000000	C8	0.14927	0.881343
B9	3.82234	0.000132	C9	-4.56488	0.000005
B10	-1.50378	0.132638	C10	-2.11392	0.034523
B11	3.81112	0.000138	C11	-3.26666	0.001088

Considering the test results displayed in Table 5, it was deemed appropriate to illustrate the disparities between opinions of respondents with and without experience using frequency procedures. The outcomes are depicted in Figure 3, highlighting solely statistically significant variables.

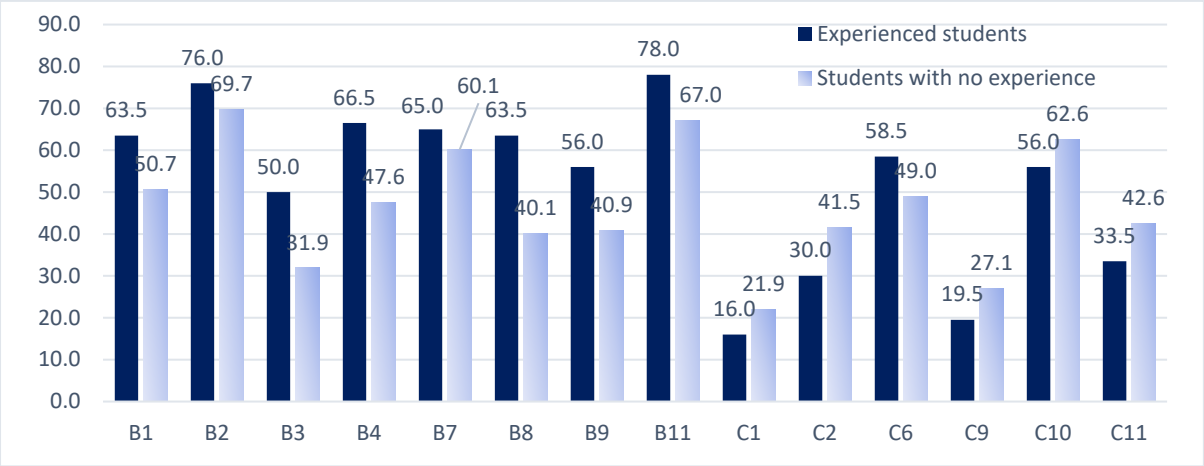

Figure 3: The benefits (B) and challenges (C), and students experience regarding cryptocurrencies [% values]

The findings illustrated in Figure 3 indicate that experienced students perceive more benefits compared to those with no experience. The most notable difference is observed in B8 [Decentralization], followed by B4 [Lack of control and independence] and B3 [No issuer]. Conversely, inexperienced students seem to face more challenges, with the most significant difference found in C2 [Lack of control and independence]. Of particular interest is the challenge highlighted by C6 [Increasing energy consumption], suggesting that experienced students view this as a greater concern and challenge compared to those lacking experience.

5. Discussion and Conclusions

Cryptocurrencies constitute a multidisciplinary, relatively nascent, and rapidly evolving domain. Cryptocurrencies have garnered significant attention in recent years, with their potential benefits and challenges subject to scrutiny across various demographics. This study aims to delve into students' perceptions of cryptocurrencies, examining how these perceptions differ based on gender, field of study, and their prior experience with cryptocurrencies. To achieve this objective, four research questions were addressed, along with corresponding hypotheses. The study addresses RQ1 by investigating students' opinions regarding the benefits and challenges associated with cryptocurrencies. As a result, [Fast transactions] and [Easy storage] turned out the most important for students whereas C3 [Unstable exchange rate] C4 [Interest from the black market, and C10 [Risk of loss] were the most important risks.

RQ2 delves into a comparison of the perceptions of benefits and challenges between males and females. Statistical analyses substantiate hypothesis H1, indicating differences between students' opinions and their genders. Our findings indicate that males tend to perceive more benefits associated with cryptocurrencies than females. This aligns with the findings of Jora and Nanda (2020), who identified gender disparities in attitudes toward cryptocurrencies, with male respondents exhibiting greater willingness to use cryptocurrencies than females. These results imply that gender influences individuals' perceptions of the benefits and challenges of cryptocurrencies.

RQ3 is investigated by analyzing differences among students based on their field of study. Although most variables did not exhibit statistically significant differences across fields of study, the identification of one significant difference for challenge C7 suggests the relevance of exploring field-specific perceptions. However, the overall support for hypothesis H2 is limited based on the findings of this study.

RQ4 examines the crucial aspect of individuals' experiences concerning benefits and challenges related to cryptocurrencies. The findings reveal variations in students' perceptions of benefits and challenges based on their prior experiences with cryptocurrencies. Experienced students tend to perceive more benefits and fewer challenges compared to their inexperienced colleagues, indicating that firsthand experience plays a significant role in shaping attitudes towards cryptocurrencies. These results are consistent with prior research (Eisenbardt and Eisenbardt, 2023a).

In summary, the study addresses research questions by analyzing students' perceptions of cryptocurrency benefits and challenges, comparing these views across genders and fields of study, and testing formulated hypotheses. The results offer valuable insights into the factors shaping individuals' perceptions of cryptocurrencies, underscoring the significance of considering gender-based and field-specific disparities in crafting strategies for cryptocurrency adoption and understanding its challenges. Furthermore, the study acknowledges the significance of experience-related factors, demonstrating that prior experience significantly influences individuals' perceptions of cryptocurrencies.

5.1 Research Contribution

This paper contributes to both practice and theory in the field of cryptocurrencies, focusing on gender and field of study differences, as well as prior experience with cryptocurrencies. The findings offer practical implications for policymakers, regulators, and industry stakeholders by highlighting nuanced perceptions of benefits and challenges among selected demographic groups. Understanding these perceptions can inform the development of targeted strategies to address concerns, enhance adoption, and mitigate risks associated with cryptocurrencies.

Policymakers can utilize insights from this study to tailor regulatory frameworks and policies surrounding cryptocurrencies. Recognizing the impact of experience on perceptions can aid in designing regulations that address specific concerns while leveraging perceived benefits. For instance, policies could focus on providing consumer protection measures for inexperienced users while fostering innovation and decentralization in the cryptocurrency space for more experienced users. Investors and industry stakeholders can benefit from understanding how experience influences perceptions of cryptocurrencies. Recognizing the biases introduced by varying levels of experience can guide investment strategies and decision-making processes, helping stakeholders navigate the complexities of the cryptocurrency market more effectively.

Insights into gender-based differences in perceptions can guide efforts to promote inclusivity and diversity in cryptocurrency-related initiatives and investments. The paper extends existing theoretical frameworks by empirically examining the influence of gender, field of study, and prior experience on perceptions of cryptocurrencies' benefits and challenges. By integrating findings from the literature review with empirical data, the study enriches our understanding of the factors shaping individuals' perceptions of cryptocurrencies.

The conceptual model presented in Figure 1 synthesizes the literature on benefits and challenges of cryptocurrencies, providing a comprehensive framework for future research and theoretical development. Overall, the paper bridges the gap between theory and practice in the field of cryptocurrencies, offering actionable insights for stakeholders while advancing theoretical understanding and knowledge in the domain..

5.2 Limitations and Implications

The study's findings are constrained by the sample size and demographic representation, suggesting the need for future research to employ larger and more diverse samples to enhance the validity and generalizability of

the results. Furthermore, longitudinal studies could offer valuable insights into the evolving dynamics of perceptions and behaviors surrounding cryptocurrencies and blockchain technology, taking into account the changing trends and advancements in the field over time. Additionally, qualitative research methods, such as interviews or focus groups, could provide a deeper understanding of the underlying factors that shape perceptions of benefits and challenges across various demographic groups and academic disciplines.

Expiring Technologies Face to the Development of Generative AI: Programming Languages

Tomasz Eisenbardt
University of Warsaw, Warsaw, Poland

teisenbardt@wz.uw.edu.pl

Abstract: The rapid development of AI, and Generative AI in particular, offers incredible opportunities for all humanity. However, this development carries serious threats and dangers. The topic of job reduction and the obsolescence of some professions that were previously downright lucrative is often raised in the literature. Such a phenomenon of disappearance of certain professions or abandonment of old technologies has occurred many times, which was related to technological development or simply the development of civilization. Information and communication technologies are particularly susceptible to change. Virtually every IT issue has gone through an individual development path, resulting in a departure from the original solutions in favor of more modern, more flexible, more easily scalable, or simply more intuitive for humans. Meanwhile, there is a danger that the solutions proposed by GenAI may become dehumanized. The author delved into the topic of the potential phasing out of certain technologies due to the influence of GenAI, using the example of programming languages that have been used thus far. Their collection turns out to be quite extensive. Some of these languages fell into oblivion before the GenAI era, naturally replaced by other programming languages, or gradually became increasingly niche or redundant. The research question posed in this work is: Will GenAI lead to a departure from currently used programming languages, which were typically designed to be user-friendly (in the sense of being human-readable)? The aim of the work is to answer this question, as well as several smaller ones, such as: Are there any chances that programming languages will remain understandable to humans? The work employs literature analysis, critical analysis of selected technologies, and the case study method.

Keywords: Expiring Technologies, AI, Generative AI, Genai, Programming Languages

1. Introduction

The issue of fading technologies has long been part of natural civilizational development. It is strongly associated with the phasing out of specific solutions and tools, as well as the obsolescence of some professions. Some technologies have completely eradicated what was previously in use, reducing certain inventions to the level of technological curiosities, artifacts, or even sentimental mementos. Some technological advancements have led to what was once very popular being relegated to niche status.

A. Toffler in The Third Wave (Toffler, 1994) described in a model-like manner the historical development of our civilization. The allegory of three waves simplifies the fate of humanity, which transitioned from the agrarian era to the industrial era, and then to the digital era. The current digital era is still in a phase of intense development, the ultimate destination of which is essentially unknown. Regardless, each transition carried a significant cost of replacing the old with the new. This includes various artifacts, technologies, professions, and even ways of life. Much of this has been lost irretrievably because it was no longer needed.

Let's focus now on the present day. The tools and technologies we currently use typically have their predecessors or prototypes. We usually opt for the latest version of a device, technology, or tool. When we need to perform calculations, it's not a dilemma whether to choose an abacus or a personal computer. Only someone deeply sentimental might choose a typewriter for their professional work when they have word processing software available. A photographer is more likely to use a digital camera rather than an analog one. It would be quite eccentric to travel by horse when we have fast trains, cars, and airplanes. Mobile phones have replaced landlines, and email has replaced traditional letters. The list could go on endlessly.

However, the above examples were deliberately chosen to illustrate a fragment of technological evolution that we essentially have already experienced. The examples describe the world from several decades ago. What is happening in the 2020s has a different character. Currently, changes largely encompass the digital and informational sphere of human life.

Around the world, successive generations cannot imagine a normal existence in which they would be disconnected - to some extent - from rather sophisticated information services. Currently, having access to efficient broadband internet, the ability for instant global VoIP communication, specific computer applications allowing for quick resolution of highly complex problems, various commercial web services, and on-demand multimedia access hold immense significance. Examples like these can be multiplied for a long time.

Therefore, there are many solutions that are used in our daily lives, without which we cannot imagine a day, and which not long ago were merely futuristic ideas straight out of science fiction movies. The fact that such services and conveniences exist at all is a result of the application of digital machines and various programming languages.

2. Literature Background

2.1 The Wide Scope of Past and Actual Programming Languages

Programming languages have been with us for decades. It is indicated here as the progenitor the first programming language, developed in 1883 by Ada Lovelace (Kim, Toole, 1999). This year computer program, to compute Bernoulli numbers for a primitive mechanical computer, was created. The next achievement in this matter was the first computer programming language prepared by Konrad Zuse: Plankalkül - in early 1940s. Next, in 1949, assembly language emerged and - around the same time - Shortcode appeared (Brief…, 2024; The history…, 2023; Computer History…, 2018).

Since then, the pool of languages has steadily expanded. Some of them have been in use for several decades. However, some have almost completely faded into obscurity, making way for others.

The history of programming languages is shown in a simplified way in Figure 1. In reality, there were many more programming languages (Most Used…, 2023). Another timeline of this kind was once published by O'Reilly Media (see References: History of Programming Languages, 2008) - it's available on the World Wide Web, and it hasn't been included here due to the size and complexity of the diagram. It's evident from the chart that many languages have faded into obscurity and are now considered extinct languages.

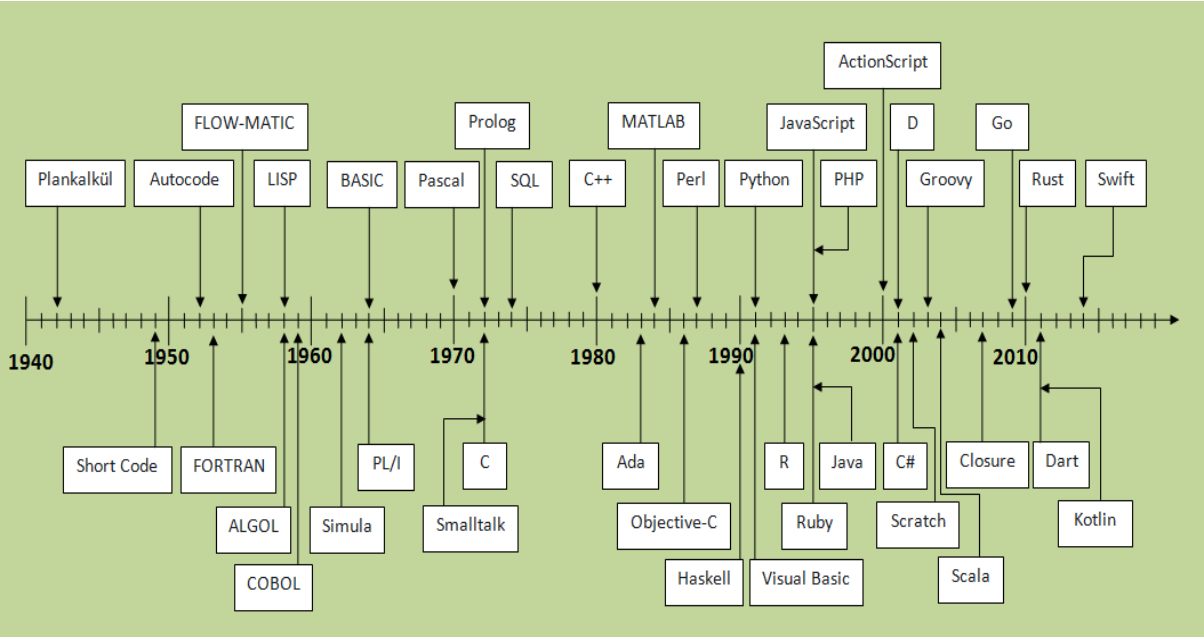

Figure 1: History of programming languages – simplified. Source: (History of Programming Languages, 2019)

So, we are still in the process of programming language evolution. Much has already happened in this regard. But are we perhaps on the verge of another turning point in programming language development? Because can an algorithm create algorithms on its own?

In recent times, various bold statements have been appearing in the media, such as: Jensen Huang (2024), CEO of Nvidia, stated that computer programming education will become unnecessary because natural language will be entirely sufficient for programming, and the emphasis should be placed on "*understanding domain expertise*." These assertions have sparked heated debate.

2.2 Generative AI - Basics

The next step in civilization appears to be the development of artificial intelligence, which began in the 1950s with the proposal of the Turing machine (Turing, 1950). Since then, a lot has happened (Eisenbardt, 2023). However, crucial from the perspective of this paper may be the year 2018. It was then, when the first version of ChatGPT[1] was released by OpenAI[2] (Introducing ChatGPT; History and Future…, 2023; Reynoso, 2021).

The ChatGPT itself can now confidently be called the "flagship" of GenAI - Generative Artificial Intelligence. There are currently many such tools, just as there are many definitions of Generative AI. They are quite similar in wording, so only one of them will be cited here:

> Generative AI is „*a class of machine learning technologies that can generate new content—such as text, images, music, or video—by analyzing patterns in existing data*" (Brynjolfsson, Li, Raymond, 2023).

Around the year 2022-23, there was a true explosion of interest in GenAI. This is evident from the attached chart (Chart 1). A similar peak was observed, and other researchers came to similar conclusions, such as García-Peñalvo, Vázquez-Ingelmo (2023).

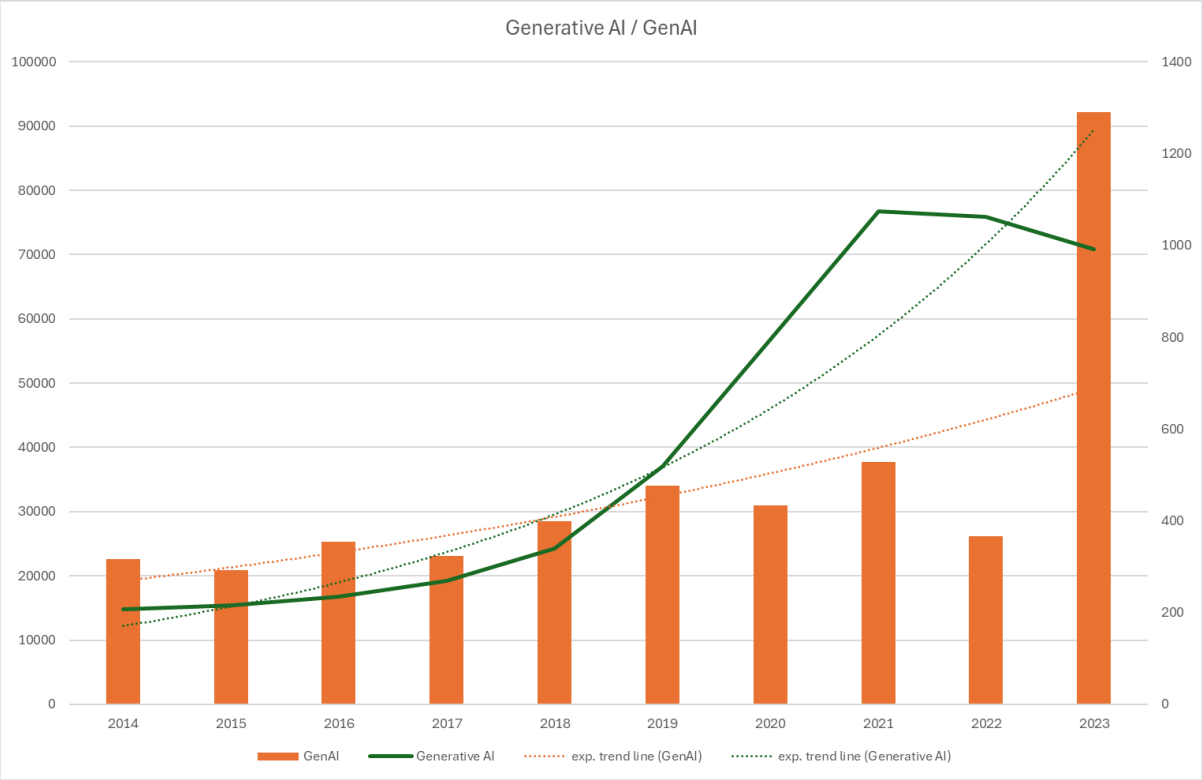

Figure 2: Number of publications according to Google Scholar regarding Generative AI and GenAI in the last 10 years. Source: own work based on Google Scholar[3], access: 2024-04-0

Currently (spring 2024), there are many solutions in the field of GenAI. The present discussion is limited to chatbots. There are many available chatbots (Haan & Main, 2024; Rebelo, 2023). In the study, only three of them were used, namely:

- ChatGPT[4] (Chat Generative Pre-trained Transformer) - produced by OpenAI,
- Copilot[5] - created by Microsoft Corp.,
- Gemini[6] - developed by Google (Alphabet Inc).

[1] ChatGPT, https://chat.openai.com
[2] OpenAI, https://openai.com
[3] Google Scholar, https://scholar.google.com
[4] OpenAI ChatGPT, https://chat.openai.com
[5] Microsoft Copilot, https://copilot.microsoft.com
[6] Google Gemini, https://gemini.google.com

These chatbots were subjected to trials aimed at assessing their usefulness in code generation in popular programming languages.

3. Research Methodology

3.1 Research Goal and Questions

The main goal of the study was to test three chatbots for code generation in several popular programming languages and to subject the chatbots to an attempt to create a new programming language. An additional objective was to verify the popularity of these three chatbots over time based on the number of publications about them.

The following research questions were formulated:

[Q1] Which chatbot currently enjoys the highest popularity in terms of publications about it?

[Q2] Do the chatbots handle generating typical code in selected languages?

[Q3] Can the chatbots optimize this code?

[Q4] Do the chatbots handle less obvious problems?

[Q5] Can the chatbots create alternative programming languages?

The answers to these questions are found sequentially in the Results section of this paper.

3.2 Research Procedure

In the first step, the interest in each tool over time was verified. Google Scholar listings for the three chatbots (ChatGPT, Copilot, and Gemini) were used. The period of the last 10 years was examined. This allowed us to gain knowledge about the level of interest from researchers and knowledge disseminators in these three tools and which one is currently the leader [Q1].

In the next step, these three chatbots were tested. It was checked whether they were able to generate simple code in several programming languages [Q2] and whether they could optimize it [Q3]. Subsequently, they were challenged with solutions to less typical problems [Q4]. Then it was verified whether the chatbots allowed for the generation of a completely new programming language [Q5] that could replace the previous languages.

4. Results

4.1 Popularity of Chatbots

The number of publications on the three analyzed chatbots was tracked. The analysis covered the last 10 years (2014-2024), as shown in Chart 2. Trend lines were added, and they were exponential in nature. The last year (2024) was not included in the charts because only one quarter of that year had passed. However, the results obtained until the end of March 2024 clearly indicate that the peak will be even higher (for each of the tools, the results obtained so far suggest a rapid surpassing of the record from the previous year).

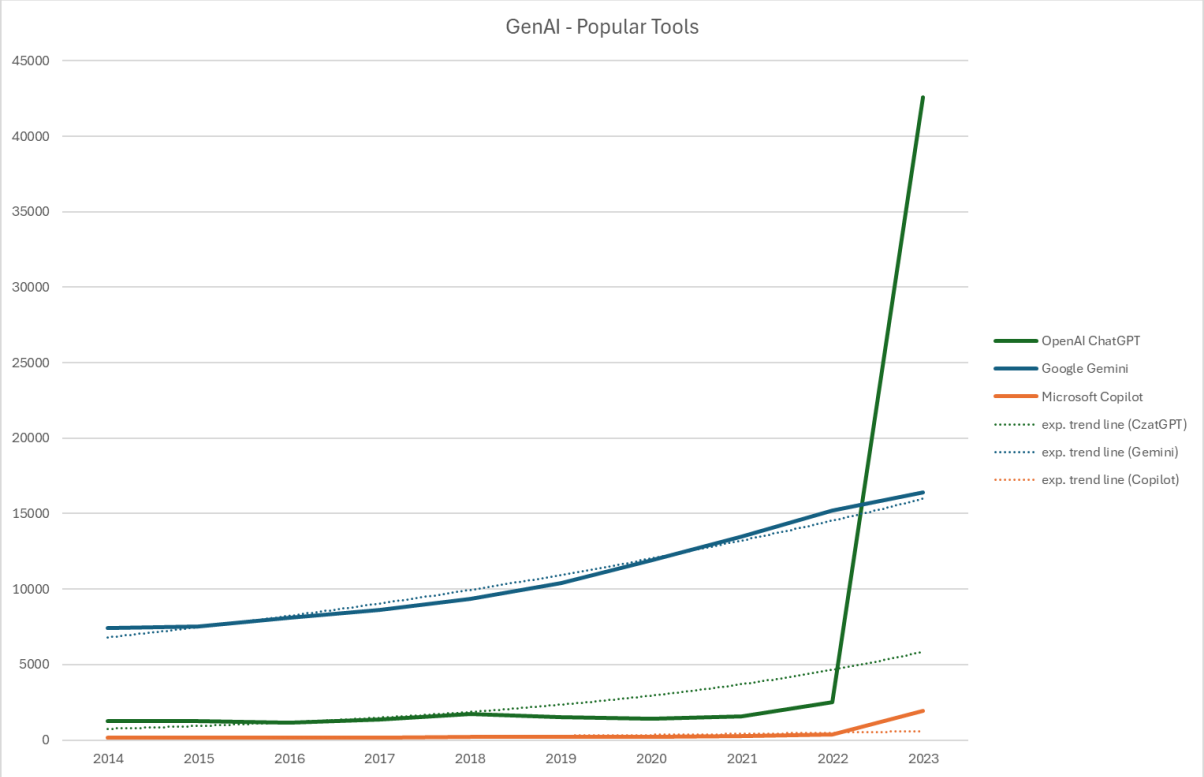

Figure 3: Number of publications according to Google Scholar regarding selected GenAI tools in the last 10 years. Source: own work based on Google Scholar, access: 2024-04-02

The chart quite clearly indicates that initially, the greatest interest and expectations were aroused by the Google Gemini tool. However, after 2022, the lead has been taken by the OpenAI product: ChatGPT.

4.2 The Test of Generating Simple Code

Each of the chatbots was asked to prepare a factorial algorithm. The code was to cover four programming languages: two relatively young and currently popular ones (Python, C#) and two with a very long, over 50-year history. This included the currently niche language C and the practically extinct Pascal. The results of this experiment are shown in Table 1. This test serves as an attempt to answer the research question [Q2].

Table 1: Results of the code generation test in multiple programming languages

Chatbot	Python	C#	C	Pascal
OpenAI ChatGPT	Yes (2 solutions: recursion and iteration)	Yes (2 solutions: recursion and iteration)	Yes (2 solutions: recursion and iteration)	Yes (2 solutions: recursion and iteration)
Google Gemini	Yes (2 solutions: recursion and iteration)	Yes (2 solutions: recursion and iteration)	Yes (2 solutions: recursion and iteration)	Yes (2 solutions: recursion and iteration)versions)
Microsoft Copilot	Yes (2 solutions: recursion and iteration)	Yes (even 4 versions)	Yes (2 solutions: recursion and iteration)	Yes (2 solutions: recursion and iteration)

Source: own study

Each of the chatbots coped excellently with such an elementary, popular, and thoroughly described computer science problem as the factorial algorithm. As seen in the table, Copilot stood out for its particularly meticulous treatment of the C# language, proposing 4 different solutions to the problem.

4.3 The Test of Optimizing Simple Code

Next, each of the chatbots was asked to optimize the recursive algorithm. The results of this operation are presented in Table 2. This is an answer to the research question. [Q3].

Table 2: Results of the code optimization test in multiple programming languages

Chatbot	Python	C#	C	Pascal
OpenAI ChatGPT	Yes (using memoization)	Yes (using memoization)	Yes (using memoization)	Yes (using memoization)
Google Gemini	Yes (using memoization)	Yes (using memoization)	Yes (using memoization)	Yes (using memoization)
Microsoft Copilot	None	None	None	None

Source: own study

The chatbots demonstrated the ability to delve deeper into the subject related to the described algorithm. They proposed optimization, but each time only through one method: memoization. Copilot, on the other hand, rather disappointed in this matter.

4.4 The Chatbots Test for Solving an Atypical Task

The next task was to draw a four-leaf clover on the screen using a programming language. The task is not particularly difficult, but it may be challenging to find ready-made solutions on the World Wide Web. Additionally, it requires including additional libraries beyond the standard ones. Results [Q4] are in Table 3.

Table 3: Results of the code generation test in multiple programming languages

Chatbot	Python	C#	C	Pascal
OpenAI ChatGPT	Task completed (Included turtle library)	Task completed (Included Windows Forms library)	Task completed (included Simple DirectMedia Layer)	Task completed (included Graph library)
Google Gemini	Task completed (Included turtle library)	Task completed (Included Windows Forms library and System.Drawing)	He included the header file <cairo.h> and completed the task	He couldn't solve the task in Pascal; he only proposed a solution in Delphi
Microsoft Copilot	At first, he misunderstood the context of the command and drew a clover on the screen. Only after being given a similar command for the C# language did he correct his previous response. The turtle library was used.	The solution was not complete; in fact, it was only the preparation of the form	Proposed a text-based solution	Proposed a text-based solution

Source: own study

The task was well executed by ChatGPT and Gemini. Copilot had some issues understanding the contextual nature of the command, and its solutions were slightly inferior.

4.5 Test of Artificially Generated Programming Languages

In the online sphere, there have been few mentions of attempts to generate new programming languages using GenAI tools. What this current study proposes is another such attempt. The chatbots were given a rather challenging task: "*Prepare a new programming language that uses double characters instead of commands and only hexadecimal values*". The results of this challenge are presented in Table 4.

Table 4: Results of code generation testing in multiple programming languages

Chatbot	Proposed new programming language	Results (sample)
OpenAI ChatGPT	HexLang	VA1A5 ; Assign value 5 to variable A VA2B8 ; Assign value 8 to variable B AA ; Add variables A and B VA3 ; Assign result to variable C FF ; End of program
Google Gemini	HexaScript	A1 // Assign value 0x01 to variable A B2 C3 // Add values at B and C, store result in variable 2 D5 0F // Compare value in D with 0x0F, jump to instruction at 5 if equal EF // Perform some operation (specific meaning depends on instruction code) 01 // End of program (could be a different code)
Microsoft Copilot	HexaGlyph	O ## 0x42 # Set memory address 0 to 0x42 O ## # Print the value at the current memory address

Source: own study

And here's a Python-based interpreter for this language:

python Copy code

```
class HexLangInterpreter:
    def __init__(self):
        self.variables = {}

    def interpret(self, code):
        lines = code.split("\n")
        for line in lines:
            if line:
                command, value = line[:2], line[2:]
                if command == 'VA':
                    var = value[0]
                    val = int(value[1:], 16)
                    self.variables[var] = val
                elif command == 'AA':
                    var1, var2, var3 = value[0], value[1], value[2]
                    self.variables[var3] = self.variables[var1] + self.variables[var2
                elif command == 'FF':
                    break
        print("Variables:", self.variables)

# Example usage
interpreter = HexLangInterpreter()
code = """
VA1A5       ; Assign value 5 to variable A
VA2B8       ; Assign value 8 to variable B
AA          ; Add variables A and B
VA3         ; Assign result to variable C
FF          ; End of program
"""
interpreter.interpret(code)
```

Figure 4: A fragment of the library for handling the conversion of the new programming language HexLang to Python. Source: ChatGPT, access: 2024-04-03.

As can be observed, each of the chatbots demonstrated a certain level of creativity in creating the foundations of a new programming language. Each of them named the new language and proposed its initial assumptions.

ChatGPT seems to be the best in this regard, as it immediately constructed a library in Python[7] (Figure 2) that would be responsible for translating and interpreting the code of the HexLang language.

5. Conclusions

The conducted analyses allow for answering the research questions. Thus, sequentially:

[Q1] Initially, Gemini enjoyed the greatest interest from researchers and knowledge disseminators in the field of GenAI. However, since 2022, ChatGPT has been the leader in this regard.

[Q2] All three examined chatbots perform well in generating typical code in several programming languages. These languages include Python, C#, C, and Pascal. Their language models are well-developed, and their knowledge bases allow for accurate formulation of responses.

[Q3] The chatbots are capable of optimizing code to the extent allowed by their model and knowledge base. Clearly, Copilot was weaker in this regard.

[Q4] It turns out that the chatbots handle less obvious, "non-textbook" problems quite well. They adeptly suggested libraries that extend the languages, and the methods and functions of these libraries were used rather skillfully. However, contextual understanding of commands by Copilot was an issue here.

[Q5] The chatbots are capable of laying the groundwork for creating alternative programming languages. However, to what extent they deviate from the languages that have been created so far and how creative and unique this approach is, is a highly debatable matter. Preliminary results suggest a certain level of imitation by artificial intelligence in this field.

Analyzing the above results, it is important to consider the significant capabilities of current GenAI technology. It is truly an emerging technology. It already has incredible capabilities, and the spectrum of its potential applications continues to grow. This study, along with many others, points to certain shortcomings in the creativity of solutions suggested by artificial intelligence, as well as certain problems with contextual understanding.

However, on the other hand, GenAI poses a significant threat to many professions, including those related to the IT industry. There is a reason why the potential of machine-generated code was tested here. It's a significant threat that coding might one day escape our control, and code written in languages created in such an artificial way would be completely incomprehensible and impossible to verify by humans. It is already worth ensuring that the code remains “humanized”.

The main conclusion, however, is that GenAI-supported chatbots are already an incredible support for programmers' work today. Their language models support not only natural language transcription but can also be equally successful in transcribing code in multiple programming languages. This applies to both currently used languages and those that are becoming obsolete or have long been forgotten.

5.1 Research Contribution

The study focuses on programming languages, considering extinct languages, in the context of using GenAI tools to write code in these languages. The proposed approach is original and authored. It was decided to test 3 GenAI chatbots: ChatGPT, Google Gemini, and Microsoft Copilot. Due to the high relevance of the compared solutions and the high interest in the topic by many researchers, it may serve as inspiration and encouragement for further research in this area.

5.2 Limitations and Implications

It should be noted that the examined solutions are still being developed. The study diagnoses the current state as of the present time (spring 2024). The conducted study was based on verifying the capabilities of the

[7] Python, https://www.python.org

examined tools by formulating one-time queries. Although a comprehensive study in this area would be more reliable, it should still be expected that the results achieved would vary greatly over time.

A Sentiment Analysis Framework for Estimating Relational Capital

G. Scott Erickson[1] and Helen N. Rothberg[2]
[1]Ithaca College, Ithaca, USA
[2]Marist College, Poughkeepsie, USA

gerickson@ithaca.edu
helen.rothberg@marist.edu

Abstract: This paper continues research to create a metric for relational capital, a progressively important type of knowledge asset. Knowledge concerning customers and how to engage with them is increasing at an exponential rate in some organizations due to customer relationship management (CRM) and related software gathering customer data. As such, understanding relational capital as a critical piece of an organization's intellectual capital (IC) is ever more important. But measuring the level of relational capital in a firm is difficult. Several consultancies publish brand equity assessments every year (a closely related concept) but these usually only include the biggest and most valuable brands. Popular metrics for studying IC either don't break out the relational capital and other individual components (Tobin's q) or don't include relational along with the others reported (VAIC). In previous work, we've explored using sentiment analysis as a measure of brand value/relational capital, studying the results of a number of firms in several specific applications (consumer brands, tech brands, media brands, etc.). Those results have been interesting but were also only exploratory. At last year's ECKM conference in Lisbon, we received a suggestion that it was time to take some of these metrics and put them together into a brand equity/relational capital predictor. This paper takes that first step, looking at some sentiment analysis results over time and evaluating their relationship with known brand equity estimates. Activity level for brand mentions, variance in activity level, sentiment (positive, negative, neutral), influencer levels, and other potential inputs can be fed into some scenarios for predicting relational capital. The scenarios could include both different variables and different weights, experimenting to determine if an algorithm providing the best fit to the data exists. Once this type of research establishing some benchmarks, additional comprehensive quantitative tests can be conducted in future research, validating and adapting the predictor to different industries and different circumstances. Consequently, we should be able to develop a much better understanding of the role of relational capital and its contribution to firm success as well as ways to help organizations manage it.

Keywords: Intellectual Capital, Relational Capital, Brand Equity, Smartphones, Sentiment Analysis

1. Background/Literature Review

Measuring knowledge assets or intellectual capital is an unsettled issue in our field even after decades of attention. While individual firm estimates and even periodic intellectual capital reports have been produced, with greater or lesser acceptance in terms of methodology, the final step of identifying a generally accepted knowledge metric to establish impact on organizational performance remains elusive. Conceptually and intuitively, the entire discipline believes that superior management of knowledge resources can lead to better financial and other results. But we still lack the means to prove it. And that includes in the area of relational capital.

1.1 Relational Capital

Knowledge management theory suggests that identifying and sharing knowledge resources can lead to competitive advantage (Grant, 1999; Teece, 1998). As tangible assets are ubiquitous and widely available, the potential of intangible assets unique to the firm may be the most available differentiator for many organizations (Nonaka & Takeuchi, 1995). This offshoot of the resource-based view of the firm (Barney, 1991; Wernerfelt, 1984) is the impetus for much of the interest in knowledge management (KM) and related disciplines.

One key related discipline is intellectual capital (IC). If one is to manage knowledge assets more effectively, it helps to be able to identify and measure them. IC grew out of several fields but one was accounting, an attempt to better account for intangible assets such as knowledge. Different approaches, some well-known such as the Balanced Scorecard (Kaplan & Norton, 1992) and the Skandia Navigator (Edvinsson & Malone, 1997), established a basis for later research. That research then generally centered on a framework including human capital, structural capital, and relational capital (Bontis, 1999; Edvinsson & Malone, 1997).

Human capital is most closely associated with KM and was often the core connection between the fields as individual knowledge about job performance is key to both concepts. Structural capital is more about knowledge embedded in the organization, captured in processes and procedures. Essentially, one objective of KM is to turn human capital into structural capital, so it is a key concept in connecting KM and IC. Relational capital,

knowledge about interactions with those outside the organization itself (Roos & Roos, 1997), has typically been more of an afterthought. Termed customer capital in some early IC frameworks, it was expanded to include all external publics. Customers, however, do remain the core constituency about which a firm desires knowledge (Gupta & Bhasin, 2014), and with the advent of customer relationship management systems, loyalty programs, customer logins and other advances related to customers and now available big data, the capabilities and value of relational capital have grown considerably in recent years. The volume of information and knowledge has exploded, so the potential value of the asset has similar increased, including relative to other aspects of intellectual capital.

Even with its burgeoning value, relational capital's lack of attention plays out in some of the traditional IC metrics. In firm-specific measures such as the Balanced Scorecard and Skandia Navigator mentioned earlier, indirect measures such as marketing expenditures have some value. But to evaluate a wider number of firms, a relational capital component can be difficult to isolate. Tobin's q (Tobin & Brainard, 1979), for example can be applied in estimating total IC but not the individual parts. Pulic's (2000) relatively popular VAIC method does break out individual components with a direct measure of human capital but then lumps everything else into a structural capital remainder that presumably includes an unidentified relational capital value.

So what is the contemporary view of customer relationships and how we might better measure those to guide knowledge management in organizations? One avenue is to borrow from other disciplines, including the concept of brand equity prominent in the marketing literature. The basic theory of both fields is that ongoing interactions between buyer and seller build relational capital as the seller increasingly learns what satisfies that individual buyer (Sussan, 2012; Stahle & Stahle, 2012). Brands have value because customers trust them, based on previous encounters and experiences, word-of-mouth from other users, and a general sense that the brand knows what to do to make them happy. That comes from learning turned into knowledge, and as the firm/brand can leverage that knowledge across customer service providers, it increases not only brand equity but relational capital (Chang & Tseng, 2005; de Castro, et al., 2004). And, again, in today's world with a wealth of data on customer likes, dislikes, interactions, digital media chatter, and other inputs, that aspect of knowledge management takes on increased importance.

1.2 Brand Equity

Branding is central to modern marketing. In an age of trillion-dollar companies, much of which can come from brand equity, a strong brand is seen as a unique and differentiating business asset. Sometimes misunderstood, brands are not necessarily successful because of the name chosen or from a clever catchphrase but more because, over time, repeated successful interactions with users builds trust. Customers develop expectations about the brand promise and as that is delivered and expectations continuously met or exceeded, the value of the brand increases. High brand values reflect firms with extensive knowledge, gained over time, about customer expectations and how to meet them effectively. As such, brand equity is directly related to relational capital or customer knowledge.

Branding is also an old concept, but in today's world, opportunities for brand building have increased in line with customer data, information and knowledge. Digital interactions with customers have mushroomed, not only online and through social media but also through on-the-ground loyalty programs and online/on-the-ground combinations. These interactions are based on what the literature calls information and communication technologies (ICTs), extended networks with individually identified participants (Lechman, 2017). Browsing behavior, website behavior, transactions, social media, mobile apps, and all sorts of other data-gathering opportunities present themselves and can be attached to known, identifiable customers. This customer data-gathering is one of the key trends driving big data and analytics, illustrating the common definition of big data as the "three V's: volume, velocity, variety (Rothberg & Erickson, 2017). Massive stores of real-time data of all sorts (structured and unstructured) provide opportunities for brand-building and for enhancing relational capital, turning data/information into knowledge/intelligence (Rothberg & Erickson, 2017; Sigala & Chaikiti, 2014; Levy, 2009).

Contemporary branding theory started with Aaker (1991), recognizing the value of a signaling mechanism of a better product worth a premium price. The later idea of brand equity encompassed brand value as a function of awareness, associations, and loyalty (Aaker, 1996). As noted, the value is created over time via successful interactions between brand and customer (Keller, 1993). As interactions differ, the perceived value will be different for different users, but a summation of the extra value across all customers provides the sense of total brand equity (Seggie, et al., 2006; Aliwadi, et al., 2003).

The brand equity estimate is somewhat fuzzy as we generally don't actually have these perceived brand values gathered anywhere nor is there anything resembling brand equity in financial reports or related documents. In some ways, that is where intellectual capital makes a connection as differences between firm value and tangible assets is generally thought to include brand equity somewhere, but not in a manner that can be readily accessed. Were we can obtain brand equity estimates is from consultancies preparing "top brands" lists (Interbrand, 20024), though those are often limited to only the biggest brands and so might be of less use for other firms.

What the growth in ICTs brings to the table are not only the exponential increase in brand-customer interactions but also a better understanding of the impact of those interactions. Data by itself doesn't lead to more brand equity/relational capital, but it can lead to deeper insights into how to further delight the customer, actions that do result in an increase. Existing, longstanding knowledge theory supports this line of thought.

Ackoff (1989) is among those credited with developing the DIKW hierarchy. Raw data (D) can be organization as information (I) from which relationships can be discerned (knowledge, K) capable of then providing deeper insights and understanding (wisdom, W). Substitute intelligence for wisdom, and we have the key contemporary concepts of big data and analytics as they related to our core concept of knowledge. DIKW incorporates all intangible assets of the firm and provides a guide for how they relate to each other and the progression from raw data to actionable intelligence. But the important conclusion is that all parts of the hierarchy can have value, even if not immediately. Knowledge is not the only valuable intangible asset.

Following this line of thought, Snowden's Cynefin framework updates DIKW and removes the hierarchy aspect, seeing data/information not only as inputs for other intellectual capital but as valuable assets in and of themselves (Kurtz & Snowden, 2006). Knowledge is also viewed more broadly, with tacit and explicit knowledge broken out separately and also seen as uniquely present and of value in specific circumstances. As is intelligence, forming a DIKW-like structure running through data/information, explicit knowledge, tacit knowledge, and intelligence (Rothberg & Erickson, 2017). And so decision makers have a range of tools and, with a range of circumstances (complex, chaotic, etc.), the successful strategy will fit the most useful intangible assets to the situation.

This perspective is extremely important in puzzling out the meaning and value of relational capital. As noted, ICTs provide considerable big data to companies with strong customer relationship capabilities. Sometimes that is only data/information, and just having a database concerning customers can be a huge competitive asset—identifying which customers to pay more attention to, tracking behavior and communications, and other data-centric activities can yield strategic advantages. But some organizations also have the ability to learn from the databases, customer preferences, customer reactions to marketing activities, and other such knowledge. Sometimes more tacit (leveraged through personal contact or individual learning), sometimes more explicit (more database-driven, leveraged across IT platforms). And, of course, some firms are able to create predictive, actionable intelligence, with intangible assets being used to find insights about the future help decision-making. The recent explosion of interest in artificial intelligence only adds potential value to this last level of DIKW.

Understanding all of this, contemporary intangible assets related to customers are not only varied and valuable but may contain natural metrics that can be used to assess specific areas of value such as relational capital. The most recent research on brand equity recognizes these possibilities, including incorporating social media metrics as a key input into brand value assessments (Fagundes, et al. 2023) from the academic side. From an applied perspective, the potential for applying social media data in estimating brand value is also gaining favor (McDowell, et. al 2023), especially given the wealth of data and the array of means to analyze them. Including, again, artificial intelligence.

For an individual company, standard metrics such as website visits and behavior, social media interactions, loyalty programs, and similar contacts are routinely tracked and can give a good sense of that firm's specific trends in relational capital. More importantly from a broader perspective, these data can be tracked to assess and compare relational capital across firms. That includes quantitative measures as well as qualitative. User chatter on social media and elsewhere can be brutally honest as well as complementary (Rovai, 2002), but can also provide deeper, more illuminating feedback. And, again, these inputs can reveal true feelings about a brand (Rizun & Kucharska, 2018), and platforms are available to allow gathering of the data and comparisons across companies. As a result, we have new ways to judge relational capital as a concept linked to but separate from brand equity.

2. Methodology

After several studies over the past few years to look at patterns in companies' digital media and how they might relate to relational capital or brand equity, we wanted to take the next step and start lexploring at statistical relationships that might allow identification of the key variables driving relational capital. If those can be determined, then relational capital can be predicted by new metrics, allowing more effective management of this particular aspect of knowledge. Consequently, this is preliminary, exploratory research with the core research objective of uncovering the basic relationships between available digital media metrics and relational capital.

In past studies, topics have included tech brands (Erickson, 2023), media brands (Erickson & Rothberg, 2023), ingredient brands (Erickson, Schmidt & Rothberg, 2020), and major consumer goods brands (Erickson & Rothberg, 2017). Preliminary findings from these small sample exploratory studies were that the more valuable brands tended to have a lot more digital media activity (volume), more neutral and more stable (lower standard deviation) sentiment, higher-rated influencers, and few obvious patterns in terms of platforms or other available variables.

The studies employed Salesforce's Social Studio software (now discontinued though other options are available), allowing "social listening" over designated time periods. Social Studio tracks activity concerning keywords (in this case brands) across the entire web, including social media platforms (X, Facebook), YouTube, blogs, forums, news aggregators and commenters such as Reddit, reviews, and other postings. Results provide data on volume of brand mentions, sentiment (positive/negative), top influencers, country, language, and activity by each digital platform. If one desires the actual posts behind the data, for qualitative research and descriptions (including word clouds), that is also available. Note again, results are from the entire internet, not just owned social media accounts.

For this exercise, we pulled the data from the tech brands study (Erickson, 2023) which included two different time periods of results. The brands included were from the smartphone industry, including high-value brands Apple iPhone and Samsung Galaxy as well as relatively high-value Chinese brand Xiaomi, and lesser-known brands Vivo and Oppo. In addition to the Social Studio data, brand equity estimates were available from Interbrand's (2024, 2023) Best Global Brands report for the Apple, Samsung, and Xiaomi names. The brand equity for Vivo and Oppo would be considerably lower, and we plugged in a number for each midway between Xiaomi's value and zero.

Preliminary variable correlation analytics were run using SAS Viya visual analytics software, allowing rapid comparison of the explanatory value of all statistics and easy variable manipulation of identified candidates for additional testing. Note the results are *very preliminary* as the sample is quite small. But the initial insights can then be applied in wider and more statistically significant manner in future studies.

3. Results and Discussion

Initially, we performed a correlation analysis on each of the available variables in the model. These included:

- Brand equity (dependent variable)
- Volume of digital media activity
- Volume range
- Sentiment (positive)
- Sentiment range
- Influencer index (1-100, higher is more influential)
- Twitter volume
- Twitter range
- YouTube volume
- YouTube range
- Forum volume
- Forum range

While the full correlation matrix was obtained and reviewed, we'll only report on the correlation of each variable to the brand equity value the exercise is meant to estimate. These results are included in Table 1.

As indicated, strong positive correlations are seen with the Volume, Twitter, and, to a lesser degree Influencer variables. The Volume and Influencer results are in line with expectations coming into this analysis. The Twitter

result was more surprising. But the initial conclusion is that digital media volume, influential influencers, and Twitter (now X) attention are related to strong relational capital. Strong negative correlations are seen with Sentiment, Twitter range, YouTube range, YouTube volume, and, to a lesser extent, Forum range. This also agrees with previous research indicating high equity brands tend to have less extreme feelings (sentiment) but more steady, neutral reactions. The digital media results were less expected but may also indicate more stability (all three ranges) and less YouTube volume (for no obvious reason).

Table 1: Correlation Results

Variable	Correlation with Brand Equity	Regression	Neural Network
		R^2 = .8908 **ASE** = 2296.3	**ASE** = 0.098
Intercept		-830.62 (.062)	
Volume of digital media activity	0.607	.003 (.206)	
Volume range	0.309	.011 (.198)	
Sentiment (positive)	-0.639	973.5 (.111)	
Sentiment range	-0.138	1205.8 (.152)	
Influencer index (1-100, higher is more influential)	0.398	-1.23 (.018)	
Twitter volume	0.694	330.6 (.118)	
Twitter range	-0.713	-674.8 (.432)	
YouTube volume	-0.498		
YouTube range	-0.516		
Forum volume	-0.239		
Forum range	-0.414		

The table also includes results from a linear regression including the all the variables except the less correlated digital media platforms (YouTube, Forums). Regression adds the ability to see the impact of each variable on the predicted value of brand equity, its statistical significance, and how the explanatory variables work together rather than in isolation.

Before analyzing the regression results, it's important to stress once again that the sample is very small, so any statements about the outcomes in general or statistical significance in particular need to be made with some care. There is not enough data to make confident predictions or to discern fine distinctions. The point of this more exploratory work is to identify potentially interesting variables for future work with bigger, intentional data sets.

Initially, note the results are presented with the coefficient for each item first, with the p value in parentheses. Which also raises a caution about the coefficient as it may be misleading in terms of magnitude and size with relation to the dependent variable—in a complex regression of this sort, with potential between-variable correlations among the many variables, the coefficients would not have the interpretive meaning of a slope in a more simple equation. As a predictive model is refined, we may be able to overcome this aspect in time. But for now, the size and magnitude of the coefficients can't be trusted (collinearity), even if we do include them.

The intercept term is both large and has the second lowest p-value (second highest significance), something that would likely be a concern in a different setting. One typically doesn't want a lot of the equation's explanatory power in the constant. But, again, in a small sample exercise, one can take the result as just part of making the equation work and leave the more rigorous interpretations for future study.

Of the variables, the one with the largest p-value significance is Influencers, at a 98% confidence level. Influencers does have a negative sign for the coefficient but that doesn't match up with what the correlation matrix tells us and makes little intuitive sense. The relative importance of the variable, however, is clear. The next highest p-value significances were Sentiment (positive) and Twitter Volume, at the 89% and 88% levels, respectively. The coefficients both make little intuitive sense, predicting single unit changes in these variables corresponding to hundreds of billions of dollars in valuation, but the Twitter variable at least agrees with the correlation result in sign. That case is similar to what we see with a fourth variable, Sentiment Range, with p-value matching an 85% confidence level but a wacky coefficient value.

The overall quality of the regression is quite good, with an R^2 of .8908, explaining 89% of the variation in brand equity. Average Squared Error (ASE) is also reported, a quality metric of prediction error whose importance will become clear shortly. So, in summary, the regression shows good fit with these variables, even with such a small sample. Moreover, we can identify some key variables that might merit further study, specifically Influencers, Sentiment, Twitter Volume, and Sentiment Range.

A different way to take a preliminary statistical look at the data is to apply an AI approach with a Neural Network. The SAS Viya software performs this analysis easily, grouping the initial variables into new predictors based on iterations to identify the best way to include and weight the inputs for maximum predictive capability. While the underlying relationships are complex and difficult to fully describe, the interactions of the variables uncovered by the analysis can be used to substantially amplify the predictive power. A neural network does provide a straightforward overall quality score and a sense of which variables are most important to the predictive power of the analysis. A visual of what this result looks like within the software is included in Figure 1.

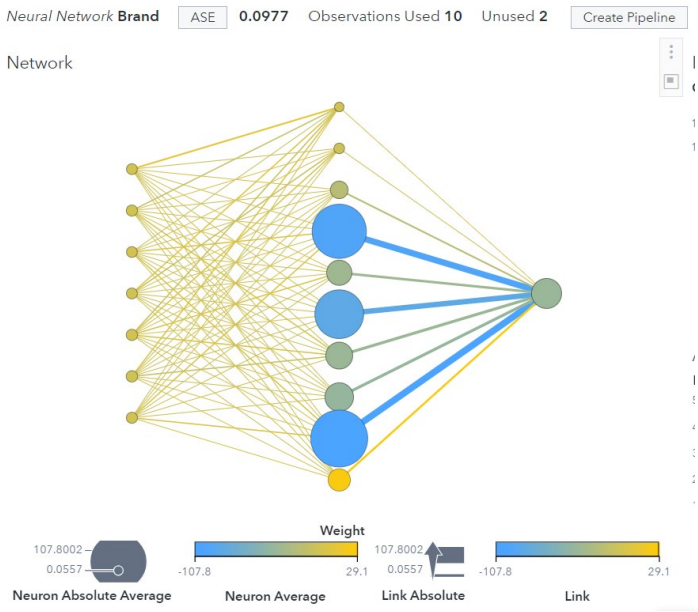

Figure 1: Neural Network Structure

As indicated in the figure, the individual original variables all feed into the newly constructed variables. These latter variables have different levels of correlation with the dependent variable, with the three coded blue showing a strong relationship. Again, we don't know how the original variables specifically fit into these most important constructed variables, but the system has uncovered the manner in which to arrange them and their interconnections in a manner such that the constructed variables have a high degree of predictive power. The quality metric of the overall equation is quite high, an average squared error (ASE) of only 0.0977. Note that figure in relation to the regression ASE of 2296.3, a much lower error rate is obtained with the Neural Network approach.

Further, although we don't have detailed specifics about the relationships between the original variables and the constructed variables, we do have some metrics on relative importance available if we use SAS Viya's Model Comparison feature (Figure 2). While we had already drawn some conclusions from the regression output itself about variable impact, the model comparison shows Influence and Sentiment Range as the most important inputs with all aspects of the process included. These were two of the top four in the discussion above, but the model comparison draws on additional details to isolate the most important contributors. These variables are further validated and even more emphasized in the Neural Network model (note the darker shade of blue). Whatever their relationship with the key constructed variables, these two are the most impactful original variables in a model with high predictability.

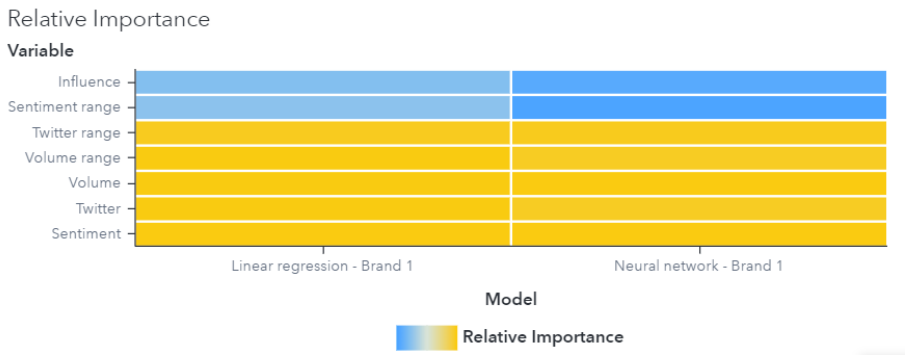

Figure 2: Model Comparison

What we're left with is a much better idea of what the key variables available from sentiment analysis might be, confirmed by a more quantitative approach. Influence, what other widely followed individuals/sites might interact with the brand, and Sentiment Range, how much brand sentiment varies (probably less variation, the higher the brand equity), appear to be the variables on which to focus more research. With more data, bigger sample studies, and other approaches, we can use these initial results to uncover a reliable relational capital metric.

4. Conclusions

This paper reports on initial work to quantify and structure variables that might reliably predict relational capital in organizations. An increasingly important part of firms' intellectual capital holdings, relational capital remains an understudied area in the field.

Using available data on brand equity, a closely related concept to relational capital, we used additional data gathered through the Social Studio sentiment analysis program. Although a very small sample and not statistically reliable in any way, the data are useful to provide initial confidence in concept validity and direction for future research. Previous studies, using data but more qualitative in analysis, had identified some key variables associated with high brand equity/relational capital. These included volume of digital media activity, brand sentiment and sentiment variability, influencers, and, potentially, activity on individual digital platforms.

This analysis used SAS Viya, both regression and neural network modeling, to plug these variables into a more advanced, quantitative analytical framework. The regression results were interesting and surprisingly powerful (high R^2) though the amount of collinearity in the high number of variables limited the ability to make assumptions on individual impact beyond significance. The neural network provided surprisingly impressive results, with a very high level of predictive power. The details of the constructed variables the neural network AI provided are opaque, but their reliability is quite high, with an error rate magnitudes lower than the already high R^2 regression results.

What the indicates is that there is a strong statistical relationship present, apparent even in a model with low statistical reliability. The neural network provides initial guidance to ferreting out this relationship and confirms there is something powerful to be uncovered. A significant, reliable predictive model is apparently available to be found.

Trust is a Factor Determining the Sharing of Knowledge Among Employees of Modern Organizations

Joanna Gajda
Częstochowa University of Technology, Częstochowa, Poland

joanna777gajda@vp.pl

Abstract: In the conditions of a knowledge-based economy, the basic and necessary factor responsible for the transfer of this resource is organizational trust. Organizational trust triggers employees' willingness to cooperate to share knowledge. Without trust in the work environment, skepticism and reluctance to participate in the exchange of knowledge prevail among employees, which makes it difficult to use it in everyday activities. **Aim.** The aim of the article is to examine the relationship between trust and knowledge sharing due to the importance of these factors in building organizational effectiveness. **Method.** Quantitative research was carried out in Poland using the CAWI method. In order to carry out the research, an original survey questionnaire was prepared and distributed to respondents via the Internet. The research group consisted of 358 people. **Results:** The research results revealed differences between the socio-demographic characteristics of research participants and the factors of trust in the management staff and members of the employee team that favor knowledge sharing. **Conclusions:** The research results expand knowledge of the conditions that should be met in an organization so that its members can gain confidence in sharing knowledge. Knowledge obtained from the analysis of own research results may be useful for the organization. It allows you to increase your superiors' awareness of the need to make efforts and take actions to build trust among employees.

Keywords*:* Trust, Sharing Knowledge, Managers, Employee Team

1. Introduction

In a knowledge-based economy, knowledge resources are of great importance for the efficient functioning of an organization. Skillful management increases the transparency of all activities. Processing and transferring knowledge prevents it from shrinking, and what's more, it increases knowledge (Bulińska-Stangrecka,2018). The efficiency of information flow depends on the attitudes adopted by employees. In an atmosphere of mutual support, cooperation and openness to the exchange of knowledge, bonds and trust between team members are developed. The article is of a theoretical and empirical nature. The first part explains the essence of organizational trust and characterizes the concept of knowledge sharing. Next, the research methodology is described and its results are presented. The aim of the study is to analyze the relationship between the factors of trust in the superior and team members and the socio-demographic characteristics of the study participants. The presented research results provide knowledge about the conditions that the organization must meet towards employees in order to make them trust in sharing knowledge.

2. Literature Review

2.1 The Essence of Organizational Trust

Effective solution of problems that a team of employees has to face requires access to information and its rapid flow. In order to expect a positive result in this respect, trust between the members of the organization is necessary. Some of its employees sometimes find it hard to believe that they can trust someone. In order to convince ourselves and others that trust enables people to achieve common goals, it is necessary to build it within the organization.

When considering the concept of organizational trust, it can be related to the general assessment of the organization in terms of caring for its internal stakeholders, being honest and open towards them, creating the opportunity to identify with it. Trust in the organization is associated with the belief that the organization conducts its activities effectively in order to increase the level of satisfaction of its employees with their duties (Rudziewicz, 2017).Trust is built based on the quality of work and the authority of the manager. By paying more attention to building trust, it inspires employees to take action, increasing their level of commitment to everyday duties. This approach to subordinates allows them to believe in their abilities, personal potential, as well as talents and passion for the profession. Trust contributes to increasing employee loyalty, efficiency and shaping a positive attitude towards the company if their superiors actively participate in building a climate of trust, focusing on expanding their managerial competences, creating relationships based on truth and values, and communicating good will towards ordinary employees (Rudziewicz, 2016).Trust is compared to an important

relationship between an employee and his or her superior, in which both parties undertake to fulfill the obligations imposed on them by the employer. Organizational trust concerns the mutual fulfillment of their obligations by the parties involved in the interaction (Kapuścik, 2015).It can be present in a horizontal and vertical arrangement. Horizontal trust occurs among people cooperating in the workplace when they work at the same organizational level. Vertical trust occurs when there are relationships between employees and their superiors, top management and their superiors, or members of the entire organization (Bugdol, 2010).Good management of an organization should come down to fulfilling the integration function between all its members. Good management is about maximizing the company's value, communicating and fulfilling promises to employees, and enabling them to identify with the workplace. Trust is achieved by building good relationships between team members and between the manager and employees (Józefowicz, 2015).The bond makes employees feel greater trust in other members of the organization and engage in the process of mutual implementation in joint work, contributing to building internal motivation to achieve greater work efficiency. Companies' activities aimed at bringing employees closer to achieving this goal should contribute to strengthening organizational trust, which, according to the authors of the Organizational Trust Index, means "the ubiquitous belief that the organization in its communication and behavior is competent, open and honest, committed, reliable and deserving of identification with its goals, norms and values" (Shockley-Zalabak et al, 2010). Based on previous research in the field of management sciences, it is indicated that the level of organizational trust depends, among others, on the mutual interactions that take place between organization members, the effectiveness of communication, employee competences and their motives (Bulińska-Stangrecka).Certainly, management behavior, regardless of management level, has a major impact on the development of organizational trust. Undoubtedly, what is important is the tendency to express empathy towards others, to genuinely show respect for each other, and to ensure compliance with the principle of fair treatment of employees in various situations that occur in the workplace (Józefowicz, 2015).

2.2 Sharing Knowledge - Characteristics of the Concept

Modern organizations achieve success on the market in a dynamically changing reality thanks to knowledge about the market, potential and commitment of employees for the efficiency of their operations. These factors are directly or indirectly related to knowledge. Perceiving knowledge as a determinant of the efficient functioning of the organization results from the experience and skills of employees and constitutes a serious challenge for the organization on the way to growth. C. Sołek emphasizes, following Bagshaw, that if knowledge is not translated into action, it will not be used correctly and continuously, and therefore it will not bring benefits to the organization. In order for it to be considered a company resource, a special role is played by those members of the organization who take part in its creation and transfer (Sołek, 2012).If there is a belief in the existence of individual or team knowledge and it is possible to recognize who has it, it is said that the organization has conditions for sharing knowledge. Sharing knowledge in an organization is, according to J. O. Paliszkiewicz, a process consisting in making information available to employees who need and seek it, or the flow of knowledge between co-workers or teams of employees within the company (Paliszkiewicz, 2007). Therefore, sharing knowledge is two-sided and interactive, during which people who decide to participate exchange it with each other. As S. Spałek and his colleagues note after M. Ipe, "the person transmitting knowledge does so consciously and voluntarily, at the same time relinquishing ownership of the knowledge in favor of sharing it with the recipient and with the intention that it will be understood, assimilated and used appropriately by him" (Spałek et al, 2018). Therefore, sharing knowledge leads to the acquisition of new knowledge or the effective application of existing knowledge (Flaszewska, 2019). According to G. von Krogh, by sharing knowledge one can notice a change in the level of knowledge and behavior of people who disseminate it and who can use it (Rudawska, 2013).

3. Methodology

The aim of the study was to verify the relationship between organizational trust factors and knowledge sharing in Polish organizations . It was checked what factors of trust in the superior and team members influence decisions about the willingness to share knowledge for the organization in which they are employed. Relationships were determined between the answers provided by respondents and their characteristics in terms of gender, age, seniority and size of the organization. Respondents from all over Poland took part in the study. The research was conducted in the first quarter of 2023 using online technology, anonymously. The CAWI method used a survey questionnaire sent to respondents via the Internet to answer the questions. Ultimately, the research group consisted of 358 people. The characteristics of the study sample are presented in Table 1.

Table 1: Characteristics of the research group

Features of the study group		N	%
Gender of employees	females	188	52,5
	males	170	47,5
	SUM	358	100
Seniority	Up to 1 year	6	1,67
	2-5 years	33	9,21
	6-15 years	115	32,12
	16-25 years	91	25,41
	26 and more	113	31,56
	SUM	358	100

Source: own study

χ2 independence tests were performed for the given research sample. The level of statistical significance was assumed to be $p<0.05$. The calculations were performed with the statistical program STATISTICA 13.3 by Statsof. Based on the study, it was assessed which factors of trust in the superior and members of the employee team translate into the willingness to participate in the exchange of knowledge with members of the organization. Additionally, the aim of the study was to determine whether the nature of the answer to the question depends on the socio-demographic characteristics of the surveyed group.

For the purposes of this study, the following research hypotheses were formulated and verified:

1. Socio-demographic factors of respondents differentiate their answers to the question: what attitudes and behaviors do superiors demonstrate to strengthen employees' trust in sharing knowledge?
2. Factors in the dimension of the characteristics of the employee team determine the involvement of employees in the exchange of knowledge and are closely related to the socio-demographic characteristics of the respondents participating in these studies.

4. Results

Building employee involvement in sharing knowledge is one of the challenges for direct superiors of modern organizations, because the effectiveness of activities in this area largely depends on them. One of the foundations of a supervisor's success is gaining the trust of employees.

In order to verify H1, the correlations were examined between the respondents' answers in the context of specifying the factors of trust in the superior, which are intended to inspire them to share knowledge, and the respondents' socio-demographic factors. It is essential that managers have the willingness and appropriate competences to provide employees with opportunities to be active in the exchange of knowledge. What conditions managers in Polish organizations create to gain employees' trust and encourage them to share knowledge are shown by these research results, which are included in the tables below. This hypothesis was largely confirmed.

Table 2: Relationships between trust factors in the superior that influence knowledge sharing and the gender of the respondents

Supervisor's behavior that inspires trust among employees to share knowledge	Sex %		The value of the statistic	
	Women	Men	Chi2(χ2)	p
Encourages maintaining good relationships between team members	50,96	49,04	0,935	0,333
Builds a sense of shared responsibility for achieving goals	50,58	49,42	13,174	0,000
Individual approach to the employee, interest in his opinion	50,16	49,84	6,926	0,008
Inspires employees to act and achieve goals in line with his expectations	54,85	45,15	1,537	0,214

Supervisor's behavior that inspires trust among employees to share knowledge	Sex %		The value of the statistic	
	Women	Men	Chi2(χ2)	p
Reliably and sympathetically assesses employees' efforts and work results	46,79	53,21	16,910	0,000
Helps employees develop and professional career	51,43	48,57	7,399	0,006
Initiates contacts with team members after work	49,28	50,72	0,359	0,548

Source: own study

The results of testing the relationship between the supervisor's attitudes and behaviors listed in the table above and the respondents' gender indicate in four cases a positive, statistically significant relationship between the variables ($p<0.05$). This means that the observed distribution of observations within variables 2,3,5,6 depends on the variable gender. The Chi2 test result showed differences between women and men in relation to these variables. Women are more likely to notice the above-mentioned competencies of the superior, which constitute the foundation of trust in sharing knowledge based on which the organization can function efficiently in a competitive environment. The position expressed by women regarding the tendencies shown by superiors to build a sense of co-responsibility for achieving goals proves the desire to build trust in it by positively motivating employees to work, encouraging them to actively participate in the exchange of knowledge and experiences, and presenting different points of view. Such involvement of employees in common successes becomes profitable for the organization, as it brings positive results, especially in the form of integration of team members, looking for ways to reach each other, and building awareness of conscientious fulfillment of one's duties. The summary of superiors' behavior also shows that an individual approach to an employee and interest in his opinion are very important for women; reliable, sympathetic assessment of employees' efforts and results. It can be concluded that superiors use such methods of approaching women to build trust in them and encourage them to take initiatives to exchange knowledge. Men believe significantly more often than women that providing employees with access to development and support in their professional career can have a positive impact and constitute an incentive to participate in the knowledge sharing process.

Table 3: Relationships between trust factors in the supervisor that influence knowledge sharing and the respondents' work experience

Supervisor's behavior that inspires trust among employees to share knowledge	Seniority					The value of the statistic	
	up to 1 year	2-5 years	6-15 years	16-25 years	26 and more	Chi2(χ2)	p
Encourages maintaining good relationships between team members	2,30	7,28	32,57	27,59	30,27	8,507	0,074
Builds a sense of shared responsibility for achieving goals	1,74	9,59	33,43	24,71	30,52	11,030	0,026
Individual approach to the employee, interest in his opinion	1,87	10,28	29,28	27,10	31,46	15,764	0,003
Inspires employees to act and achieve goals in line with his expectations	1,27	1,27	40,51	23,63	33,33	65,728	0,000
Reliably and sympathetically assesses employees' efforts and work results	2,14	11,79	37,86	21,07	27,14	41,534	0,000
Helps employees develop and professional career	1,71	8,57	31,43	26,00	32,29	14,251	0,006
Initiates contacts with team members after work	0,00	31,88	47,83	5,80	14,49	76,471	0,000

Source: own study

The above results indicate that there is a significant statistical relationship between seniority and virtually all factors of trust in the superior that facilitate knowledge sharing. The only exception is factor 1, which does not differentiate the respondents' statements. It can be noticed that work experience in the range of 6 - 15 years differentiates the respondents most strongly in terms of trust in their superior in the context of sharing

knowledge if he or she displays behaviors characteristic of variables 2, 4, 6, 7. It should be assumed that superiors, out of concern for the activity of employees with longer work experience, expect them to share responsibility for achieving goals. This may result from the need to build awareness among employees that they are a key part of the organization, the success of which depends on their willingness to work and their involvement in acquiring the knowledge necessary to perform their duties at the workplace. When a superior inspires employees to take actions related to sharing knowledge and therefore achieving goals in line with his expectations, he can make them willing to be open to taking up challenges and overcoming the difficulties resulting from them. In the case of long-term employees who have proven their professionalism and enjoy a strong position in the workplace, the superior uses other motivators to encourage the sharing of knowledge, such as: initiating contacts with team members after work and offering help and support in career development.

Employees with 26 years of experience and more have great trust in their superiors and are willing to share knowledge if their superiors demonstrate behavior towards them consisting of: an individual approach to the employee, interest in his or her opinion, and when he or she helps in professional development. It follows from the above that employees have the right to trust their superior because he is aware of their competences and can count on better use of their potential.

Comparing the differences in the statements of employees with short work experience - a maximum of 5 years, it should be noted that with its increase confidence in sharing knowledge increases if the superior helps build it.

In order to verify H2, the relationships between the analyzed variables in the research area regarding trust factors in co-workers and the socio-demographic characteristics of the respondents were examined. Trust in the employee team has a positive impact on the work efficiency of its members and the quality of cooperation between them in terms of engaging in knowledge exchange. What conditions must be met in a team so that its members are willing to share the necessary knowledge that the company needs to increase its chances of achieving business goals? The answers to this question are provided by the results obtained from this research, which are presented in the tables below. The results presented therein show that in most cases there is a statistically significant correlation between the analyzed variables and inform that this research hypothesis is true.

Table 4: Relationships between the factors of trust in members of the employee team, conducive to knowledge sharing, and the gender of the respondents

Actions of team members that build trust in sharing knowledge	Sex %		The value of the statistic	
	Women	Men	Chi2(χ2)	p
Willingness to help each other	52,86	47,14	0,060	0,805
The team creates favorable conditions for fulfilling one's ambitions	49,06	50,94	5,014	0,025
Mutual appreciation of experience and knowledge	62,45	37,55	25,136	0,000
Openness to understanding the needs and problems of team members	62,95	37,05	26,119	0,000
Openness to new solutions and ideas	52,92	47,08	0,103	0,747
Openness to expressing one's own opinions and views	57,87	42,13	10,073	0,001

Source: own study

Based on the obtained research results, it was observed that women are significantly more likely than men to gain confidence in sharing knowledge if the team is characterized by the following features: mutual appreciation of experience and knowledge; openness to understanding the needs and problems of team members; openness to new solutions and ideas. Men are more inclined to exchange knowledge if the conditions in the team are conducive to fulfilling their own ambitions.

Table 5: Relationships between the factors of trust in members of the employee team, conducive to sharing knowledge, and the work experience of the respondents

Actions of team members that build trust in sharing knowledge	Seniority					The value of the statistic	
	Up to 1 year	2-5 years	6-15 years	16-25 years	26 and more	Chi2(χ2)	P
Willingness to help each other	2,14	10,00	31,79	23,21	32,86	5,707	0,222
The team creates favorable conditions for fulfilling one's ambitions	0,00	10,49	25,84	32,21	31,46	51,395	0,000
Mutual appreciation of experience and knowledge	0,00	3,06	37,12	26,20	33,62	42,765	0,000
Openness to understanding the needs and problems of team members	2,68	5,80	29,02	36,61	25,89	48,522	0,000
Openness to new solutions and ideas	1,37	10,65	29,55	24,05	34,36	12,513	0,013
Openness to expressing one's own opinions and views	2,36	9,06	34,65	27,17	26,77	11,625	0,020

Source: own study

In terms of the work experience variable, statistically significant positive correlations ($p<0.05$) were revealed in relation to all trust factors towards the employee team, except point 1. Employees with 16-25 years of experience engage in knowledge exchange significantly more often than other respondents if the conditions in the team are conducive to fulfilling their own ambitions. People with 6-15 years of work experience are more willing to share knowledge when their experiences and knowledge are appreciated and they are open to expressing their own opinions and views.

Employees with long work experience (26 years and more) are significantly more likely to express readiness to share their knowledge with others if the team is open to new solutions and ideas.

5. Discussion

The research hypotheses set out in the article were confirmed and allowed to expand knowledge about the described issue. Based on the obtained research results, it can be concluded that there is a relationship between the analyzed factors of trust in the superior and members of the employee team in the context of knowledge sharing, and the socio-demographic characteristics of the respondents participating in the study. The research results clearly indicate differences between genders in the level of trust in the superior resulting from his positive attitude and behaviors that encourage sharing knowledge. Women's trust in the exchange of knowledge within the organization is greater than that of men and is the result of the attributes possessed by the superior. One example to support the above statement is the concept of Pamela Shockley-Zalabak, Kathleen Ellis and Gaynelle Winograd (2000), which shows that management staff is more effective when they demonstrate skills, demonstrate openness, honesty, concern for employees and approach the performance of their duties reliably.

It can be concluded from this that women are more willing to share ideas, knowledge and experience when they are led by a leader who creates an atmosphere of trust by being open to subordinates. When a highly inspiring supervisor guides them on their way to achieving their professional goals and behaves freely, it triggers the desire to cooperate and maintain better relationships with each other, so that they want to work more productively.

Moreover, research indicates that men have significantly greater trust in their superiors when they reliably and sympathetically assess employees' efforts and work results. The results obtained from the research are consistent with the research of other authors regarding the impact of employee trust on knowledge sharing. In the context of key factors in relation to the discussed issue, it is possible to point out the current results of analyzes confirming the relationship between management support and employee participation in knowledge exchange. A. Cabrera, W.C. Collins, J.F. Salgado (2006) draw attention to the importance of the role that management is to play in building employee involvement in active participation in this process. Moreover, they emphasize that they should influence employees' positive perception of the importance of activities aimed at mutual transfer of knowledge that the organization needs.

Hsiu-Fen Lin and Gwo-Guang Lee (2004) emphasize that support from management is a necessary condition for shaping an organizational culture conducive to the effectiveness of these activities.

Based on the obtained research results, it can be concluded that the seniority of the respondents clearly differentiate their trust in the management regarding the behavior encouraging their subordinates to share knowledge. Employees with 6-15 years of work experience and 26 years or more of experience have significantly greater trust in their superiors. They are not newly employed, which means that, compared to other groups of employees, they may be more mature and aware of the competencies that a superior should have to make them trust in carrying out activities requiring cooperation in the workplace.

The results of previous research emphasize the role of trust as a factor supporting the improvement of the quality of the relationship between the superior and the subordinate, which is reflected in the mechanism of social exchange. The principle of reciprocity is at the basis of social exchange, and the employee, guided by it, should, in gratitude for the support shown to him, including the actions of his superior, creating conditions for the fulfillment of professional duties, repay him by actively participating in the exchange of knowledge for its application in real situations (Wnuk, 2020). To meet the organization's requirements and demonstrate loyalty to it, employees have specific expectations of management. They require positive attitudes and behaviors towards them, helping to create trust that determines the effective sharing of knowledge within the organization.

Based on the results obtained, it should also be noted that there are positive relationships between the analyzed socio-demographic factors and trust in members of the employee team. Women declare a higher level of trust in the team and, therefore, a greater participation in the exchange of knowledge, if colleagues appreciate their experiences and knowledge, there is openness in the team to understand the needs and problems of team members and the ability to express their own views. Men have a higher level of trust in the work team if the conditions in it are conducive to fulfilling their own ambitions. When assessing individual aspects of trust in the team, employees with experience are significantly more likely to engage in knowledge exchange: 6-15 years of work (mutual appreciation of experience and knowledge; openness to expressing one's own opinions and views), 16-25 years of work (the team creates favorable conditions for fulfilling one's ambitions; openness to understanding the needs and problems of team members), 26 and more years of work (openness to new solutions and ideas). These results are consistent with other studies cited in the literature review (Biesok, 2013), which show that women have a higher level of trust in their colleagues, which makes them willing to share knowledge with them. A similar position is expressed by people with greater work experience. They point to several reasons for active participation in knowledge exchange, resulting from trust in colleagues: they enjoy the recognition of their colleagues, they have the opportunity to implement their ideas in the team, their involvement is appreciated. A low level of trust occurs among young people with short work experience. They are reluctant to share knowledge due to low job satisfaction, poorer cooperation and lack of recognition in the team.

6. Conclusions

The aim of the research was to determine the impact of socio-demographic factors on employees' tendency to trust management staff and co-workers, which determines the willingness to engage in active participation in the exchange of knowledge necessary in everyday work. The research results revealed differences between the characteristics of research participants and the factors of trust in other members of the organization. In order for employees who are research participants to trust them, certain conditions must be met that create an atmosphere conducive to strengthening the relationship between them. It follows that people will be willing to share their knowledge when their expectations are met by other members of the social interaction. The formation of organizational trust is influenced by the attitudes and behaviors displayed towards others, which result from having specific competences. Trust also appears when the person from whom it is expected is characterized by kindness, openness, reliability, and concern for others.

Taking into account the limitations resulting from the conducted research, it was found that the majority of study participants assessed a high level of trust in their superiors and the employee team thanks to the attitudes and behaviors they demonstrated (factors that build trust in sharing knowledge) proving their involvement in the process of including other employees in activities related to the knowledge sharing process. The author faces the challenge of conducting research on the impact of respondents' characteristics on trust in knowledge exchange in organizations due to their size, on a representative sample using a more extensive measurement tool.

Abstract: The issue of effectively learning from experience through Lessons Learned (LL) is a long-standing one. Its deployment in the space sector, although more recent, is a well-established issue in the space business. Both the European Space Agency (ESA) and the French Space Agency (CNES) include Lessons Learned capitalization in their processes regarding development of orbital systems. One of the goal of these activities is to improve the risk assessment managed by the project teams, by providing them with lessons learned coming from previous projects. Management procedures, technical standards and handbooks used by the projects can also be improved as a result of the lessons capitalization. There are several steps in the capitalization process. Lessons Learned proposals need to be collected, then analyzed by experts, shared and agreed before being turned into understandable and usable lessons. Finally, these lessons need to be made available to the potential users. The first step in the capitalization is to collect the lessons, which is time consuming. People working in space projects do not usually produce lessons on their own. In order to help them, both agencies have organized Lessons Learned capture events, gathering people working on a project, and inviting them to elaborate collectively the Lessons Learned from their project experience. Attendees can come not only from the agencies, but also from their partners (for example other agencies, industrial companies). The paper deals with how ESA and CNES apply their LL processes. It especially describes the case study of capture events (preparation, typical description of an event, outcomes). The emphasis is put on the methods used both to have participants committed to the approach and to produce useful lessons. Events typical examples are given. Finally, the paper compares ESA and CNES approaches and insists on the benefits capture events can bring to Organizations.

Keywords: Space Sector, Lessons Learned, Knowledge Sharing, Cooperation, Event

1. Introduction

The issue of lessons capitalization - effectively learning from experience through Lessons Learned - is a long-standing one. Both the European Space Agency (ESA) and the French Space Agency (CNES) include Lessons Learned capitalization in their processes regarding development of orbital systems

The first step in the capitalization is to collect the lessons coming from the projects. There are several ways to do that. For example, we can analyze reports written by the projects teams, reports written by investigation committees on anomalies, anomaly sheets. But this is not enough. That is why a more collaborative approach such as capture events to collect the lessons has been put in place both at ESA and CNES.

After a brief description of the Lessons Learned processes in both agencies, the paper will focus on a case study of how ESA and CNES organize these capture events. The aim is to show what kind of methods can be applied to collect lessons, and what their respective advantages and drawbacks are.

2. Lessons Learned Processes

2.1 At ESA

The Lessons Learned (LL) process is an ESA level (corporate) implementation of the principles set out in the ESA Lessons Learned Policy.

The objectives of the Lessons Learned are to:

- Continually improve the quality and value of all the Agency's activities through improving standards, processes, tools and training;
- Identify changes needed as a result of experience in the execution of the Agency's activities, through deployment of appropriate processes and associated tools;
- Create an environment within which continuous improvement occurs.

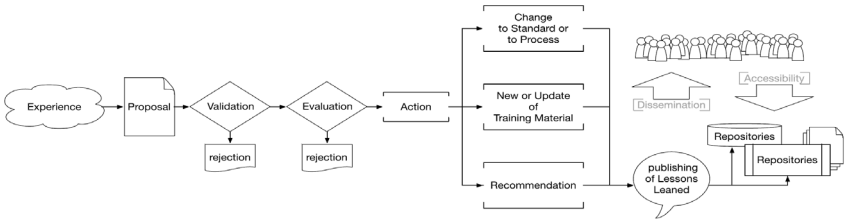

Figure 1 : Overview of ESA Lessons Learned process

The Lessons Learned process allows captured experiences, both positive and negative, to be transformed into knowledge shared for current and future use, as part of everyday practice throughout the Agency. The ESA Lessons Learned process is based on the following principles:

1. The Agency ensures effective communications and knowledge sharing throughout the organisation, including across organisational boundaries;
2. The Agency ensures that staff has access to relevant organisational experience and information;
3. No one in the Agency is excluded from proposing valuable lessons to be learned;
4. The Lessons Learned process is based on all experiences, positive and negative ones;
5. All Lessons Learned proposals are systematically screened (i.e., validated by the activity / project manager, evaluated by the ESA or Directorate level Board);
6. The Lessons Learned process is supported by appropriate tools (ESA Lessons Learned Portal**), training and resources;
7. Respective Directorate processes are aligned and comply to this Agency Lessons Learned process;
8. Actions are to be taken, following positive evaluation of a proposal, to implement proposed changes and thereby learn the lessons (i.e., Learning actions assigned to process owners to assess experience and adoption in the relevant process, its related documentation and training);
9. Originators of Lessons Learned receive feedback on their proposals;
10. The Agency ensures that approved Lessons Learned are appropriately disseminated within the organisation and that Lesson Learned records are retained and archived (ESA Lessons Learned Portal**);
11. The Agency actively promotes and supports the Lessons Learned process;
12. Confidentiality is respected where necessary, although the focus is on organisational learning.

As a lesson is not learned through its identification only, the Lessons Learned process is to be understood to involve the identification and learning of lessons as two discrete but interfacing processes:

- identification of potential lessons and their validation; and subsequently
- organisational learning of the lessons through implemented action.

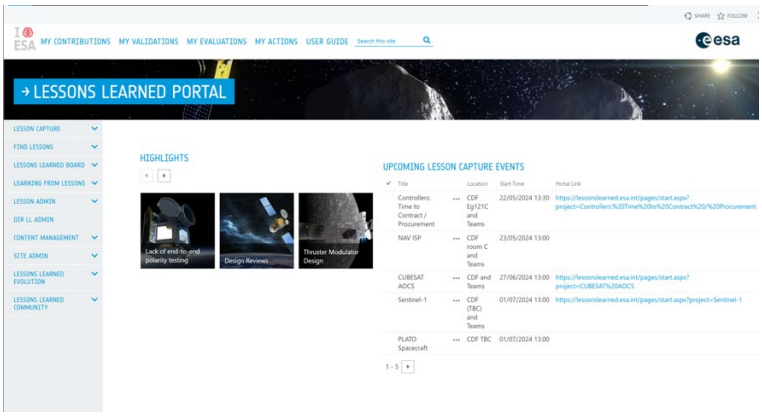

Figure 2 : Homepage of the ESA Lessons Learned portal **

Lesson identification is a process that identifies topics where experience and/or expertise need to be transferred within the Agency. Lesson identification is relevant for every aspect of the Agency's activities, but the nature of experience gained and the manner in which they are assessed, validated and disseminated may vary considerably according to organisational area and/ or domain. Proposed and dispositioned lessons are captured in an ESA central repository, the ESA Lessons Learned Portal**, which contains the history of validations, evaluations and the learning action closure of all proposed lessons, specifically:

- the context in which and a description of the experience gained;
- a proposed learning /improvement derived from the experience,
- if rejected, the justification for rejection, and if approved, the action needed for systematic learning

2.2 At CNES

The organization of the CNES Orbital Systems Lessons Learned (LL) is described in the CNES Management System, certified by ISO 9001 and ISO 14001.

The first issue of this process was written in 1996. Prior to that date, the various CNES departments operated independently regarding LL. Then, as a lesson learned, the need for centralization became obvious.

LL deals with the following topics:

- The technical outcomes of an orbital system project (for example engineering and quality),
- The operational issues at system or subsystem levels,
- The project management.

The organization is based on a LL Bureau, in charge of the technical coordination and of the LL tool management. The Bureau supports the secretariat and animation of the Comity of Return of Experience (COREX), which is a board of 20 senior experts, deciding the validation and publication of Lessons Learned. Members of the board come from the different CNES directorates, and the board covers the different kinds of orbital systems projects, and all associated technical skills. They are the LL points of contact for their respective directorates.

LL proposals are collected from different sources:

- The COREX members,
- The projects managers and their teams: the inputs coming from projects can be Anomalies, Non Conformances, quality alerts, technical Working Group and Review reports, but also End of Projects evaluations, which include LL proposals.
- Each CNES employee, who can propose LL directly through our database (Figure 3).

From these proposals, the Bureau and the COREX prepare LL sheets, completed by generic RIDs (Review Item Discrepancy), to be used by the other projects teams and reviewers, to help them better managing the risks. The goal of the LL process is also to capitalize by improving the CNES Normative System. The LL can generate change request proposals to update both the CNES Internal Standards and the applicable ECSS (European Cooperation for Space Standardization) standards.

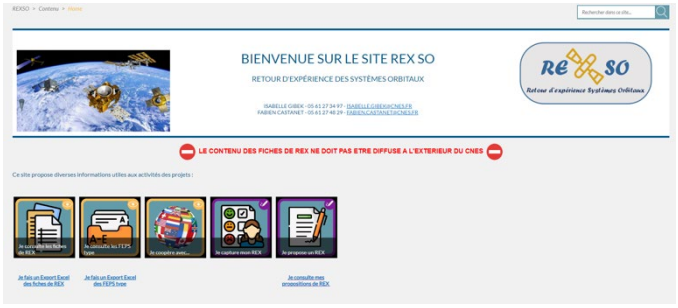

Figure 3 : Homepage of the CNES LL database, called REXSO

The LL are published in a cooperative tool: the REXSO database. Each LL sheet contains lessons and recommendations, and is pointed towards one or several generic RIDs. These generic RIDs suggest adequate questions, built from the LL sheets recommendations, to help reviewers as reminders during the project reviews. They are written both in French and English, and they depend on the project phases.

We have decided to keep a total of less than one hundred (100) active LL sheets inside the database, so that the analysis remains feasible for the projects team members, in compliance with their workload. LL sheets are regularly evaluated and archived in a backup folder, for example each time a related topic is included either in the standards or in our internal training material. The database is also used to preserve these archived LL sheets.

The projects teams only use the active LL sheets. The Bureau holds a LL kick-off meeting with the Project team at the very beginning of a project. The project team, with the help of the Product Assurance people, analyses

the potential applicability from the list of active LL sheets and selects the valuable ones. To manage the verification of conformity with these project useful selected sheets, experts are identified and tasked to take into account the associated LL. Then the conformity status is presented during the main reviews all along the project development.

CNES existing LL process has remained at internal level in the collection of lessons since many years. This is changing with a common plan to also capture and share lessons with ESA LL process, from projects developed in cooperation with integrated teams (Herd et al, 2022).

3. Capture Event

3.1 In General

There are in general, three capture techniques that could be employed by any organization to capture learning from experience. The techniques each have their strengths and weaknesses, and require different levels of investment to prepare for carry out and complete the experience capture process.

3.1.1 Interview Technique (Teams)

Team member interviews (carried out at the individual level) are a resource-intensive approach to lesson capture, but one which overcomes reluctance for team members to "speak up" during collective or group meetings, and ensures all voices are heard. This approach is a combination of an After Activity review questioning and the "Learning History" approach used at the Massachusetts Institute of Technology (MIT). The technique affords both Individual and (project) team based involvement with validation by the authorized individual. The outcome of this technique is the publication of individual lessons to be learnt and may include lesson prioritization. This technique's capture event typically has a duration spanning weeks to months and may be performed at any point within or at the end of a project.

Involvement - Individual or (project) team based collection

Validation - Individual validation

Outcome - Publication as individual lessons to be learnt

Lesson prioritization - on Team-based highest ranked learning taken from:

project objectives and outcomes, and

ranking of the key learning points (impact to the project) and,

their transferability to other projects

When to capture - no predetermined time

Capture event duration - weeks to months

Applicable time-span of lesson capture - At any point within or at the end of a project

3.1.2 After Activity Review

This technique is a short and focused meeting conducted by project teams, lasting for around 30 min. It is intended for immediate and in-the-moment learning. The After Activity Review allows for the capture of useful operational knowledge that can be discretely implemented for immediate repetition, allowing for improving performance by:

- Initiating course corrections during activities based on what is being learnt
- Addressing and optimizing a team's way of working
- Building collective operational knowledge resources

Involvement - (project) team-based lesson collection

Validation - immediate / in the moment

Outcome - immediate learning within the team

Lesson prioritization - no selection - all lessons where there was a deviation in outcome from expectation

When to capture - Immediately after each "activity" - single time-slot based on event or pre-specified time duration

Capture event duration - 30 minutes

Applicable time-span of lesson capture - Focus on a daily or limited period of time (discrete action, and proposed immediate repetition of that discrete action) - may also be since last After Activity Review

3.1.3 Retrospective View

The Retrospect is one of the most effective processes with a duration ranging from ½ to several days, for capturing Lessons from a project team, at key milestones/deliverables, or at project end. A Retrospect can bring out the key knowledge and experience developed by a project team, and capture it for future reuse and for the benefit of future projects. By facilitating a dialogue within the whole team, knowledge can be identified that comes from the whole team experience - knowledge that any one individual may be unaware of, but which the team as a whole knows. Good facilitation ensures high quality lessons which can be understood by people outside the project team.

Involvement - Team-based collection of lessons at the end of a project

Validation - by team during dialogue

Outcome - learning is captured in the form of a lesson by facilitator

Lesson selection - on Team-based highest ranked learning taken from:

project objectives and outcomes, and

ranking of the key learning points (impact to the project) and,

their transferability to other projects

When to capture - at the end of the project

Capture event duration - 4hrs to 4 days

Applicable time-span of lesson capture - entire project - however known limitations with memory of individuals based on the following

i) the limited recall

ii) preference on recently (better remembered events) than those of by-gone years

3.2 At ESA

At the corporate level, ESA has adopted an adaptation of the retrospective approach – improving it to fit within project lifecycle and the dynamics of the space sector in the definition, design manufacture and test and finally commissioning operations and de-commissioning of a space mission.

3.2.1 Event-Based Lesson Capture (and Validation)

The event-based focuses on collaborative team lesson collection and validation, facilitated in 3 modes – physical meeting, on-line videoconference (called e-capture) or a mixture of the two (called hybrid capture). Initially (from 2019) carried out as only a physical meeting, using the Concurrent Design Facility (at the largest ESA site, both in terms of workforce and footprint – ESTEC, The Netherlands), ESA created an immersive and safe environment to share experience from projects (both positive and negative). This meeting enabled the experience and associated proposed learning to be captured effectively on the basis of team discussion and agreement by the activity / project management. Discussion was supported through the use of ESA Lessons Learned Portal (based on Sharepoint) using a dedicated project-specific webpage, which could be shared by the portal administrator to all those in the meeting. During COVID (2020 / 2021) the capture events were adapted to on-line only, and the format reduced to 1/2day.

13:00	Introduction I) Overview of Project / Activity (Activity / Project Manager) II) Lesson Capture Process (ESA LL Secretariat)
13:30	Lesson Capture Collection of Lessons
14:30	Break
14:45	Validation Group discussion on each lesson Validation of lessons by Activity/Project Manager
17:15	Event Feedback and e-questionnaire
17:30	Meeting Ending

Figure 4 : Typical agenda of an ESA (corporate) Lesson Capture Event

It was found still effective using this technique with the added benefit of efficiency regarding reduced time of the event and removing the need to travel. As such it was found that participation of experts in the e-event increased significantly over the COVID period. Now out of COVID constraints, the ½ day format remains, with the event being both physical and on-line – creating the so-called “hybrid” event.

Figure 5 : ESA Project (AEOLUS) capture event using the Concurrent Design Facility (CDF) in 2019

It is typically a space mission project focused technique which is initiated at discrete significant milestones in the project (at least 3 times, relating to key project phases). It involves project and technical teams who have been directly, indirectly or partially and temporarily involved in the project, and includes validation authority (typically the activity or project manager) and can also involve evaluation entities. The validation of captured lessons happens by the project manager during the event through sharing of the captured lesson and dialogue that is initiated with the team present in discussing their content. Once lessons are validated, they are immediately visible to all ESA colleagues, as well as being forwarded to the Lessons Learned board for evaluation. This technique is applied equally to projects as it is to technical and non-technical topics.

Focus over a period of time (typically years)

Involvement - project and technical teams

Validation - by project manager during event dialogue

Outcome - proposed and validated lessons (ready for LL Board evaluation)

Lesson selection - none - all considered equal (if validated - pending evaluation)

When to capture - at discrete significant milestone in the project

Capture event duration -1/2 to 1 day

Applicable time-span of lesson capture - from previous lesson capture event (i.e. part of a project)

3.3 At CNES

Two years ago, CNES decided to improve the collection process of LL from projects, because there were less and less written end of project reports. Moreover, projects can last several years, and these reports, often available

only at the end of a project, did not present the LL learned from people that have moved away during the project time frame.

We studied ISO 16192, which outlines LL principles and guidelines that are applicable in all space project activities. It is a good basis which can help to define an in-house process. But each step of the LL process is not precisely defined, especially, the collection of relevant information.

NASA White Paper (2004-2006) describes a Pause and Learn (PaL) session, which is a structured discussion that focuses on recent project developments, challenges, and critical milestones. Consequently, the PaL process is a critical project management tool for learning during the project life cycle. PaL sessions enable project team members to collectively reflect on their experiences and articulate their LL and insights.

That is why we proposed accordingly to put in place capture events and the organization of a moderation process consistent with the objectives of efficiently capturing feedback.

3.3.1 Some observations from a knowledge engineering viewpoint

A particular feature of the proposed approach, as will be detailed shortly, is that it involves two colleges in the selection process: a first college made up of project members, and a second college made up of COREX members.

From a cognitive point of view, this corresponds to two significantly different objectives.

The first panel is tasked with identifying - unanticipated - circumstances that have prevented the production of knowledge that would have been necessary at a given time, or those that have, on the contrary, enabled the production of knowledge that has proved to be particularly useful in solving a problem. This collective awareness of unfavorable and favorable circumstances corresponds to the production of one or more pieces of knowledge. As we shall see, this stage is followed by a selection process based on their representativeness in relation to the project.

The second group will select this knowledge as *data* that is sufficiently new to be included in the REXSO database and to complement existing processes, standards and norms for orbital systems, on condition that it constitutes a corpus that can be processed by humans.

3.3.1 Event Preparation

A capture event consists of a dedicated meeting, attended by the project manager, the project team and as far as possible the main project stakeholders. The project manager is the technical facilitator. He or she is accompanied by the LL Bureau and organizational facilitators. Facilitators manage the brainstorming process during the session, highlight the key messages and control time. The project manager is asked to prepare before the collocation meeting the list of participants among the project team members, which number is on purpose restricted to about 15 people to ease the discussions, even if the project team is often much bigger. Most of the events have yet been organized with CNES people only, but it is encouraged to invite, when appropriate, people from participating research laboratories and from industry.

The meeting date must be fixed long time in advance, so that people can get available. The meeting takes place in person only. It is held in a big open room called “Crealab”, where we can move from one zone to another one according to the different steps of the meeting. A timeline tracing the main stages of the project is displayed, with the aim of encouraging participants to think back to the history of the project. It is mandatory and of high value to get LL proposals not only from the most recent project events.

Prior to the event, a questionnaire is established in order to:

- Inform the participants of the process and give them the opportunity to go back over the project before the capture session,
- Make a preliminary collection of event records likely to be the material for a LL proposal.

This questionnaire is in the form of an Excel file to be sent to participants. It contains LL proposal forms to be completed, as much as possible, by the participants. Participants are asked to send it back several days before the event.

Questionnaires to be completed during the session are also prepared.

3.3.2 Event Sequence

Table 1 shows a typical agenda. Flexibility should be maintained in the event program so that it can be adjusted according to the number of proposals. The duration is a compromise between:

- Not too short to obtain usable results,
- Not too long and dissuasive for participants' availability.

At the beginning of the meeting, we take time for participants to get and share together. It is important to create a good productive atmosphere.

There are three workshops steps during the event:

- The first workshop step, entitled "Vide-greniers", is divided into two phases: an initial presentation of their proposals by each contributor, followed by a second phase during which participants who had not completed the questionnaires beforehand, but who have nonetheless feedback proposals, can express their views.
- A second workshop step is called "The Stations". Participants are divided into sub groups and asked to think about events that could be the subject of feedback based on evocation of three "emotions" (joy, disappointment, pride). A discussion is then led on a priori anecdotal situations occurred during the project, in order to bring into light events likely to be material for new LL proposals.
- A third "sharing" workshop step is held to review and complete the proposals to be submitted to the COREX for decision to include them or not in the LL database.

During this last workshop step, people receive flags for voting. Only proposals considered as lessons sufficiently representative of the project and agreed by the majority of participants are completed. Some proposals can also be gathered according to their similarities and their complementarity.

Enough time must be kept at the end of the event, because clear and elaborated proposals are needed, so that the COREX can analyze them properly.

Table 1 : Typical agenda of a capture event

Phase	Duration
Welcoming participants	30 minutes
General presentation	15 minutes
« Vide-greniers » workshop	2h00
Break	15 minutes
« Les Stations » workshop	45 minutes
Lunch	1h15
« Sharing » workshop	45 minutes
Drafting of the final version of selected LL proposals	1h30
Conclusion	15 minutes

3.3.3 Event Outcomes

Table 2 shows the number of LL proposals obtained at the end of a capture event, and the number of corresponding LL sheets validated by the COREX.

We can see that the number of LL proposals at the end of the collecting event is of the order of a few dozens. After analysis and selection by the COREX, the number of new LL sheets is limited to a few of them. That is to say that only one tenth of the proposals are considered as new lessons to be added to the Orbital Systems LL database.

This drastic selection can be explained in different ways:

- The proposal can be used to update or complete an existing LL sheet, without creating a new one.
- The proposal is not retained as LL sheet, but will be used to update internal trainings, especially the trainings dedicated to people working on projects.
- The recommendations written in the proposal are not mature, and it is necessary to put in place a Working Group on the subject to produce the relevant recommendations. This can later lead to a new LL sheet.
- The proposal is covered by existing processes, standards and norms.
- The proposal corresponds to normal work, the lessons are well-known (It may have been difficult for the project to apply them, for various reasons (human resources, budget, planning, etc.)).
- The proposal needs to be shared with ESA, when it comes from a project in cooperation between ESA and CNES. This can later lead to a new LL sheet.
- The proposal is limited to a specific technical skill, it is not published at system level, but is managed at experts'level.
- The proposal is not generic enough, too specific to a project and its background, and cannot be easily reused.

Table 2 : Number of lessons

LL Capture event	Total number of proposals	Number of proposals after project team vote and gathering	Number of new validated LL sheets	Number of participants in the event	Analyzed project duration (years)
Project A	33	33	3	12	8
Project B	51	31	6	21	3
Project C	62	45	4	18	12

4. Comparison Between ESA and CNES Approaches as Concerns Capture Events

Table 3 shows some differences between the ESA and CNES approaches for capture events.

Table 3: Comparison between ESA and CNES LL events

Category	ESA	CNES	Advantages / Drawbacks
Is capture mandatory as part of normal project process?	Stated as policy, and locally in Directorates implementation varies between best practice and mandatory	Proposed	Mandatory : LL not missing Proposed : People want to come
Language of capture	English	French	English : multi-national organization French : clearer in native language, both for preparation and use of the LL
Is event physical meeting or held on-line (remotely)?	In-person, remote or hybrid techniques	In person only	Remote : easier for participants In person : better discussion and team event
How many lessons are generated (per event)?	No limit placed on lesson capture numbers (averaging around 30 lessons per event, with approx. 10 events per year)	No limit	Most often, people have a lot of things to say

Category	ESA	CNES	Advantages / Drawbacks
How many lessons are held in the database overall?	1600 hundred lessons currently – increasing at around 300 per year	100 active lessons maximum Continuous “cleaning” required	The way projects use the LL contained in the respective databases must be different (see below)
Means to learn from the lessons (portal only, dedicated lessons summaries or lessons embedded in processes document and training)	About 70% lessons are incorporated in our processes and related documents. The remaining 30% is uniquely accessed in the Portal. Function specific views allow for users to easily retrieve their learning.	LL sheets inside the database New versions of processes and standards Internal trainings	Same principles
Is the Agency applying new techniques or technology to ease access to lessons / learning ?	AI techniques are being applied and will be released this year (2024) – knowledge graph and ChatBot techniques assist the user in the ease and quality of both lesson capture and retrieval	AI techniques not required up to now On-line help for the principal operating modes of the database (Confluence pages)	Techniques depend on the amount of data

Thanks to capture events, new lessons are available on a regular basis. The last three lines of the table show the consequences for the overall functioning of the LL process.

5. Conclusion

Both ESA and CNES agencies have organized Lessons Learned capture events, gathering people working on a project, and inviting them to elaborate collectively the Lessons Learned from their project experience. These events are effective, as a great amount of LL material is produced. Projects teams really enjoy the opportunity, when the process is completed, even if some of them are reluctant at the beginning.

These events require a dedicated organization. The organization principles are the same in both agencies, and common capture events could be envisaged. It must be noted that ESA already invite partners to this kind of events.

The lessons coming from capture events are either incorporated in processes and standards, or used to prepare dedicated LL sheets, available in a database. Up to now, ESA and CNES have a different approach as regards the number of applicable lessons in their respective databases. But this does not prevent from organizing common capture events. The common lessons coming from these events can be processed by each agency, according to its own methods.

Acknowledgements

CNES would like to thank the company COUP DE PUCE EXPANSION for its involvement in the capture events.

Our Knowledge Safeguards our Jobs and We're not Sharing! Knowledge Withholding Experiences of Emirati Private Sector Employees

Valerie Priscilla Goby
Zayed University, Dubai, United Arab Emirates

Valeriegoby@gmail.com

Abstract: Since the beginning of its rapid development following the oil boom of the 1960s, the United Arab Emirates has relied heavily on imported labour, largely from low GDP countries. This has resulted in a massive workforce imbalance with currently only about 4% of citizens in the private sector and 60% in the public sector. To address this, the government has implemented workforce localisation policies which provide better conditions, including greater job security, to citizens than to expatriates. Many expatriates perceive the presence of Emirati workers in their organisation as a direct threat to their own employment security. Research has demonstrated that this leads to Emiratis experiencing discriminatory behaviour. This qualitative study gathered data through narrative interviews with 16 Emirati private sector employees conducted to probe their experience of knowledge sharing within their organisations. The dominant themes that emerged from analysis of this data were 1) outgroup identity marking of Emirati employees; 2) purposeful knowledge withholding on the part of expatriate colleagues. Exclusion from knowledge sharing practices were accounted for by participants as due to the perception of employees from low GDP countries that Emiratis enjoy exceptional privilege because of their citizenship of a high GDP country. The implication of these findings is that exclusion from knowledge sharing exerts substantial restriction on the successful integration of citizens within the country's heavily expatriate dominated labour force. This study's contribution is its demonstration of citizenship and job security status as moderators of knowledge sharing practices in multicultural workforces.

Keywords: Emiratisation**,** Job Security, Knowledge Sharing, Multinational Workforces, Nationality Clusters, United Arab Emirates

1. Introduction

This study was conducted in the United Arab Emirates (UAE), an affluent, politically stable country in the Arabian Gulf, which hosts a massive expatriate population. Given much anecdotal evidence on information withholding from Emirati employees by their expatriate colleagues and limited academic research (Al-Ali, 2008; Al-Waqfi and Forstenlechner, 2010, 2012; Goby et al., 2015; Goby et al., 2017), it aimed to provide further empirical evidence on this issue. It explores the complex and challenging relationships between the small number of institutionally privileged local workers and the massive majority of expatriate employees who are substantially unprotected from profit-based corporate decisions regarding salary, work conditions, and job security. This chasm between the entitlements of local versus expatriate employees results in exclusionary tactics on the part of expatriates which frequently manifests in a refusal to assist their Emirati colleagues' integration into the organisation. A key tactic in this is denying their access to common information-sharing practices.

This study provides a theoretical contribution by its demonstration of citizenship and job security status as moderators of knowledge sharing practices in multicultural workforces and its analysis of the cultural variables dominant in the UAE which impact attitudes to organisational knowledge sharing. Its practical contribution lies in its identification of specific barriers to workforce localisation which can provide a guide to policymakers concerned with Emiratisation and the development of managerial strategies to reduce the gap between what local employees expect versus what they find in the country's private sector workforce.

The paper begins with an overview of the UAE labour force followed by a discussion of relevant literature. It then describes the methodology used, data collection, analysis, and results. It concludes with a discussion of the findings and limitations of the study.

2. UAE Labour Market and Workforce Localisation

The population of the UAE is currently around 10 million, but only 12% is local, and 88%, expatriate (Infographics, 2024). This demographic composition stems from the country's need for skilled labour which emerged during the oil boom of the 1960s when the population was only 90,000 and predominantly unskilled (Lahmeyer, 2001). To develop infrastructures funded by oil revenues, the UAE recruited vast numbers of expatriate workers across all skills levels who were attracted by the higher salaries on offer (Rees et al., 2007). UAE legislation facilitates the influx of foreign workers, making it an attractive destination for multinational corporations seeking to

participate in post-oil boom economic diversification. The country has emerged as a significant economic hub, ranking 12th of the 141 countries survey in the 2019 *Global Competitiveness Report* for quality of infrastructure, 15th for institutions, and second for ICT adoption. For diversity of workforce, it ranks second after Singapore, fifth for ease of hiring foreign labour, and 116th for workers' rights (Schwab, 2019).

The workforce in the UAE reflects the population imbalance, with the private sector comprising only 4% Emiratis (PWC, 2024). The primary reason for this phenomenon stems from organisations' continued preference for expatriate employees. These individuals typically have modest salary expectations shaped by significantly lower salary scales in their home countries (Goby, 2015). Moreover, their employment can be more easily terminated (Kerr and England, 2009).

To facilitate Emiratis' entry into the private sector and to promote the socioeconomic benefits of a stable, indigenous workforce (Sarker and Rahman, 2020), the government has implemented Emiratisation policies since the 1990s, aiming to increase Emirati representation in the private sector through training, incentives, and quotas (Elbanna, 2022; Zeffane and Kemp, 2020). Under these regulations, Emirati employees enjoy considerably more work-related rights and job security than expatriates. This contributes to greater inequality between the two groups, and expatriate workers often feel threatened by Emiratisation and losing their jobs means being legally required to leave the country, all of which contributes to work dissatisfaction (Ali et al, 2020). Additionally, the private sector's "hire and fire at will" culture further undermines expatriates' job security (Al-Waqfi and Forstenlechner, 2012, p. 621). Despite rapidly rising educational levels among citizens, a broad range of training schemes, incentives, and other initiatives, the Emiratisation policies have had limited success (Al Jawali et al., 2021).

3. Literature Review

Recent research has explored knowledge management and cultural context (Liu et al., 2022), the connection between knowledge management technologies and national culture (Liu et al., 2023), and the relationship between organisational learning and performance as facilitated by knowledge sharing within specific economic and cultural contexts (Liu et al., 2024). The importance of national culture in relation to knowledge management and transfer necessitates an account of cultural traits of the UAE context most especially those variables that have a strong impact on how communication is conducted. To demonstrate how Emirati culture shapes communication and perception, we can refer to Hofstede's influential framework for cultural analysis. According to Hofstede (2011), the UAE exhibits high power distance (90/100), indicating strongly hierarchical tendencies. It also demonstrates high uncertainty avoidance (80/100), suggesting a preference for risk aversion and rule-based approaches to minimise uncertainty. As a result of these cultural propensities, Emiratis will typically seek validation from their superiors to ensure clarity in work-related expectations. The culture also exhibits a prominently collectivist orientation, scoring a low 25/100 on the dimension of individualism, indicating Emiratis' disposition to prioritise group needs. Central to this collectivist ethos is the significance placed on face, defined as "the positive social value a person effectively claims for himself by the line others assume he has taken during a particular contact" (Goffman, 1955, p. 213). Although face is recognised as a universal construct (Zane and Yeh, 2002), its prominence is more marked in collectivist societies (Chan et al., 2009). Given these cultural tendencies, Emiratis are more comfortable with a group-oriented approach to activities and are likely to strive to avoid conflicts and to identify collective needs before acting individually. The specific gap in the literature which this study addresses is the impact of national citizenship status on organisational knowledge sharing.

4. Study

Narrative research represents a person-centric approach to data gathering and analysis. It attempts to unravel the stories people tell about their own lives and how they make sense of these, and this allows the researcher to gather insight from these subjective interpretations. This investigation employs narrative methodology adopting an interpretivist approach and seeking to identify commonalities from the stories participants relate about their working worlds and their nuanced understanding of these experiences.

4.1 Narrative Methodology

Narrative data inevitably involves a certain collaborative process between the narrator and the researcher, a fact which makes the role of reflexivity central in the investigation (Ozturk and Berber, 2022). The researcher minimised her impact (Gioia et al., 2013) by adopting an interview approach akin to a conversation. This tactic aimed to nurture a relationship built on trust (Dundon and Ryan, 2010) and to reduce any perceived distance

between the researcher and the participant (Essers, 2009). A conscious effort was made to avoid steering the conversation beyond introducing the issue of support or challenges encountered in the workplace. This approach aimed to create an environment in which participants felt comfortable enough to freely discuss experiences that held significance for them. Such an unstructured approach, through which participants had the freedom to share their personal narratives as they saw fit, justified considering these employees to be experts or "knowledgeable agents," remaining faithful to their interpretation of reality, and prioritising it in the analysis of the interview data (Gioia et al., 2013, p. 17).

4.2 Data Collection

Purposive sampling, a non-probability sampling technique, was used to identify participants. Snowball sampling, an approach which leverages on the interconnectedness of individuals, facilitated the recruitment of participants with sufficient experience to provide rich and valuable information. The researcher contacted Emiratis encountered in professional settings, requested their participation, and solicited their referrals to other Emiratis in the private sector. Emails were sent to these referred people inviting them to take part in the study. Interviews were conducted with a total of 16 Emiratis, nine men and seven women, aged between 22 and 45, all graduates, and three holding postgraduate degrees. The interviews took place in person at a venue of the participant's choice. They were conducted in English and all participants had a high level of facility in English which was one of the selection criteria. Interviews lasted between one hour and an hour and a half, and an audio recording of each was made with the permission of the participant. These recordings were then transcribed.

4.3 Analysis

Thematic coding was used to analyse the interview transcripts. An Emirati research assistant was engaged for this stage of the study, and both she and the researcher independently conducted fine-grained readings of the transcripts. This collaboration allowed the comparison of the themes identified by each and the discussion, validation, or dismissal of each theme (Gibbert and Ruigrok, 2010; Silverman, 2005). This approach addressed the issue of reflexivity in research and helped mitigate the potential influence of a single researcher's preconceptions regarding the analysis of the data (Ozturk and Berber, 2022, p. 220).

5. Findings

Given the rich data that emerged from these interviews, it was a challenge to make sense of this abundant material and identify significant patterns that could serve to construct a framework which would condense the data to specific issues that could guide both policy implications and the furtherance of this research stream (Patton, 1990). This dual aim was considered to be best met by a process of axial coding in which second order theoretical categories were inferred from the open codes and then amalgamated into aggregate theoretical dimensions (Strauss and Corbin, 1990). A process of constant comparison of statements led to the emergence of two overarching themes that can be stated as:

- Outgroup identity marking of Emirati employees
- Purposeful knowledge withholding on the part of expatriate colleagues

5.1 Outgroup Identity Marking of Emirati Employees

This dimension encapsulates a variety of perspectives all indicative of a sentiment of not being accepted as an integral part of the larger organisational body. The most frequent types of expressions relating to this perception include:

- Being assigned very basic duties, such as photocopying, despite holding high qualifications and job title.
- An abundance of strongly negative stereotypes of Emiratis. Participants reported a range of hostile comments that they frequently hear, such as "What the hell are they doing here?" "Why don't they hang out in the coffee shop!" "They don't need the money; their government takes care of them."
- Sense of personal incompetence even though their qualifications are adequate.
- Sense of needing to work harder than expatriate colleagues to diminish the stereotype that Emiratis are lazy.
- Far greater occurrence of Emiratis being rejected and marginalised than being welcomed by immediate colleagues.

- Hostility was generally of an implicit nature although some expatriate employees were highly vocal in their criticism of Emiratis.
- Perception of acute jealousy on the part of many expatriate colleagues often expressed with the notion that Emiratis enjoy so many financial benefits that they do not need to work at all and have no right to be in the workplace.
- Perception that Emiratis enjoy an excessive degree of privilege because of their citizenship of a high GDP country.

Hostile stereotypes of Emiratis' work ethic, such as those that emerge in these findings, have been found to adversely impact their organisational socialisation and retention (Karam et al., 2023). Much of the negative stereotyping of Emirati employees was accounted for by one participant with the explanation that in the 1970s it was quite common for an Emirati to be appointed as a manager and then do no actual work. This is an example of legacy thinking from a period in which the country was very new, and its citizens were largely professionally unprepared and unaware of the requirements of their organisational role. Since those times, however, there has been an exponential advance in Emiratis' qualifications and professional readiness. The government provides free education for all citizens up to undergraduate level and has fully sponsored large numbers of citizens for undergraduate and postgraduate studies at well-ranked universities overseas. Moreover, many Emiratisation policies provide specific professional training. However, the stereotype remains a comfortable one for expatriates seeking to assert their own greater value to the organisation.

5.2 Purposeful Knowledge Withholding on the Part of Expatriate Colleagues

Most participants reported a chronic lack of access to vital information which makes it difficult or impossible to secure task-essential information and leads to a drop in their morale. Expressions of this perception include:

- Sense of feeling lost while observing expatriate colleagues appear to know exactly what they are to do. This isolation was expressed by one participant as "I'm not in the box."
- Existence of nationality clusters in which individuals engage in high degrees of exclusive knowledge sharing among people from their own country and which function easily through the use of their native language even in the presence of members of other language groups.
- Overt expressions by expatriate colleagues that, given Emiratis' high degree of job security, they did not need to be further privileged by inclusion in organisational knowledge sharing networks. "Let him find out by himself" is an example of a type of comment frequently overheard.
- Much experience of asking for advice on how to perform a new task and, rather than receiving an explanation, having an expatriate colleague complete the task. This insistence on doing rather than teaching was interpreted as a means to prevent Emirati recruits from learning on the job and developing their own skills.
- Difficulties experienced in ensuring the correct execution of their duties due to receiving inadequate information or guidance.
- Expatriate managers as well as employees withhold important information.
- Three participants mentioned that restrictions on knowledge sharing with Emirati employees also operate in the public sector.

6. Discussion

This investigation into a central component of the integration of citizens into the private sector, namely, their access to organisational information sharing networks, provides data which can help shape focussed policy to enhance the success of the workforce localisation initiatives. Its findings suggest a case of knowledge sharing being weaponised as a means to exclude the full integration of a particular population group, namely, citizens, by other groups, namely, non-citizens, as part of an attempt to safeguard job security. It highlights the role of national citizenship and cultural affinities within knowledge sharing domains. Through its exploration of the sociocultural issues involved in working relations between Emirati minority and expatriate majority employees, it reveals embedded, context-specific dynamics that need to be addressed in policy and training.

Due to their deeply ingrained collectivist values, Emiratis tend to gravitate to collaborative endeavours rather than individual efforts when approaching tasks and working towards organisational goals (Goby and Nickerson, 2011). This cultural propensity inclines Emirati employees to strive for integration within groups rather than enacting personal autonomy. The impact of this in relation to information sharing is that Emirati employees prefer to seek required information from individuals with whom they feel personally connected. The

prioritisation of group solidarity and the affordance of mutual assistance are robust behavioural norms within traditional UAE culture (Salzman, 2008). This deliberate fostering of good personal relationships is also demonstrated in Emiratis' behaviour to foreigners (Goby and Nickerson, 2015). Given this historically embedded behaviour, the absence of mutual support identified in this study can be particularly damaging for Emirati employees who view any reluctance on the part of colleagues to provide help as constituting workplace incivility, a practice which has been demonstrated to curtail professional development (Chen et al., 2012).

7. Managerial Implications

This study's findings imply a wilfully imposed sense of isolation which undoubtedly affects Emiratis' integration into their organisations and their retention outlook. This calls for managers to consider the development of specific accommodations for Emiratis to assist their integration into the organisation. There are many sociocultural issues impacting the satisfaction and retention intention of Emiratis in the private sector (Rutledge, 2023). While there are organisational socialisation policies and practices in relation to Emiratis in the private sector (Waxin et al., 2020), the exclusion that this study's participants report demonstrates the need to refine these. The specific area of information withholding experiences of Emirati employees might become a strategic action field in which the minutia of the experience of each Emirati employee is elicited and tracked and specific individual responses developed. The need for special accommodations for minority groups in the workforce is well documented and their absence can lead to rapid attrition (Greer and Wyant, 2024). In the UAE context, managers could consider accommodations such as assigning a mentor to each new Emirati recruit mandating the mentor to gather a full account of the employee's experience with specific employees in terms of knowledge sharing and withholding. This would identify precise problems and provide data for specific solutions to knowledge withholding and strategies for full access to the knowledge sharing networks necessary for Emirati integration and satisfaction in the workplace. Typically, the dynamics involved in affirmative action plans involve giving advantage to a minority group that has been historically disadvantaged. But in the case of the UAE, the minority is actually a powerful one whose disadvantage derives from its numerical inferiority. This accounts for the complexity of the Emiratisation aspirations and the obstacles Emirati employees experience in adjusting their individual selves to a complex and sometimes hostile work environment.

8. Limitations

This study did not seek to establish broadscale, generalisable findings that could apply in diverse geopolitical settings. Nonetheless, it has direct relevance for other Arabian Gulf countries which rely on a vast majority of expatriate labour and are also seeking to achieve adequate localisation of their workforces.

The fact that the study dealt with a sensitive socio-political issue could have impacted on the interview data (Alvesson, 2010, p. 37). The sensitive nature of the topic under investigation meant that the data collection had to be approached with caution. Negotiating access to participants with a clear understanding of the purpose of the research and the absolute anonymity of information shared meant that the sample was restricted to respondents who demonstrated willingness to discuss their experiences and opinions openly. This methodological decision resulted in a significant limitation of the size of the data pool, but it was considered essential to prioritise the likely authenticity of participant input over quantity.

Global Integration of Artificial Intelligence in Higher Education Sector: A Bibliometric Analysis

Olga Gordienko and Konstantin Bagrationi
Graduate School of Business, HSE University, Frankfurt am Main, Germany

oagordienko@hse.ru
kbagrationi@hse.ru

Abstract: In modern perspective, the phenomenon of artificial intelligence (AI) has witnessed considerable advancements, extending its influence across various sectors, with higher education emerging as one of the most significant areas of impact. Researchers who have found the revolutionary potential and essential contributions of AI in boosting educational practices and approaches have extensively emphasized this trend. (George & Wooden, 2023; George & Paul, 2020). The higher education domain is progressively acknowledging AI as a key factor for competitive edge (Hannan & Liu, 2021). This paper aims to examine the existing research on AI implications in the higher education segment. Grounded on the theory of technology diffusion (Rogers, 2003), our research systematically examines the scientific field, identifying emerging research topics. Using SCOPUS as a database for peer-reviewed article selection (publication period 2011–2024) and bibliometric analysis, we provide an insight into the varied geographic spread of research within the realm of AI in education. Our findings shed light on the evolution of models for the adoption of AI technologies in higher education, revealing six main areas of research in the field: (1) teaching and involving students in the educational process using generative AI, (2) using chatbots to improve the educational process, (3) improving the literacy of teachers and students in the field of AI, (4) AI and blockchain in educational practices (5) development of regulations for the use of AI and (6) improving operational processes at universities. This article explains current influences on research prospects in the context of higher education. By offering an understanding of the challenges and opportunities presented by AI, this paper encourages educators to investigate possible uses of AI in the context of higher education.

Keywords: Artificial Intelligence, Resistance to Change; Digital Technologies; Digitalization; Leadership; Leadership in Higher Education.

1. Introduction

The emergence of the ChatGPT served as a catalyst for a global technological breakthrough in almost all sectors of the economy and lead to the exponential increase in the interest of scientific community in implementing AI, especially in higher education sector (George & Wooden, 2023; Kroshilin, 2022). The latest phase in the digital transformation of higher education is AI. Although when introduced, its full extent and impact have not yet been comprehended (Solís et al., 2023). Representing an important watershed of pedagogical methodologies for higher education, AI has been grafted into the body of higher education. A cutting-edge technology moving ahead speedily, AI capability can be used in learning processes all sorts of exciting ways (Zaman, 2023). From the increasing output of academic words published during 2019-2023 it can be clearly observed that higher education is now obsessed with AI.

As field of AI in higher education matures, understanding its evolving landscape becomes vital. Researchers in this dynamic discipline continually seek fresh insights to enrich the knowledge base and unveil new research directions that stimulate debates on pivotal topics (Crompton & Song, 2021). Systematic reviews of the existing research in AI implementation within higher educational contexts are needed to recognize key contributions and to construct well-founded arguments about the field's progression (Zawacki-Richter et al., 2019). Literature reviews play a critical role in mapping the intellectual terrain for further scholarly exploration (Anand et al., 2021a), offering valuable insights into prominent authors, institutions, countries, and the predominant themes and works shaping this field (Anand et al., 2021a). However, a review employing bibliometric analysis to unravel the intellectual foundations and emerging trends in this area of AI diffusion in higher education has not yet been extensively undertaken, indicating a gap in scholarly inquiry (Zawacki-Richter et al., 2019).

Previous studies tended to be narrowed to specific aspects of AI and did not present a complete picture of the development of the field. For example, the work of Takahashi and colleagues (2024) in a bibliometric review of the diffusion of innovations demonstrates this shortcoming by not specifically focusing on AI in work. Simultaneously, several studies emphasize the need for a detailed analysis of the role of AI in higher education (Zaman, 2023).

While there have been attempts to review the diffusion of AI technologies in educational settings, these efforts often need scope and clarity. For example, some scholars have focused on specific aspects of AI in education, such as its impact on learning outcomes or its integration in curriculum design, without offering a broad overview

of the field's evolution (Zawacki-Richter et al., 2019). This study aims to overcome these limitations by employing systematic bibliometric methods to explore and systematize the existing literature on AI technology diffusion in higher education.

2. Background and Research Questions

Bibliometric techniques, combined with science mapping software, offer a robust approach to categorize, conceptualize, and reveal trends in literature, surpassing the capabilities of traditional review methods such as narrative or structured reviews (Anand et al., 2021a; Anand et al., 2021b,). This study adopts relational techniques (Benckendorff and Zehrer, 2013), to analyse qualitative, quantitative, and structural growth in this research field (Anand et al., 2021a). These techniques also help identify theoretical foundations (Zupic and Cater, 2015) and emerging trends (Walsh and Renaud, 2017).

Thus, the current study seeks to fill this gap by systematizing and analysing existing publications on AI in higher education through bibliometric data analysis (Anand et al., 2021a; Walsh & Renaud, 2017). This research applies both evaluative and relational bibliometric methods to analyse the global landscape of AI in higher education, identify influential authors, most cited papers, and identify emerging research trends.

Within this objective, the following research question was identified:

RQ: What are the emerging research topics and trends in the diffusion of AI technologies in higher education?

3. Methodology

Our study of AI in higher education relies on a systematic literature review conducted according to the five-step methodology proposed by (Anand et al., 2021a; Tranfield et al., 2003). To ensure the reliability of the results, this methodology was aligned with the Preferred reporting items for systematic reviews and meta-analyses (PRISMA) program to ensure academic transparency and reliability (Moher et al., 2009). Scopus was chosen as the database, with a focus on current and relevant publications in the field of AI and education, excluding irrelevant papers and other types of papers to maintain a rigorous methodological discipline. The collected data was analyzed and presented visually using VOSviewer.

Step 1. Firstly, our research process encompassed several steps, such as constructing SCOPUS search strings, and choosing the appropriate databases, among other tasks, all in line with the established guideline of Anand et al., 2021a.

3.1 Database Selection for the Search

To conduct this comprehensive literature review, the Scopus database was utilized for article selection and bibliometric analysis. This database provides access to a vast repository of research articles, making it a suitable resource for a review of AI in higher education.

3.2 Identification of Relevant Keywords and Subject Areas, Followed by the Construction of Precise Search Strings

Consequently, we executed a search in title and abstract to retrieve publications from this database for more in-depth analysis (Table 1). A term search in topic and abstract employing various combinations was conducted on the Scopus database to retrieve publications. We established specific inclusion criteria for selecting these publications, focusing on the subject codes related to business and economics. The data was collected in January 2024, and considering the regular updates to the Scopus database, it's expected that the figures might vary in future searches. We limited our inclusion to journal articles, deliberately excluding editorials, conference papers, and book chapters. This decision was based on the methodological rigor these articles hold in the scientific community, following guidelines by Anand et al, 2021a and Thyer, 2008. Later, the data was processed via MS Excel to remove duplicates and form a sample. This resulted in a total sample of 2652 articles related to AI in higher education.

Step 2: Secondly, to analyze the trends in the literature based on the 2652 publications we obtained, we employed bibliometric methods. These methods are commonly used in conjunction with science mapping tools and techniques to visualize the structure of a discipline (Anand et al., 2021a; Walsh and Renaud, 2017; Zupic & Cater, 2015) and to analyze clusters (Anand et al., 2021a; Walsh and Renaud, 2017). In our paper, we utilized Van Eck and Waltman's (2010) VOS Viewer software for mapping bibliography and citation trends, which are

represented through clusters, tables, and maps, as shown by Anand et al (2021a) and Walsh and Renaud (2017). Over the last decade (2013-2024), VOS Viewer has been increasingly adopted and applied in various literature reviews published in top-ranked journals, as evidenced by Kirby (2023).

Step 3: Relational techniques, as described by Anand et al. (2021a) and Benckendorff and Zehrer (2013), provide a more nuanced understanding of the connections and relationships within the field. These techniques involve analyzing the links between different academic works, authors, and themes, enabling a deeper exploration of the intellectual structure and network dynamics characterizing AI technology diffusion in higher education. The bibliographic coupling was performed, and 6 clusters were identified.

Step 4: Following Anand et al. (2021a) guideline, we embarked on a qualitative descriptive coding of the abstracts of these publications. Based on the content of abstracts, 102 out of 2652 publications were selected. The content of 102 abstracts from selected articles was analyzed in accordance with the parameters of Anand et al., (2021a). As emphasized by Salager-Meyer (1990, p. 367), abstracts are crucial for consolidating research ideas and fully grasping the arguments of the original articles. This process involved two researchers independently examining the abstracts and compiling notes, followed by a verification process for consistency by one other author.

Step 5: Fifth, synthesis was performed. In the line with the methodology of our study on AI technology diffusion in higher education, we conducted systematic reviews with a focus on synthesis, following the framework established by Anand et al. (2021a). The synthesis approach is a systematic method for amalgamating, integrating, and synthesizing diverse literature, offering a cohesive narrative and summary of the field (Schick-Makaroff et al., 2016). This approach is particularly useful in handling the multifaceted nature of AI technology diffusion in higher education.

4. Findings

RQ. What are the emerging research topics and trends in the diffusion of AI technologies in higher education?

Based on the bibliographic coupling in the research, six primary clusters were identified (Figure 1)

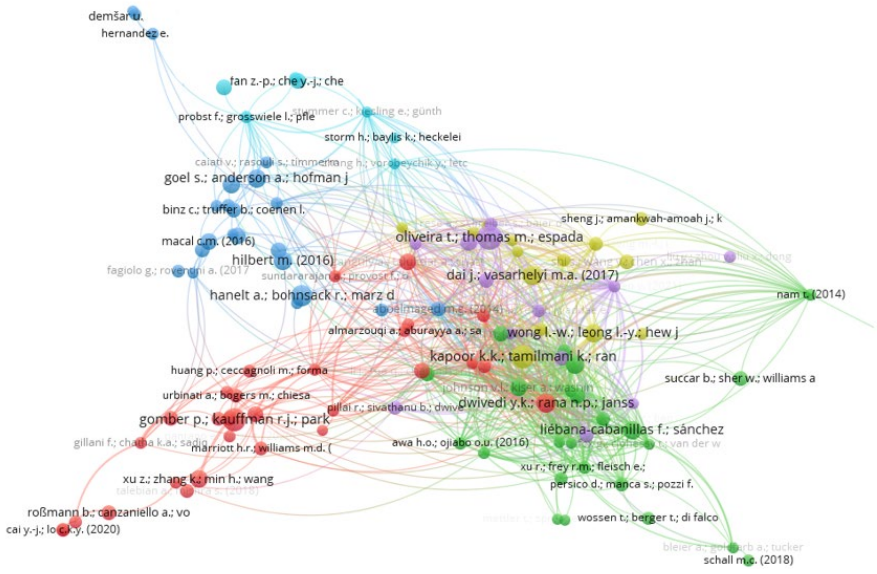

Figure 1: Bibliographic coupling (made in VOSviewer)

The first cluster (red) "*teaching and involving students in the educational process using generative AI*" (n=26) uncovers the application of generative AI in educational environments, not merely to improve student involvement in education, but also to promote individualized learning experiences and enable research tools. This cluster contains a seminal work by Dwivedi et al., 2019 "Re-examining the unified theory of acceptance and use of technology (UTAUT): Towards a revised theoretical model. Information systems frontiers" which serves as a conceptual framework for many studies observing AI implementations in educational context. Another seminal work Gomber et al., 2018 "On the fintech revolution: Interpreting the forces of innovation, disruption, and transformation in financial services" serves in articles as a framework to interpret AI innovation

implementation within educational context. The second cluster (green) *"using chatbots to improve the educational process"* (n=24) describes how the development of chatbots proceeds to improve the educational processes. The cluster is characterized by the representative capacity of chatbots, as a key tool for achieving guided learning. The third cluster (blue) "*improving the literacy of teachers and students in the field of AI*" (n=23) is focused on the expansion of AI literacy among educators and students. From this perspective, this cluster stresses the urgency of familiarizing teachers and learners with the principles of efficient utilization of AI devices in their educational environments. Fourth cluster (yellow) "*AI and blockchain in educational practices*" (n=12) analyzes the merger of AI and blockchain technology in universities. It specifically focuses on the use of AI for analysis of educational data, which is securely stored on blockchain platforms. Fifth cluster (purple) "*development of regulations for the use of AI*" (n=11) highlights the development of guidelines for an ethical and efficient approach to AI in education. The studies in this cluster focus on the call for a regulatory structure and deployment necessitate an ethical and comprehensive, regulatory framework, policy and responsible AI guideline's structure. Sixth cluster (light blue) "*improving operational processes at universities*" (n=6) is centered around optimizing operational processes in universities through developing guidelines for the use of AI .

5. Discussion

A deeper look into the first cluster demonstrates that AI is adept at improving student participation in interactive problem-solving exercises and the shift of AI from aiding teacher instruction to that of active learner management (Chan & Lee, 2023; Dehouche & Dehouche, 2023). AI provides a personalized educational solution that adjusts learning methods to cater to the needs of individual students, thereby fostering a more personalized learning environment (Cox et al., 2021; Chrisinger; 2019; Kumar, 2019). This cluster also focus on AI capabilities to ease research in educational processes (Kitamura, 2023; van Dis et al., 2023). Despite the advantages presented in the first cluster there still are controversial thoughts within AI research discourse. Resent research states that although AI can help higher education to significantly evolve, the models are biased and need development (Ouyang et al., 2022; Roshanaei, 2024). All in all, the findings reveal much promise and difficulty in implementing generative AI into educational practice which aligns with the findings of Farrokhnia et al. (2023).

In the second cluster, studies by Hwang & Chang (2023) and Lin's et al (2022) state that chatbots are effective in guiding students through data-driven and practice-based learning to develop discipline, learning perseverance and activate participation. Some articles within the cluster highlight that AI chatbots are enhancing students' collaborative learning and information exchange thus effectively supporting the assessment of peers and interactive learning (Bauer E. et al. 2023, Cachero et al., 2023; Darvishi et al., 2022, Chang et al., 2022). Other articles within the cluster focus on AI chatbots as assistants in scheduling and managing time or preparing for exams (Arruda et al., 2019, Fuchs, 2023; Frommert et al., 2018). Even though some scholars state that chatbots with, for example, FAQs and short answers can provide many improvements for teaching students and providing content to teachers (Cunningham-Nelson et al., 2019; Ismail & Ade-Ibijola, 2018) some sholars actively oppose the use of chatbots due to their inaccuracy and inability to be creative in response (Kooli, 2023; Toader et al., 2019).

Third cluster discusses the literacy of teachers and students in the field of AI. Some articles like Mizumoto & Eguchi (2023) and Crompton & Burke (2023) feature examples of how AI helps automate the process of checking students' papers, making it less biased and, at the same time, less time-consuming. Apart from simplifying certain personnel-related activities, this tool helps teachers concentrate more on applied aspects of their work than on organizational. Furthermore, the cluster discusses the application of AI as an enabler of synchronous studying in the form of group assignments or problem-solving tasks (Han et al., 2023). Although the positive aspects presented in the cluster, some studies in the existing research field raise concerns about teacher's trust in AI systems and the impact they can have on educational communities, suggesting that future work should explore not only the possibilities of using AI, but also the perception and understanding of these methods by students (e.g. Pishtari et al., 2023).

The fourth cluster uncovers the possible co-use of blockchain and AI. Blockchain is used to securely store educational records and student achievements, and AI can analyze this data to personalize curricula and teaching methods (Aliane & Salim, 2023). Such technologies have demonstrated effectiveness in managing student data and preventing fraudulent decryptions in higher education. However, there are several difficulties in implementing these technologies, including due to data privacy issues and a shortage of technical staff. (Aliane & Salim, 2023).

The fifth cluster indicates a strong need within educational systems to guide policy development and ensure responsible AI usage. Some studies such as Nguyen et al., 2023 and Dieterle et al., 2024 indicate the need for a normative framework that will regulate the deployment and use of AI in addition to preventing its misuse, but also innovation. There is also a concern about the vision of ethics the two parties between the educators and learners should have when it comes to operating and using AI. For example, Flores-Vivar & García-Peñalvo, 2024 focused on promoting a culture that maintains ethics in the use of AI. This signifies a call for a collaborative approach to responsible implementation and use of AI in education.

The last cluster states that AI can be used to help management in universities. For example, AI can be used to generate standardized templates for administrative communications, which can mitigate the bottlenecks created by the lack of standardized forms of communication between administrators (Parycek et al., 2023). However, there is a resistance towards AI among employees within universities which can have a different background for each case (Muñoz & Chimbo, 2023).

6. Conclusions

In this bibliometric analysis of the global integration of artificial intelligence (AI) in higher education, we provided a set of emerging research topics and trends in the diffusion of AI technologies in higher education. By synthesizing 102 papers, six clusters were found to be the main landscapes in this area: generative AI in education, chatbots for teaching and learning, AI literacy, AI and blockchain, ethical usage of AI and AI for administrative processes optimalization.

The research illustrates AI's potential to improve teaching and learning practices. The impact this might have includes encouraging student involvement, facilitating personalized instruction and automating administrative processes. In the education field, generative AI could offer the answer. While these are hugely complex systems which might exhibit bias or other vulnerability, it remains feasible when individuals concern themselves with their own educational direction (Chan & Lee, 2023; Dehouche & Dehouche, 2023; Cox et al., 2019). Chatbots are another promising app; they can improve student interaction with teachers and provide guided learning modes (Hwang & Chang, 2021). But their effectiveness depends very much on exact use, and this underscores the need for careful applications (Arruda et al., 2019). The research also indicates that educators require a greater understanding of AI (Mizumoto & Eguchi, 2023). With integration of AI and block-chain technology, educational data can be stably stored and then analyzed. However, adoption is obstructed by privacy anxieties as well as technical blockages (Aliane & Salim, 2023). The ethical problems arising from use of AI in education is a crucial issue. There is a general demand for comprehensive regulatory frameworks and codes of practice to be created, with consensus on balance innovation with responsible use (Nguyen et al., 2023; Flores-Vivar & García-Peñalvo, 2024). Finally, for universities and other higher education institutions AI presents potential, although this is contested because of potential technological bias or mistrust of automation (Muñoz & Chimbo, 2023).

Abstract: Knowledge represents a crucial part of the development of intellectual capital (IC). Therefore, the way knowledge is managed can impact IC creation and/or loss in an organisation. However, the need to manage knowledge resides in the strategic perspective of knowledge to sustain competitive advantage in a knowledge economy, especially in the context of international assignments. This work has the goal of understanding how personnel mobility affects the knowledge and intellectual capital management of a knowledge-intensive organisation. This study therefore applies a qualitative methodology to analyse how knowledge and intellectual capital are managed in the context of international assignments from a Portuguese knowledge-intensive organisation. Exploratory interviews and direct observation were used to achieve the goal of this study. This work identifies three main knowledge management processes that are involved in the context of international assignments, namely knowledge transfer, knowledge sharing and knowledge hiding. The goal is to increase knowledge transfer and sharing behaviours while reducing knowledge hiding ones. This study goes further and identifies that power, motivation and culture can influence the way these processes occur in an organisation Considering the work here presented, the results cannot be generalised to other organisations and industries due to the nature of the applied methodology, but it can serve as a benchmark for other organisations in the same industry. If other researchers find this topic interesting, it would be pertinent to conduct research in other organisations and industries to achieve a broader understanding and compare results.

Keywords: Knowledge Management, Intellectual Capital, International Assignments, Knowledge-Intensive Organisation

1. Introduction

The importance of managing knowledge from international assignees is crucial in knowledge-intensive business organisations (KIBOs) where knowledge is the most important strategic resource and employees are the main source of that knowledge (Steyn and Kahn, 2008; Nakash and Bouhnik, 2023). Therefore, managing knowledge in these settings becomes a primary focus in developing IC. KIBOs are defined in this study as organisations whose primary activities are dependent on knowledge management (KM) and that can produce exceptionally good outputs using a workforce of an intellectual nature that usually detains a high level of education or training (Millar, Lockett and Mahon, 2016; Nakash and Bouhnik, 2023).

Pharmaceutical companies are an example of KIBOs (Amaya *et al.*, 2022). This industry employs more than 750,000 people with 16% of them working in research and development (Ramy, Af Ragab and Arisha, 2022). In Portugal, the pharmaceutical industry, although important, is not as developed as in other European countries. This is due to a lack of resources and knowledge to move further and remain competitive. However, the pharmaceutical industry in Portugal has a place to grow and improve and can be a fundamental mechanism for the country's economic growth (European Federation of Pharmaceutical Industries and Associations, 2022).

Over the years, the research field regarding KIBOs has been frequently connected to KM and IC. However, there is a gap in the literature regarding the connection of these themes with international assignment management. As mentioned by Millar et al., (2017, p.273), more research is needed to understand how KIBOs, who rely on their people as their most valuable asset, manage the knowledge from their international workforce. Two KM processes are most researched in IAs literature, namely knowledge sharing and knowledge transfer. These two processes are seen as positive processes to foster KM in an organisation. On the contrary, knowledge hiding has emerged in the literature as a process that can negatively impact the previous two processes and compromise the management of knowledge in the organisation (He *et al.*, 2021; Phookan and Sharma, 2021; Issac *et al.*, 2022). Therefore, there is a need to understand which factors can lead to employees engaging in KM activities to develop IC.

Several factors can be identified as antecedents of KM. Knowledge sharing, transfer and hiding are all influenced by personal (e.g., motivation, empowerment, absorptive capacity, power, reputation), organisational (e.g., organisational culture, organisational hierarchy, work design, management support) and cultural factors (e.g., language of a country, culture of the country) (Lee and Al-Hawamdeh, 2002; He *et al.*, 2021; Xiao, 2023). Therefore, it is crucial to consider the relationship between the knowledge holder and the knowledge recipient. To increase knowledge sharing and transfer activities while reducing knowledge hiding ones, knowledge holders need to be motivated to share their knowledge while not fearing losing power in an organisational culture that promotes and rewards knowledge-sharing and transfer activities. On the other hand, the knowledge recipient needs to be motivated to receive and apply the knowledge from the holder by understanding that the received information is crucial for its job while being promoted to engaging in a knowledge sharing culture (Ado, Wanjiru and Su, 2021; Phookan and Sharma, 2021; Yeboah, 2023). From all the factors it seems that there is a stronger focus on motivation, power, and culture.

This work aims to understand how personnel mobility affects the knowledge and IC management of a knowledge-intensive organisation. The following research question then guides this study:

How and why to manage knowledge and intellectual capital in the context of personnel mobility?

2. Methodology

For this work, qualitative methodology was applied which allows maximum access to the human experience since its premise is "that there is no single absolute reality with an external ontic status" (Nakash & Bouhnik, 2023, p.705). The use of a single case study has gained importance in the literature over the years since it allows the generation of new theoretical concepts while giving examples from practitioners (Yin, 2009, 2018; Amaya *et al.*, 2022). In terms of data collection, three methods were used namely semi-structured interviews, direct observation and document analysis.

A first round of exploratory interviews was conducted at BIAL headquarters in Trofa, Porto between April and May 2023. The interviews were conducted both online (via Microsoft Teams) and in person. Also, some interviews were carried out in Portuguese while others were in English. These interviews aimed to understand how the company manages mobility (those who went abroad and those who came to work in Portugal) and if a knowledge management system exists. All participants (n=11) were interviewed and consent for the interviews was signed. For the interviews, different guides were produced with research questions related to the management of knowledge and intellectual capital in their position. The interviews were audio-recorded using the researcher's phone and laptop and notes were also taken. Interviews last on average forty minutes. The interviews were then transcribed by the researcher both in Portuguese and English according to the language used in the interview. The Portuguese transcriptions were then translated into English to achieve a coherent analysis of the results.

On May 9th, the first observation included an informal meeting with three human resource management team elements to understand how international assignees are managed. This meeting was also important to analyse the existence of systems to manage the human resources of the organisation and the knowledge produced, namely a talent and succession app and a career framework. Another element of observation occurred on May 25th when the researcher met an element of this team to analyse how SharePoint is used in the organisation to share and access information by the employees.

3. The Case Context

BIAL is a Portuguese pharmaceutic company that was founded in 1924 by Álvaro Portela. BIAL is an innovative pharmaceutical company dedicated to the research, development and marketing of medicines. BIAL's mission is to find, develop and provide therapeutic solutions in the field of health guided by the strategic lines of quality, research, and development (R&D) and internationalisation.

In Europe, BIAL has a production and R&D unit in Portugal and affiliates in Spain, Germany, the United Kingdom, Italy, and Switzerland. In the US, in 2020, BIAL established BIAL Biotech Investments Inc. (BIAL Biotech). In French West Africa, it has operated since 1999. Through partnerships with local promotion agents, BIAL Francophone Africa operates in 18 countries in the region. BIAL Angola is one of the leading pharmaceutical companies in the country and has a wide range of products (over 40 medicinal products). In Mozambique, BIAL owns Medimport. Established in 1996, the company is engaged in the import and distribution of pharmaceutical specialities, representing several pharmaceutical companies, with which it has licencing agreements for Mozambique. BIAL

also establishes partnerships/licensing agreements with leading pharmaceutical companies to be able to access other markets. This is the case in some European countries, the USA, Japan, China and South Korea. This broad network of partnerships has enabled BIAL to share innovative products in the neurosciences field in various countries.

Therefore, considering the previous description of the organisation and what is mentioned in the literature regarding KIBOs and pharmaceutical companies, BIAL is identified as a KIBO in this study. Moreover, the existence of subsidiaries in different locations suggests that the organisation has cross-border mobility as part of its business operation, making it a fit for the study of international assignments. Because BIAL can be considered a KIBO and to a certain extent a multinational company with IAs, it fits the goal of this research to be used as a case study. This study is then important for theoretical as well as practical reasons since the pharmaceutical industry in Portugal can be a fundamental mechanism for the country's economic growth, namely BIAL (BIAL, 2024).

4. Results and Discussion

4.1 Interviews

In terms of interviews, three groups of employees were included, namely auto-expatriates, expatriates and HR employees since these are the ones involved in cross-border mobility in the organisation. This study finds it pertinent to include different types of international assignees and different hierarchical levels to achieve a more detailed understanding of the analysed theme.

4.1.1 Expatriates

For this study, from the few available expatriates, two agreed to participate. These are two long-term expatriates since they have been in foreign countries for more than 20 years. Both occupy senior director positions which gives them the knowledge to speak about the subject from a managerial perspective. In terms of the expatriation process, both were career progression opportunities.

In terms of the interaction between the headquarters and the subsidiaries, INT1 believes that headquarters must be responsible for the main guidelines and corporate rules while monitoring the processes and practices in the various subsidiaries. For that to happen, there must be a permanent exchange of knowledge through meetings. In BIAL's case, there are local as well as global meetings. For example, INT2 comes to the country periodically to make a personal update on the activities and develop further strategic plans.

Regarding the reduced number of expatriates in the organisation, INT1 believes that this happens because Portugal does not have all the resources it wants, and BIAL still does not have the dimension to externalise. From the literature, it is possible to conclude that the reduced number of expatriations can then be associated with the difficulty of creating subsidiaries in Europe in the pharmaceutical market since it is very regulated (European Commission, 2020; European Federation of Pharmaceutical Industries and Associations, 2022) Therefore, BIAL ends up hiring local labour instead of using expatriates since it depends on the candidate profile and business needs that leads to the hiring of locals. Still, companies must keep in mind and prepare staff to externalise (Alexandre and Martins, 2023). This preparation must be a bidirectional process of culture management and INT2 believes that the expatriation process can be improved by giving greater support.

In terms of KM in the organisation, INT1 believes that the "(…) *sharing of information must come naturally*" to employees to work for the common good which must be the maximum sharing of information with the different layers. However, considering the information given by the interviewees, there is no guarantee that this information sharing will happen at all the subsidiaries since it depends on the country manager. At the same time, INT1 and INT2 believe there is no guarantee that people are willing to freely share the information they possess because information means value and power. BIAL can then educate its people to believe that information sharing is an added value and not a threat to reducing knowledge-hiding behaviour. This can be done by developing career models for future perspectives, so it reduces the fear of people losing their positions. Still, both expatriates believe that BIAL has improved its knowledge-sharing culture through the hierarchical change that took place. However, improvements are still needed. INT1 agrees that the creation and implementation of a proper KM mechanism in the organisation is crucial. This can be done by ensuring that people the organisation recruits the right people (those open to a knowledge-sharing culture), keeps them motivated (through the

development of career plans) and is ready to collaborate (hold accountable the people who want to own the information).

4.1.2 Self-Initiated Expatriates (Sies)

To start, to be considered a SIE, people need to move to a different country from that of origin and this decision must be a personally motivated choice. All involved confirmed that the decision to move to Portugal was an entirely personal decision motivated by the search for a new career opportunity and to live in a different country. Moreover, all of them are part of the R&D division since this is the division in the organisation that must look out for international talent to fulfil its needs. The search for international talent in the R&D department is motivated by the need of the organisation to have the best experts to guarantee its success in the pharmaceutical industry.

In terms of the recruitment process, all SIEs received a relocation package and sufficient support from the organisation. This package includes the travel expenses for the interviews and relocation to Portugal. Also, it includes two-month accommodations with a storage place to keep personal belongings as well as participation in Portuguese classes to develop their knowledge of the language. Finally, informal support is given regarding the obtention of identity cards and social security as well as fiscal numbers. In this aspect, the interviewees all agree that the organisation could provide additional emotional and informal support to family members as confirmed in the literature (Black and Stephens, 1989). Lastly, regarding the integration of new elements, participants feel that the time for the introduction could be reduced or more focused on the division they will be working in. The implementation of this relocation package must be seen as a good practice for companies with mobility since it allows a smoother relocation for the employee while promoting integration both in the organisation as well as the country's cultures.

Considering the contact of the interviewees with subsidiaries this is reduced as mentioned by INT6: "(…) *working in R&D division we don't have any contact with them because they are working in the marketing. So, they are not part of our direct network*." Participants feel that as they integrate the most important division of the organisation, additional knowledge could be shared. This leads to a sense of disconnection from the members of this division to the rest of the organisation. Some participants feel that more connection with subsidiaries could increase their motivation and reduce this sense of loss.

Regarding KM processes, the R&D division has been implementing some changes to facilitate the integration of new elements and improve the workflow and knowledge sharing. The participants feel that the hierarchical change in the organisation facilitates information sharing while fostering a knowledge-sharing culture in the organisation and has brought some fundamental improvements to KM. However, some barriers to knowledge sharing still exist and are perceived by the interviewees. As mentioned by INT5: "*I think that now there is perhaps more transparency, above all (…) but all this openness only comes from the top. I think that in Portuguese culture, the lower levels, still don't open doors to each other*". The participants recognise that information sharing is highly dependent on individual motivation and individual perception of the use of knowledge. At the same time, they still feel that some people hold knowledge as a way of maintaining power and their positions in the organisation. Also, the participants feel that these changes have improved communication within the teams but not among the teams. This implies that Team A does not know what Team B is doing which can reduce the chances of collaboration among team members. Lastly, due to the nature of the knowledge in the R&D division, it can be difficult to implement a proper KM mechanism that considers all the regulations of this division due to the confidential nature of knowledge. However, BIAL is trying to stay up to date with a new electronic system, derived from the hierarchical modification, to help manage knowledge. Although significant and positive changes are being made regarding the creation of a knowledge-sharing culture, the organisation still lacks control mechanisms that ensure that people are motivated and actively engaged in information-sharing activities without the fear of losing their position or power.

4.1.3 Human Resource Employees

The interviews included three human resource employees. In terms of the mobility processes, there is a general approach adopted by the team to recruit whether employees are going to a foreign country to work at a subsidiary (expatriation) or coming from a foreign country to work at the headquarters (self-initiated expatriation). To note that the company is much more flexible when it comes to timings for starting a role as a foreigner, because of the moving from one country to another and the various administrative processes that also must be completed. Also, the HR team needs more time to prepare.

In terms of expatriation, these are punctual processes in the organisation that are used to serve certain purposes normally associated with the creation or renovation of a subsidiary. Also, due to the seniority of the HR employees involved in this study, the participants did not have the experience of managing an entire expatriation process. In terms of other mobility processes, they exist for specific business needs and are transversal to the organisation. In total these people move for about a week of work outside.

Considering KM, there is no formal process or tools in the organisation. What exists is a culture of sharing in terms of work. This culture of sharing starts with the onboarding process (when someone new enters the organisation) which allows contact with different areas of the company to quickly get to know or identify key people for specific matters. Normally it ends up being the manager who transfers the knowledge of what happens in a team, the work that is supposed to be done, and the project to work on. And then the transfer of knowledge is very much out of necessity. Since a knowledge mechanism is lacking in the organisation, the three participants find it useful for future management and it can make the work easier.

4.2 Direct Observation and Document Analysis

The direct observation for this study was conducted to understand how BIAL uses online systems to manage knowledge from the employees and share it in the organisation which leads to document analysis. Namely, training plans and the talent and succession app were observed in detail since they are the ones with the most information.

In terms of general management, BIAL uses Sharepoint to have all the documents each department and employee needs to access and use. Furthermore, it uses DocX as a platform for recording standards and procedures.

In terms of training, for each employee, there is a record of training carried out since joining the company. The HR team, together with the heads of each department, also create annual training plans where each department has a plan. A training plan is then drawn up containing the following information: name of the person or team to receive training (team when there are many people in the division and name of the person when there are few), the training that will be received, the date of the training and its total cost. After going through HR, this plan must be approved by the administration board. HR always seeks to monitor whether training is being completed to guarantee that the total number of training hours is achieved. Additionally, to facilitate the work of HR regarding training management, an application is being implemented that helps to plan the budget and see if the training was carried out.

In terms of the talent and succession mapping app, the organisation has a biannual analysis conducted in March and October. This is based on the 9-box grid which is a well-known talent management tool in which employees are divided into nine groups, based on their performance (in this case, (under, effective, outstanding) and potential (in this case, (low, medium, high). In terms of functioning, when entering the application, the manager can see the talent and succession tabs as well as a box next to it with the names of the people to be evaluated. Only people who have been with the company for more than 6 months (and excluding temporary employees) are mapped and the mapping is common to all hierarchical levels, with the only person not mapped in the company being the chairman.

In the succession tab, only the management levels are mapped, and a list of names is presented to map immediate, short-term, and long-term successors. However, this term is not mandatory to identify for these three periods. Afterwards, people are identified by the HR team and a career development plan is prepared so that the successor can be ready when necessary. To emphasise that the organisation has plans to extend this mapping to different levels to improve succession management.

The introduction of these new human resource management tools allows the employees to feel heard and valuable within the organisation giving them the possibility to progress in their career in different ways. At the same time, it allows employee mobility in the organisation (cross-border as well as internal) because it opens the possibility of being selected and promoted to different positions in the organisation.

4.3 Conclusions

Regarding the management of knowledge in cross-border mobility, this study aimed to confirm if all processes of KM are crucial for this context. Considering the context of this research and aligned with previous authors, this work confirms that while talking with people involved in IAs, the main processes that need to be managed are knowledge sharing, knowledge transfer and knowledge hiding (e.g., Ado et al., 2021; Chang, 2012; Huang et

al., 2013). Second, this exploratory part of the work made it possible to understand that three main concepts can act as antecedents of KM in this context, namely motivation, culture, and power as mentioned in the literature (Tams and Arthur, 2015; Santos and Gonçalves, 2018; Linder, 2019; van Bakel and Salzbrenner, 2019; Issac *et al.*, 2022).

Considering, the creation of IC in the mobility context, IC is seen as the result of KM activities in cross-border mobility processes. In terms of structural capital, it is positive to notice that BIAL has been up to date by creating and promoting the use of digital tools for internal management and use by its employees. Regarding, relational capital this is positively developed by the development and promotion of culture sharing in the organisation motivates people to relate with one another in the pursuit of a common goal. Considering human capital, at BIAL this is a crucial IC dimension due to the nature of its core work. Therefore, the organisation has developed several tools that allow to keep employees motivated and equipped with the right skills to develop their work. Lastly, regarding social capital, it seems that the network of resources for international assignments can be further expanded both for SIEs as well as expatriates. SIEs working at the headquarters could engage more with colleagues working at subsidiaries to increase their knowledge of the work abroad and the results obtained that can influence their performance. On the other hand, expatriates need to feel more connected with the headquarters to reduce the fear of not belonging. Social capital is then crucial to be developed for knowledge workers who engage in international assignments (see Millar, 2016, p. 851).

From the development of this work and answering the research question "How and why to manage knowledge and intellectual capital in the context of personnel mobility?" it is possible to conclude that a robust mechanism to manage knowledge in the context of cross-border mobility is lacking. The development of such a tool is seen as an improvement and helpful resource for both the collaborators as well as human resource managers because it could help to reduce the complexity of some tasks (such as initial training to perform a job) as well as to integrate knowledge in a transversal way to the organisation. The overall feeling is that the organisation has been given important steps to see KM from a more strategic perspective to create IC.

Considering the work here presented, the results cannot be generalised to other organisations and industries due to the nature of the applied methodology, but it can serve as a benchmark for other organisations in the same industry. It would be pertinent to conduct research in other organisations and industries to achieve a broader understanding and compare results.

Guntis.Bahs@rsu.lv

Abstract: In the 21st century, the healthcare sector faces formidable challenges, including the rapid proliferation of medical technology innovations, the extension of life expectancy, and the concurrent trend of ageing within society. Moreover, healthcare grapples with an acute shortage of workforce, accompanied by significant skills gaps and mismatches. The consequences of skills shortages, gaps, and mismatches are profound, potentially impeding the treatment process and compromising healthcare outcomes, thereby jeopardizing both the quality of healthcare and the safety of patients and healthcare professionals alike. These signals underscore the imperative for transformative adjustments within the healthcare sector. Amidst this dynamic landscape, healthcare institutions must cultivate systems and approaches capable of rapid adaptation to evolving circumstances while facilitating future planning and data-driven decision-making. Of paramount importance is the establishment of systems that ensure effective knowledge management for healthcare professionals, identify knowledge and skills gaps, and highlight improvement opportunities. In light of these exigencies, the authors have crafted a conceptual model of human capital management based on skills monitoring and tailored to the healthcare sector. This model encapsulates a human-centric management ethos, seamlessly integrated with a data-driven business strategy within a patient-centric healthcare paradigm. The practical implementation of the Human Capital Management Model would empower healthcare institutions to make informed, data-driven decisions to reach the strategic goals of the institution: ensuring efficient human resource provision with appropriate skill-mix, improving health quality, increasing patient and healthcare professional safety, and the sustainable use of financial resources.

Keywords: Human Capital, Skills Monitoring, Knowledge Management, Healthcare Institution, Healthcare Workforce

1. Introduction

Healthcare service coverage, workforce provisions, healthcare quality, and patient and healthcare professional safety are key criteria for the quality of healthcare systems. With rapid advancements in medical technology, increased life expectancy, and simultaneous trends in population ageing, the necessary changes in the healthcare sector are becoming increasingly evident. Anticipating future challenges, as early as 2007, the European Commission (EC) developed the European Union (EU) health strategy White Paper Together for Health: A Strategic Approach for the EU 2008-2013, where one of the objectives was outlined as the development of dynamic healthcare systems and new technologies (European Commission, 2007). Subsequently, in the European Commission's 2008 Green Paper (COM(2008) 725 final) on the EU workforce for health, ~~it~~ was indicated that continuous professional development, relevance of professional skills, enhancement of the safety of both patients and healthcare professionals, and also mechanisms to implement healthcare workforce monitoring are very crucial to support workforce capacity, education, and needs planning (EC, 2008). In 2016, the World Health Organization (WHO) identified as priority tasks until 2030 - ensuring data availability on human resources in healthcare to monitor and ensure accountability for the implementation of national, regional, and global strategies, as well as investments in healthcare workforce education, skills provision, and alignment with labour market and societal health needs (World Health Organization 2016). To promote investments in the education, skills and employment of the healthcare workforce, a multisectoral partnership, coordination, and funding are necessary; therefore, the WHO has established the "Working for Health platform" and implementation mechanisms to support countries in investment strategy development, monitoring, and management for the planning and financing of healthcare workers, education and employment, as well as protection and performance (World Health Organization, 2022).

The initiatives mentioned above serve to move toward a future perspective – 1) United Nations (UN) Sustainable Development Goals by 2030, to ensure a healthy life and promote well-being for all at all ages (Goal No.3), where among the tasks outlined is the provision of universal health coverage, protection against financial risks, and increasing healthcare financing and workforce (United Nations, 2015), and 2) also to reach the goal set by WHO - to create at least 40 million new jobs by 2030 and to address the projected shortage of healthcare workers,

ensuring that "right number of jobs for health workers with the right skills and in the right places to deliver universal health coverage" (World Health Organization, 2016).

International level guidelines emphasize the significant role of the healthcare workforce in the overall healthcare system. Furthermore, the effective development of human resource management in healthcare is a critical prerequisite to strengthening the healthcare system. Data-based analysis of healthcare workforce, healthcare economics, and societal health needs promotes evidence-based decision making at the institutional and national levels, as well as policy development in the sector, ensuring the needs-based development of the healthcare sector. However, to implement the EU strategy and achieve the objectives of the UN and WHO, it is essential to develop a systemic approach that involves all stakeholders shaping the healthcare system. Consequently, beyond state policies or national strategies, there is considerable importance in the investments made by healthcare institutions and their strategies at the institutional level. These strategies should promote workforce planning, skills management, and professional development of the workforce. Therefore, to address this issue, the authors have crafted a Conceptual Human Capital Management Model tailored to the healthcare sector.

2. Methodology

The aim of this theoretical paper is to propose a Conceptual Model of Human Capital Management based on skills monitoring and designed for the healthcare sector. Drawing on current trends in the healthcare sector as outlined in guidelines, standards, and regulatory documents, the authors identified the sector's needs to enhance the relevance of the skills of the healthcare workforce. A literature review was conducted to identify aspects of human capital management and intangible asset accounting, revealing a deficiency in qualitative human capital disclosure. Based on these research findings and considering the contextual factors of the healthcare sector, the authors developed a novel Conceptual Model of Human Capital Management to address the gap identified, which has emerged due to the current need for a skills-based approach in healthcare sector. Following the analysis, the authors have also delineated the foundational principles for the conceptual model and impact on strategic goal of healthcare institutions. This model is specifically designed for the healthcare sector to navigate contemporary workforce planning, healthcare quality, patient and healthcare professional safety, as well as financial sustainability challenges.

3. Theoretical Framework

3.1 Human Capital and Its Management

Knowledge management is the management process of creating, sharing, and using organizational information and knowledge (Girard and Girard, 2015). In healthcare knowledge management can encompass various strategies, practices, and technologies aimed to facilitate knowledge creation and dissemination to support evidence-based practice, to improve patient care, and drive organizational effectiveness and innovations in healthcare delivery. Knowledge management can be implemented through various pathways, and one of the approaches involves the learning and training of employees to disseminate knowledge, update clinical skills, and promote continuous professional development among healthcare professionals. According to human capital theory, when employees start their jobs, their knowledge and skills become part of the organization's human capital. Originally seen as just a mix of employees' knowledge and skills, the theory has evolved and now more various factors that characterize human capital are identified. These include intelligence, qualifications (Bontis *et al*., 1999), competencies (Bontis *et al*., 1999; Wang, Wang, and Liang, 2014), behaviour and personal energy (Davenport and Prusak, 1998), experience (Abdulaali, 2018; Wang, Wang, and Liang, 2014), mental capacity, thinking style, and ability to act (Lapina, 2010), social competence, professional competence, leadership skills, motivation, and expertise (Abdulaali, 2018), innovations, attitude, commitment, wisdom (Wang, Wang, and Liang, 2014).

The significance of human capital as an intangible asset of the organization has recently become increasingly pronounced. Studies have demonstrated a positive correlation between human capital development within organizations and performance at both the individual and the organizational levels. Moreover, this correlation can be examined from two perspectives: the influence of individual human resource knowledge and skills on organizational performance (Ployhart *et al*., 2014), and the impact of organizational performance on the individual level (Crocker and Eckardt, 2014). Considering the significant impact of human capital at the organizational level, it is imperative to manage this capital purposefully. Successful implementation of human capital management can attract and retain a high-quality workforce, creating a competitive advantage and

excellent company performance (Delery and Roumpi, 2017). Human capital is a unique internal resource and a key driver of organizational outcomes (Barney, 1991). Human capital has a significant positive impact on innovation (Sima *et al*., 2020), operational and financial performance, and company growth (Rauch and Rijsdijk, 2013). Researchers also point out that human capital must be integrated through corporate management, as management approach and style influence human capital growth (Khan *et al*., 2020). Therefore, human capital must be managed purposefully to overcome organizational and contextual challenges.

Similarly to other professions, the healthcare sector often faces a mismatch between the existing skills of employees and the skills required for their roles. This disparity highlights concerns about the potential underutilisation of human capital, where employees may have skills that exceed the requirements of their roles, or about the quality and safety of healthcare services, where employees may lack essential skills (Organisation for Economic Co-operation and Development, 2016). Hence, the authors have taken the initial step of developing a Conceptual Model for Human Capital Management in healthcare institutions. This model is predicated on the notion that an institution's human capital is constituted by the knowledge and skills of its workforce, and that effective human capital management is context-specific, considering the unique dynamics of the healthcare sector.

3.2 Human Capital Data Metrics and Disclosure

As the concept of human capital continues to evolve and the paradigm shifts, the issue of human capital disclosure grows in significance. With a company's intangible assets now estimated to represent an average of 52% of its market value (Klemash, Neill, and Smith, 2019), the measurements and the value of human capital become extremely relevant to the company's management, stakeholders, shareholders, and investors. The Standard and Poor's 500 index (S&P 500) summarizes the performance of approximately 500 high-value companies in the United States, reflecting the performance of the US stock market and the entire US economy. And, as the study shows, since 2009, the market value of non-material assets in S&P 500 companies has increased by 255%, while the volume of material assets during the same period has increased by only 97% (PricewaterhouseCoopers, 2021). Despite the increasing importance of non-material assets, the accounting model has remained largely unchanged. Human capital is not treated as an asset that requires accounting and valuation compared to financial or physical assets, and its value is predominantly absent from the organization's balance sheet or other financial statements. Consequently, traditional reports typically provide minimal or no information on human capital value, skills, management effectiveness, and productivity in relation to revenue and profit. However, there is a growing recognition in the literature of the significance of measuring and analysing human capital data to enhance strategic decision-making. To enhance employee performance, metrics are required to gauge the value of human capital (such as accumulated knowledge, skills, experience, etc.), and the garnered knowledge should be leveraged to efficiently administer the organization. Human capital measurement presents challenges, and assessing its value can be subjective. Without a unified understanding and widely accepted methodology or consistent approach, there is no avenue to incorporate the value of human capital into the annual balance sheet. Nevertheless, this does not hinder organizations from addressing this issue in a separate report on organizational human capital or integrating it into annual financial or other types of reports to showcase company value and transparency.

Currently, initial efforts are underway to find ways to reflect the intangible value of the company. For example, in 2018, the international audit and tax consulting firm 'Deloitte' introduced the 'Human Capital Balance Sheet,' a document designed to transparently consolidate human resources from cost, expense, and risk perspectives (Deloitte, 2018). Furthermore, trends that underscore the need for accounting and reporting of human capital are evident in various documents and initiatives at the international level. In 2018, the International Organization for Standardization (ISO) issued a new standard - 'ISO 30414:2018 Human resource management - Guidelines for internal and external human capital reporting' (International Organization for Standardization, 2018). In 2020, the International Financial Reporting Standards (IFRS) Foundation established the International Sustainability Standards Board (ISSB) and the Sustainability Accounting Standards Board (SASB) to address non-financial reporting issues, including human capital reporting (Sustainability Accounting Standards Board, 2021). The World Economic Forum (WEF) in its report "Human Capital as an Asset: An Accounting Framework to Reset the Value of Talent in the New World of Work" indicates that a robust framework for measuring and accounting human capital provides a more precise approach to workforce management and that differentiated accounting practices and isolated metrics need to be replaced with a more integrated, holistic approach (World Economic Forum, 2020). Adopting the principles of a paradigm shift, human capital accounting can help organizations to focus on long-term strategies, invest in human resources, and to create value by embracing the thinking of

people, work, and skills. Organizations should identify themselves as socially responsible participants in the broader ecosystem and thus create a three-way win-win-win situation, where beneficiaries are the organization, employees, and the wider society (WEF, 2020). In the report developed in collaboration with Deloitte, Ernst & Young, KPMG, and PricewaterhouseCoopers - "Toward Common Metrics and Consistent Reporting of Sustainable Value Creation" (2020), WEF proposes human capital accounting metrics: “1) Average hours of training per person that the organization’s employees have undertaken during the reporting period, by gender and employee category (total number of trainings provided to employees divided by the number of employees); 2) The average training and development expenditure per full time employee (total cost of training provided to employees divided by the number of employees)” (World Economic Forum, 2020). At the same time, WEF points out that these indicators may not reflect the overall impact of learning on measurable performance improvements.

These initiatives are highly valuable and desirable; however, the authors believe that within this novel framework, deeper transformative adjustments are imperative based on two considerations. Firstly, human capital accounting remains fragmentary and is not widely developed or implemented in practice, unlike financial accounting, which is a common standard in organizations. Secondly, existing solutions focus primarily on the collection of quantitative data, such as the number of training sessions attended or the time spent in training, but do not provide a deeper insight into the qualitative and substantive aspects of human capital. The authors suggest that human capital metrics should be based on qualitative skills management, ensuring human capital disclosure, and transparently reflecting the value of an organization's human capital. All stakeholders should have access to transparent information, specifically regarding the knowledge and skills possessed by the employees who constitute the organization's human capital. This should include detailed insights into the specific knowledge and skills acquired or refreshed by employees, and also the proficiency levels achieved, and recency or regularity of these acquisitions. This transparency not only allows better assessment and utilisation of human resources, but also fosters trust and engagement among stakeholders, including investors, clients, employees, and regulatory bodies. By providing a comprehensive view of the capabilities of the workforce, organizations can more effectively align their human capital with strategic objectives, drive performance improvements, and support informed decision-making processes.

3.3 Context of the Healthcare Sector

For particular organisations, such as healthcare institutions, especially those that are state-funded, the primary objectives are not focused on revenue generation, improving competitiveness, or expanding market share. Therefore, the approach to human capital management should be evaluated within the context of the healthcare sector, including the functions mandated by the state, providing a minimum level of medical assistance and ensuring the quality of healthcare, as well as the safety of patients and healthcare professionals. Over recent years, since the European Commission introduced the "New Skills Agenda for Europe," which promotes balancing skills acquisition, developing skills systems, and enhancing lifelong learning, there is still a notable lack of evidence regarding the practical implementation of a human capital management approach in healthcare sector institutions (Grigorovica *et al*., 2022). The quality of healthcare and the safety of patients and healthcare professionals are the key factors distinguishing enterprises and institutions in the healthcare sector from other sectors. Therefore, human capital management in this sector is context-dependent, and healthcare aspects are paramount in the development of the Human Capital Management Model.

According to the WHO, patient safety is the reduction of risk of unnecessary harm associated with healthcare to an acceptable minimum. The acceptable minimum refers to the collective judgment of current knowledge, available resources, and context in which care was delivered, and evaluated against the risk of non-treatment or alternative treatment (World Health Organization, 2009). Patient safety is a framework of organized activities that creates cultures, processes, procedures, behaviours, technologies, and environments in healthcare that consistently and sustainably reduce risks, reduce the occurrence of avoidable harm, make error less likely, and reduce its impact when it does occur (World Health Organization, 2021). Consequently, the failure of healthcare institutions to ensure safe care incurs additional expenses, paradoxically reducing funding for healthcare provision. The WHO also notes that investments in promoting patient safety can lead to financial savings, as evidenced by estimates showing that costs associated with medical errors amount to approximately $42 billion annually, excluding lost wages, productivity, or healthcare expenses, collectively comprising nearly 1% of global health expenditures (World Health Organization, 2019).

As indicated in the report 'Patient Safety 2030', reducing harm requires the development of an integrated, systemic approach that includes fostering a culture of safety, placing patients and healthcare personnel at the

centre of all intervention measures, and implementing evidence-based policy (Yu *et al*., 2016). Evidence-based policy aligns with human capital management, as the costs that healthcare institutions incur to reduce harm to patients would be more meaningfully invested in improving healthcare quality by primarily investing in institutional human capital, developing healthcare personnel skills, ensuring systematic human capital development and making data-driven decisions, thus also reducing risks to patient safety. Therefore, healthcare institutions must integrate human capital management with systems that signal skills gaps, skills mismatch, existing or protentional skills imbalance in the healthcare process, to reduce and prevent patient harm.

4. Conceptual Human Capital Management Model for Healthcare Institutions

In the dynamic contemporary work environment, the workforce is a dynamic asset that requires intentional human capital management. To improve the effectiveness of forecasting and planning human resources in healthcare and to address increasing workforce shortages and skills mismatches within existing staff, healthcare institutions must adopt a comprehensive human capital management strategy. The Human Capital Management Model proposed by the authors ensures not only the accounting numerical measures, but also incorporates qualitative, in-depth skills monitoring at the individual employee level. Skills monitoring as a central part of human capital management enables the acquisition of current employee skills levels, reflecting the extent and level of individual performance. It should be noted that within this model, the term 'skills' is used according to the European Commission's programme 'A New Skills Agenda for Europe' - skills refer 'broadly to what a person knows, understands, and can do' (European Commission, 2016).

Following the analysis, the authors have delineated the foundational principles for the Conceptual Model of Human Capital within healthcare:

- *Human capital management is grounded in skills monitoring.* A skills digital monitoring system should be established within the Human Capital Management Model, facilitating the accumulation and analysis of skills information. The skills digital monitoring system captures a wide range of skills data that are integrated into individual and institutional skills portfolios, enabling qualitative disclosure of the value of human capital. The authors assert that the improvement of healthcare quality and the safety of patients and healthcare professionals can only be achieved through rigorous validation of knowledge and skill acquisition. Monitoring skills effectively cannot solely rely on the collection of training programmes and course attendance certificates, as these do not guarantee the actual acquisition of knowledge and skills by the employee. Skills monitoring should be based on qualitative skills management, ensuring transparent human capital disclosure and revealing the specific knowledge and skills employees possess (including also the date of skill acquisition and refreshment).
- *Human capital management is based on an ecosystem of healthcare systems.* Human capital management must ensure seamless information integration between the skills digital monitoring system and other healthcare-specific data acquisition systems. These systems can vary between different institutions and can change over time, but systems such as patient satisfaction surveys, patient safety reporting systems, general quality surveys, and performance management systems, among others, can serve to identify existing or potential skills shortages or mismatches.
- *Human capital management is integrated at all levels of the institution*. At the strategic level, the management of a healthcare institution is responsible for defining the human capital management strategy, fostering a culture of learning, and incorporating an analytical approach and data-driven decision making. At the operational level, the human resources management unit performs the functions of collecting human capital data and performing data analytics, coordinates learning activities, and monitors all skills portfolios. Meanwhile, at the tactical level, the healthcare workforce, through active training and skills development, enriches the institution's human capital.

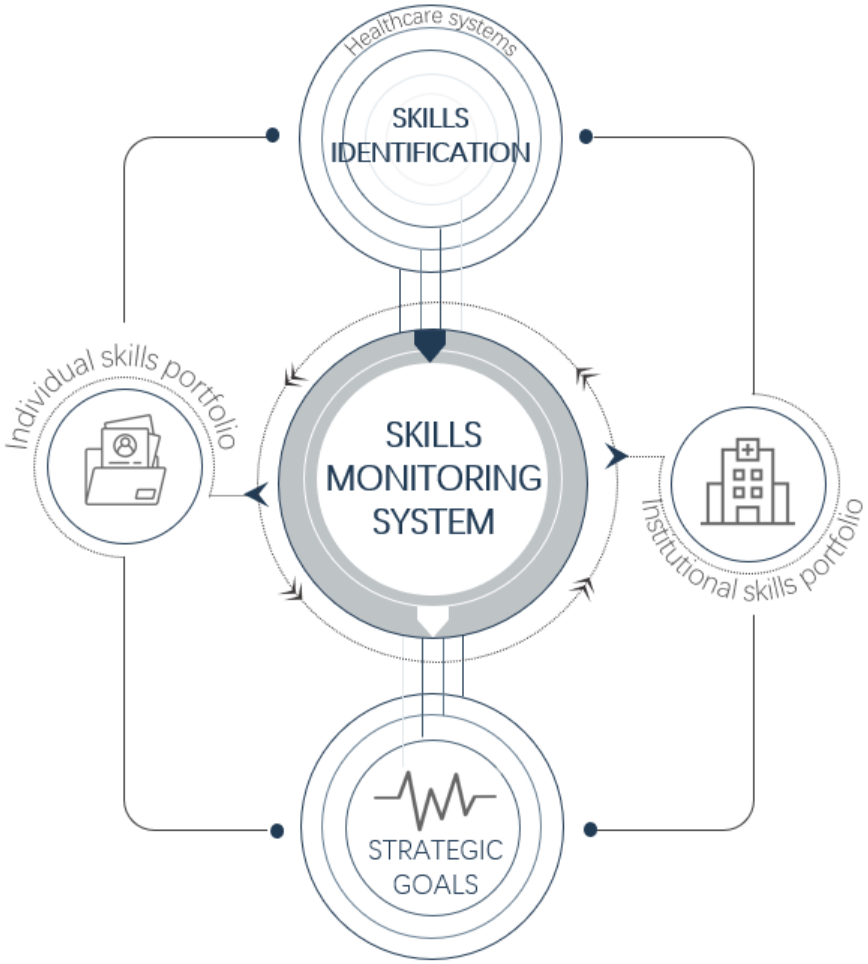

Figure 1: Conceptual Human Capital Management Model for Healthcare Institutions (by authors).

The model provided (Fig.1) is dynamic and flexible and can be customized to suit diverse settings and institutional needs. The implementation of the Human Capital Management Model can yield benefits across various operational levels of the institution, and through effectively executed human capital management, healthcare institutions have the opportunity to enhance the achievement of strategic goals:

- *Provision of Human Resources.* Skills monitoring supports the management of employees' skills, the implementation of professional development plans, the development of career paths, and the management of individual healthcare personnel's recertification plans. Managing these data enables more qualitative and precise forecasting and planning of human resources, performance evaluation, annual goal definition, and the preparation of precise, data-driven human capital reports for board, shareholders, stakeholders, and public administration from various perspectives.
- *Healthcare Quality & Safety*. With a suitable workforce with up-to-date skills, the risks of harm to patients are reduced and the results of healthcare processes are improved. If signals about existing or potential skills shortages or mismatches are linked with skills monitoring at an individual level, it is possible to ensure timely acquisition or refreshment of skills. This approach promotes quality enhancement, reduces the occurrence of avoidable harm, and allows for the prevention of potential future risks to patients or healthcare personnel.
- *Financial Sustainability*. By conducting human capital management equally as managing other types of capital and investing resources in employee knowledge and skills, institutional financial sustainability is promoted, as well as financial planning grounded in data-driven decisions. As incidents causing harm to patients decrease, the expenses of the healthcare institution related to harm reduction and compensation diminish. Concurrently, this demonstrates deliberate long-term action and fosters a positive institutional reputation.

5. Conclusions

Human capital is a crucial intangible asset for healthcare institutions, comprised of the knowledge and skills of their employees. In the healthcare sector, targeted and effective human capital management can improve the achievement of strategic objectives – ensuring efficient human resource provision, improving health quality, increasing the safety of patients and healthcare professionals, and the sustainable use of financial resources. The Human Capital Management Model provided by the authors deepens transformative adjustments in the field and drives to shift the mindset – from numeric measures to qualitative valuation, from systems to integrated ecosystem, and from costs to investments.

By implementing human capital management based on this novel Human Capital Management Model, healthcare institutions have the opportunity to navigate through contemporary challenges and to meet the health sector goals set by the World Health Organization and the United Nations – to ensure healthcare coverage with sufficient human resources and an appropriate skill-mix by 2030.

Future research should aim to (1) develop a detailed concept for a skills digital monitoring system designed to the healthcare institution (establishing skills levelling, categorization, and process integration), (2) develop a human capital management process from the perspective of innovation integration, and (3) expand the analysis of the impact of human capital management on the strategic objectives of healthcare institutions.

Seeing is Believing: 3D-Printed Boundary Objects for the Additive Manufacturing Twin Transition

Trond Halvorsen, Raymond Andreas Stokke and Gunnar M. Lamvik
SINTEF Digital, Trondheim, Norway

trond.halvorsen@sintef.no
raymond.stokke@sintef.no
gunnar.lamvik@sintef.no

Abstract: This article describes the use of 3D-printed demonstrators as boundary objects in intra-firm collaboration processes aimed at implementing additive manufacturing (AM). AM is a disruptive digital technology with large potential environmental benefits. Demonstrators are common early in the learning process to familiarize organisations with AM, and it's important to understand both their benefits and the limitations and risks involved. The results suggest that 3D-printed demonstrators can be effective in establishing a common minimum level of knowledge across diverse professions within the same organisation. Having physical objects available makes conversations about AM more engaging and legitimizes the idea of utilising AM as realistic. However, the fabrication of demonstrators can be a lengthy and costly process, and the result may not be a good representation of the final design. Negative experiences in such initial trials may turn managers away from AM prematurely. Many of the benefits of demonstrators can be obtained by producing low-cost miniatures and/or polymer parts that will mitigate the risks.

Keywords: 3D-printing, additive manufacturing, boundary object, twin transition.

1. Introduction

Additive Manufacturing (AM) has been proclaimed as a paradigm shift in the production landscape, offering a range of benefits that promise to redefine manufacturing processes (Mehrpouya et al, 2019). AM's ability to produce customized, complex components swiftly and with reduced material waste positions it as a pivotal technology in the ongoing industrial modernisation (Gibson, Rosen, and Stucker, 2014). Despite its potential, the assimilation of AM into the intricate structures of large organisations is fraught with challenges. For example, a lack of collective understanding and acceptance of AM's capabilities and benefits across diverse business units, often hinder its widespread adoption (Ford and Despeisse, 2016).

In addressing these challenges, the concept of boundary objects, particularly in the form of 3D-printed demonstrators, emerges as a useful tool for fostering cross-disciplinary collaboration and knowledge sharing (Swann et al, 2023). Boundary objects serve as physical interfaces that facilitate communication and understanding among different social worlds within an organisation, thereby aiding in the alignment of objectives and the harmonisation of efforts towards a common goal (Star and Griesemer, 1989). In the context of AM, 3D-printed demonstrators not only provide tangible examples of AM's potential, but may also act as catalysts for discussion, exploration, and learning across various departments (Bosch-Sijtsema and Postma, 2010).

This paper delves into the utilisation of 3D-printed demonstrators as boundary objects within large organisations to promote a twin transition, i.e. green and digital (Rehman et al, 2023), towards the acceptance and integration of AM. Drawing on a qualitative research design that incorporates action research and semi-structured interviews across multiple industries, this study aims to shed light on how 3D-printed demonstrators can bridge knowledge gaps and facilitate collaborative exploration and adoption of AM technologies. The empirical evidence gathered from managers, engineers, and operational staff across sectors such as shipping, oil and gas, and research offers a multifaceted perspective on the role of demonstrators in advancing organisational understanding of AM.

This paper contributes to the existing body of literature on cross-disciplinary learning in large organisations by showcasing multiple examples of designs and discussing the benefits and limitations of using 3D-printed demonstrators as boundary objects. By building on use cases and developing a strategic roadmap for exploring business opportunities with AM, organisations can navigate the complexities of integrating this disruptive technology into their operations.

2. The use of Demonstrators When Integrating AM in Manufacturing Processes

The integration of AM into established value chains represents potential for a significant shift towards more agile, and customized production methodologies. AM production processes, characterized by their ability to add material layer by layer to create objects, offers unprecedented flexibility in design and manufacturing,

challenging traditional manufacturing paradigms (Gibson, Rosen, and Stucker, 2014). This technology holds the potential to revolutionize industries by reducing lead times, minimizing material waste, and enabling the production of complex geometries that are otherwise impossible to achieve through conventional methods (Ford and Despeisse, 2016).

Despite these advantages, the adoption of AM technologies within large organisations is fraught with challenges. One of the primary obstacles is the disparate understanding and acceptance of AM across various departments and business functions. The novelty of the technology, combined with its perceived complexity, often leads to resistance or scepticism among stakeholders (Rogers, 2003). This challenge underscores the importance of effective intra-firm collaboration and knowledge sharing to foster a conducive environment for AM integration.

The concept of boundary objects, introduced by Star and Griesemer (1989), offers a valuable framework for facilitating such collaboration. Boundary objects are artifacts that serve as points of reference that different social worlds within an organisation can understand and use, despite holding divergent viewpoints or expertise. In the context of AM, 3D-printed demonstrators have emerged as potent boundary objects, enabling diverse stakeholders to visualize, discuss, and explore the potential applications of AM technologies (Carlile, 2002; Swann et al, 2023). In our study we posit demonstrators as a form of prototype or final product which offer a tangible solution to showcasing the potential of 3D-printed parts in large organisations.

Research on the use of prototypes and demonstrators in industrial design and innovation highlights their role in enhancing communication and collaboration among interdisciplinary teams. Prototypes enable stakeholders to tangibly interact with a concept, fostering a shared understanding and facilitating consensus-building (Thomke and Fujimoto, 2000). This interaction is particularly critical in the early stages of technology adoption, where abstract concepts need to be translated into concrete examples to gain organisational support (Bosch-Sijtsema and Postma, 2010).

3D-printed demonstrators have emerged as essential tools across various organisational functions, notably for sales and design purposes (Gao et al, 2015; Robinson, Lagnau and Boon, 2019; Schniederjans, 2017). In sales, these demonstrators serve as tangible representations of AM's capabilities, allowing sales personnel to distinctly showcase the potential of AM to clients and stakeholders. The physical presence of 3D-printed parts can significantly enhance customer engagement and comprehension, providing a concrete example of abstract AM benefits, thereby facilitating a more effective sales process.

Within the design phase, 3D-printed protypes enable a hands-on approach to product development, fostering a collaborative environment among designers, engineers, and other stakeholders (Swann et al, 2023). These items act as boundary objects that facilitate communication and understanding across disciplinary divides, allowing for rapid prototyping and iterative design processes. This not only accelerates the design phase but also ensures that the final product is more attuned to the practical requirements and constraints, embodying a collective vision shaped by diverse inputs.

However, the production of 3D-printed demonstrators is not without its challenges. The process can be time-consuming and costly, and the resulting artifacts may not always accurately represent the final product. This discrepancy can lead to misunderstandings or misplaced expectations regarding the capabilities and limitations of AM technologies (Thompson, 2012). Despite these challenges, the benefits of using 3D-printed demonstrators extend beyond mere knowledge dissemination. By providing a tangible representation of AM's capabilities, demonstrators can stimulate interest, inspire innovation, and legitimize the exploration of AM technologies within an organisation (Berman, 2012). They serve as a catalyst for engaging discussions, enabling stakeholders to envision the practical applications of AM in their respective domains (Horne and Nissen, 2006).

Organisations can build on the use of demonstrators to develop a strategic roadmap for exploring business opportunities with AM. This roadmap should encompass a thorough evaluation of potential applications, considering both the technical feasibility and the economic viability of AM. By systematically leveraging demonstrators to showcase AM's capabilities, organisations will be more likely to identify and prioritize high-value applications, aligning their AM initiatives with broader business objectives.

This underscores the important role that 3D-printed demonstrators have as boundary objects in facilitating the twin transition towards AM adoption in large organisations. By serving as tangible points of reference, demonstrators enable diverse stakeholders to collectively explore, understand, and embrace the potential of AM technologies. Despite the challenges associated with their production, the strategic use of demonstrators can significantly enhance intra-firm cross-disciplinary collaboration, knowledge sharing, and innovation, paving the

way for the successful integration of AM into organisational processes (Star and Griesemer, 1989; Carlile, 2002; Gibson, Rosen, and Stucker 2014; Robinson, Lagnau, and Boon 2019).

3. Methodology

This study adopts an explorative qualitative research design to document the utilization of 3D-printed demonstrators as boundary objects in intra-firm collaboration towards the industrialization of AM within large organisations. A case-based approach (Yin, 2014) was deemed most suitable for obtaining in-depth insights into the complex processes and interactions associated with the adoption of AM technologies.

The primary data collection methods employed in this study were action research (Greenwood & Levin, 2006) and semi-structured interviews, which enabled the gathering of empirical evidence from the field. Action research was chosen for its participatory and iterative nature (Kindon, Pain, and Kesby 2007), allowing researchers to engage directly with the phenomena under study and to implement and observe the impact of 3D-printed demonstrators in a real-time organisational setting. This was carried out by providing coworkers and research managers access to various demonstrators. Semi-structured interviews provide a flexible yet structured means of capturing the diverse perspectives of individuals involved in the AM integration process. These interviews were conducted with managers, engineers, and operational staff of large organisations, ensuring a comprehensive understanding of the experiences and perceptions surrounding the use of 3D-printed demonstrators in AM adoption. The demonstrators were photographed by the authors or interview subjects.

The selection of cases for this study was guided by the objective of covering industries where AM has the potential to significantly impact large-scale manufacturing processes, and where we see that organisations are working actively to foster intra-organisational learning. As such, large Norwegian firms from the oil and gas industry, the maritime industry, and our own research organisation were included in our study. This diverse selection of cases allowed for incorporating a wider range of industry-specific challenges, opportunities, and strategies related to the adoption of AM technologies. The collected data were subjected to narrative analysis, with the aim of identifying recurring patterns, themes, and insights related to the use of 3D-printed demonstrators as boundary objects in AM adoption. This analytical approach facilitated the extraction of meaningful information from the qualitative data, enabling the formulation of conclusions and recommendations grounded in empirical evidence.

The study was carried out between October 2023 and March 2024, in the context of a three-year innovation project aiming to promote the use of AM in the maritime industry. Table 1 describes the interview subjects.

Table 1: List of interview subjects

Organisation	Role of interview subject
AM service provider 1	AM engineer
AM service provider 2	Chief Commercial Officer
Ship management	Fleet manager
Oil and gas operator	Head of AM team
Maritime OEM	AM ambassador
Research organisation	Research manager and research director

4. Examples of 3D-Prints Used as Boundary Objects

The photos below illustrate a variety of items that are 3D-printed and obtained with the purpose of illustrating unique aspects of AM production processes. Figure 1 shows metal items suitable for daily use in an office setting. Example 1a is a titanium coffee mug designed, printed and used by an engineer on from a Norwegian AM service bureau, currently working for a large oil and gas operator. In addition to the intricate pattern, the cup conveys the light weight and heat conductivity of the material. Example 1b shows two bottle openers. The one on the left is an unpolished titanium piece that illustrate the surface finish of parts as they come from the printer. At the back end is a small remnant of the support structure that fixed the item to the build plate during the printing process. The one on the right is a multi-functional stainless-steel item that combines a bottle opener with a flute and a loop for a key ring (not printed). The flute is attached to the logo and rotates freely within the cylinder. Example 1c are two pens with 3D-printed bodies made in titanium. Both display a lattice structure on large areas of the surface, and an integrated logo. The pen on the left has a two-piece body that screws together with 3D-printed threads, while the pen on the right has a solid body with an ink cartridge inserted from the bottom.

Figure 1: Metal prints for daily use

Figure 2 shows three examples of polymer card holders. The Figure 2 shows three examples of polymer card holders. These are used to hold identification cards that are common at many workplaces, exhibitions and conferences. Example 2a is made by sintering nylon powder with a laser. It has a slot on top to insert a business card, which is held in place by a clip on a lanyard. Example 2b is made with polylactic acid (PLA) filament in a fused filament fabrication (FFF) process. It displays a small boat, known as the 3D benchy, at the top to showcase the level of detail that the process can achieve. It also has varying surface textures and overhangs that can hold a paper conference badge. Lastly, example 2c is an access card holder with movable gears. The model does not require any manual assembly as it's a build-in-place design. The front is customized with text displaying four company core values.

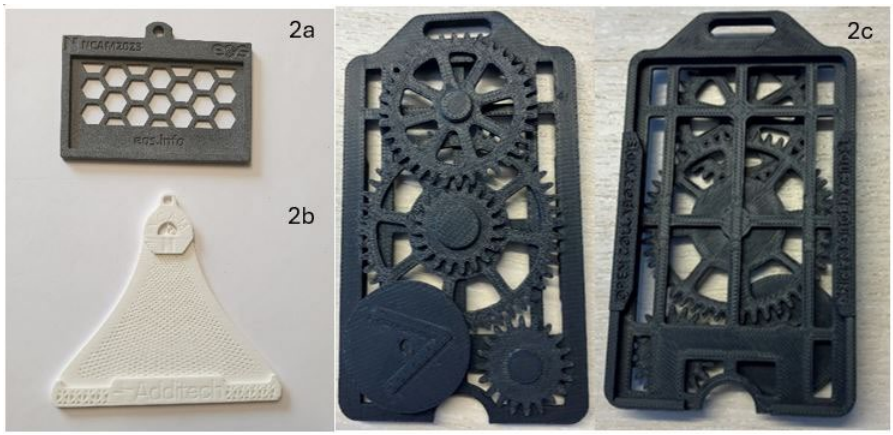

Figure 2: Polymer card holders

Figure 3 presents a few examples of items that are made for display and education, i.e. not actual use. Example 3a is a working Rubic's cube, with each small cube showing different patterns and textures. Some of them also include moving pieces, such as springs. The piece illustrates the design freedom of 3D-printing, but the polymer material is relatively fragile. Example 3b is a replacement for a PC keyboard support. It was made to illustrate the importance of part orientation during FFF-printing. The visible layer lines that are orthogonal to the length of the clips make them prone to breaking. Example 3c is a holder for tips of silicone tubes sold in hardware stores. It represents a product for which resin printing can compete economically with injection moulding for mass manufacturing. Examples 3d and 3e are made from the same digital design file. The difference is that the build process was stopped prematurely for example 3e to display the internal structures. These items are used together to illustrate the material savings that can be achieved with AM relative to subtractive manufacturing processes.

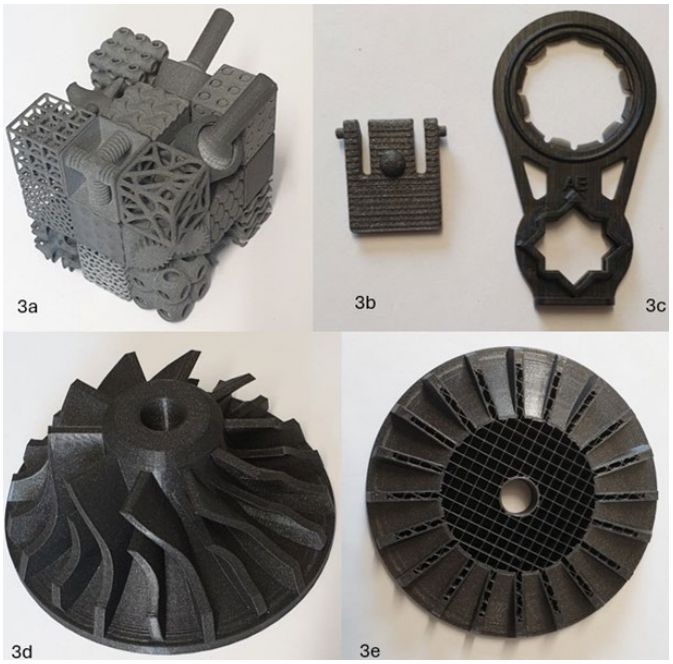

Figure 3: Illustrative polymer prints

Figure 4 shows two examples of 3D-printed products that have full production quality but are used by large organisations to create awareness about the capabilities of metal 3D-printing. Example 4a is a bike with a 3D-printed titanium frame, and an accompanying rollup with basic information about the item. The bike is painted with a company logo, and the rollup highlights some benefits. Example 4b is a pipe connector made with binder jet technology using 316L stainless steel. This item is part of a collection of 3D-printed spare parts for the maritime sector. A ball pen is included in the picture for size reference.

Figure 3: Display pieces of metal prints

5. Findings From Interviews

The interviews reflect the wide variety of settings in which the demonstrators are used, and his section summarises key findings across the subjects. Firstly, the need for and challenges of creating awareness about the value proposition of AM within large organisations was confirmed. Even though the technology is being described as sufficiently mature to produce both critical and non-critical components, the standards needed to certify the parts were not available until a few years ago. Therefore, the use of AM is not reflected in many policy documents such as maintenance plans, approved vendor lists, and project descriptions. Now there's a particular need to educate the teams responsible for renewing such documents, and those people are distributed across different departments and geographical locations.

Secondly, the organisations included in this study typically utilize more than one kind of demonstrators. Each individual item may highlight a few aspects of AM, but providing more examples is necessary to generate a better understanding of both the potential and limitations of AM production methods. Demonstrating a variety of materials and production processes is one goal. Another goal is to inspire enthusiasm and the attitude that the potential of AM is broader than one first realized. The oil and gas operator has identified “AM mindset” as a strategic concept that they refer to on this topic. “AM awareness” is another term that is used with similar connotations.

Thirdly, the knowledge level that is generated with these demonstrators is not deep, and it doesn’t have to be. Each organisation has some experts on AM, and the job of designing and producing the demonstrators, such as examples 1a and 4b, provided them with additional in-dept knowledge. But as a boundary object, the function of the demonstrator is to provide opportunities for discussing 3D-printng with non-experts and inspire questions.

Fourthly, the impact of the demonstrators can be enhanced if it’s tailored to a specific context. The bike in example 4a was acquired in relation to a bike race that the company sponsored and was used in promotional posts on social media. The card holders of examples 2a and 2b were made for AM conferences. If they were to be used in other settings, people seeing them may not realize that they are 3D-printed. The organisation that provided example 2c also make this access card holder in a separate colour for their AM experts team. This helps to build a sense of shared identity across geographical and organisational locations.

Fifthly, the tangible aspect of demonstrators is seen as important. In the interview with a ship services employee and a fleet manager, the fleet manager asked specifically for AM parts that could be shown to other officers within his company. Seeing and touching actual parts is thought to provide additional realism compared to seeing a picture of the item on a presentation slide, or just hearing about it. The research director noted that particularly holding the pens in example 1c was inspiring to him. This changed his perception of AM from being useful for making cheap plastic copies (e.g. prototypes) to seeing it as a viable alternative for making actual functional items of good quality.

The interviews also uncovered some important challenges of inter-organisational learning from demonstrators. The AM expert at the maritime equipment OEM explained that a different department than hers had experimented with making a part with a metal powder bed fusion (PBF) process and comparing it with conventional manufacturing in a low-cost country. Since PBF is a relatively expensive process and there was no redesign of the part to optimize it for AM, the head of department had concluded that AM was not a viable alternative for them. This sentiment then influenced other heads of department within the company, despite the AM expert’s opinion that another AM process would have been more cost efficient for that specific part. This story illustrates that demonstrators can also facilitate the spread of misperceptions and misunderstandings across inter-organisational boundaries.

The second challenge is that the information that is meant to be transferred between individuals is not contained, or not readily apparent, in the object itself. For example, some people may see the demonstrator without realizing that it is 3D-printed. A way to overcome this is by displaying it with signs with a short description of the item and production process. The demonstrators are also used in combination with digital presentations, such as power point slides and social media posts, that provide additional information. Thirdly, the most convincing demonstrators are typically the most expensive to produce. It makes little sense to make several identical copies of large metal parts for educational purposes. In contrast, the access card holder (example 2c) has the benefit of being very portable and visible. It is also relatively cheap and can be distributed to many employees within an organisation.

6. Discussion

The findings suggest that the use of 3D-printed demonstrators contributes significantly to the advancement of AM. By facilitating knowledge sharing, enhancing interdisciplinary collaboration, and providing tangible proof of AM's potential, these objects play a crucial role in convincing stakeholders of the value of AM, securing necessary resources, and fostering a culture of innovation. The interview subjects emphasize the role of these demonstrators in offering a hands-on learning experience, which is instrumental in building a foundational understanding of AM processes, materials, and capabilities across large organisations.

In the context of anchoring AM within organisational processes, 3D-printed demonstrators serve as concrete examples of the technology's potential impact on product development, supply chains and maintenance strategies. Physical models can significantly enhance the persuasive power of internal presentations, enabling

innovators and advocates of AM to communicate the potential applications and benefits of the technology more effectively. This can lead to a stronger buy-in from senior management, crucial for securing the necessary resources and attention for AM initiatives. Moreover, demonstrators can play a pivotal role in the acquisition of resources for AM projects. By showcasing the functional and economic benefits that can be achieved with AM, these models can stimulate interest and curiosity among different departments.

The utilisation of demonstrators as boundary objects represents a collaborative approach to adopting AM technologies. These demonstrators appear as important in bridging the some of the knowledge gaps between various departments, facilitating a shared understanding of AM's capabilities and potential applications (Halvorsen and Lamvik, 2022). This study's findings resonate with the concept introduced by Star and Griesemer (1989), highlighting the importance of boundary objects in fostering interdisciplinary collaboration. The tangible nature of 3D-printed demonstrators catalyses discussions around AM, making the technology's abstract concepts more accessible and engaging to diverse professional groups within the organisation. This also aligns with the observations made by Bosch-Sijtsema and Postma (2010), who emphasized the role of tangible prototypes in enhancing intra-firm communication and collaboration.

The challenges associated with the production of 3D-printed demonstrators, such as the time, cost, and potential inaccuracies in representing the final product, necessitate a careful consideration of their design and development. These challenges, if not managed effectively, could deter interest in AM and impede its integration within organisational processes. This is in line with Thompson's (2012) findings, which pointed out the importance of physical prototypes in mitigating risks associated with new product development. It underscores the need for a strategic approach to the development of these demonstrators, as suggested by Berman (2012), to ensure that they accurately convey the capabilities and limitations of AM technologies, thus preventing misconceptions and misplaced expectations.

7. Recommendations

Considering the findings from this study on the use of 3D-printed demonstrators in facilitating the adoption of AM within large organisations, several recommendations can be posited to enhance the effectiveness of AM integration processes:

- Organisations should consider starting small with plastic prototypes. This approach allows for the exploration of AM's capabilities without incurring significant costs or committing extensive resources.
- Organisations are encouraged to actively explore redesign opportunities and demonstrate the unique opportunities that AM presents. Demonstrators don’t need to have the same size, shape or material as original models.
- Demonstrators should be presented in connection to an information source, explaining the process and benefits of AM for each item.
- Knowledge sharing sessions, workshops, and regular discussions centred around the learnings from initial demonstrator efforts can catalyse a collective understanding of AM's potential and limitations. The physical demonstrators should be brought to these arenas.
- The establishment of a structured roadmap for AM integration, informed by the insights gained from prototyping, testing, and verification efforts, is recommended. This roadmap should outline clear milestones, objectives, and strategies for scaling AM capabilities within the organisation. It should also lay out a strategy for using demonstrators for intra-organisational knowledge sharing.

The strategic use of 3D-printed demonstrators, coupled with a focused approach to knowledge building, redesign exploration, and rigorous testing, can significantly enhance the adoption and integration of AM within large organisations. These recommendations provide a pragmatic framework for organisations to leverage AM's transformative potential, driving innovation and efficiency across their operations.

8. Conclusions, Limitations, and Future Research

Our study show that 3D-printed demonstrators serve as tangible intermediaries that not only bridge the knowledge gap across diverse professional domains but also facilitate an environment conducive to collaborative innovation and exploration. Our study highlights that, by embodying the capabilities and potential of AM, demonstrators can effectively stimulate discussions, facilitate learning, and drive the twin transition towards more sustainable and digitalized manufacturing processes. Despite the challenges associated with their

production, such as time and cost implications, the strategic deployment of these demonstrators has been shown to significantly enhance intra-firm communication, knowledge sharing, and ultimately, the integration of AM technologies into organisational processes.

This research is not without limitations. The case-based, qualitative nature of the study, focusing on selected industries within the Norwegian context, may restrict the generalisability of the findings to other sectors or geographical regions. Moreover, the production and utilisation of 3D-printed demonstrators are contingent upon the specific AM technologies, designs and materials employed, which may introduce variability in their effectiveness as boundary objects. For example, confidence in the use of AM processes for critical parts may be negatively influenced by only seeing AM used for demonstrations of non-critical parts (e.g. a pen). This makes the case for also making demonstrators of critical parts that are subjected to rigorous quality tests. Future research should aim to address these limitations by expanding the scope of investigation to include a broader array of industries and geographical contexts, thereby enhancing the generalisability of the findings. More research is also needed on optimizing the design and development process of these demonstrators to maximize their effectiveness while minimizing associated costs and challenges.

3D-printed demonstrators can also help in capturing the attention of key stakeholders outside the organisation. Bringing these tangible models to stakeholder meetings and industry conferences to demonstrate the organisation's commitment to innovation and technological advancement is a common practice that was outside the scope of this study. The benefits of this activity include positioning the organisation as a leader in AM adoption but also attracting customers, talent, partners, and investors who are interested in cutting-edge manufacturing technologies. Evaluating this behaviour in light of the literature on knowledge management would be valuable from both an industrial and academic standpoint.

From Concept to Market: Integrating Organizational Knowledge Creation to Bridge Technology and Business Gaps

Irina-Emily Hansen, Ola Jon Mork, Paul Steffen Kleppe and Lars Andre Langøyli Giske
Department of Ocean Operations and Civil Engineering, Norwegian University of Science and Technology, Aalesund, Norway

irina-emily.hansen@ntnu.no
ola.j.mork@ntnu.no
paul.s.kleppe@ntnu.no
lars.a.l.giske@ntnu.no

Abstract: This study explores the intersection of project development and organizational knowledge creation within the context of industry-academia collaboration, applying Nonaka and Takeuchi's organizational knowledge creation model as the theoretical framework. Conducted at the Manufacturing Laboratory (Manulab) at the Norwegian University of Science and Technology in Aalesund, the research investigates how integrating academic research into industrial applications can be optimized through effective knowledge management and the use of practical tools. The findings emphasize the critical role of knowledge workers, including researchers, engineers, sales managers, and decision-makers from the industry, in every project phase. A significant focus is placed on the Manulab-industry competence-building process, which progresses in parallel with the Technology Readiness Level and Business Readiness Level axes. This dual advancement strategy ensures that technological innovations meet both technical standards and market needs, enhancing their commercial viability. The study demonstrates that adopting a structured framework incorporating TRL and BRL helps overcome common challenges such as the creation of technically sound but commercially unviable technologies. Additionally, the integration of simulation platforms has facilitated the active involvement of diverse stakeholders throughout the development process, improving the practical application of Nonaka and Takeuchi's model. Specifically, the research tests two hypotheses: (1) that the use of TRL and BRL frameworks for tracking and verifying project progress is a practical tool for applying Nonaka and Takeuchi's model, and (2) that the use of simulation platforms in the product development process, by involving diverse stakeholders, significantly improves the alignment and synchronization of technology and business concept development. The research concludes that successful implementation of academic research in industrial settings requires a comprehensive understanding of organizational knowledge creation, strategic collaboration, and the use of practical tools like TRL and BRL. These findings advocate for a systematic approach to project development that emphasizes both theoretical knowledge and actionable insights for effective industry-academia collaboration.

Keywords: Organizational Knowledge Creation, Industry-Academia, Technology Readiness Level, Business Readiness Level, Collaboration, Innovation

1. Introduction

The interplay between academia and industry is a cornerstone for pushing the boundaries of technological innovation. Yet, the path from academic research to tangible industrial applications often encounters numerous hurdles. Recent research conducted at the Manufacturing Laboratory (Manulab) within the Norwegian University of Science and Technology in Aalesund highlights these challenges and illuminates the crucial role that knowledge workers play in every phase of organizational knowledge creation to ensure the success of projects (Hansen *et al.*, 2023). These knowledge workers include a diverse group of individuals, from researchers and students at Manulab to engineers at technology integration firms and various stakeholders within industrial companies such as operators, engineers, sales managers, and decision-makers.

Drawing upon the Manulab-industry competence-building process, which is inspired by Nonaka and Takeuchi's seminal model of organizational knowledge creation, this research explores the vital elements required to synchronize all participants into a unified, collaborative effort (Hansen, Mork and Welo, 2019; Nonaka and Takeuchi, 1995). A key element of this framework is the strategic use of virtual and physical prototypes, which provide a tangible medium for both industry and academic stakeholders to collaborate effectively.

The aim of this article is to evaluate the effectiveness of integrating Technology Readiness Level (TRL) and Business Readiness Level (BRL) frameworks, along with simulation platforms, in enhancing the practical application of Nonaka and Takeuchi's knowledge creation model in industry-academia collaborations. Specifically, this study tests two hypotheses: (1) that the use of TRL and BRL frameworks for tracking and verifying project progress is a practical tool for applying Nonaka and Takeuchi's model, and (2) that the use of simulation platforms in the product development process, by involving diverse stakeholders, significantly improves the alignment and synchronization of technology and business concept development.

This article delves into a comprehensive case study involving Manulab and the FishMech company to dissect the factors that contribute to successful research implementation. This partnership not only resulted in immediate project successes but also set the stage for a strategic, long-term competence-building initiative that continues to benefit both the university and the company. Moreover, the paper advocates for the implementation of TRL and BRL as critical tools to monitor and guide project development from its inception in the lab to its full-scale implementation in the industrial arena.

The forthcoming sections of this article explore the theoretical background, methodology, case study, and findings. Section 2 outlines the theoretical premises and hypotheses tested. Section 3 describes Manulab-industry competence-building process and details the TRL and BRL frameworks. Section 4 elaborates on the methodology, including the case study approach and workshops for data collection. Section 5 details the collaboration between Manulab and FishMech, highlighting key stages and outcomes. Section 6 presents findings from the case study and workshops, showing the impact of TRL, BRL, and simulation platforms. Section 7 discusses the verification of hypotheses and supporting evidence. Finally, Section 8 summarizes the findings, discusses practical implications, outlines limitations, and suggests future research directions.

2. Theoretical Background and Hypotheses

The need for an effective knowledge management (KM) approach in industry-academia collaboration projects is critical for facilitating technological advancement and innovation. Studies by Hermansand and Castiaux (2007) and Johnson and Johnston (2004) highlight the significance of knowledge conversion processes and enabling conditions, which are positively associated with technological achievements. This underscores the necessity of a structured KM approach to achieve successful outcomes.

In the context of Norwegian marine and maritime industries collaborating with academia through Manulab, the organizational KM model developed by Nonaka and Takeuchi has been adapted to suit the local context (Hansen, Mork and Welo, 2019). This model has proven valuable in fostering knowledge creation and innovation across several projects. However, there remains a pressing need to develop more practical tools for the effective implementation of this model.

Several other studies underscore this need for practical applications of the organizational knowledge creation model by Nonaka and Takeuchi. Researchers like Balde, Stoyanov, and Cabana advocate for tools that better address practical KM aspects. Balde (2018) and Stoyanov (2018) build on the SECI model, focusing on team trust, intrinsic motivation, and the conversion of tacit and explicit knowledge. Cabana (2021) emphasizes the role of wise leadership in balancing knowledge types and prioritizing long-term sustainability.

Additional studies explore KM dynamics in industry-academia collaborations. Marijan and Gotlieb (2021) proposes a participative knowledge creation model with active stakeholder involvement to meet both academic and industrial objectives. Gómez-Marín et al (2022) suggest a comprehensive KM model tailored for academics and business stakeholders, highlighting systematic management of knowledge flows. Hansen et al (2022) and Talab et al (2020) emphasize the critical role of universities in fostering innovation through agile principles and extensive knowledge collaboration.

While the Nonaka and Takeuchi model provides a solid foundation, there is a clear demand for the development of practical tools to enhance its application in organizational knowledge creation. Addressing team dynamics, leadership, and the balance between tacit and explicit knowledge is essential to drive innovation and achieve successful industry-academia collaborative outcomes.

Researchers working in Norway with Manulab observed that using simulation platforms in product development significantly increases the implementation of research results in real industrial settings. These platforms enable the involvement of operators, engineers, sales personnel, and decision-makers throughout the entire development process. This integration connects technology development with the evolution of business concepts. Consequently, the Manulab-industry competence-building process, derived from Nonaka and Takeuchi's organizational knowledge creation model, advances simultaneously along both the TRL and BRL axes. Building on these observations, the following hypotheses are proposed to explore the potential benefits of integrating TRL and BRL frameworks with simulation platforms:

Hypothesis 1: The use of Technology Readiness Level and Business Readiness Level frameworks for tracking and verifying project progress is a practical tool for applying Nonaka and Takeuchi's organizational knowledge creation model in industry-academia collaborations.

Hypothesis 2: The use of simulation platforms in the product development process, by involving diverse stakeholders (operators, engineers, sales personnel, and decision-makers), significantly improves the alignment and synchronization of technology and business concept development.

These hypotheses aim to evaluate the effectiveness of TRL and BRL frameworks, along with simulation platforms, in facilitating the practical application of knowledge management principles and improving collaboration outcomes between academia and industry.

3. Manulab-Industry Competence Building Process, TRL, and BRL

Drawing on the framework developed by Nonaka and Takeuchi, Manulab researchers have outlined a comprehensive six-stage process for competence development in Manulab- industry projects, as illustrated in Figure 1 (Nonaka and Takeuchi, 1995; Hansen *et al.*, 2023). This framework reflects the model of organizational knowledge creation by Nonaka and Takeuchi but also introduces specific stages tailored to Manulab.

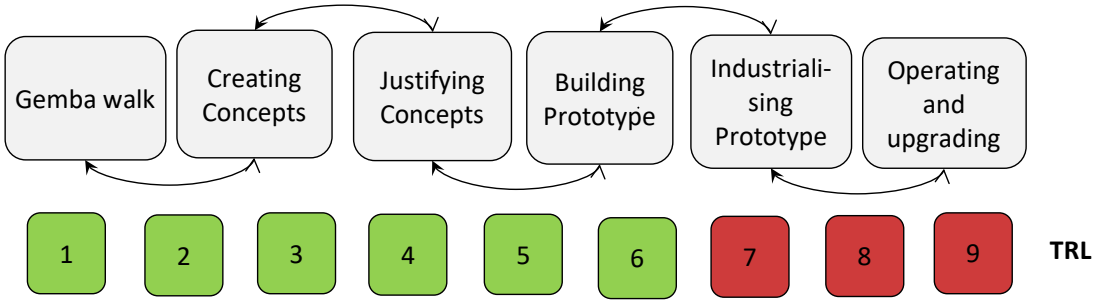

Figure 1: Manulab-industry competence building process in relation to TRL – when the research results are not implemented in industry

The process begins with a Gemba-walk, which promotes interaction between the corporate team and Manulab personnel (Womack, Jones and Roos, 2007). These Gemba-walks initiate cooperation through visits to manufacturing sites and Manulab, enhancing mutual understanding of methods, fostering connections, and identifying industrial challenges.

Following phases include "creating concepts" and "justifying concepts," as well as "building prototype." These phases are deeply connected and involve repeated adjustments between the conceptualization and prototyping stages.

The “industrialising prototype” stage signifies the deployment of the technological solution at the industrial facility. Typically managed by a system integrator, this stage requires detailed planning and may disrupt ongoing production. The system integrator is also charged with training staff and ensuring that the technology integrates smoothly into the current production environment.

The concluding stage, "operating and upgrading," involves industrial personnel and engineers who maintain and improve the system, while the system integrator focuses on maintenance and upgrades. Through collaborations between Manulab and industry, the Manulab-industry competence building process aims to close the gap between technological innovation and its practical implementation in industry. The technological innovation develops alongside the competence building process. As Figure 1 shows, the Technology Readiness Level rises together with the projects’ development. TRL is a metric used to assess the maturity of a specific technology, progressing from conceptualization to deployment. Here is a brief overview of the TRL stages according to Innovation Norway (2023):

1. *Basic principles observed*: Initial scientific research translates into applied research. Phenomena are recognized, and potential applications are understood.
2. *Technology concept formulated:* Practical applications are formulated based on observed principles. The concept is speculative, lacking proof or detailed analysis.
3. *Experimental proof of concept:* Research and design efforts, including analytical and lab studies, validate predictions of separate technology elements.
4. *Technology validated in lab:* Technology is refined and validated through controlled experimentation.
5. *Technology validated in relevant environment:* Technological components are tested in a simulated environment, reflecting operational conditions.

6. *Technology demonstrated in relevant environment***:** A representative model or prototype is tested in a relevant environment to assess performance.
7. *System prototype demonstration in operational environment:* A near-final prototype is tested in the intended environment under expected conditions.
8. *Technology proven to work in its final form and under expected conditions:* The technology is completed and qualified through tests and demonstrations.
9. *Actual technology proven through successful deployment in operational environment:* The technology is fully developed and proven to work in its final form and under expected conditions.

These levels are essential for assessing technology maturity, managing developmental risks, and guiding technology from conceptualization to commercial deployment. Integrating TRL with the Manulab-industry model is crucial. Prior research on various collaborative projects between industry and Manulab revealed that, although project outcomes were satisfactory for the industry, they were not implemented in industrial settings. Figure 1 highlights this issue with TRL 7-9 in red, indicating project shortcomings at these levels. Previous studies using the Manulab-industry competence-building process investigated why these final phases were unsuccessful (Hansen *et al.*, 2023). A significant problem is the minimal involvement of decision-makers, system integrators, and sales leaders in the early stages, which hampers the integration of Manulab innovations into production environments. Additionally, excluding the Manulab team from later industrial stages reduces their potential to enhance operational technology.

To address the need for commercialization of research results, Manulab researchers decided to assess their projects in parallel with the Business Readiness Level framework. BRL measures the readiness of a new technology or product for successful commercialization (Innovation Norway, 2023). Since Manulab's projects success are evaluated by the commercial deployment of technology solutions, the BRL metric was crucial in the workshops. The BRL framework assesses commercial maturity across nine levels:

1. *Basic Principle Observed:* The core idea or principle behind the business initiative is identified, recognizing the potential opportunity.
2. *Technology Concept Formulated:* The concept is structured into a basic business model, outlining potential markets and preliminary value propositions.
3. *Proof of Concept:* The business concept is experimentally tested for feasibility through small-scale experiments or pilot studies.
4. *Business Model Validated in Lab***:** The model undergoes rigorous testing in a controlled environment to validate its functionality and effectiveness.
5. *Fidelity of Business Model Validated:* The model is tested in a simulated environment to assess its performance under near-real conditions.
6. *Prototype Model Tested:* A working prototype is developed and tested in a relevant environment, encountering real-world variables.
7. *Business Model Demonstrated in Operational Environment:* The model is fully implemented on a limited scale, including all aspects of operations and market engagement.
8. *Actual System Completed and Qualified:* The model is finalized and integrated into the operational framework, ready to meet specified performance standards.
9. *Business Model Proven and Ready for Full Deployment:* The model has been successfully proven through full-scale operations and is ready for widespread deployment, fully viable and sustainable in the market.

4. Methodology: Case Study and Workshops

Recently, Manulab has seen an increasing number of projects that not only reach industrial realization but also spawn subsequent initiatives with the same partners, often extending to include additional companies. To understand the drivers behind these successful outcomes, several workshops were conducted. Workshops serve as an effective research tool for gathering accurate and insightful data on advanced strategies (Ørngreen and Levinsen, 2017). The workshops aimed to identify the key factors contributing to project success and to determine how best to leverage these insights across other projects.

Three researchers and two engineers working in Manulab, and one the researcher and the chief of the research and development team in the industrial company participated in these workshops.

Alongside these workshops, the research team reviewed various project documents, including applications, meeting summaries, and final reports. The focus of the total four workshops was to examine industry-

collaborative projects within the framework of Manulab-industry competence building process, as well as to promote the advancement of projects in terms of Technology Readiness Levels and Business Readiness Levels.

Four projects were selected as case studies for the workshops: one collaborated with a company that specializes in air filters, while the other three were associated with enterprises in the fish industry. The sizes of the companies involved vary significantly. The air filter company employs approximately 90 people. Two of the fish industry cases involved the same company, which has around 200 employees. The third case relates to a smaller fish company with about 40 employees. The case study focusing on this smaller company, which we will refer to as "FishMech" for the purposes of this article (this is not the company's real name), is detailed in the next section.

5. Case Study Fishmech-Manulab

FishMech, a company specializing in fish processing equipment, approached Manulab for expertise in camera vision and machine learning to enhance their market competitiveness. In addition to creating new devices, FishMech also upgrades and refurbishes existing equipment for resale.

The collaboration followed the structured phases of the Manulab-industry competence building process, starting with the Gemba work phase, which included multiple meetings at Manulab. During these sessions, researchers and engineers showcased their equipment, software, and case studies, emphasizing the importance of active participation from FishMech.

Attendees from FishMech included decision-makers, sales managers, engineers, and operators. Manulab also visited FishMech's facilities to understand their operations, equipment, production methods, market dynamics, and customer interactions.

After several discussions, Manulab and FishMech agreed to focus on integrating camera and machine learning technologies into a fish cutting machine, with an interested customer already identified. The technology integrator, familiar with both organizations, had previously collaborated with them, completing the initial Gemba work.

The project team included two engineers and three researchers from Manulab, one engineer, two operators, a sales manager, and a decision-maker from FishMech, and three engineers from the technology integrator. The project progressed through phases: "creating concepts," "justifying concepts," and "building a prototype," advancing from TRL 1 to 5. Figure 2 shows the project meeting where Manulab, FishMech, and the technology integrator discuss the virtual prototype.

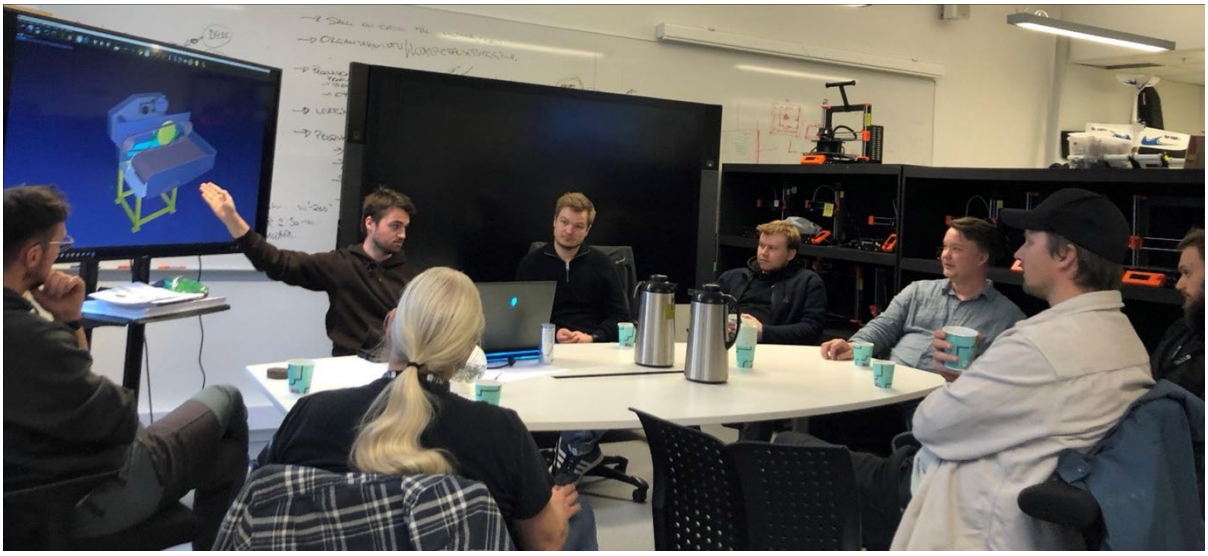

Figure 2: Project meeting FishMech, Manulab and technology integrator company

Several concepts were developed and justified by testing the virtual prototypes in simulation programs before the physical prototypes was first built in the Manulab facility as Figure 3 illustrates. This corresponds to the TRL 6.

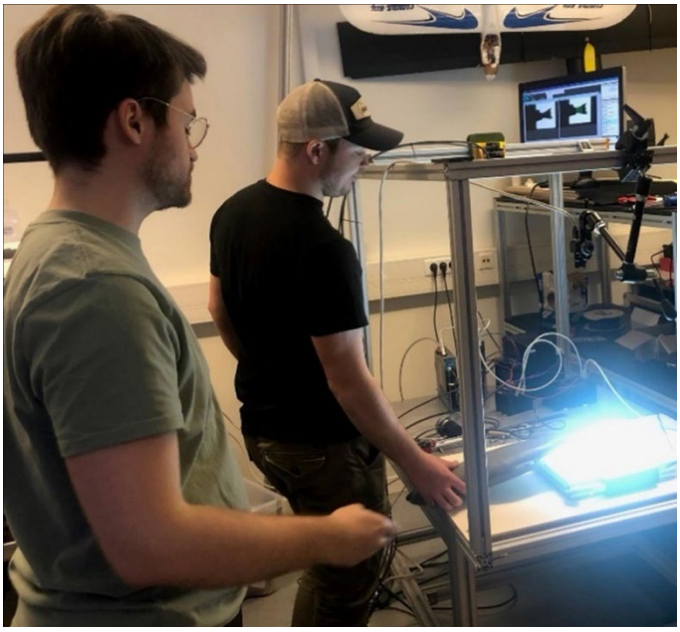

Figure 3: Building physical ptototype in Manulab

When this prototype was verified by the company and the technology integrator, it was transported in the manufacturing facilities of FishMech and integrated in the fish processing machine to test if the system was working as intended in the operational environment, which corresponds to the TRL 7. This is shown in Figure 4.

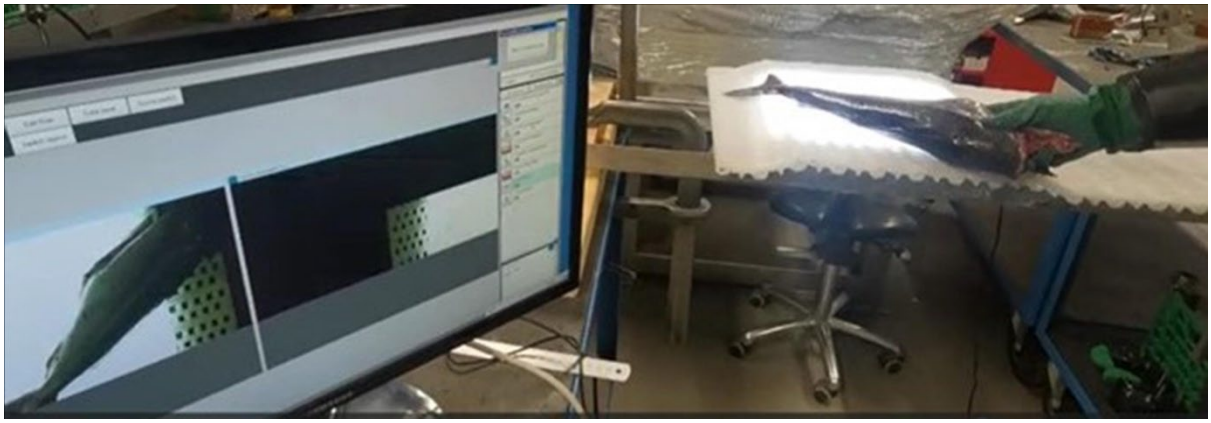

Figure 4: Test of the prototype in the FishMech facilities

Throughout the project, the partners actively collaborated in knowledge exchange and creation. A skilled operator from FishMech, with a professional diploma in automation, dedicated one day each week to develop a prototype in the university lab. Working closely with Manulab engineers, the operator gained significant insights into equipment design and simulation programs, while the Manulab team learned practical aspects of fish processing. This mutual exchange greatly influenced the design of fish processing equipment, especially in understanding the unique behaviors and anatomical features of fish.

The technology integrator company contributed their expertise in vision technology throughout the project. Numerous formal and informal meetings ensured consistent involvement and rich knowledge exchange among project members.

The developed solution has been successfully integrated into FishMech's machinery, demonstrating efficacy and reliability under operational conditions, achieving TRL 8. This milestone showcases the technology's readiness for broader application. FishMech has already attracted interest from customers, indicating market receptivity and a shift toward advanced methodologies in fish processing.

Manulab's expertise in advanced manufacturing and prototyping was instrumental in transitioning the concept into a viable product. Their optimization of machine learning algorithms and vision systems ensured the solution

met industry standards. The technology integrator played a crucial role in seamlessly incorporating new systems into existing processes, addressing deployment challenges and ensuring a smooth transition.

The enthusiastic customer response brings the project closer to commercial deployment, aligning with BRL 8. This level involves not only launching the product but also expanding and optimizing business operations. For FishMech, this means refining their go-to-market strategy, enhancing customer support, and potentially scaling production to meet demand. With the combined efforts of FishMech, Manulab, and the technology integrator, the project is set to revolutionize fish processing operations, improving efficiency and sustainability in the industry.

6. Findings

This section elaborates on the results derived from the workshops evaluating four distinct projects, focusing on their progression through key developmental metrics and stakeholder engagement. Figure 5 shows Manulab-industry competence building process alongside TRL and BRL development.

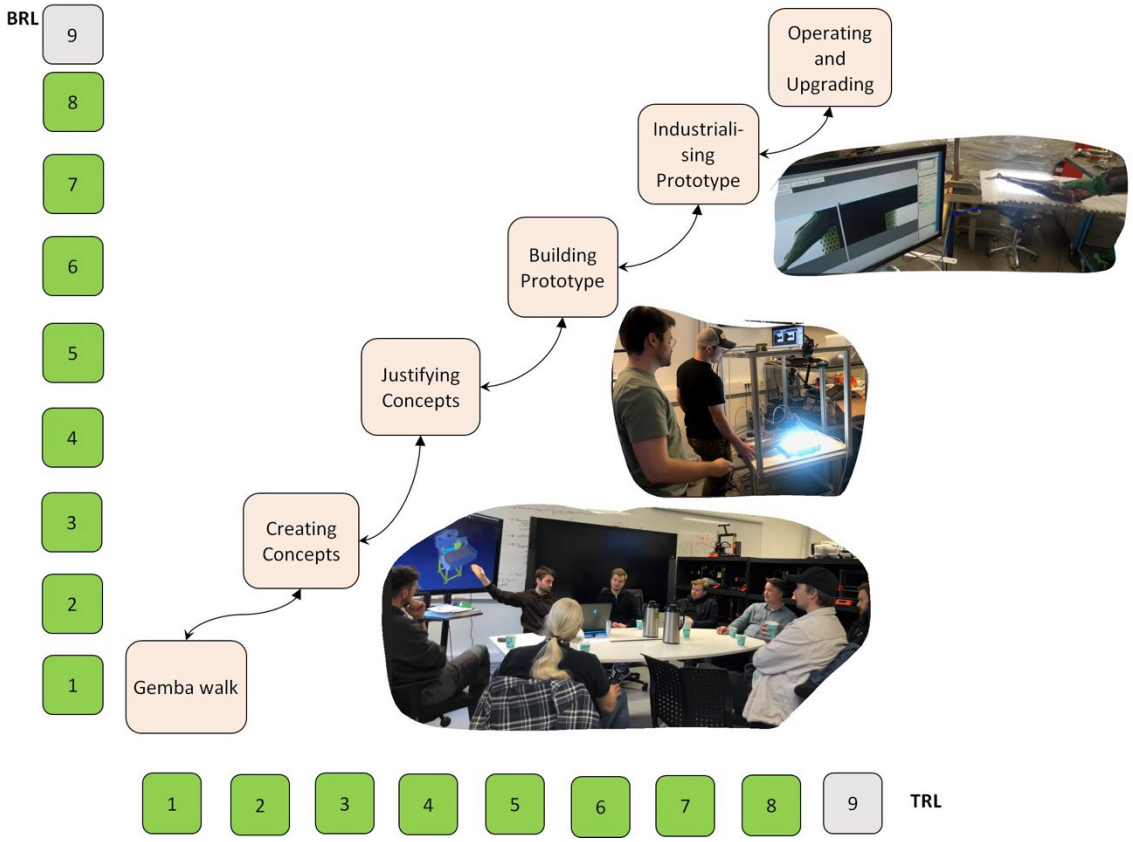

Figure 5: Manulab-industry competence building process alongside TRL and BRL

7. Utilization of TRL and BRL as Project Development and Competence Building Indicators

The projects, including the collaboration between Manulab and FishMech, successfully progressed through the Manulab-industry competence building process by simultaneously advancing along both TRL and BRL metrics, as depicted in Figure 5 . This concurrent advancement is crucial as it ensures that research outcomes are not only technically feasible but also economically viable and ready for real-life implementation. The findings suggest that the TRL and BRL metrics are effective tools for mapping the journey of a project from concept to execution, providing a clear framework for tracking progress in both technological development and market readiness. By understanding and utilizing these metrics, organizations can better navigate the complex landscape of collaborative project development, ensuring that each phase aligns with both technical specifications and business objectives.

7.1 Enhancing Project Effectiveness Through Inclusive Engagement of Stakeholders, and all Organisational Levels in the Industrial Company

The analysis underscored the significance of inclusive engagement, involving a diverse range of personnel- from ground-level operators and engineers to upper management and decision-makers within the industrial company. This comprehensive involvement ensures that strategic decisions, such as finalization of production strategies, small-scale operations, and marketing tactics for the technological solutions, are well-informed and broadly supported. Moreover, engaging technical staff like operators and engineers in the process facilitates a smoother transition of innovations from the laboratory to real-world applications. This strategy not only maximizes the effectiveness of the projects but also expands their impact by incorporating diverse perspectives and expertise, which is essential for addressing real-world challenges effectively.

7.2 Strategic Commitment to Knowledge and Business Development

For the partnership between a company and a university to be fruitful, both parties must recognize and commit to filling a specific knowledge gap that promises long-term competitive advantages. When such a need is identified, the company is more likely to dedicate necessary organizational and financial resources, fostering an environment conducive to effective collaboration. This strategic alignment between the partners' goals and the project's objectives ensures that both parties are equally invested in the project's success and can reap substantial benefits from their joint efforts. This commitment is crucial for the seamless translation of laboratory research into practical, industrial applications, enhancing the overall value and impact of the collaborative project.

7.3 Important Role of Simulation Platforms in the Competence Building Process

The use of simulation platforms is instrumental in bridging the gap between diverse stakeholder groups, such as engineers, financial analysts, and decision-makers. These platforms serve as critical tools for knowledge exchange and co-creation, allowing for iterative testing and refinement of project designs in a virtual environment. They enable stakeholders to provide direct feedback on both the technical and business aspects of a project, thus enhancing the design and functionality of the solutions. By demonstrating technological effectiveness and market viability, simulation platforms play a pivotal role in attracting investment and ensuring alignment with broader business strategies. This iterative, inclusive approach to simulation-based development and evaluation not only fine-tunes the project outcomes but also significantly contributes to the robustness and readiness of the technology for market introduction.

8. Discussion: Verification of Hypothesis

Hypothesis 1: The use of Technology Readiness Level and Business Readiness Level frameworks for tracking and verifying project progress is a practical tool for applying Nonaka and Takeuchi's organizational knowledge creation model in industry-academia collaborations.

The case studies from Manulab provide robust evidence supporting this hypothesis. Projects that incorporated TRL and BRL frameworks demonstrated a more systematic and structured approach to development. These frameworks facilitated a clear progression from conceptualization to commercialization, ensuring that technological innovations were both technically mature and market ready. For instance, the FishMech project showed that by systematically advancing through the TRL stages, the team could effectively validate technological components and integrate them into operational settings. Similarly, the use of BRL helped align the project's business objectives with market needs, ensuring commercial viability. This dual tracking of technological and business readiness enhanced the overall effectiveness and implementation of research outcomes in industrial settings, confirming the practical utility of TRL and BRL frameworks in applying Nonaka and Takeuchi's model.

Hypothesis 2: The use of simulation platforms in the product development process, by involving diverse stakeholders (operators, engineers, sales personnel, and decision-makers), significantly improves the alignment and synchronization of technology and business concept development.

The FishMech project highlighted the critical role of simulation platforms in fostering effective stakeholder collaboration. By providing a virtual environment for testing and feedback, these platforms allowed for continuous interaction among operators, engineers, sales personnel, and decision-makers. This inclusive approach ensured that diverse perspectives were integrated into the development process, leading to more

comprehensive and aligned technological and business strategies. The iterative nature of simulation platforms facilitated real-time adjustments and improvements, which enhanced both the technical robustness and market readiness of the final product. The active involvement of all stakeholders not only improved the project's outcomes but also strengthened the collaboration between academic and industrial partners, thereby validating the second hypothesis.

9. Conclusion

This study confirms that integrating TRL and BRL frameworks with simulation platforms effectively applies Nonaka and Takeuchi's knowledge creation model in industry-academia collaborations. The use of these practical tools enhances the systematic development of projects, ensuring that innovations are both technically sound and commercially viable. The case studies from Manulab demonstrate that such an approach leads to better alignment and synchronization of technological and business developments, fostering more successful project outcomes.

For organizations seeking to enhance their collaborative projects, adopting TRL and BRL frameworks and utilizing simulation platforms are critical steps. These tools not only help track project progress but also ensure that both technological and business objectives are met. Engaging diverse stakeholders throughout the development process is essential for achieving comprehensive and effective project outcomes. The structured approach demonstrated in this study provides a practical roadmap for organizations to follow, facilitating better alignment between research and real-world application.

While the study provides valuable insights, it is based on a limited number of case studies, which may not fully capture the diversity of industry-academia collaborations. Additionally, potential biases in project selection and participant involvement may influence the results. The specific context of Manulab and the Norwegian industrial environment may also limit the generalizability of the findings. Further research with a broader range of case studies and more diverse participant groups is needed to validate and expand upon these findings.

Future studies should explore the long-term impacts of integrating TRL and BRL frameworks on project success across various sectors. Additional research is needed to refine the role of simulation platforms at different stages of project development and across different industries. Understanding how these tools can be tailored to specific contexts will provide deeper insights into their effectiveness and broader applicability. Furthermore, investigating the role of power dynamics, tensions, and stakeholder differences in the use of these tools can offer a more nuanced understanding of their impact on collaboration outcomes.

Impact of Chatbots on Satisfaction and Loyalty in Lima's Telecom Sector

Catherine Alexandra Herrera Fallaque
University of Lima, Lima, Peru

20190938@aloe.ulima.edu.pe

Abstract: The migration towards digital environments has transformed the expectations of consumers, who now not only look for quality products and services, but also convenience, personalization and efficiency in each interaction with the brand. This change presents significant challenges for companies, as they need to constantly adapt to meet their needs and thus maintain loyalty in a highly competitive market. The pressure to offer added value and maintain customer preference is intensified by the ease with which consumers switch to competitors. which drives companies to innovate and adapt AI such as chatbots, which could be the answer to this challenge. The objective of this research work is to know if the use of chatbots positively influences the satisfaction and perceived loyalty of consumers of telephone services, since in this case the speed, quality of the service and the customer's need for understanding. They are critical and represent a greater challenge to differentiate. The methodology used for this research maintains a quantitative, correlational, non-experimental approach. The type of sampling was non-probabilistic, and the strategy was snowball. The instrument used was a questionnaire with a sample of around 130 consumers in the city of Metropolitan Lima in Peru. The findings suggest that chatbots are not only innovative tools, but also strategic ones for telephone companies seeking to improve customer satisfaction and loyalty. The implementation of appropriate chatbots can transform the customer experience, providing a more agile, personalized and effective service, thus seeing a close relationship between the dimensions of the chatbot with the satisfaction and loyalty perceived in consumers. In a world where these variables are key to business survival, chatbots represent an opportunity to create exceptional experiences. Uncover how cutting-edge AI chatbots are revolutionising customer satisfaction and loyalty in the competitive telephone service industry, offering transformative, personalised, and efficient interactions.

Keywords: Chatbots, Customer Satisfaction, Loyalty, Telephone Services, Digital Innovation

1. Introduction

Today, we live in an era where consumers spend more time in digital environments, seeking services in an accessible and fast way, regardless of location, time or channel (Escobar, 2016). In Peru, delays in customer service and low information accuracy have negatively impacted sales and customer satisfaction (Gestión, 2018). Consumers value convenience, personalisation and efficiency in all their interactions with brands. Companies face the challenge of remaining robust and efficient in all their digital channels to attract and retain customers, seeking their preference and loyalty (Hasberg et. al., 2016). In response to digitalisation and business issues, several countries have incorporated chatbots as an effective solution to address customer queries and concerns through AI (Dhaoui, 2014).

The main purpose of the paper is to draw insight into the relation between the use of Chatbots and the perception of customer satisfaction and loyalty, with a focus on the telephone service sector that has been criticized for poor customer care. This is further echoed by the study by Anda Peru (2021), stating issues such as slow service, poor customer care, and bad processes. This study tries to comprehend the relationship that the use of chatbots, satisfaction (S), and loyalty (L) perceived in consumers of telephony services in Metropolitan Lima (LM) would have in 2024. The research studies three dimensions: dimensions such as chatbot interactions (I), personalization (P), problem resolution (RP) capabilities, which are related to influences on perceived S and L. The following will present the research objectives of analysing such relationships and its effect on perceived S and L. Overall Objective: To analyse the relationship between the use of chatbots, "S," and "L" in consumers of telephony services in "LM" in 2024. The specific objectives vary along the above-mentioned dimensions. The research aims at extending theoretical knowledge on customer satisfaction by using chatbots, aligning with Feine et al. (2019). It also aims to update the conceptual framework on chatbots and customer experience, identifying gaps and establishing a solid foundation for future research, as suggested by Xu et al. (2023). Furthermore, it seeks to provide information on tools to improve customer satisfaction in business strategies, following Dhaoui (2014). The research has practical relevance, as it will analyse the usefulness of chatbots in customer satisfaction among users of telephony services in Lima, influencing investment decisions and strategies of consolidated entities, like Sanny et al. (2020). According to Antonio et al. (2022), the results will provide guidance and practical knowledge for domestic and international consumers, helping them to understand the benefits of chatbots and their proper employability. The migration of customers to digital channels has increased interest in chatbots in the Peruvian economy because of their novel nature and the improvements they promise

in digital offerings (Medina, 2019). Chatbots stand out not only for their 24-hour availability, but also for their ability to collect valuable information from users (Guzmán, 2020). The importance of chatbots as an additional method of customer service in the Peruvian market is underlined, with high growth potential in digital developments aimed at improving customer satisfaction, according to INEI (2023).

Regarding the background, it can be mentioned that relevant findings with similar views were found among several authors, such as the studies by Surjandy & Cassandra (2023), Naqvi et al. (2023), Bhattacharya & Sinha (2022) agree on the idea of a positive relationship in the e-commerce context, highlighting factors and such as response time, reliability and chatbot usability as key factors of the customer's "S" and "L". Meanwhile, Naqvi et al. (2023), in their study entitled "Impact of service agents on customer satisfaction and loyalty: mediating role of Chatbots", with focus on the essence of fashion retail brands in Pakistan, find that chatbots can provide personalised treatment that improves the quality of communication and, consequently, the customer's "S" and "L". Bhattacharya & Sinha, looking at the banking sector, find that chatbots are crucial for improving customer interactions, aiding and recommendations that increase customer's perceived "S" and "L".

Naqvi et al. (2023) and Antonio et al. (2022) agree on the importance of the "P" in the customer-chatbot "I" to increase customer "S". Naqvi et al. emphasise that chatbots can offer personalised treatment by adapting to individual customer needs, leading to a higher "S" and "L". Antonio et al., in "Study Literature Review: Discovering the Effect of Chatbot Implementation in Ecommerce Customer Service System Towards Customer Satisfaction", further argue that the implementation of chatbots does not guarantee high levels of "S" if there is no adequate "P" in the conversation with the user.

Sanny et al. (2020), in "The analysis of customer satisfaction factors which influence chatbot acceptance in Indonesia", Zhang et al. (2023), Eren (2021) and Feine et al. (2019) provide a measured view of the elements that affect the customer's "S" with chatbots. Sanny et al. recognise factors such as usability, brand image development, personality and ease of use as crucial determinants of the customer's "S". Zhang et al. (2023), in "Emotional expression by artificial intelligence chatbots to improve customer satisfaction: Underlying mechanism and boundary conditions", highlight the importance of emotionality in the "I", while Eren (2021) highlights the relevance of received performance, perceived trust and company reputation. Feine et al. (2019) introduces sentiment analysis as a tool to improve customer "S", demonstrating its usefulness in understanding chatbot behaviour and being able to adjust it according to the user's needs.

Huang et al. (2023) and Xu et al. (2023) address the comparison between chatbots and human service in relation to customer "S". Huang et al., in "Can chatbot customer service match human service agents on customer satisfaction? An investigation in the role of trust", find that, while chatbots contribute to improving customer "S", there is room for improvement compared to human attention. On the other hand, Xu et al. (2023) explore the mixed effects of chatbot-human "I" on customer "S", concluding that chatbots with accurate responses are preferred over those with social orientation biases, highlighting the importance of accuracy in "I".

Chung et al. (2020), in "Chatbot e-service and customer satisfaction regarding luxury brands", and Xu et al. (2023) focus on the importance of accuracy in chatbot responses. Chung et al. find that the accuracy of the information provided by chatbots, along with the credibility of the information, significantly affects the customer's "S". Xu et al., on the other hand, highlight that chatbots with concise responses are more highly valued, evidencing that the accuracy of responses is a crucial component in influencing the customer's "S".

In the theoretical framework of this research, three key variables are presented: the independent variable, which are the service agents (chatbots), and the dependent variables, which are the customer's "S" and the customer's "L". Chatbots are defined as a type of AI that use Natural Language Processing (NLP) to understand and process human language, enabling conversations in text or voice format (Shawar and Atwell, 2007). ELIZA, the first chatbot, was developed in 1960 by Joseph Weizenbaum at MIT. Since then, significant advances have been made with systems such as WeChat (2009) and personal assistants such as SIRI and Alexa. In real life, chatbots are AI systems that interact with users through a chat interface, designed to simulate human conversations, help, answer questions or perform specific tasks. They are widely used in customer service, sales and technical support.

The qualities of a chatbot can be assessed in four dimensions: entertainment, trendiness, customization and problem-solving accuracy, credibility and communicative competence, i.e. the ability to converse effectively (Chung et al., 2020). Naqvi et al. (2023) proposed four dimensions of service agents: Interaction as a social quality, Personalisation for adapting to customer needs, Problem Resolution (RP) as an effective solution, and the last one which it was not taking into consideration is Entertainment. These dimensions are essential to verify

the ransmission and processing of language by chatbots. The design of chatbots uses NLP techniques and AI algorithms, such as machine learning and neural networks, to improve their interaction capabilities. Human-Computer Interaction (HCI) theory is also relevant, focusing on the design of interfaces that facilitate effective human-computer interaction (Dix et al., 2004). The dependent variable of customer "S" is defined as the emotional reaction to the quality of the product or service received (Silva et al., 2021). Mora Contreras (2011) extends this definition by considering a sequence of emotional states that culminate in a positive or negative response before and after the purchase. Chiou and Droge (2006) suggest that customer "S" occurs when products or services meet or exceed expectations. In practice, customer "S" reflects how well a product or service meets prior expectations. In light of the above, this research prefers the Chiou and Droge definition over that of Silva et al. (2021). However, it is pertinent to mention that the cognitive-affective customer "S" model, developed by Caro and Garcia (2007), considers that the behaviour behind the "S" is marked by rational judgements (cognitive) and emotional aspects (affectivity). The dimensions of this model include perceived information quality, perceived delay time and positive emotions during the interaction with the chatbot. There are two approaches to how emotions influence on "S": one view sees emotions as mediating the relationship between cognition and "S" (Bigné and Andreu, 2002), while the other sees them as independent sources of "S" (Oliver, 1993).

As for the dependent variable of customer "L", this refers to the degree to which a customer remains loyal to a company or brand and continues to purchase its products or services over time. Customer "L" is closely related to customer "S", as a satisfied customer is more likely to develop "L". According to Dick and Basu (1994), the customer "L" can be understood as a deep commitment to repurchase or continue using a product or service in the future, despite situational influences and marketing efforts that might cause a change in behaviour.

Customer "L" can be measured along several dimensions, such as repurchase intention, recommendation of the product or service to others, and resistance to switching to competitors. According to Oliver's (1999) "L" Model, "L" develops in four stages: cognitive, affective, conative and action. The cognitive stage is based on the consumer's beliefs about the quality of the product or service; the affective stage includes the consumer's feelings towards the brand; the conative stage refers to the customer's intention to continue purchasing; and the action stage involves the performance of loyal behaviours, such as repurchase and recommendation.

In practice, customer "L" can also be measured through metrics such as customer retention rate, purchase frequency, market share, willingness to recommend the brand (NPS) and price sensitivity. In addition, surveys and purchase behaviour analysis can be conducted to assess "L" (Zeithaml et al., 1996)

The general hypothesis of this research is: "The use of chatbots positively influences the perceived "S" and "L" of consumers of telephony services in Metropolitan Lima 2024". In line with was previously stated with the problem and objectives, there are six specific hypotheses in relation to the three dimensions brought about using chatbots.

The first hypothesis would be "the interaction of chatbots positively influences the "S" in consumers of telephony services in Metropolitan Lima in the year 2024". The second hypothesis would be "the interaction of chatbots positively influences the "L" in consumers of telephony services in Metropolitan Lima in the year 2024".

Both hypotheses are in line with Sanny et al. (2019), Antonio et al. (2022) and Naqvi et al. (2023).

The third hypothesis would be "the "P" of chatbots positively influences the "S" in consumers of telephony services in Metropolitan Lima in the year 2024". The fourth hypothesis would be "the "P" of chatbots positively influences the "L" in consumers of telephony services in Metropolitan Lima in the year 2024", both according to Chung et al. (2020), Eren (2021) and Naqvi et al. (2023); rejected by Xu et al. (2023).

The fifth hypothesis would be "The "PR" provided by the chatbot positively influences the "S" in consumers of telephony services in Metropolitan Lima in the year 2024". The sixth hypothesis would be "The "PR" provided by the chatbot positively influences the "L" in consumers of telephony services in Metropolitan Lima in the year 2024". Both according to Zhang et al. (2023) and, Moran and Agüero (2022), rejected by Huang et al. (2023).

2. Methods

The focus of this research was quantitative because it could contribute to the resolution of practical problems, knowing the reality through limited and measurable data. In relation to the scope, it is descriptive-correlational with a "non-experimental" cross-sectional design, where data can be placed in space-time. In this study, the focus was on consumers of telephone services in Metropolitan Lima in the year 2024.

In relation to the design of the model, we considered the population data of Metropolitan Lima up to January 2024, where we found that the capital had 10,292,408 inhabitants (Gestión, 2024). It was also further narrowed down to those people who used the internet via mobile phone in the capital, as it is understood that by using and having access to the internet, users could make queries to their mobile phone company's chatbots. To this end, it was found that 94.1% of the population of Metropolitan Lima that is older than 6 years of age complies with the above (INEI, 2023). Therefore, by performing a simple multiplication, we have a population of 9,345,507 inhabitants.

According to this population a sample of 130 observations is adequate for PLS-SEM as it ensures reliable and robust estimates (Hair et al., 2017). In relation to the type of sampling it will be non-probabilistic, as the present research will be bounded with certain parameters seen above, and finally regarding the sampling strategy, this will be Snowball. The data collection instrument was an improved, adapted, and refined version based on an instrument by Naqvi et al. (2023). The article has been tested and published in the English Language, so it was translated into Spanish (free translation) for practical research purposed. It is also important to mention that moderating variables are not being considered as part of the model.

On the data collection side for the present research, it was through dissemination via email and social networks. The results collected were tabulated in Excel for better data manipulation, coded and the PLS-SEM method was used. Finally, descriptive statistics were used, taking into consideration Cronbach's Alpha, estimated parameters and correlation coefficient to analyse the results.

3. Results and Discussion

The JAMOVI platform was used to calculate the previously collected data, which has been tabulated both in filter questions and in relation to the questions asked for each variable, in the case of the dependent variables, and to the independent variable in relation to its dimensions, both on a Likert scale. Thus, the structural equation model (SEM) is presented in Figure 1, where each circle represents each variable. Recall that, Personalisation is manifested by the letter "P", Problem Solving is "RP", Interaction is "I", Loyalty is "L" and Satisfaction is "S".

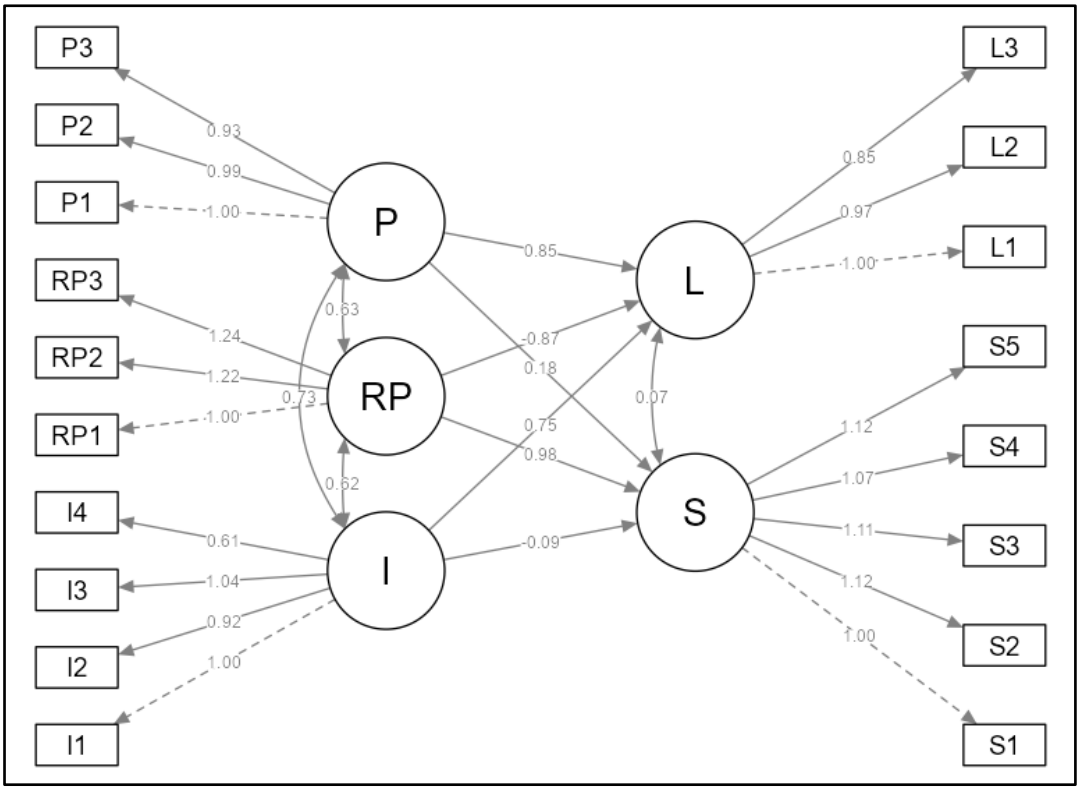

Figure 1:SEM Model

Dashed lines in the model generally represent hypotheses that are being tested and do not have strong empirical confirmation.

Table 3: Model Fit Indices

			95% Confidence Intervals		
Type	**SRMR**	**RMSEA**	**Lower**	**Upper**	**RMSEA p**
Classical	0.055	0.053	0.027	0.074	0.394
Robust	0.052				
Scaled	0.052	0.100	0.083	0.117	< .001

Table 4: Model used vs reference model

	Model
Comparative Fit Index (CFI)	0.999
Tucker-Lewis Index (TLI)	0.999
Bentler-Bonett Non-normed Fit Index (NNFI)	0.999
Relative Noncentrality Index (RNI)	0.999

	Model
Bentler-Bonett Normed Fit Index (NFI)	0.996
Bollen's Relative Fit Index (RFI)	0.995
Bollen's Incremental Fit Index (IFI)	0.999
Parsimony Normed Fit Index (PNFI)	0.814

Regarding the RMSEA indicator, which, according to Xia and Yang (2019), "assesses how well the model, with the estimated parameters, fits the covariance matrix if it were available". In this case, the value came out to be 0.051 which indicates an acceptable model fit. Also, in relation to the CFI (Comparative Fit Index), which is an "(…) incremental fit index that compares the fit of a hypothetical model with that of a reference model" (Xia and Yang, 2019), a value of 0.999 it can be concluded that the model has a very strong fit and is adequate to explain the relationships between the variables being analysed.

The results of this research provide an interesting insight into the influence of chatbots on the "S" and "L" of consumers of telephony services in Metropolitan Lima in 2024.

The provided PLS-SEM model analyzes the relationships between several dimensions: Personalization (P), Problem Solving (RP), Interaction (I), Satisfaction (S), and Loyalty (L). The analysis of the results shows that the interaction has a non-significant negative relationship with customer satisfaction (coefficient: -0.0913, p-value: 0.718), which could be because the quality of the interaction is not consistently perceived as positive. by clients. On the other hand, the ability to solve problems has a positive and significant relationship with customer satisfaction (coefficient: 0.9773, p-value: 0.017), suggesting that effective problem-solving increases satisfaction. Personalization has a positive but non-significant relationship with customer satisfaction (coefficient: 0.1768, p-value: 0.272), indicating that customization alone is not a determining factor in satisfaction.

Regarding loyalty, interaction has a marginally significant positive relationship with customer loyalty (coefficient: 0.7503, p-value: 0.066), suggesting that good interaction can influence loyalty, but not conclusively. The ability to solve problems has a non-significant negative relationship with customer loyalty (coefficient: -0.8684, p-value: 0.170), which is counterintuitive and could indicate that problem solving does not always translate into loyalty. In contrast, personalization has a positive and significant relationship with customer loyalty (coefficient: 0.8512, p-value: 0.004), indicating that personalization is a key factor in fostering loyalty.

The results of the measurement model show that the construct indicators have high and significant loadings, except for the Interaction indicator I4, which has a lower loading (0.607), which could suggest problems with this item, this is an opportunity to improve future research. The Problem Solving and Personalization constructs have indicators with high and significant loadings, which indicates that they adequately measure the constructs. Customer Satisfaction, measured by indicators S1 to S5, and Customer Loyalty, measured by L1 to L3, also present very high and significant loadings, indicating that they are good measures of their respective constructs.

A negative coefficient on structural relationships, such as RP to L, may indicate an unexpected inverse relationship and may be due to problems with the operationalization of the constructs, cultural differences, or unmet customer expectations. Given that this research is original in a geographical context not extensively explored, this finding constitutes an opportunity to explore this phenomenon in detail rather than a weakness.

Values of 1 in the indicator loadings indicate that these are perfect reflections of their respective constructs, which can occur when the construct is measured by a single indicator or when the model has been standardized in this way.

For the results that we will call unexpected, the following alternative explanations are proposed. Interaction and Satisfaction: The negative relationship could indicate that the quantity of interaction is not as important as its quality. Excessive interactions could be perceived as annoying or invasive by customers. Problem Solving and Loyalty: Problem solving could be linked to previous serious problems that reduced initial loyalty, and even if they are resolved, the damage to loyalty could already be done.

4. Conclusions

In conclusion, personalization is a critical factor for customer loyalty, the ability to solve problems significantly increases customer satisfaction, although it does not have a significant impact on loyalty, and interaction has a marginal impact on loyalty and has not a significant impact on satisfaction, which suggests that the quality of the interaction must be improved. It is recommended to improve the quality of the interaction, encourage personalization and review the problem resolution strategy to understand why it does not translate into loyalty. It is necessary to note that analysis has highlighted both the expected and unexpected results of structural equation modeling using PLS-SEM for these study variables in a little explored geographic context. Alternative explanations for the unexpected results have been proposed and future lines of research have been suggested to address these issues. Based on the findings and the proposed alternative explanations, the following lines of future research are suggested: Quality vs. Quantity of Interactions, to investigate the influence of the quality and quantity of interactions on customer satisfaction, differentiating between types of interaction. Delve into the impact of Previous Problems, thus studying the impact of previous problems on loyalty and how problem resolution can restore, but not necessarily improve, loyalty. Although further research is crucial to better understand these dynamics and incorporate cultural or geographic variables in future research.

How to Create New Business Knowledge Through Multi-Disciplinary Discussion

Yayoi Hirose
Toyo University, Tokyo, Japan

yayoi.hirose@iniad.org

Abstract: Generating innovative high-tech business in the DX (digital transformation) era requires the formation of multi-disciplinary teams, which include engineers and business experts or large companies and technology ventures. However, each team member tends to focus on certain objectives: Engineers aim to develop highly advanced technology, believing it will be in high demand, whereas business experts want engineers to follow their marketing strategies. The knowledge that is deemed necessary for generating innovative products or services differs between these groups. Thus, generating new business knowledge requires that members of multi-disciplinary teams disrupt their conventional ways of thinking, understand each other, exchange knowledge, and ultimately generate new knowledge. Previous literature on knowledge creation mainly discusses the generation of new knowledge within or between organizations that have relatively the same goals and organizational values, such as how to build trusting relationships for knowledge creation and exchange. However, as modern society comprises various fields of experts and numerous values, the discussion of knowledge exchange and creation needs to include knowledge creation among experts who have previously focused on different goals and values. Furthermore, generating innovative business requires individuals to disrupt their conventional ways of thinking, but previous studies on knowledge creation rarely mention how to do so in order to create innovative knowledge. Thus, this study aims to explore the impediments to new knowledge creation and proposes a new model that overcomes these impediments through multi-disciplinary discussions.

Keywords: Knowledge and Digital Transformation, Multi-Disciplinary Discussion, creation of Innovative Knowledge

1. Introduction

Generating innovative business in the Digital Transformation (DX) era requires the formation of multi-disciplinary teams that include both engineers and business experts, as DX is a business transformation strategy that enhances and engages relationships with customers and other stakeholders using advanced digital technologies. It is crucial for companies to transform and deepen their relationships with their stakeholders – such as customers, suppliers, and employees – by leveraging advanced digital technologies, including artificial intelligence and robotics, for their competitive advantage (Wade et al., 2019). To conduct innovative digital business, it is necessary to transform employees' mindsets from a conventional approach, disrupting their conventional ways of thinking and creating new business (Rogers, 2016; Wade, 2019). Yet according to business surveys, over 70% of DX projects fail (Bonnet, 2022; Saldanha, 2019). One of the reasons for such failure is that large firms struggle with bureaucratic structures that sap initiative and they also have a tendency to maintain conventional ways of thinking. These factors make it challenging for firms to generate innovative business knowledge (Hamel & Zanini, 2018). Thus, managers and employees need to disrupt their conventional business knowledge and practices, gain more insight into external knowledge and ultimately create innovative business with other experts.

Christensen (1997) points out it that long-term successful companies find it difficult to disrupt their conventional business models because they tend to stick to their past successful experiences. This study points out three impediments for generating innovative business. In the first stage, managers and staff have difficulty disrupting their conventional business knowledge and ways of thinking because their conventional knowledge has been constructed through their experiences (Bolisani & Bratianu, 2018). The second impediment is difficulty understanding other experts' knowledge because they lack the ability to understand such knowledge (Cohen & Levinthal, 1990; Zara & George, 2002). After disrupting their conventional knowledge and practices, managers and staff need to exchange specialized knowledge, understand the each other's knowledge, and generate innovative business knowledge with other specialists. Past literature discusses the difficulty of understanding other specialized knowledge without any preparation. The third impediment is the difficulty of sharing innovative knowledge at the organizational level, because if only a limited number of people can grasp an innovative idea, such knowledge tends to be regarded as merely subjective knowledge (Brunsson, 1982).

For two decades, numerous practitioners and academics have stressed that knowledge regarding the managerial process and technology knowledge serve as major competitive assets for organizations (Nonaka, 1994; Grant, 2006; De Long & Fahey, 2000; Nonaka & Takeuchi, 1997; Suzulanski, 1996; Crossan, et al.,1999; Zahra & George, 2002; van Winkelen & Mckenzie, 2007). With increasing globalization, firms are being required to manage an

increasing number of relationships between organizations and even across borders, such as joint ventures and strategic alliances (Inkpen & Dinur., 1998; Larsson et al., 1998). Owing to the severe international competition brought about by globalization, firms are now required to effectively learn specific knowledge from external sources through various types of relationships that they previously lacked (McKenzie & van Winkelen, 2004).

Past literature discusses that modern society is comprised of specialized knowledge (Beck, 1992; Schon, 1983) and points out the limitations of rigorous professional knowledge when it comes to solving uncertain and unique practical problems (Schein, 1972; Schon, 1983). Schein (1972) points out the gap between convergent basic and applied science and divergent practice. He claims that dealing with professional practice requires taking a convergent knowledge base and tailoring it to the unique requirement of practice based on "divergent thinking skills". Thus, in order to generate innovative business knowledge, "divergent thinking" must be adopted, which includes both technological and business ways of thinking, based on practical business strategy. Innovative business requires the disruption of conventional values and practices, understanding the value of other participants' knowledge, and finally collectively generating new transformative knowledge (Christensen, 1997).

Previous studies on knowledge creation mainly address how tacit and explicit knowledge can be exchanged and extended from an individual to organizational level (Crossan et al., 1999). However, little research has investigated the detailed process of innovative knowledge creation in the DX era: how people disrupt their conventional ways of thinking and practices, understand other experts' knowledge, and create innovative knowledge with other experts at the organizational level. Moreover, a gap exits in previous research as to how members of different organizations understand innovative knowledge.

2. Difficulty in Disrupting Conventional Ways of Doing Business

Sveiby (2001) divides knowledge into two categories: "a justified true belief" and "capacity-to-act". Sveiby (2001) claims that a justified true belief acts as a filter when a person is trying to make sense of a new situation as such a belief can be used by the individual to create meaning. People often develop ways of justifying that their beliefs are true based on their norms and values, rather than questioning whether those beliefs hold true for changing circumstances. A capacity-to-act, however, is an individual competence that is reflected in action and developed through experience (Calhoun & Starbuck, 2005; Sveiby, 2001). People's capacity to act may be limited by the norms and values that they have absorbed and rely on. Thus, even if they learn something new from a cognitive perspective, meaning that they understand it, they may still find it difficult to put such knowledge into practice and therefore fail to change their behaviour. Thus, it can be difficult for individuals to doubt their conventional, justified true beliefs and accept the different beliefs upon which others within an organization rely. Berger and Luckmann (1967) argue that academic experts and practitioners can come into conflict because their understandings of reality differ in their work.

Schumpeter (1942) defines innovation as creative disruption; society is always looking for new processes. Innovation can be defined as generating new knowledge which has been rarely recognized by disrupting conventional, widely shared perceptions of beliefs. However, people have difficulty disrupting their conventional "justified true beliefs", as these have served as the correct knowledge for a long time. As Schumpeter (1934) claims, innovation needs to be diffused. Thus, innovative ideas need to be shared by group members. A perception of belief held by only one person may be regarded as subjective (Calhoun & Starbuck, 2003). Thus, it can be said that in high-tech innovative discussions, every participant may hold their own "subjective belief" and try to disrupt their own differing conventional belief. As Christensen (1997) points out, a company that has achieved success through their conventional business activities may have difficulty in disrupting their way of business. It is hard to disrupt their conventional values and practice because people accumulate knowledge by reflecting on their social experiences (Berger and Luckmann, 1967; Cohen & Levinthal, 1989).

2.1 Difficulty in Understanding Other Experts' Knowledge in Multi-Disciplinary Discussions

The importance of considering the tacit dimension of knowledge is highlighted in previous literature. Here, knowledge is categorized into two types: rationalism, and empiricism (Bolisani & Bratianu, 2018). Knowledge in rationalism is comprised of a reasoning process and does not include human perception (Bolisani & Bratianu, 2018; Russel, 1972). On the other hand, empiricism claims that knowledge is created through human sensory experience of the real world. According to Polanyi (1969), knowledge in empiricism, which includes tacit knowledge, should be distinguished from explicit knowledge. He explains that while explicit knowledge can be transferred through writing and verbal expression between people, tacit knowledge cannot, as this knowledge

is produced based on human experiences associated with their contexts. Nonaka (1994) claims that tacit knowledge is created by interaction between various individual experiences and rational external knowledge.

Thus, based on the past literature, participants in multidisciplinary discussions need to consider other participants' tacit dimensions of knowledge, which are generated by social integration within their organizations. Past discussions suggest that expert knowledge differs depending on careers and social rules. Berger and Luckmann (1967) point out the difficulty of accepting of knowledge of a different field of experts; individuals often avoid accepting knowledge which is inconvenient and only apply knowledge within their familiar community (Berger & Luckmann, 1967).

Cohen and Levinthal (1990) point out that people's understanding of external knowledge depends on their accumulated prior knowledge within an organizational context, which means how they accumulate organizational-related experience and cognitively understand external knowledge. Thus, in order to understand other experts' knowledge, one must avoid mere surface learning (Marton & Salig, 1984). Moreover, understanding external knowledge requires that individuals obtain the capacity to understand the knowledge (Cohen & Levinthal, 1990; Zara & George, 2002; Todorova & Durisin, 2007). Cohen and Levinthal (1989, 1990, 1994) use the phrase "absorptive capacity" to describe the capacity to understand. They claim this capacity is path-dependent because it is developed based on already-accumulated knowledge within an organizational context.

2.2 Difficulty in Exchanging Different Experts' Knowledge in Multi-Disciplinary Discussion

Past literature on knowledge creation mainly discusses new knowledge generation within or between organizations that have relatively the same goals and values, such as how to build trusting relationships for knowledge exchange and creation（Nonaka, 1994). Lane & Lubatican (1998) point out the importance of selecting companies which have the same salary system and organizational structure to successfully understand the knowledge generated from external companies. However, as modern society is made up of various fields of experts, the discussion of knowledge exchange and creation needs to consider various experts who have been focused on different goals and values.

At this stage, the pattern of interaction affects the partner's feeling of psychological attachment to their relationship (Kumar & Nti, 1998). For example, the difference in each individual way of understanding can be an impeding factor to exchanging different specialized knowledge. Regarding the flow of knowledge among humans, Walsham (2002) cited Polanni's (1967) paper and found that when A, who went on a trip, explained the details of his trip to B, who had never been to the area, Polanni (1967) explained sense-reading and sense--giving using an example in which the information is not necessarily transmitted to B. Thus, within a group, the ways in which new knowledge is understood differ from person to person, and it is important to be aware of the different interpretations each person may have.

Tacit knowledge is made up of people's values, beliefs, and assumptions, and because these cannot always be clearly expressed it can be difficult for people to obtain others' tacit knowledge (Baumard, 1999; Polanyi, 1967) Collective behaviour is generated when the collective tacitly accepts tacit knowledge as holding true for them and relies on it to guide collective behaviour (Calhoun & Starbuck, 2005). People tend to rely on their organizational, collectively accumulated knowledge rather than external knowledge, which is unfamiliar to them. Thus, if each individual way of understanding differs, knowledge cannot be widely shared because a belief held by only one person would be subjective and result in only that person's action (Brunsson, 1982). On the other hand, a widely shared perception or belief acquires the status of being objective (Brunsson, 1982). It can be difficult to collectively generate new knowledge by integrating various kinds of "subjective beliefs" by disrupting conventional objective knowledge.

Another impeding factor can be the differences in routine processes and local language among team members. For example, discrepancies in their business processes, including "speedy decision making," impede trust relationships among team members. This is particularly true when the work objectives or technical terms they can share differ (Lei et al., 1997).

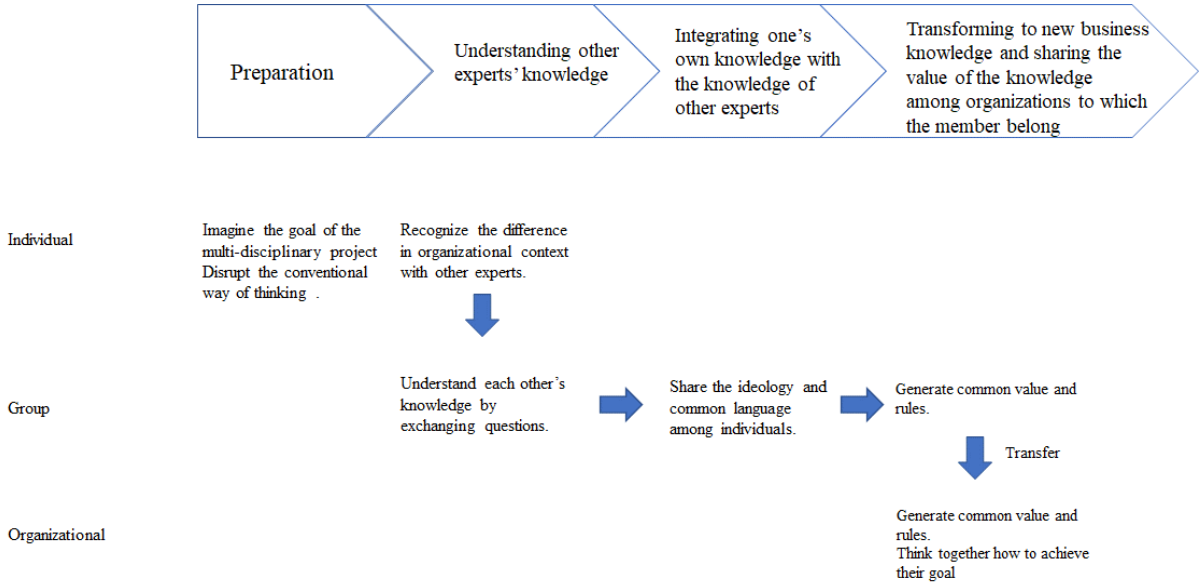
3. Creation of Innovative Knowledge in Multi-Disciplinary Discussion

This paper aims to propose a process for creating innovative knowledge in a multi-disciplinary discussion (Figure 1). Based on past discussions on knowledge creation, the model can be divided into three levels: the individual, group and organizational level. Previous literature on knowledge creation mainly discusses how individual levels

of knowledge can be extended to group and organizational collective knowledge by connecting it to existing organizational knowledge (Crossan et al., 1999; Nonaka & von Krogh, 2009). To generate knowledge at the organizational level it is important to obtain individual understanding at the initial phase (Nonaka, 1994; Taylor & Osland, 2003). In particular, multi-disciplinary knowledge creation should consider that individuals tend to follow conventional ideas that have been socially constructed in the initial stage because their social reality is constructed in individual everyday life (Berger & Luchman, 1967).

Based on these discussions, Figure 1 assumes that one specialized field of knowledge can be created by the individual experience which occurs in each organization. It suggests that the longer individuals belong to their organizations, the harder it is to disrupt their conventional mindsets. There are, however, few discussions regarding how individuals attempt to create innovative knowledge by disrupting their conventional organizational knowledge. Figure 1 considers the necessity of this disruption.

Figure 1: Process of Innovative Knowledge Creation in Multi-disciplinary Discussion



3.1 Preparation: Individual level

As Christensen (1997) claims, creating innovative knowledge requires that people disrupt past successful business knowledge. The model indicates the importance of having and envisioning a goal during the preparation phase of multi-disciplinary discussions in order to disrupt conventional way of thinking and understand the external knowledge. As Figure 1 shows, individuals need to envision their goal and understand why they need to disrupt their conventional way of thinking. Hirose (2023) points out the importance of having an image of the goal to disrupt one's conventional way of thinking and that companies which successfully launched new transformational projects succeeded in enabling the employees and managers to understand their business goal. Doing so allowed people to obtain the capacity to understand other knowledge. (Cohen & Levinthal, 1990; Zara & George, 2002; Todorova & Durisin, 2007). The past discussions emphasize that this capacity is path-dependent (Cohen & Levinthal, 1990; Zahra & George, 2002) because it is developed based on already-accumulated prior knowledge within an organization. In multi-disciplinary discussions, participants need to disrupt the path-dependency way of thinking and accept new value of external specialized knowledge. This capacity includes know-how regarding how to collaborate with other experts. After understanding their business goal vision, people will be able to understand the value of other specialized knowledge in multi-disciplinary discussions.

3.2 Understanding Other Experts' Knowledge: Individual and Group Level

As argued by Nonaka (1994) and Taylor and Osland (2003), understanding knowledge at the individual level at the initial stage is key to creating knowledge in an organization. However, most of the past literature that focuses on transferring technological or scientific knowledge lacks the perspective of managing knowledge generated in a different organizational context, which may disrupt the conventional organizational values of the knowledge receivers (Almeida, et al., 2005; Grant & Baden-Fuller, 1995; Hargadon and Sutton, 1997; Katz & Tushman, 1980; Makhija & Ganesh, 1997). These studies do not discuss the effect of organizational difference on the process of

knowledge transfer, such as how knowledge receivers reconsider and change their conventional norms, values, and assumptions to adapt to knowledge providers. As Walsham (2002), in quoting Polanyi (1967), explains, the process by which individuals transfer knowledge to one another is extremely difficult, particularly when the interest is to share knowledge among individuals who live in separate communities with different backgrounds, because they have conflicting assumptions based on their localised priorities and values.

To overcome this impediment, individuals need to transform their cognitive structure (Todorova & Durisin, 2007; Lei et al., 1997). In multi-disciplinary discussions, people need to understand the differences in the value evaluation of knowledge brought about by differences in organizational context and understand the value of other experts' knowledge. Doing so will enable to build a new cognitive structure that is incompatible with the conventional structure because their organization needs to counteract the tendency of conventional competence to undermine change. (Todorova & Durisin, 2007; Tushman & Anderson, 1986).

When individuals attempt to present their knowledge to other experts, they are not necessarily able to transfer their knowledge in the way they had expected (Crossan, et al., 1999; De Long et al., 2000). Past literature suggests that in the case of transferring technological or scientific knowledge, it is easier for the knowledge provider and receiver to share much of the same lexicon. In this case, knowledge can be transferred simply by assimilation. (Almeida, et al., 2005; Inkpen & Tsang 2005; Leonard & Swamp, 2004) However, in the case of knowledge exchange for generating innovative business, people need to interact and ask each other questions in order to understand each other's values and content (Brymer, et al., 2018). Thus, this is not simple assimilation because these individuals do not share the same lexicon.

3.3 Integrating With Experts of Other Fields: Group Level

In this phase, people need to exchange the value and contents with other experts and generate new knowledge by integrating their specialized knowledge at a group level. It is expected that as individuals create their own different cognitive maps depending on their environment, group discussion creates and refines common language, clarifies images, and creates shared meaning and understanding in order to distribute knowledge (Crossan et al., 1999).

When knowledge transfer is difficult, individuals try to clarify their communication through the use of metaphors (Crossan et al., 1999). Therefore, at group-level discussions, a shared understanding will be achieved by defining a common language called social activities. In order to promote understanding among other fields of experts, it is important to build a common language and image of various knowledge by interactions among individuals. At this stage, exchanging questions within the multidisciplinary group is the most important factor (Bentley Brymer, et al., 2018).. Participants' interactions and critical thinking through participatory processes and integration of different knowledge can lead to changes in participants' cognition or knowledge (Schneider et al., 2009).

Maltz and Kohli (2000) show that cross-functional teams, cross-functional training, and social activities improve internal communication and help to overcome internal conflict. De Long et al. (2000) point out the importance of the culture in encouraging social interaction to promote new knowledge sharing. They identify the cultural factors that promote social interaction as (1) organizational norms and practices that make possible frank exchanges between executives and members, (2) formal and informal interactions between individuals and groups, and (3) collaborations and learning from mistakes. Thus, group members should encourage social interaction to make clear what norms and practices need to be changed to reinforce more collaborative knowledge use before they directly try to convince individuals to share human knowledge (De Long et al., 2000).

3.4 Expanding Innovative Knowledge to the Organizational Level

In contrast with past discussions on knowledge creation, this model considers that each team member may belong to a unique organizational context, including large companies and high-tech ventures, business people, and engineers. Schein (2004) claims that if a group generates a common value, the group members will be able to transfer the new knowledge to other group of members. Larsson et al. (1998) point out that group members need to consider how to build their common achievement. Thus, in this phase, it is important to create a common business goal and values through multi-disciplinary discussion.

It is also important to understand the organizational differences among team members. Group members need to build trusting relationships by understanding differences in language use, practices, and ways of thinking among each member's organization (Lei et al., 1997; Van Winkelen, 2009). Some related articles stress the need to adjust both partners' "protocols" to enable alliance partners to learn from one another and share and create

knowledge (Lei et al., 1997; Van Winkelen et al., 2009). Doz (1996) stresses that a strategic alliance can be strengthened when a company recognizes and prepares for differences in organizational practices and rules with an alliance partnering company. Companies may need to set a rule that rewards innovative activities and encourages risk taking to create new knowledge (Kumar & Nti, 1998; Reid et al., 2001). This is because organizational values often prevent employees from sharing knowledge.

4. Conclusion

This study aimed to propose a new model for generating innovative knowledge through multi-disciplinary group discussions. Two main points set this study apart from past discussions on knowledge creation. The first is the importance of disrupting conventional ways of thinking and accepting the value of other experts' knowledge in order to understand it. While past literature on knowledge creation has emphasized the importance of sharing the same organizational values and practices, this study proposes how such innovative knowledge can be generated by disrupting conventional values and practices. Individuals tend to understand external knowledge based on their own past experiences. The study proposes that the model needs to consider how to disrupt these conventional ways of thinking to generate innovative knowledge. The second point is that this study provides a strategy for promoting understanding among various experts within a group. As a first step, group members need to recognize the differences in organizational context among team members, and provided they exchange questions based on this recognition, they will be more able to understand the specialized knowledge of other members. If group members share the ideology and common language, it will be easier for the team to generate innovative knowledge and extend that knowledge to other members of the organization. Finally, it is also crucial to generate common values and rules among team members.

Abstract: Many organisations are exploring the field of knowledge management to improve and sustain their competitiveness and competitive edge over their rivals. Knowledge Management (KM) can be referred to set of processes and activities to change organisations' knowledge processing pattern, and organisations need to focus on management of knowledge for obtaining optimum results and efficiency to draw various benefits towards gaining competitive advantage. There are several enablers of KM that have a bearing on the success of KM in an organisation. Enablers of KM can be defined as factors that positively influence the success of KM activities to implement changes or are conducive to effective KM to take place in organisations. However, not all organisations are affected by these factors the same way. Most of these factors are associated with the organisation within which KM processes are carried out. A qualitative study was conducted in one of the government transport agencies, which has recently embarked on KM initiatives to find out which KM enablers played a key role in the successful implementation of KM activities in the transport agency and how this played a role (impact). The study used the Knowledge Management Capability Assessment Tool (KM CAT) theory to assess the role of KM enablers in the transport agency. The data were collected by purposefully interviewing senior officials/managers in the agency's KM directorate. The results showed that several factors played a positive role in the success of KM activities in the transport agency. The study recommends a holistic approach to KM with less emphasis on a single aspect or a few factors presumed to have a positive influence on or are important in creating a conducive environment for the successful implementation of KM in organisations. There is limited literature or research on the use of KM strategies in South African transport industry. Therefore, this study is worth sharing with scholars, practitioners, and policymakers to contribute to the scientific dialogue of KM in all sectors, including the transport industry, to create an enabling environment for the successful implementation of KM activities.

Keywords: Knowledge, Knowledge Management, Knowledge Management Enablers, Government Transport Agency, Knowledge Management Capability Assessment Tool (KM CAT), Holistic Approach

1. Introduction

Many organisations are exploring the field of knowledge management (KM) to improve and sustain their competitiveness and competitive edge over their rivals (Kumar, Singh & Haleem, 2014). KM may be referred to set of processes and activities to change an organisation's knowledge processing pattern (Joseph & Elroy, 2005), and organisations need to focus on the management of knowledge for obtaining optimum results and efficiency (Wong, 2005) to draw various benefits towards gaining competitive advantage (King, 2001; Ofek & Sarvary, 2001). Much literature has defined KM, but Davenport (1994) postulates KM as "the process of capturing, developing, sharing, and effectively using organizational knowledge." Later, Duhon (1998) provided another definition: "KM is a discipline that promotes an integrated approach to identifying, capturing, evaluating, retrieving, and sharing all of an enterprise's information assets". According to Gloet and Terziovski (2004), KM is the interpretation of experience and how to access that knowledge and proficiency, which produce new competencies, empower superior routine, boost innovation, and increase customer satisfaction. Thus, knowledge is considered a valuable asset for organisations, critical for achieving long-term sustainable competitive advantage. As a result, many organisations are making efforts toward the implementation of KM initiatives, recognising that their competitive advantage depends on their ability to effectively collect, capture, retain, store, transfer and share knowledge. Although companies are increasingly competing based on their ability to effectively manage knowledge, there are still numerous challenges for organisations that intend to implement a KM system. Thus, for a successful implementation of KM in organisations, it is crucial to understand which factors are critical in creating an enabling environment for the successful implementation of KM processes and lead to competitive advantage (Onofre & Teixeira, 2022). Although there are many studies related to enablers of KM in organisations, few have been explored within the context of the transport industry in a developing country like South Africa.

As a developing country, South Africa is witnessing fast population growth, which drives up the travel demand. Many of the country's citizens continue to rely on public transport to get to work, school, healthcare, recreation and tourism sites. To manage an innovative, rapid rail transport system in the country, an agency was formed as

a public-private partnership (PPP) project to provide a more affordable and accessible transport system to alleviate traffic congestion, while also providing a reliable and quick mode of public transport. In the intervening process, a wealth of skills and technical knowledge, particularly in the management of the protracted design and construction review process and the legal and environmental compliance processes, are organically produced. Today, organisations are increasingly dynamic, ever changing and continuously re-inventing themselves to achieve sustainable competitive advantage to an extent that what works for one organisation may not necessarily work for others with the same degree of impact.

This paper provides an overview of a qualitative study conducted in one of the government transport agencies in South Africa. The purpose of the study was to answer the following research questions:

- What are key enablers of KM systems?
- Which KM enablers played a key role in the successful implementation of KM activities in the transport agency?
- How do these KM enablers interact with each other for the successful implementation of KM initiative.

For practical purposes, this study used the Knowledge Management Capability Assessment Tool (KM CAT) theory to assess the role of KM enablers in the transport agency. The data were collected by purposefully interviewing senior officials/managers in the agency's KM directorate. A thematic approach was used to analyse the data to obtain the results.

The results showed that several factors played a positive role in the success of KM activities in the transport agency. The study recommends a holistic approach to KM with less emphasis on a single aspect or a few factors presumed to have a positive influence on or are important in creating an environment that is conducive to the successful implementation of KM in organisations.

Given that there is limited literature or research on the use of KM strategies in the South African transport industry, this study is worth sharing with scholars, practitioners, and policymakers to contribute to the scientific dialogue of KM in all sectors including the transport industry to create an enabling environment for the successful implementation of KM activities.

2. Knowledge Management Capability Assessment Tool

To assess knowledge management maturity in the organisation, the study used the KM CAT. The KM CAT is divided into four major sections, each of which is subdivided into subcategories assess as follows:

- Strategy (objectives, business case and budgets)
- People (resources, governance structure and roles, change management and communication)
- Process (knowledge flow process, KM approaches and measurement)
- Content and information technology (content management and IT processes and tools)

The KM CAT is best suited for reviewing procedures, recognising intellectual assets in an organisation. According to APQC (2022), the KM CAT helps an organisation assess its capabilities and maturity in KM and focus its KM investments on producing the highest return on value. Thus, the use of KM CAT gave the researcher a broad perspective when assessing the role of KM enablers in the transport agency for improved efficiency, increased productivity and enhanced organisational performance.

3. Overview of KM Initiative in the South African Transport Agency

The agency's KM strategy (2016) was firmly established by the South African transport Act, (Act No. 5 of 2006). Section 5(e) and (f) of the Act requires the agency to establish and operate information and management systems for transport projects in the Gauteng province, and liaise and exchange information with institutions, authorities or professional bodies regarding rail matters in South Africa or in other countries. As part of the Gauteng province, the agency is required to support and contribute to the implementation of the Gauteng 25-year Integrated Transport Master Plan (ITMP25). Given the mandate of the agency and public transport development imperatives for the province, a KM strategy is critical for the organisation. Tremendous efforts have been made on electronic document control and management, particularly during the development phase of the transport projects in Gauteng province.

4. Literature Review

Knowledge is a vital resource for having a sustainable competitive advantage (Manesh, Pellegrini, Marzi & Dabic, 2020). Two types of knowledge can be distinguished, namely tacit knowledge and explicit knowledge. According to Powell (2023), tacit knowledge, is often difficult to share or articulate. This is because this type of knowledge resides in human minds. It is often acquired through personal experiences, intuition and expertise. One of the primary challenges with tacit knowledge in an organisation is that, due to its intangible and often subconscious nature, it has proven to be to transfer and share tacit knowledge throughout the organisation (Chen, Nunes, Ragsdell & An (2018). On the other hand, explicit knowledge can be easily communicated and shared. Due to its tangible nature, explicit knowledge can be communicated through perceptible channels such as documents or computer programs, or in a personal context such as verbalisation to knowledge workers through networking competence (Fryczynska & Ciecierski, 2020). Tacit knowledge is generally accepted as expertise that exists solely in the minds of individuals and is intangible, while explicit knowledge is the know-what aspect of knowledge, which is tangible and exists outside the human mind. Therefore, tacit and explicit knowledge can be seen not as two distinct knowledge typologies (Gamble, 2020), but as two sides of the same coin. This further was initially alluded to by Panahi, Watson and Partridge (2016), stating that "there exists many cases of a middle ground between them."

KM is defined in many ways because it has been increasingly evolving and integrating business strategies, processes and goals. Zvobgo, Chivivi and Marufu (2015) define KM as the systematic process for organisations to create, identify, capture, obtain, secure, share, and control knowledge. However, Yee, Tan and Thurasamy (2019) define KM as the systematic management of an organisation's knowledge assets for the purpose of creating value and meeting tactical and strategic requirements. It consists of the processes, strategies and systems that sustain and enhance the creation, storage and sharing of knowledge. It is evident in the literature that KM plays a strategic role for the survival, competitiveness and profitability of the organisation (Omotayo, 2015; Clark, 2020).

5. Knowledge Management Enablers

KM enablers are the operational or service settings in an organisation that are accountable for the success of a KM initiative and treated as the mechanism or factors for facilitating knowledge creation, sharing, application and protection within the organisation (Yang, Marlow & Luc, 2009). In the literature, several critical enablers in successfully implementing effective KM initiatives and techniques in organisations are explored. Some of the key KM enablers identified from previous studies consist of organisational culture, organisational structure, management support, leadership, strategy, champion support, design of KM strategy, performance and evaluation, training and technologies (Boamah et al., 2022); Gupta, Singh, Kamble & Ruchi Mishra, 2022; Aldhaheri & Ahmad, 2024); Dang, Wipulanusat, Nuaklong & Witchayangkoon, 2024); Shehzad, Zhang, *Dost*, *Ahmad* & *Alam*, *2024)*. These KM enablers are the key focus in many studies on KM processes across several and diverse industries or fields such as education, health, libraries, engineering, construction, among others.

In another study by Menon and Suresh (2021), rewards and recognition and employee empowerment were among the highest driving force behind KM. However, management support was found to be the most crucial KM enabler. In addition, teamwork, reward structure, learning, collaboration and employee empowerment (Atapattu & Huybers, 2021; Osupile & Makambe, 2021), are motivational antecedents of KM engagement and sharing. Furthermore, knowledge-oriented leadership, environmental uncertainty (Sahibzada, Latif & Xu, 2022), organisational climate (Farooq Sahibzada, Thomas, Sumbal and Malik (2023) and trust have a significant impact on KM processes.

Another study by Iftikhar and Lions (2022) sought to identify the different KM enablers at different levels of the organisation. The found that, at individual level, interpersonal relationships and social interactions are knowledge-sharing enablers. In contrast, the study found that well-defined objectives were found to be team level enablers; while at organisational level, appropriate knowledge sharing requires organisation to design their structures adequately to be consistent with both the environment and the necessary level of interaction among employees. Pham, Lokuge, Nguyen and Adamopoulos (2024) conducted a study to explore KM enablers for blockchain-enabled food supply chain implementations. The study found external enablers, including regulation and market competition, and internal enablers, such as people, organisational learning, strategy and leadership, culture, information technology, organisational infrastructure, processes and activities.

6. Methodology

To address the main research question, this qualitative study used a case study research design because a case study enabled the researcher to conduct an in-depth study of the KM process in the agency. The case study research design enabled the researcher to explain the complex situations where important factors could be lost or not described completely enough in a generalised method. This study used semi-structured interviews to gain an understanding of how the loss of knowledge (tacit) affected this South African government agency, rather than acquiring a more superficial overview.

The researcher purposefully selected senior management involved in the agency's KM directorate. The interview guide was prepared to help the researcher to comprehensively cover identified topics relevant to the study objectives. Each participant was allocated one and a half hours for the interview.

The interviews were conducted using the Microsoft Teams app, which is a virtual platform the researcher deemed fit to use due to the Covid-19 pandemic. The interviews were recorded with the consent of the participants.

Owing to the semi-structured nature of the interviews, participants were encouraged to elaborate on the subject and provide as much information as they could. Apart from the interviews, internal documents of the agency, such as the KM policy and strategy plan, were used to achieve data triangulation to enrich the data collected.

The collected data were analysed using Atlas.ti version 9 according to a thematic approach, in which the data were aligned to the study themes, and a coding procedure was followed.

7. Profile of the Participants

The study initially targeted 10 senior managers in the KM directorate who were actively involved in the agency's KM projects and processes. These included the executive manager of KM, five KM specialists, a senior records officer, a registry officer, a senior manager for reputation and a senior manager in stakeholder relations. Owing to the Covid-19 pandemic, four employees were unavailable because of ill health and death. Finally, six senior managers in the KM directorate with the relevant knowledge and experience in KM programmes and processes of the agency were interviewed.

8. Discussion of the Findings

8.1 Key Enablers Of Knowledge Management System

The study results revealed that several factors play a critical role as KM enablers in the implementation of a KM system in the transport agency in South Africa just like in any organisation throughout the world. The general view of the participants in the South African transport agency, was that these KM enablers include, but are not limited to, organisational culture, organisational structure, management support, champion support, design of KM strategy, performance and evaluation, training and technologies. In addition, the participants also indicated that policies, organisational philosophy, business innovation, business procedure and populace also affect the KM strategy in the transport agency.

8.2 Role of KM Enablers in the Successful Implementation of KM Activities in the Transport Agency

Most participants noted that, in different measures or degree, several KM enablers positively influence or are conducive to effective KM in agency. The support of top management is crucial for providing necessary resources, communicating the importance of developing the KM system. Senior management in the transport agency was also credited for giving essential directions for successfully integrating the KM system in the transport agency. The participants also indicated that it was important to develop suitable strategies with the active participation of all stakeholders from various departments in the transport agency to align the strategies with organisational goals and objectives. Regarding organisational culture, most participants in the transport agency were of the view that a knowledge-friendly culture encourages and embraces better ways of knowledge sharing, it helps adopt new tools and techniques. Apart from creating awareness and knowledge of KM theory and practice, the view of most participants was that top management should also focus on the provision of the necessary information and communication technology (ICT) and training. Training provides skill and expertise to human resources of how KM operates and functions. On the other hand, technology is usually seen as the enabler of KM practice. The all-encompassing view of the participants was that advanced ICT infrastructure was needed to promote KM through improved knowledge sharing. In addition, the participants indicated that KM

policy provides a context of rules and methods to guide how the KM system is implemented in the transport agency.

8.3 Interaction of KM Enablers for the Successful Implementation of KM Initiative

The study revealed that collaboration and coordination between and among the various KM enablers were crucial for organisational performance, survival, profitability and competitiveness. The results strongly suggest that all the KM enablers in the organisation should be harnessed to create value by aligning with the overall organisational strategy, goals and objective. This is because the results showed that several factors, and not just one factor or enabler, played a positive role in the success of KM activities in the transport agency. A holistic approach to KM practice is important in creating an environment that is conducive to the successful implementation of the KM initiative in organisations.

9. Conclusion

This study showed that there are several key KM enablers that positively influence or are conducive to effective KM to take place in organisations, which include, but are not limited to, organisational culture, organisational structure, management support, champion support, design of KM strategy, performance and evaluation, training and technologies. Individually, each of these KM enablers plays a vital role. However, organisations should strive to holistically harness and coordinate all the KM enables systematically to accomplish organisational functions, operate and succeed in the current global knowledge-based economy.

Abstract: Recent publications in the field of KM emphasize the importance of topics such as Spirituality (e.g. Bratianu, 2017; Kaiser, 2023; Rocha & Pinheiro, 2021), Phronesis (practical wisdom) (Kragulj, 2022; Nonaka & Takeuchi, 2019; Rocha et al., 2022; Serenko, 2024), Organizational Purpose (Kerschbaum, 2022), dealing with future potentials and future-oriented innovation (Peschl, 2018, 2020) and Responsible KM (Durst, 2021) as future avenues for KM research. However, it seems that these topics have not yet entirely found their way into practice, or, although the phenomena described are inherently present in organizations, they do not receive much attention from practitioners these days. With this paper we seek to initiate discussion on how to deploy research results on topics like Spirituality, Practical Wisdom, non-rational Knowledge, future-oriented knowledge work, and Organizational Purpose into applied contexts. We argue that an essential step is to adequately train students at universities with the new content. Todays students are the leaders, entrepreneurs, and managers of tomorrow. Therefore, we present selected educational concepts that help students build competencies in understanding and applying non-rational forms of knowledge. The intention of these newly designed teaching concepts is to move our field of research out of the metaphoric ivory tower towards the application in organizations. We argue that this is a necessary step for the development of the field of KM, enabling our research to remain relevant in modern-day business and organizational environments.

Keywords: Non-rational Knowledge, Phronesis, Practical Wisdom, Spirituality, Future Orientation, Management Education

1. Introduction

The field of Knowledge Management (KM) has recently been facing somewhat of a decline in popularity (Davenport, 2015). Arguably, this development has begun with the rise of ever-so-efficient web search technologies and culminated in the widespread application of artificial intelligence, which started to be accessible to everybody who knows how to operate a personal computer. However, although successful in addressing clear and defined problems, rational-analytic problem-solving methods face challenges when applied to ambiguous or ill-defined problems, indicating also the need for different approaches in KM (Kragulj *et al.*, 2018). As a result, we believe in a renaissance of Knowledge Management at its core, which has made it a social science endeavor (Nonaka and Takeuchi, 1995): tacit knowledge. This renewed interest in the manifold types of non-codified and subjective knowledge has led to new topics in KM, such as spirituality (e.g. Bratianu, 2017; Rocha and Pinheiro, 2021; Kaiser, 2023), phronesis (practical wisdom) (Nonaka and Takeuchi, 2021; Rocha, Kragulj and Pinheiro, 2022; Kragulj, 2023), organizational purpose (Kerschbaum, 2022), dealing with future potentials and future-oriented innovation (Peschl, 2018, 2020) and responsible management (Durst, 2021). Moreover, the focus on non-rational knowledge (Warren, 2008) signals a shift from a mere analytic-rational understanding towards a deeper, more nuanced engagement with knowledge. For instance, Serenko (2024) recently published the first large-scale empirical study of practical wisdom (phronesis) in KM, reigniting the discourse surrounding the significance of practical wisdom in work environments (Serenko, 2024). Consequently, the traditional understanding of explicit and implicit knowledge has long been dissolved and expanded into a more holistic definition of KM (Peschl, Kaiser and Fordinal, 2023).

For this new wave of knowledge management to be effective in organizational practice, universities are key to helping students understand forms of non-rational knowledge and their relevance to real-world problems, shaping the behavior and attitudes of future leaders, entrepreneurs and managers. This aligns with universities' primary goal of growing students' skills and preparedness for real-world organizational learning environments while simultaneously being forced to adapt to an ever-changing environment rapidly (Brewer and Brewer, 2010). Effectively sharing knowledge to create a lasting learning impact requires innovative and diverse teaching

strategies that create personal and emotional engagement, promoting reflection-in-action as well as active learning involvement amongst students (Kragulj *et al.*, 2018). To promote learning and the cultivation of skills, Bratianu and Vatamanescu (2017) propose supplementing lectures with practical activities such as simulations, gaming, or real-world projects, which enhance the tacit knowledge base (Bratianu and Vatamanescu, 2017).

In an earlier contribution, we reported on the importance of teaching students feasible ways to deal with unstructured, ill-defined problems. There, we used the Design Thinking Framework to equip students with creative strategies for problem-solving, enabling them to integrate theories of Organizational Learning and KM into live case studies provided by business partners (Kragulj *et al.*, 2018). With this contribution, however, we aim to go a step further and reflect on the types of knowledge required to engage in contemporary challenges of KM and how we can convey them to students utilizing innovative course designs. By doing so, we extend the existing body of knowledge in the field of KM by introducing innovative didactic approaches that convey the mentioned new types of knowledge. After providing a theoretical background on management education in terms of the relevant knowledge, the paper presents three examples of course/curriculum designs and summarizes the findings and implications in the final section.

2. Theoretical Background

Typically, study programs in business and management emphasize formal learning and qualification (Adams & Ingersoll, 1990; Schön, 1987). It is considered important to know, understand, and be able to apply well-known models of prominent management thinkers, as well as to be able to read, understand and interpret a balance sheet. While these things are undoubtedly important, there exists somewhat of a counter-movement, whose proponents argue that management is more about tacit knowledge of organizations than about technical-rational analytical thinking and that managers can benefit from cultivating non-rational forms of knowledge in decision-making in order to foster more sustainable and responsible business practice (Hedlund *et al.*, 2003; Schaltegger and Wagner, 2011; Bas, Sinclair and Dörfler, 2023). As early as in the 1930s, management theorist Chester Barnard wrote that in addition to its rational, analytical component the process of management is characterized by “the sensing of the organization as a whole and the total situation relevant to it” (Barnard, 1938, p. 123). Accordingly, management may rather be a matter of art than science (Barnard, 1938). In line with Mintzberg’s concise formulation that we need managers, not MBAs (Mintzberg, 2004; Chia, 2005), we were looking for course designs that would build students capacity to manage in between the lines of formal theories and tools. An essential requirement resulting from the tacit nature of the knowledge we aim to teach, is that respective course designs must enable experiential learning. Following Polanyi (1966), tacit knowledge can only be acquired through direct, personal, and often sensory-based experience within the learning context (Polanyi, 1966). In addition to direct experience, participants need reflective practice to acquire knowledge (Schön, 1987). In this regard, the university setting allows for the unique opportunity to incorporate both direct experience as well as reflection-in-action and reflection-on-action in a safe learning environment and under the supervision of methodically and substantively experienced lecturers. Such course designs can incorporate elements of problem-based-learning that introduce the students to complex real-world problems in order to develop their problem-solving and self-directed learning skills (Savery, 2006). Yet, it appears that university education often falls short of these goals and relies heavily on the teaching and assessment of explicit knowledge. This is partly due to the lack of well-developed teaching concepts for spiritual KM, practical wisdom, responsible KM, and future-oriented thinking. With our contribution, we aim to address this gap by presenting blueprints for teaching these concepts. By doing so, we provide an initial basis for discussion and pave the way for the integration of non-rational knowledge into university- and vocational education.

According to the criteria described above, we will progress by presenting three course- or curricular designs and our experience and learnings from them. All courses were initially designed against the background of conveying non-rational forms of knowledge, ideally from both an analytical perspective, i.e. understanding what types of knowledge are in use (know what) and an applied perspective, i.e. learning by doing, experimenting and reflecting the students' learning experience. The courses were part of different study programs held at two Austrian universities and a c-VET training program delivered by an international Erasmus+ consortium. One university is a large public business university focusing on business and economics, and the other is the country's largest public university offering a wide variety of study programs.

We first evaluated the courses on the basis of formal evaluations, according to the respective formats that each institution suggests. Those evaluations partly include Likert-scale questions and also written answers to open questions. The formal evaluation was complemented by verbal feedback that we received from students during

and after class as well as insights from the reflection exercises within the courses. The c-VET training program reported is about to be piloted and has not yet been evaluated by the learners.

3. Course Designs

In the following we will give the reader a detailed picture of the respective course or curriculum designs.

3.1 Course: "Knowledge, Wisdom and Innovation"

This course is part of a specialization program titled "Knowledge Management" at a public business university. Undergraduate students have to choose up to two specialization programs from around 35 available options. Each specialization program consists of five courses with 4 ECTS points each. The respective course "Knowledge, Wisdom and Innovation" is the follow-up course to the introductory course "Knowledge-based Management" within the KM specialization. It can, therefore, be expected that students have already acquired basic competencies in KM and organizational learning. In total, each semester 16 students take part in this course.

3.1.1 Content and aim of the Course

The course "Knowledge, Wisdom and Innovation" targets students who enjoy interdisciplinary thinking and are open to exploring "non-mainstream" content from arts, literature, philosophy, and theology, which can be considered extraordinary for a business university.

The concept of this course is to address the topic of wisdom in a collaborative learning lab and try to learn and discover step-by-step how wisdom can be integrated and fostered in organizations and companies. Questions addressed within the course include: What is wisdom in general and can wisdom be "learned"? What processes help us to make wise decisions in companies and organizations? How can we recognize the effects of wise decisions? What is the connection between wisdom, knowledge, and innovation? And how can insights in the field of wisdom from entirely different disciplines (art, literature, biology, philosophy, theology, etc.) help us make wise decisions in business and our personal lives?

The goal is to convey to the students contemporary research in wisdom, innovation, and organizational learning, including current approaches and discourses in various fields of wisdom research, dealing with interdisciplinarity and applying the acquired knowledge in practice, including the reflection of its impact.

The course content is taught within an open classroom environment driven by situational questions. Presentations and input from the lecturers, exercises, and project work in small groups as well as discussions and reflections in plenary sessions allow the defined learning objectives to be achieved.

3.1.2 Structure of the Course

The course consists of a theoretical part and a practical part. The central idea is to teach students a few selected concepts of wisdom in the theoretical part so that they can then apply them in a case study. This only works if the theoretical part includes a few specific exercises. As the entire course only covers 4 ECTS credits, we had to make a selection of wisdom concepts that we teach in the theory part. Hence, we decided to focus on the following wisdom-related aspects:

- The multi-layered nature of knowledge in the late modern age and the shift towards an information age
- Egyptian wisdom, also known as Ma'at
- Plato's philosophical ethics which is deeply rooted in the idea that virtue and knowledge are inseparably linked
- Chapter 13 of the Nicomachean Ethics by Aristotle which explains the practical importance of prudence and wisdom.
- Wisdom, education and science. The complex relationships between wisdom, education and science are briefly examined, as considered by philosophers such as Nietzsche and Hegel.
- A short introduction to the wisdom literature of the Hebrew Bible
- Ina Roesing's wisdom triangle which is a concept that places wisdom in the context of essentiality, meaning and value.
- The aspect of resonance in the context of wisdom inspired by Hartmut Rosa

In the practical part of the course, we used a live case study of a consulting and training company that had to decide on its further development. The students worked in small groups and not only had to solve the case and try to make wise decisions in various situations in the company concerning further development but also had to justify their decisions in detail and transparently. They were asked to explain which concepts of wisdom they used as a basis for their decisions and how they applied them to the specific case. The students presented their findings in a plenary session and then critically discussed them with the lecturers. The results were compelling and exceeded the expectations of the lecturers. Almost all students not only made interesting and creative suggestions for the company's decision-making situations but were also able to link their decisions very well with the concepts of wisdom they had learned in the theory section.

3.1.3 Evaluation of the Course

Students evaluation at the end of the course revealed impressive results. 100 % of the participants indicated that they would recommend this course to their colleagues, 91 % rated the ratio between theory and practice as the highest possible. 100 % of the participants mentioned that the practical part of the course was an added value for them and 83 % of participants rated the course as helpful for their professional future.

In two open questions, we asked what was particularly positive about the course and what should be improved. What impressed the students the most was the fact that the content of this course was completely different from any other course offered at a business university. Furthermore, most students emphasized that the content of the course also touched them personally and encouraged them to reflect on aspects of their own lives. This finding was underlined by several personal conversations and questions between some students and the lecturers at the end of the final exam. On the other hand, the students argued that the course content was not easy to understand because the wisdom approaches were new and unfamiliar to them. This is precisely why good course materials (slides, handouts, etc.) are essential.

3.2 Curriculum: “Co-Creating and Enacting Future Purpose Through Future-Oriented Innovation”

The following educational design is based on Otto Scharmer's (2016) concepts of "learning from the future as it emerges" and Emergent Innovation (Peschl and Fundneider, 2017; Peschl, 2020). It is a transformative and future-oriented approach to innovation that is centred around the Theory U framework (Scharmer, 2016), anticipation and futures literacies (Miller, 2015, 2018; Poli, 2021; UNESCO, 2021), as well as dealing with self-transcending knowledge (Scharmer, 2001), future purpose and making use of future potentials (Glaveanu, 2022). These approaches propose that the most important sources of innovative change do not come primarily from traditional data, trend analysis, design thinking methods or extrapolation from past knowledge; rather, they claim that (radical) novelty arises from deep and mindful engagement with the world and its possibilities that are unfolding in the present moment and directing towards an emergent future purpose. In that sense, innovation is not brought into being by materializing our own creative ideas in the world in a hylomorphic manner (e.g. Ingold, 2013, 2014); rather, future is co-created by integrating the creative agency of the creator’s mind with the creative agency of the world by enacting both the cognitive system and its environment (Newen, Burin and Gallagher, 2018; Gallagher, 2023; Hutto, 2023).

3.2.1 Content and aim of the Curriculum

Compared to classical innovation strategies (e.g. Chen, Brem and Wong, 2019; Tidd and Bessant, 2020), such a radically future-oriented and purpose-driven approach to innovation involves alternative forms of socio-epistemic processes (e.g., knowledge about potentials and future purpose, self-transcending knowledge [e.g., Scharmer, 2001], dialogical social formats, etc.). Consequently, one needs to develop strategies of how to deal with these forms of knowledge and how to “teach” necessary alternative (epistemic and social) skills and mindsets supporting them. That is why we designed and implemented a so-called extension curriculum entitled “Innovation and Knowledge Creation: How novelty comes into the world”[1]. It is a 15 ECTS “mini curriculum” that is open to bachelor students from all disciples and comprises 3 courses (see below).

The primary objective of this curriculum is to foster processes and capabilities of collaborative knowledge creation as well as futures literacies (Miller, 2015, 2018; Ehlers and Eigbrecht, 2024). The goal is to develop an innovation (project) that culminates in the realization of a tangible prototype over the course of the semester.

[1] https://innovation.univie.ac.at/

Admitting students from various disciplines promotes diversity, which in turn stimulates different perspectives, knowledge cultures, and creativity. This curriculum is designed in a project-based and open-ended manner encouraging and promoting group work, interdisciplinary interaction, collaboration, self-reflection, as well as challenging students' assumptions and beliefs.

The instructors' self-conception rests on the belief that they do not offer definitive or "true" knowledge or solutions. Instead, they prioritize guiding and facilitating the innovation process while providing an enabling learning environment ("enabling spaces", Peschl and Fundneider, 2012, 2014). They focus on establishing an atmosphere of trust and appreciation, creating a setting in which students independently collaborate in groups to develop their own perspectives, arguments, and innovation concepts/projects.

3.2.2 Structure of the Curriculum

The curriculum is organized around an innovation process that is based on Scharmer's (2016) Theory-U and Emergent Innovation (Peschl, 2020). It is structured as a sequence of interlinked and recursive phases, workshops, and class events. Formally, it is organized as 3 courses: (i) a lecture providing theoretical foundations, (ii) a course bridging theoretical and practical topics, and (iii) an "innovation atelier" where students have to work practically on an innovation project. These courses are closely interwoven and teach both theoretical knowledge and practical skills (including innovation attitudes) over the course of a semester.

Between these courses in-person events, workshops, and coaching sessions are provided for the innovation teams, which serve as a forum for receiving feedback, asking in-depth questions, and discussing social issues within the group with the instructors. The most important phases of the innovation process are described below. Further details can be found in Peschl *et al.* (2014) and Hartner-Tiefenthaler *et al.* (2018).

In the first phase, students identify a personally meaningful question and develop their topic of genuine interest. This fosters personal engagement throughout the process. After reflecting on hidden assumptions, students form Knowledge Creation Teams (= KCTs) around shared interests using semantic mapping techniques. They then enter a phase of deep observation, exploring their chosen field through mostly qualitative methods, such as ethnographic observation, generative interviews, or desk research. Afterwards, insights are discussed in a world café (Brown and Isaacs, 2005) and dialogue setting, enabling participants to challenge, reflect, and integrate diverse perspectives, fostering creative synthesis.

Students then enter the presencing phase (Scharmer, 2016), spending a day in nature to encourage new ideas in a silent, distraction-free environment. They suspend their own ideas and engage in a process of "listening to what wants to emerge," encountering future potentials and novel knowledge. The insights gained are then shared within the KCTs, where initial intuitions and concrete ideas for an innovation artifact or prototype begin to crystallize. During iterative prototyping and coaching, ideas are refined, implemented, or discarded in a fast cycle learning process, leading to a final prototype. Finally, this prototype is presented in class, receiving feedback from instructors and peers. At the end, the KCTs and the whole class reflect on the entire knowledge creation process, discussing both theoretical and experiential insights.

3.2.3 Evaluation of the Curriculum

This curriculum was accompanied by a multi-year research project by using mostly triangulation of qualitative and quantitative methods, focusing primarily on qualitative approaches to describe how new knowledge emerges in a future-driven manner (see Peschl *et al.*, 2014, 2019; Hartner-Tiefenthaler *et al.*, 2018). In the instance evaluated in the research project, a total of 30 students participated, including both PhD and Master's students.

Based on diary entries, observations, personal conversations, and group reflections, several key socio-epistemological aspects for this knowledge creation process leading to innovations were identified. These include social and personal identity, individual and group mindsets, decision-making, emotions, course design impact, and the transition from uncertainty to clarity. Basic ground values such as trust and respect turned out to be essential for fostering an innovative and enabling learning environment; they were crucial for providing a "safe space" and effective group dynamics. Fairness ensured equal engagement and valuing individual contributions. This led to (epistemic) openness and curiosity driving creative thinking and being led by future potentials.

Uncertainty played a significant role in the innovation process, initially causing discomfort but ultimately driving creativity and knowledge creation. Effective coping strategies included personal and emotional involvement,

creating a playful atmosphere, and enjoying group interactions. High-performing groups exhibited intrinsic motivation, taking collective responsibility for their projects and engaging deeply in the creative process, often planning to continue their work beyond the course. In contrast, low-performing groups struggled with internal conflicts and lacked cohesive responsibility, highlighting the importance of shared commitment for successful innovation. Although it was a challenge at first, students appreciated that their creative autonomy was taken seriously and that they had to take a great deal of responsibility for their own innovation process.

3.3 Curriculum: "Cultivating Phronesis for Practically Wise Entrepreneurial Decision"

According to Bachmann et al., "practical wisdom can be a source for integrating the multifarious social, moral, cultural, and environmental realities and challenges that business has to meet" (Bachmann, Sasse and Habisch, 2018, p. 126). The concept of practical wisdom (phronesis) originates with Aristotle who defines it as an intellectual virtue rooted in a person's character that "is a true state involving reason, concerned with action in relation to human goods". After reviewing more recent literature on practical wisdom, we can differentiate the concept, namely in relation to the phronimos, i.e., the practically wise person, in three different ways: such a person can 'be' phronetic, they 'have' phronesis, or they 'act' practically wise. While the first notion aligns with the perspective of phronesis as a personality trait, the latter point at its quality of being a learnable skill or behavioral pattern over time (Kragulj, 2023; Rocha, Pinheiro and Kragulj, 2024). This aligns with the argument that 'good' decision-making stems from managerial experience (c.f. tacit knowledge) more than from applying universal management rules (c.f. explicit knowledge) (Thomassen and Jørgensen, 2021). From this ontological point of view, it seems particularly important to systematically cultivate practical wisdom and develop a praxis of 'good' decision-making. To this end, providing learning environments that leverage practical decision-making (e.g., moral dilemma or case study) as the 'learning vehicle' to cultivate practical wisdom (phronesis) seems promising. In this way, learners can build their decision-making skills for business sustainability and responsibility (Melé, 2010).

3.3.1 Content and aim of the Curriculum

The "Wise Up to Succeed" Erasmus+ project[2] aims to strengthen the decision-making competencies of business successors by cultivating their practical wisdom (Kragulj *et al.*, 2024). In continuous vocational education and training (c-VET), it pioneers in converting our conceptual understanding of practical wisdom (phronesis) into education practice. The project leverages the perspective of phronesis as being a skill that manifests in action. In building practical wisdom in managers, decision-making is considered the focal point (i.e., action) of learning and applying.

The core of the project is an educational framework (Kragulj et al., 2024) that aligns with the Principles of Responsible Management Education (Storey, Killian and O'Regan, 2017) and is substantiated by three key theories on critical pedagogy and social development: Freire's (1970) Pedagogy of the Oppressed, Piaget's (1983) cognitive development theory and complimentarily Vygotsky's 'activity theory' (1986).

3.3.2 Structure of the Curriculum

Derived from the educational framework, the project offers a curriculum and a blended training program (2 ECVET credits / 50 working hours) on wise decision-making for business successors. These target six skills of practically wise business successors, which inform current decision-making (Kragulj *et al.*, 2024):

1. Phronetic business successors think future-oriented and plan strategically. Adopting a future perspective, they think long-term and anticipate the consequences of their decisions.
2. They critically reflect on past failures and successes to understand the legacy of their organization, both from a within and outside perspective.
3. They take a holistic perspective on a decision situation. This is to realize the "social, cultural, ecological and ethical complexity and interdependence in which they have to make their decisions".
4. They "seek an in-depth analysis of the decision-making situation" at hand. They understand the particular circumstance of this situation and consider the "subjective influences on a decision-making situation".
5. They gain from the experiences of peers. They can transfer what they have learned to their own field.

[2] https://www.wiseup2succeed.eu

6. They have an open mind in their thoughts and actions. In this way, they can deal with ambiguity in complex environments using a wide behavioral repertoire.

Table 1: Learning Perspectives and Axis (Kragulj *et al.*, 2024).

Axis	Learning Perspective	Short Description
"Time: Vision and Reflection"	"Viewing Ahead"	Envisioning the future outcomes of a decision, anticipating future developments, and, complementarily, shaping future scenarios that are desirable and normative.
"Time: Vision and Reflection"	"Viewing Backwards"	Reflection on personal and others' experiences (success and failure) involving thorough analysis.
"Locus: Ego and Eco Transcendence"	"Viewing from Above"	Understanding the ecological complexity, embeddedness, and interconnectedness of cause-and-effect relationships beyond the decision situation; awareness of the influence of overarching ecosystems and their impact.
"Locus: Ego and Eco Transcendence"	"Viewing from Below"	Empathy and understanding of stakeholders' contexts, comprehending diverse perspectives, and sensing the social and situational aspects of the decision-making situation.
"Ethos: Peer Learning and Inspiration"	"Viewing Near"	Interdisciplinary learning from peers by engaging with their experiences and wisdom, using these insights as a valuable resource.
"Ethos: Peer Learning and Inspiration"	"Viewing Far"	Creativity and open-mindedness toward alternative decision-making approaches; engaging with the practices of professionals from other fields.

The training program implements the educational framework. As a blended format, it comprises six online learning units (reflecting the six learning perspectives) for individual learning and an on-site workshop for peer learning. It draws from six learning perspectives organized along three axis (see Table 1).

The six online learning units consist of pre-recorded lectures that introduce concepts or methods, outline their relevance to the context of the target group, and provide examples, as well as ad-hoc and long-term tasks and quizzes to anchor what they learned in their own decision-making practice. In the peer workshop, business successors from different industries but at the same career stage (i.e., business succession) apply the learning perspectives to decision-making situations that reflect moral dilemmas in teams. By applying the concepts and methods provided in the decision-making process, learners can gain experience and cultivate their practical wisdom. In conclusion, the project aims to improve the decision-making skills of business successors for more sustainable and responsible business management. This group has been largely neglected in the literature despite its importance to the European business landscape (De Freyman and Durst, 2023). In particular, the training program provides young entrepreneurs with tools to methodically substitute the decision-making experience of their predecessors, which is commonly seen as an important source of practical wisdom. The training program is being piloted in a consortium of three European universities in different countries. The results of the evaluation are expected later this year.

4. Conclusion

Recent contributions highlight that a considerable branch of knowledge management is shifting towards non-rational forms of knowledge. Increasing demand for and interest in topics such as practical wisdom, spirituality, organizational purpose, and responsible (knowledge) management requires respective means to acquire such knowledge. Academia, on the other hand, is in charge of teaching non-rational forms of knowledge to future practitioners. We argue that incorporating experiential learning, collaborative knowledge creation, and reflective practice in course designs is crucial for effectively conveying those tacit types and non-rational forms of knowledge to students. Accordingly, we have developed three different course designs that apply these principles and evaluated them with regard to students' learning experiences and the emergence of new knowledge. Results show promising outcomes in terms of students' engagement and intrinsic motivation to learn. In particular, the element of creative autonomy was very well received by students. We also noticed that mutual trust and respect were essential to facilitate an enabling learning environment. The lecturers in such settings must create and uphold a "safe space" in which experimentation can take place, and mistakes are seen as a necessary and inevitable part of learning. In comparison, non-rational knowledge requires more open and less structured tasks than rational-analytic knowledge, which can be challenging for some students because it confronts them with the discomfort of uncertainty that may lead to internal conflicts and a lack of responsibility if the situation is framed incorrectly or insufficiently by the lecturer. Overall, through these first attempts of teaching non-rational, future-oriented types of knowledge, we seek to contribute to knowledge management education by firstly emphasizing the need to bring forth non-rational types of knowledge into practice and, secondly, providing initial cues on how to design respective formats to educate people in practically wise decision making, spirituality, and innovation through self-transcending knowledge.

Abstract: The infrastructure we build is increasingly complicated and automated. After it is designed and constructed, it needs to be maintained and updated to sustain its functioning for far longer than the careers of its designers and builders. Continuity of engineering knowledge is necessary to make future updates and adapt to changing demands, conditions and technology in a safe and reliable manner. The Dutch storm surge barriers protect the low-lying hinterlands from flooding during extreme weather events. Each of the six barriers managed by the Directorate General of Public Works (Rijkswaterstaat) was designed at a different time, to different requirements, and using different types of contracts. This has resulted in six unique structures, some of which use systems and components found nowhere else. In 1997, the Maeslant Storm Surge Barrier was completed, pioneering the use of Design and Construct contracts for major hydraulic structures. Experience with maintaining this hallmark structure through its first decades of operation provides a valuable opportunity to reflect on the effect of contracting- and design choices. Little work has been done to evaluate different contract types on the basis of delivering long-term maintainability and reducing the knowledge continuity challenge. This study views the Maeslant Barrier in the context of the earlier storm surge barriers with regard to facilitating knowledge continuity through design. It was found that the interdependent behaviour of subsystems in a high-reliability structure results in a notable increase in engineering complexity, especially in the control systems, increasing the challenge of achieving knowledge continuity. Examining the knowledge flows in a design-and-construct contract shows several advantages, but also that it does not naturally facilitate attention to important but less obvious aspects of maintainability, such as those related to knowledge continuity.

Keywords: Knowledge Continuity, Continuity Management, Maintainability, Storm Surge Barrier, Obsolescence, Life-Cycle Engineering

1. Introduction

Hydraulic structures such as locks, weirs, and storm surge barriers play a critical role in managing water levels in river delta waterways. These structures are major investments, and it is crucial that their functionality and reliability are sustained for the intended service life, typically about 100 years (Walraven, Vrolijk, and Kotshuis, 2022). Storm surge barriers are also unique structures, which are operated only when necessitated by external conditions, yet as critical infrastructure their reliability and availability must be guaranteed throughout the life-cycle (Kharoubi, 2023).

During these structures' long service life, many changes occur in their environment. These may include changes in laws on water regulation, advancements in technology, shifts in environmental- and safety regulations, and the impact of climate change, including altered water levels and storm intensities (Walraven, Vrolijk and Kotshuis, 2022). The Directorate-General of Public Works in the Netherlands, Rijkswaterstaat (RWS), has a rich history of designing, building, and managing major hydraulic structures. This paper will focus on the Dutch storm

surge barriers, the oldest of which has been continuously operational since 1958 and remains of vital importance to flood safety to this day. The long experience managing storm surge barriers has shown that the changing environment of these engineering structures has caused many cases of partial or subsystem obsolescence. (Walraven, Vrolijk and Kotshuis, 2022). A major source of obsolescence at the barriers is the control system. Electronics and operating systems need to be replaced when they are no longer supported by industry. Efforts to replace barrier control systems have proven to be challenging.

In the 1990s, RWS started outsourcing more of its (re)design work, and has since continued this policy (Brink, 2009). The outsourcing policy has reduced the number of knowledgeable engineers directly employed by RWS. RWS still requires procurement process and engineering knowledge to be an effective principal (Vinke, 2013; Walraven, Vrolijk and Kotshuis, 2022). In 2018 a program was started specifically for managing key engineering and operational knowledge of RWS's storm surge barriers.

2. Literature

Managing knowledge for complex, long lived assets has received considerable scholarly attention, especially in the nuclear energy sector, where there are scientific journals dedicated specifically to the subject. The impact of decisions in the design and procurement phase on the knowledge continuity challenge during the life-cycle of the asset has received little attention. The majority of papers take the engineering knowledge to be managed as a given. Boy and Barnard (2019) briefly touch on design choices in their study on knowledge management for safety-critical systems. Reducing knowledge continuity challenges through early design and contracting decisions remains an understudied topic.

Unique and complex storm surge barriers are found challenging to maintain long term (Walraven, Vrolijk, and Kotshuis, 2022). The science of maintainability aims to cover all design aspects affecting maintenance during the life-cycle. Dhillon (1999) offers design principles contributing to maintainability. In Section 5, we examine if these principles contribute to or oppose knowledge continuity.

Ivory, Thwaites and Vaughan (2001) studied the process of designing for maintainability in multiple cases. They found that for good results, the design process must be conceptualized from the beginning to integrate maintainability. Design for maintainability should be supported by data and practical maintenance experience (Dhillon, 1999). This knowledge is generally outside the core competence of the primary contractor and engineering consultant of a project delivery organization, forcing buyers to rethink and adjust their contracting strategy to better facilitate maintainability (Ivory, Thwaites and Vaughan, 2001). In Section 6, we examine key knowledge contributions and flows between partners in two contracting strategies used for storm surge barriers.

3. Method

The research is situated at RWS, in the research group on asset management of storm surge barriers. Work is also physically located in the asset management office for four of the six storm surge barriers. Research data collection is primarily based on interviews with current and former storm surge barrier professionals. Other data sources are public writings on the storm surge barriers and confidential policy- and consultancy documents. For this paper, only public sources are referenced, while the available confidential reports were used for validation through triangulation. Ten initial interviews were held. Participants include storm surge barrier engineering and asset management professionals, an external engineering consultant, a reliability expert and a barrier manager. The participants were selected to cover teams from multiple storm surge barriers, multiple roles, and include both current and retired professionals. The aim was to cover the distinct perspectives. Interview questions centered on current knowledge management practice, knowledge management history and experience with knowledge management challenges. During the interviews, the topic of barrier complexity recurred almost exclusively in relationship to the Maeslant Barrier. To explore this further, an ongoing series of adaptive interviews was conducted focusing specifically on barrier design choices and their effects on barrier complexity. In these complementary interviews, the main topics were complexity in barrier engineering, complexity of barrier control systems, trade-offs in complexity versus simplicity, and the process and history of how these (design) decisions were made. Interviews were recorded by audio recording and transcription or by taking minutes, depending on the preference of the participant. Transcriptions or minutes were then sent to the participant for review and approval.

Interview analyses of both initial and follow-up interviews were done using the Thematic Analysis method (Braun and Clarke, 2021). Atlas.ti was used to code the interviews, and also to facilitate the review of public and

confidential reports. Because of the immersive character of the research, any apparent contradictions between interviews or between interviews and documents could be quickly resolved by additional questions to participants or their colleagues at the barrier's office.

4. Controlling the Maeslant Storm Surge Barrier

A storm surge barrier is a very large gate, or set of gates, that can open or close a waterway depending on what hydraulic conditions require. This function by itself does not require a very complex structure. The most common type of storm surge barrier is the lifting gate (Mooyaart and Jonkman, 2017). Lifting gates, as well as the second most common design, segment gates, are 'passive' gates. When open, the gates are above the water and lowered into it to close the waterway. A passive barrier can be closed without an external power source. Lifting gates and segment gates can be closed by force of gravity if electric power fails. The potential to close by force of gravity contributes to the reliability of a storm surge barrier. Although the structures may be very large, expensive, and take a long time to build, the engineering and control systems involved are not overly complicated. All the Dutch storm surge barriers preceding the Maeslant Barrier are of the lifting gate and segment gate types. Ponsioen and Nederend (2023) provide a description of all six RWS storm surge barriers.

The design requirements of the Maeslant Barrier called for a normally open storm surge barrier that posed no height restrictions on shipping, and introduced no obstacles in the shipping lane. Because of these requirements, the Maeslant Barrier needed to be of a different type than the earlier barriers. A design and construct contract was tendered, resulting in the design of the Maeslant Barrier. It is a barrier of the floating sector-gate type, and was chosen from five proposals and a reference design (sliding gates). The working principle of all six designs is depicted in Figure 1. RWS (2012) provides a more detailed description of the Maeslant Barrier's working, engineering, and procurement process.

Because of the importance of the Maeslant Barrier for flood safety, a high reliability target was set. To avoid the possibility of operational mistakes, the barrier was designed to be fully automatic. The design and construct contract featured a maintenance period of five years, starting after completion of its construction in 1997. While RWS was preparing to take over maintenance and design responsibilities of the barrier, it became clear that the automatic closure reliability of the barrier (software reliability) could not yet be accurately assessed. It was also noticed that knowledge continuity of its complex software was going to be a major challenge. The Maeslant Barrier was the first barrier where RWS was not directly participating in the design. Because of this, RWS staff was not immediately familiar with the finer details of the hardware and software. A major improvement effort was started in 2001 to address these issues. A full barrier reliability analysis showed that the probability of failure of the automated control system was a major contributor to not meeting reliability targets for the barrier, but also that it could not be accurately determined (Nieuwenhuizen Wijbenga, 2019). To meet reliability requirements and to bypass potential software failure, a backup procedure of human intervention was instated. Also, a first knowledge management program was started as part of the improvement effort. This involved hiring knowledgeable engineers from the building combination into RWS and establishing a digital knowledge management system. These efforts led to the barrier passing audits in 2007.

Even though it has been established that primary automatic control with a highly trained operational backup team present is sufficient to meet reliability targets, accurately assessing the reliability of automated control of the Maeslant Barrier has remained elusive. To prepare the barrier for the rest of its service life, a new control system was required, but the first two attempts at its development were halted before completion (Nieuwenhuizen Wijbenga, 2019; Osch and Amerongen, 2023). The new control system must have proven reliability, modernized security features, and be more hardware-independent. Being able to provide a direct proof of a new system's reliability is very important. Because the existing system has been proven in use, a new system must be proven at least as reliable without the need for additional maritime-traffic disrupting live-tests. Efforts thus far could not prove reliability improvement beyond doubt.

Difficulties and delays in proving reliability of software systems for hypothetical adverse situations have been common in the Netherlands for other infrastructure as well, and are described for tunnels in Ruland et al. (2012). The long-term maintenance of complex legacy software systems remains a major challenge, and is largely due to inevitable attrition of knowledge during the life cycle (Anquetil et al., 2007). Experience managing its various complex assets has lead RWS to investigate whether some of the software complexity can be avoided through early design choices. Traditionally, early design focusses on the civil and hydraulic engineering aspects of the design, as these influence construction costs the most. Lately however, this view is shifting towards an early

involvement of software and control, at both RWS and the major Dutch infrastructure contractors (Rijkswaterstaat, 2019).

5. A Knowledge Continuity View on Storm Surge Barrier Design

Within RWS, many of the challenges with sustaining the control systems and other complex systems in storm surge barriers are attributed to the inability to achieve continuity of designer-level engineering knowledge. The timeframes between initial- and re-design are typically twenty to thirty-five years. During this time, knowledge loss from attrition will affect RWS, as well as the companies that designed and built the structure.

Challenges to knowledge continuity can potentially become a serious impediment to long-term sustainment. Designing systems in such a way that knowledge continuity challenges are reduced, can therefore make a meaningful contribution to the long-term maintainability of a barrier. Major contributors to the challenge of achieving knowledge continuity are the complexity of engineering, the uniqueness of some of the systems and components, long redesign cycles of systems, and high-reliability requirements. With the exclusion of the long redesign cycles, these challenge-driving characteristics can be recognized as being almost direct opposites to the established maintainability principles of simplicity, modularity, standardization, and testability (Dhillon, 1999). Complexity is the opposite of simplicity and modularity. Uniqueness is the opposite of standardization, and reliability requirements preclude most live-testing at the barriers. The long redesign cycles constitute a significant challenge to knowledge continuity, but given the cost of redesigning and updating a barrier, long cycles are desirable from a maintainability perspective.

The effect of simplicity on knowledge continuity is largely self-evident. If a design is easy to understand, less engineering knowledge needs to be passed down through generations of engineers. A modular design has a loose-coupling and clear interfaces between the modules. Therefore any module can be redesigned without having to worry about unforeseen knock-on effects on other parts. This avoids the requirement of a deep understanding of the integral workings of the whole barrier to redesign one module. Standardization means that there are many identical or very similar systems used elsewhere, increasing availability of knowledge. In a testable system, modifications and improvements can be verified before they need to be relied upon.

The Dutch storm surge barriers show significant differences in the knowledge continuity challenge over their life-cycle. The differences in knowledge continuity challenge can be related to the variations in the basic design of the barriers. The following paragraphs will show that when a storm surge barrier features a redundancy at the gate level, a favorable knowledge continuity profile is created. This will be explained in the following paragraphs using the principles of simplicity, standardization, modularity and testability.

Three of the Dutch storm surge barriers feature redundancy at the gate level. The Eastern Scheldt Barrier has 62 parallel gates. The Haringvliet sluice features 17 parallel openings. The Dutch IJssel Barrier has two gates in series, each fully capable of closing the waterway. Redundancy at the gate level is very beneficial to achieve simplicity of the operating system of the barrier. When one gate fails in a barrier with gate-level redundancy, the other barriers can close in the same way as always. The control system therefore does not need to feature separate provisions for every combination of working and non-working gates. This keeps the control program short and simple.

The control system of the Maeslant Barrier has proven to be the most challenging system to sustain in the face of obsolescence. The case of barrier control, where all systems work as intended, is referred to as the ‘happy flow’. Most of the complexity comes from what engineers involved with the barrier call ‘the unhappy flow’ of barrier control, in which the control system has to allow for one or more failed components. The Maeslant Barrier has no redundancy at the gate level, as both gates must close for the barrier to be effective against a storm surge . The barrier does have redundancy at the level of its pumps and valves. This creates a large number of possible partially failed but still operational states to account for in the control system. Allowing operation for a multitude of cases of component failure increases the reliability of the barrier, but also the complexity of the controls. The unhappy flow makes up roughly three quarters of the control program of the Maeslant Barrier. Rewriting the control system to avoid technical obsolescence requires highly case-specific and detailed knowledge of the set of built-in ‘unhappy flows’. It is very challenging to credibly and verifiably prove the reliability of this complex system with limited testability.

When a barrier has redundancy at the gate level, the failure to close one gate does not create a large enough opening to cause flooding. Redundancy of gates creates internal modularity, standardization, and testability. Having multiple identical gates to maintain increases internal opportunities for learning and intergenerational

transfer of knowledge during maintenance. This internally re-creates the benefits of standardization, even if the technology used becomes obsolete by outside standards. A barrier with multiple (almost) identical gates is also inherently modular. Each gate is a module, when its operation is independent of the other gates. When one gate fails during a storm closure, the other gates can close the same way as otherwise. Testability is guaranteed because any modification or upgrade can be tested on one gate, and only be applied at the other gates after thorough verification.

As the Maeslant Barrier was the first storm surge barrier that does not feature redundancy at the gate level. It therefore has a less favorable profile for the knowledge continuity-aspect of maintainability. In the selection of the design, general maintainability was nonetheless a major concern. Figure 1 divides the six barrier types of which designs were developed for the Maeslant Barrier into three groups. The basic designs of group 1 offer a simple, modular design with a high number of identical 'valves' or partial gates. Failure of one 'valve' or partial gate does not cause the whole storm closure to fail, providing redundancy at the gate-level. Group 2 offers fixed paths of movement, so relatively simple controls, but no gate-level redundancy. The third group has floating gates which require more complex controls, and also no redundancy. Hydraulic aspects of maintainability are however most favorable for the third group, as these designs are relatively insensitive to silting-up and require little underwater maintenance. The first group is both sensitive to silting and requires underwater maintenance, and the second group once again takes the middle position. It can be seen that avoiding complexity of controls through basic design choices is feasible for the design requirements of the Maeslant Barreir, but comes with important trade-offs in other aspects of maintainability. Participating senior engineers consider simplicity an important concern, but still secondary to other design aspects. Since all height-restriction free barrier types shown in Figure 1 are in use somewhere in the world, there is an important opportunity to record and share sustainment challenges and performance, so all relevant actors can learn more about the development of the relative importance of aspects of maintainability and knowledge continuity. The I-storm network of storm surge barrier managers is a good platform for this.

Table 1:Adapted from (Riteco, 2017)

Design & schematics	Simplicity	Standardization, Modularity & Testability	Other maintainability
Group1: Tumble gates / flap gates.  Pneumatic tumble gate  Hydraulic tumble gate	- Fixed path of movement and independent valves will result in a simple operating system	- Reliable parallel systems (14 and 24 independent gates) - Modifications can be tested on one gate before the others are renovated - Best for standardization, modularity and testability	- Silting up of valves - Underwater maintenance
Group 2: Rolling and sliding gates  Rolling sector gate  Sliding gate	- Fixed path of movement and independent valves will result in a simple operating system	- No gate-level redundancy - Modifications need to be applied to the whole barrier at once	- Gates need to plough through sediment deposits
Group 3: Floating gates	- Process control of gate closure		

Design & schematics		Simplicity	Standardization, Modularity & Testability	Other maintainability
 Barge gate	 Floating sector gate	not easy, especially for barge gate	- No gate-level redundancy - Modifications need to be applied to the whole barrier at once	- Insensitive to silting up - Ease of physical maintenance

6. An Inter-Organization Knowledge-Transfer View on Storm Surge Barrier Design

General knowledge management theory has established that knowledge exchange between departments or organizations working together can be slow and ineffective, see for example Szulanski (1996). Given that knowledge transfers best when people work together, it is possible to consider the effects of different setups for promoting or impeding the flow of knowledge. Figure 2 identifies five knowledge flows related to building a new structure. From 2a to 2b, it is shown which knowledge flows are improved or impeded, switching from a traditional Bid & Build procedure where RWS designed its barriers itself, to the Design & Construct (D&C) contract used for the Maeslant Barrier.

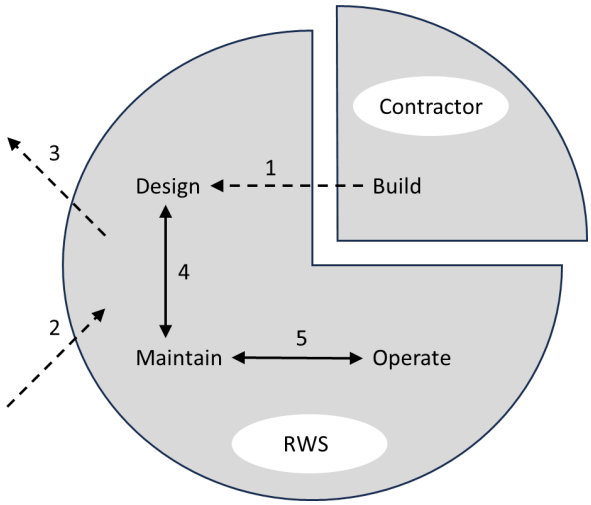

Figure 1: Dutch IJssel Barrier and Haringvliet Sluices (Bid & Build, self-designed and initially self-maintained)

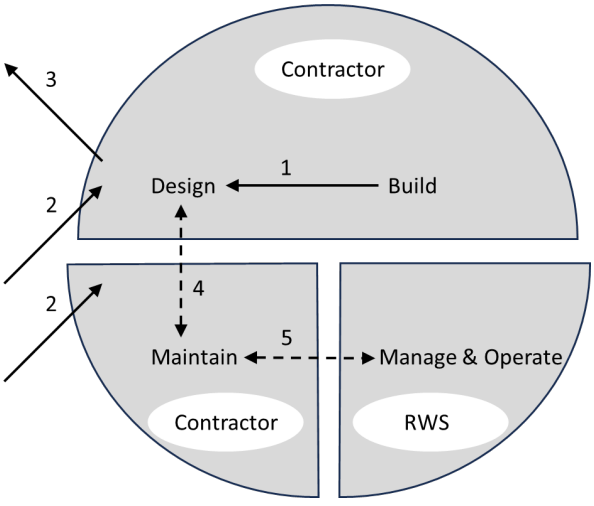

Figure 2: Maeslant Barrier (D&C, outsourced maintenance)

The dashed arrows in Figure 2 represent relatively more difficult, and the solid arrows relatively more effective flows of knowledge. The traditional Bid & Build, self-maintained model in Figure 2a has three dashed arrows. Since RWS designed, maintained, and operated the barriers by itself, there was less room to benefit from knowledge and innovation available from construction companies (Rijkswaterstaat, 2004). This is represented by arrow 1. Private engineering firms had less opportunity to input the latest design knowledge (arrow 2), and there was also less opportunity for re-use of design experience by the market (arrow 3).

Figure 2b represents a D&C contract with an outsourced maintenance model. Design services are provided by market parties (arrow 2). Re-use opportunity of design experience in the market (arrow 3) has arguably improved. Dutch firms that regularly work for RWS also consult for major hydraulic projects around the world, see e.g. Zwaan (2018). For the design of the Maeslant Barrier, RWS was specifically not to interfere with the engineering. This left little room to input its own knowledge regarding barrier maintainability to the design, leaving decades of experience managing the earlier barriers unused (arrow 4). Responding former design engineers and consulting engineers consider limited attention to maintainability in the Maeslant Barrier design as a result of the D&C contract. The contractor had a five-year maintenance obligation, and no further maintainability clauses were part of the D&C requirements. This gave the contractor little incentive to consider the impact of design choices on knowledge continuity as a factor in long-term maintainability. RWS not insisting on having a say in maintainability is also illustrative of a limited focus on maintainability from RWS during its early transition years from leading designer to professional principal. Herd and Pirretti (2022) identify a lessons learned program as a key function of knowledge management in an organization driven by a succession of major engineering projects. It is important for the transition at RWS to continue the development of internal knowledge on maintainability and design for knowledge continuity.

Finally, arrow 5 deals with the knowledge exchange between asset management and the maintenance contractor. Professionals report that detailed access to maintenance information indicating the state of the asset is less accessible compared to when internal technical services provided maintenance to the barriers. As more experience is gained with the new outsourced setup, procedures are being improved, resulting in a better flow of knowledge.

In summary, when developing truly new solutions through a D&C contract, there is a vulnerability to insufficient attention to maintainability, because a D&C contract does not create a shared work environment for those with experiential knowledge of maintainability, and those in charge of the design. The use of integrated contracts for design, therefore, requires extra attention to maintainability in general and those parameters that are crucial to knowledge continuity in particular.

7. Discussion

The benefits of producing goods in high numbers is so well-known nearly everyone has become familiar with the expression ‘economics of scale’. Flyvbjerg and Gardner (2023) note that projects in sectors with a high degree of repetition and modularity like solar and windfarms are far less likely to experience considerable cost-overruns. This study sees the benefits of standardization and modularity also applying to the long-term knowledge continuity management of complex assets. What is perhaps most surprising is that these benefits start from very small numbers. Participants from the Dutch IJssel Barrier report few issues, despite it being the oldest barrier. The paper offers an explanation to differences between respondents from different barriers in knowledge continuity challenges reported. The benefits of simplicity, standardization, modularity and testability which are present in the design of the older barriers explain the why less challenges are reported there. When making a design they must however be carefully weighed against other factors. As was seen in the discussion of Figure 1, the designs for the Maeslant Barrier that most allign with the principles of simplicity, standardization, maintainability and testability, had major drawbacks on other aspects of maintainability.

This paper has shown that with regards to knowledge continuity, even within a specific domain like storm surge barrier design and contracting, not all design and contracting methods are created equal, and it is well possible to analyze these for their knowledge continuity profile. This does however not necessarily offer a method for selecting a better design outright, as there are other major factors to consider as well. Its value is in showing how knowledge continuity can be made a key topic from the earliest discussion of design and contracting options.

8. Conclusion

It was shown that engineering complexity in the design and control of a storm surge barrier is a feature that emerges through design choices, but does not result from the design requirements as an absolute necessity. It was also shown that designs featuring redundancy at the gate level, either through parallel partitioning in a relatively large number of gates, or by putting gates in series, create favorable conditions for long-term maintainability and sustainment of function. The design principles are simplicity, modularity, standardization and testability. Achieving a high degree of simplicity requires a favorable 'unhappy flow' of control. Finally, while there are currently a multitude of commissioning or procurement contract types available, none of these are specifically geared toward the long-term sustainment and knowledge continuity of assets. It is, therefore, of vital importance to internally collect experiential knowledge on these topics and make it a consideration in future (re)designs.

Knowledge Sharing in the Adminship Communities of the Eastern-European Versions of Wikipedia Pages

Anna Karczewska
Częstochowa University of Technology, Częstochowa, Poland

anna.karczewska@pcz.pl

Abstract: Adminship in the Wikipedia community represents a specific kind of organizing activity of a virtual community of practice. It requires a high level of trust amongst the users and the engagement of an admin in the life of the community as a non-paid function, which is significant in terms of sharing and creating knowledge in the form of the content of Wikipedia. As in every form of human cooperation, it is subject to the cultural influences of the country, whose language version it represents. The aim of the research was to distinguish and describe the characteristics of the adminship and admins' social and content-creating activities in the seven East European versions of Wikipedia (among others, Poland, the Czech Republic, Hungary), while taking into consideration the cultural characteristics of the cultures involved. The method used was the quantitative content analysis of the admins' activity in different spaces of Wikipedia activity (organizing, content-creating). In order to obtain the data of admins' activity, the xTool was used, which is a dedicated online tool and database of Wikipedia's users' activity. To analyze and determine the trends and correlations of admins' activity in different language versions of Wikipedia, Statistica software was used. The results of the study suggest that despite the common history and characteristics of East European countries, there are some differences characterizing adminship work in terms of organizing and creating the knowledge process in different Wikipedia language versions, particularly considering certain cultural dimensions distinguished by Hofstede (e.g. power distance, masculinity).

Keywords: Adminship, Community Of Practice, Knowledge-Sharing, Organizing, Wikipedia

1. Introduction

In today's knowledge sharing practices, a notable role is played by the virtual communities, thus many studies have been conducted to examine this phenomenon. Wikipedia advances to become a virtual community of practice aimed at producing and organizing knowledge in numerous language versions. Organizing large numbers of volunteers for activity in a knowledge project such as Wikipedia poses certain challenges (Konieczny, 2018). It requires attracting and retaining competent and willing volunteers who learn and constantly improve the editorial policies, thus ensuring the high quality of content. The collaboration of volunteers includes a clash of opinions and resolution of conflicts which require some type of coordination of activities. Eric Raymond's portrait of "a great babbling bazaar of differing agendas and approaches" leading to a stable community of users is widely recognized in open source software development (Capiluppi, Michlmayr, 2007, p.32). Researchers have been absorbed by the concept of this complex social environment for over a decade, which prompted them to examine how individuals coordinate actions to achieve goals in open source initiatives such as Wikipedia.

In the process of the creation of open knowledge content in Wikipedia, effective management of volunteers means not only aligning people with common goals, but also taking care of the well-being of the users and providing them with technical and substantive support. Self-governing communities of practice such as Wikipedia face challenges in meeting content creation goals by optimizing volunteer efforts and a division of tasks (Smirnov, Oprea and Strohmaier 2023). Providing users with an engaging and rewarding experience is essential to attracting and retaining user participation, which is often addressed through discussions about motivations and non-material rewards. Although the information content in online communities plays a key role and serves as an important motivator of engagement, online communities go beyond the mere dissemination of information. They represent social systems that exhibit the key characteristics of small groups, voluntary associations and formal organizations (Bürger, Schlögl and Schmid-Petri 2023). Similar to the dynamics observed in various groups and organizational settings, integration into an online community typically involves establishing connections with the collective entity or its individual members, ultimately strengthening a sense of commitment to these relationships (Butler 2004, Kraut et al. 2008). Hence, there are not only pages or spaces where the knowledge content is produced, but also the so-called "meta" spaces in Wikipedia, where coordination of work, communication and discussion take place.

One of the groups of Wikipedia users which is very significant for the whole community are admins, who concentrate on "meta" tasks connected with ensuring the level of productivity of the Wikipedia community. Their main role is to monitor community activities and look for opportunities to provide help or correct mistakes, which involve removing vandalism, blocking IP addresses or editing secure pages (Kraut et al. 2010). The route to becoming an administrator is to request for the adminship (RFA). The RFA process includes three steps as

follows: a nomination statement, questions and answers about the previous and future behaviours of a user, and statements of support, opposition, or neutrality by Wikipedia community members. The voting process is transparent, thus allowing any editor to review the nominated editor's records, inquire about the nominee, and assess their proficiency in terms of using administrator privileges (Ren, Zhang and Kraut 2023).

The aim of this paper is to investigate the adminship activity in the seven languages of Wikipedia chosen from South Eastern Europe (Poland, Slovenia, the Czech Republic, Hungary, Romania, Bulgaria, Ukraine) and its relations with the cultural dimensions of the countries studied. This paper is structured as follows: Section 2 highlights the literature review by explaining the major theoretical foundations of the current trends of Wikipedia community of practices in the analyzed field. Section 3 presents the method of data collection. Section 4 reports and discusses the findings, while Section 5 concludes the paper and provides the implications of this study.

2. Literature Review

The social roles theory explains the development and influences of social roles on human behaviour, e.g., analyzing role-taking and role-playing behaviours (Eagly and Wood 2016). Likewise, in online communities there are certain roles that users may take on and perform. In Wikipedia projects in general, the relationship between users is a partnership, however, one of the roles that stands out is that of adminship. This role is based on the level of commitment to the community and eagerness to contribute to the community (Teng et al. 2022). What plays a crucial role in the emergence of leaders in Wikipedia is that of merit (Ren, Zhang and Kraut 2023). Wikipedia adminship includes not only knowledge contribution, but also social contribution, while also, among others: providing support and ensuring the quality of work.

Large-scale open source projects face management problems that involve controlling the integration of distributed knowledge resources and how to coordinate such activities in order to create shared value. Wikipedia editing activity is knowledge-intensive (Arazy and Gellatly 2013). Millions of minuscule contributions must be assessed, selected, adapted and sometimes rejected, which means that editing work should be directed to create value (Aaltonen and Lanzara 2015). For effective collaboration to prevail among project volunteers, the work is broken down into small parts. This allows individuals with different expertise, interest levels, while also availability to take part in editing. The integration of these contributions is crucial for the project's success, which is usually managed by project leaders who hold the final decision-making power. Despite the common trend of a few individuals carrying most of the workload in peer production systems, short-term contributors also play a significant role. The organizers of online collaborative projects are tasked with recruiting new members and ensuring continued engagement from the existing ones. (Bruckman 2022, pp 59-62) This is the reason why administrators' activity is so crucial for unhindered production of knowledge on Wikipedia.

The authority of the managerial activity of administrators is inclined towards facilitating rather than dictating. Although admins influence significant policy implementation, they do not dictate the specific assignments to the users. This could be attributed to admins potentially lacking the necessary time or focus to address individual personnel matters. Alternatively, the reduced managerial control observed in peer production systems may be inherently linked to the voluntary nature of these communities (Kittur, Pendelton and Kraut 2009).

Ung and Dalle (2010) investigated 644 French WikiProjects in terms of the relationship between discussion activity on the project's talk page and editing activity and concluded that the most active discussion participants were not the most active editors. In most cases, a small group of active discussion participants played a major role in organizing the work of a wider group of peripheral members rather than being involved in the larger article content creation. These smaller groups of project members may function as a hub acting as facilitators and technical support by answering questions etc.

The English language version of Wikipedia defines administrators of the user group as follows: "administrators are volunteer editors trusted with access to certain tools on the English Wikipedia. They are expected to observe a high standard of conduct, use the tools fairly, and never use them to gain advantage in a dispute" (https://en.wikipedia.org/wiki/Wikipedia:Administrators). Meanwhile, in the Polish version they are described as: "a group of committed and trustworthy users who are members of the community and have additional permissions." The tools at their disposal do not include editorial control over Wikipedia; they primarily serve organizational and preventive functions. Administrators also provide assistance in editing Wikipedia, especially for newcomers. (https://pl.wikipedia.org/wiki/Wikipedia:Administratorzy)

Administrators (also referred to as sysops, system operators or admins) have such technical abilities as the following:

- deleting and undeleting pages, while also viewing deleted revisions of pages;
- blocking and unblocking users, IP addresses (or ranges of IP);
- protecting and unprotecting pages, editing protected pages;

Other additional rights are regulated individually in different language versions of Wikipedia. Administrators commonly take responsibility for making decisions about the outcomes of certain discussions, such as deleting or moving discussions, but other editors may also close discussions in certain cases (https://en.wikipedia.org/wiki/Wikipedia:Administrators). Wikipedia's administrative tools are compared to a janitor's mop, which leads to describing the act of being granted the adminship as being "given the mop" (Figure 1).

Figure 1: Picture representing admins' work in Wikipedia

Source: https://en.wikipedia.org/wiki/Wikipedia:Administrators

Wikipedia editors and participants in other online volunteer collaborations are not ordered to participate by any manager and they are not remunerated in any material way. The question arises as to why do they do it? Benkler (2008) maintains that social–psychological rewards replace material ones. Hence, the social aspect of Wikipedia membership and adminship is significant for the users. The users with admin status perform this role with a sense of responsibility for the community, not for the economic reward. Their activity is connected with the substance of their role (fighting with vandalism, while also deleting, correcting, organizing work on the content of articles), as well as discussing, supporting, helping the users, including newcomers, thus making them more socially oriented.

Wikipedists are individuals who are loosely connected by common goals and policies creating the code of conduct. Administrators are not traditional leaders, as the leaders cannot dictate the tasks to be executed. The leadership is based on "the hierarchy that results from the respect held for experts and the rules for actions defined within the communities" (Skolik 2012; Benkler 2008). Skolik and Jemielniak (2011) analyze the partnership and leadership characteristics of Wikimedia projects particularly focusing on the process of leader emergence and projects created by them. Initially, the adminship rights in Wikipedia were granted through consensus without the need for formal procedures. However, due to growing disparities in rights access, a voting system was implemented. This process lasts 7 days, during which candidates seeking these rights are evaluated based on their past contributions and responses to questions posed during the voting process.

The user's contribution in knowledge is the main criterion to be considered in the assessment of the candidate for an admin, in which a lack of contribution results in failure. Proving the competence in the creation of knowledge and the willingness to perform admin's tasks, including interacting with people, building relationships with the community's core members are the prerequisites to be granted the rights in question. Hence, both content-creating and social aspects seem significant (Clémente, Bothorel and Jullien 2015). Burke and Kraut (2008) identified important characteristics for an administrator and created a model which may be applied as an AdminFinderBot for choosing possible future admins, as a tool for self-evaluation, or as a dashboard with statistics for voters assessing candidates for administrators. Leader emergence processes in Wikipedia were also studied by Das, Lavoie and Magdon-Ismail (2016), especially the procedures to determine if an editor would use admin rights for malicious activity, which could prevent trolling by helping to detect possible vandals before they are granted admin rights. Selecting a suitable candidate for the administrator is crucial due to the threat of overuse of admin's rights, e.g. the cases have been observed, in which post-appointment administrators focused

on more controversial topics than before their promotion or appeared to push positions which violated Wikipedia's policy on neutral points of view.

The impact of diversity of tenure and interest of users of Wikipedia on their productivity and withdrawal from Wikiprojects were investigated by Ren, Chen and Riedel (2015). The investigated variables influence the level of productivity and withdrawal of the users. Projects with a moderate level of tenure disparity had higher productivity than projects with a low or high level of tenure disparity. High tenure disparity was also related to higher withdrawal. The tenure studied concerned Wikipedia users in general.

In terms of public and private activity of administrators of an online community, Teng et al. (2022) investigated these issues in terms of administrator roles based on the case of a popular online community in Taiwan Bahamut. The results indicate that taking on the social role of an administrator helps to initiate the role-appropriate behaviour of opinion leadership and public space contribution rather than private space contribution. This analysis of the administrators' behaviour is very insightful, however, it did not include the admins' contribution in the Wikipedia community.

In order to investigate the differences between cultures, five dimensions of cultural diversity were distinguished by Hofstede, such as the following: power distance, individualism (versus collectivism), masculinity (versus femininity), uncertainty avoidance and long or short-term orientation (Hofstede, Hofstede and Minkov 2010). Some of the researchers studied what kind of impact cultural differences have on online communities or web content contribution. Pfeil et al. (2006) studied the influence of cultural differences on Wikipedia contribution with the use of Hofstede dimensions, albeit studying only the history of one article in four language versions of Wikipedia and without any particular focus on administrators. Moreover, cross-cultural analysis of four language versions' content was conducted by Hara, Shachaf and Hew (2010). The authors analyzed the typical behaviours of users in three types of discussion spaces (Talk, User Talk, and Wikipedia Talk) and obtained the results confirming the existence of culturally dependent differences in various cultural dimensions.

However, at least one gap exists in this line of research, as little has been done to investigate how different types of admins' contributions are influenced by particular cultural factors and what kinds of contributions are shaped by cultural context. Thus, this paper aims to fill in the afore-mentioned gap by examining how these phenomena occur.

The hypotheses set in this research are as follows:

1. The tenure of an admin is correlated with his/her social activity and content creating activity. The more experienced an admin is, the more active he/she is in both spheres.
2. The tenure of an admin is culturally dependent. All cultural dimensions distinguished by Hofstede are correlated with the Wikipedia admins' tenure.
3. Social activities in the seven East European versions of Wikipedia chosen are culturally dependent. All cultural dimensions distinguished by Hofstede are correlated with Wikipedia admins' activities.
4. Content creating activities in the seven East European versions of Wikipedia chosen are culturally dependent. All cultural dimensions distinguished by Hofstede are correlated with Wikipedia admins' activities.

3. Methodology

The aim of the conducted research was to study the activity of Internet users fulfilling the role of admins within Wikipedia in the East European versions of Wikipedia chosen (Poland, Slovakia, the Czech Republic, Slovenia, Hungary, Ukraine, Bulgaria), while taking into consideration the cultural characteristics of the cultures involved. The research questions asked in the research process were as follows:

Q1: What are the characteristics of the admins' social and content-creating activities in the East European versions of Wikipedia chosen?

Q2: Are tenure, social and content-creating activities of admins in the East European versions of Wikipedia chosen culturally dependent? If so, what cultural dimensions are correlated with their activities and tenure?

The method used in the research is the content analysis method, which included quantitative tools. The calculations were made on a sample of 259 users – the admins from seven language versions of Wikipedia. At the first stage of the research, the candidates lists were collected from the selected Wikipedia of seven language versions. The following number of admins from particular countries was studied: Poland –97 Slovenia –21 Hungary –23 Czech –32, Romania –15, Bulgaria –23 Ukraine -48 , in sum –259 admins.

Then, the *xTools* tool was used to generate the data about the activity of the admins. *XTools* collects statistical data for each registered account on Wikipedia and its related projects. The collected data included the following:

- the number of deleted editions of the admin,
- the number of editions deleted by the admins,
- the number of all editions made by the admin in Wikipedia,
- the number of activities in article space concerning the creation of the articles' content,
- the number of activities in the "talk" and "meta" space (discussing the content and quality of articles; interaction with others, as well as the organization of work),
- date of registration of the admin,
- date of the last activity of the admin,
- number of times thanks was expressed to the admin for his/her input,
- number of times thanks was expressed by the admin to other users.

Deletionism will be understood in this article as defined in Wikipedia, namely: the philosophy of: "selective coverage and removal of articles seen as poorly defended. Deletionist viewpoints are commonly motivated by a desire for Wikipedia to be focused on and cover significant topics, along with the desire to place a firm cap upon the proliferation of promotional use, trivia, and articles which are, in their opinion, of no general interest, the lack of suitable source material for high-quality coverage, are too short or otherwise unacceptably poor in quality, or may cause maintenance overload to the community" (https://en.wikipedia.org/wiki/Deletionism_and_inclusionism_in_Wikipedia). The proportion of editions deleted by and admin to the number of users in a language version, as well as the percentage of deleted editions of an admin may be treated as the indicators of deletionism in a given Wikipedia language version. The proportion of the sum of all activities concerning the admin's work to the number of active users may represent an indicator of the admin's general activity. The quotients with the number of people in the denominator were counted to take into consideration the variable of the size of a particular Wikipedia community. The proportion of social activities (in talk/discussions/"meta" spaces) to sum of article editions in Wikipedia was also calculated, as well as the proportion of the number of expressions of thanks to the sum of all editions of an admin as characteristics of social activity of the admins. Article space editions of an admin was treated as an indicator of the content-oriented activity of an admin. The tenure/seniority of an admin was determined by calculating the difference between his/her first and last edition (in terms of years).

At the second stage of the research, the data was collected and statistically analysed using Statistica software. The Rho-Spearman statistical measure of correlation between variables was used (with the adopted $p<0.05$). Descriptive statistics were also used to investigate the main trends in the behaviour of admins in different Wikipedia language versions.

4. Research Results and Discussion

In order to answer the research questions, the descriptive statistics concerning the studied variables were analysed. The Spearman's rho correlation was calculated between the tenure of admins in all researched versions and their social activity, the percentage of deleted editions, expressions of thanks received, article editions and Hofstede cultural dimensions (Table 1). Only uncertainty avoidance did not correlate with the tenure of an admin.

Table 1: Correlations between tenure and chosen indicators of admins' activity

	Social Activities No./Sum Of Articles' Editions	Percentage Of Deleted Editions	Thanks No./ Sum Of All Editions	Article Editions In The Space: Article (Content Activity)	Pd	Ind	Masc	Ua	Lo	Indulg
tenure	0.1435	0.2828	-0.5048	0.17242	-0.1332	-0.1905	0.1939	-0.0935	-0.2399	0.2038

N=259, p<0,05. PD – power distance, Ind – individualism, Masc – masculinity, UA – uncertainty avoidance, LO – long-term orientation, Indulg– indulgence.

The indicators of the admin's activity (relation of the entire sum of editions to the number of active users of a language version) and the level of deletionism were developed for each language version of Wikipedia. The average tenure of an admin was also calculated (Table 2).

Table 2: Average tenure, activity and deletionism in the seven East European language versions of Wikipedia. Activities concerned admins' work from the period of the last 12 months (III 2023 – III 2024)

	Language version of Wikipedia	Average tenure (in years)	Activity (sum of all editions /active users no.)	Deletionism (sum of deleted editions/ active users no.)	Social activities no./sum of articles' editions
1.	Poland	16.36	1.43	1.18	70.79
2.	Slovenia	15.14	0.92	0.71	23.22
3.	Hungary	15.30	0.78	0.61	66.92
4.	Czech Republic	12.94	0.60	0.27	41.52
5.	Romania	15.27	1.01	0.82	55.04
6.	Bulgaria	16.43	0.65	0.39	0.29
7.	Ukraine	12.54	1.08	0.87	34.72

N=259, p<0,05

The average tenure of an admin is similar for the majority of versions (15-16 years) – two are distinct from the rest, namely the Czech and Ukrainian ones (12-13 years).The highest level of activity is characteristic of the Polish, Romanian and Ukrainian versions, while the lowest – the Czech one. The highest deletionism is in the Polish version, while the lowest is in the Czech one. Subsequently, admins' activity (activities concerning admins' work) from all seven countries in sum and each country separately in the period of the last 12 months were calculated (Figure 2).

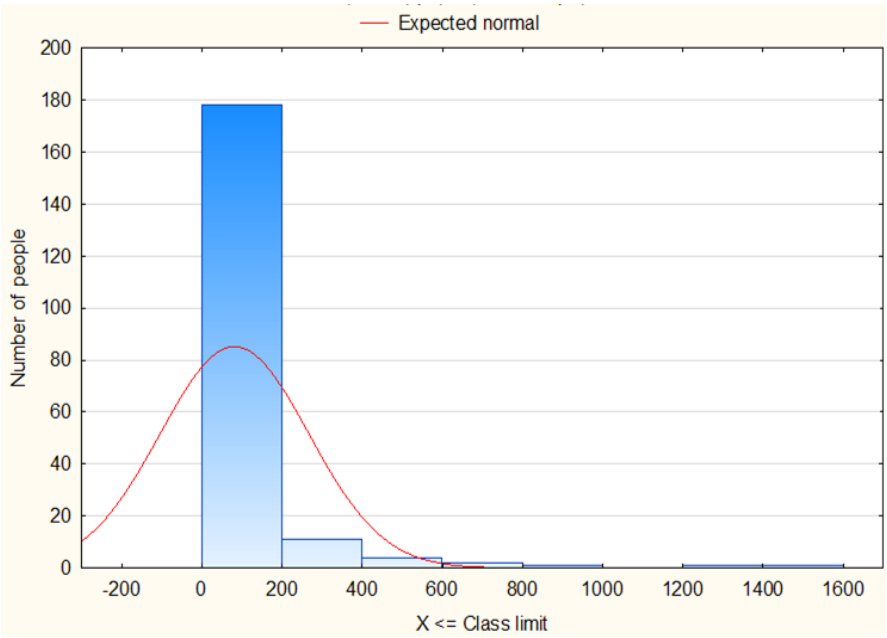

Figure 2: Admins' activity from all seven countries in sum and each country separately in the period of the last 12 months (III 2023 – III 2024)

As indicated in the diagram, the majority of admins conducts between 0-200 admin activities a year, in which the highest activity is performed by the minority of admins. Similarly, admins' activity from Poland, Slovenia and Bulgaria in the period of the last 12 months was calculated (Figure 3).

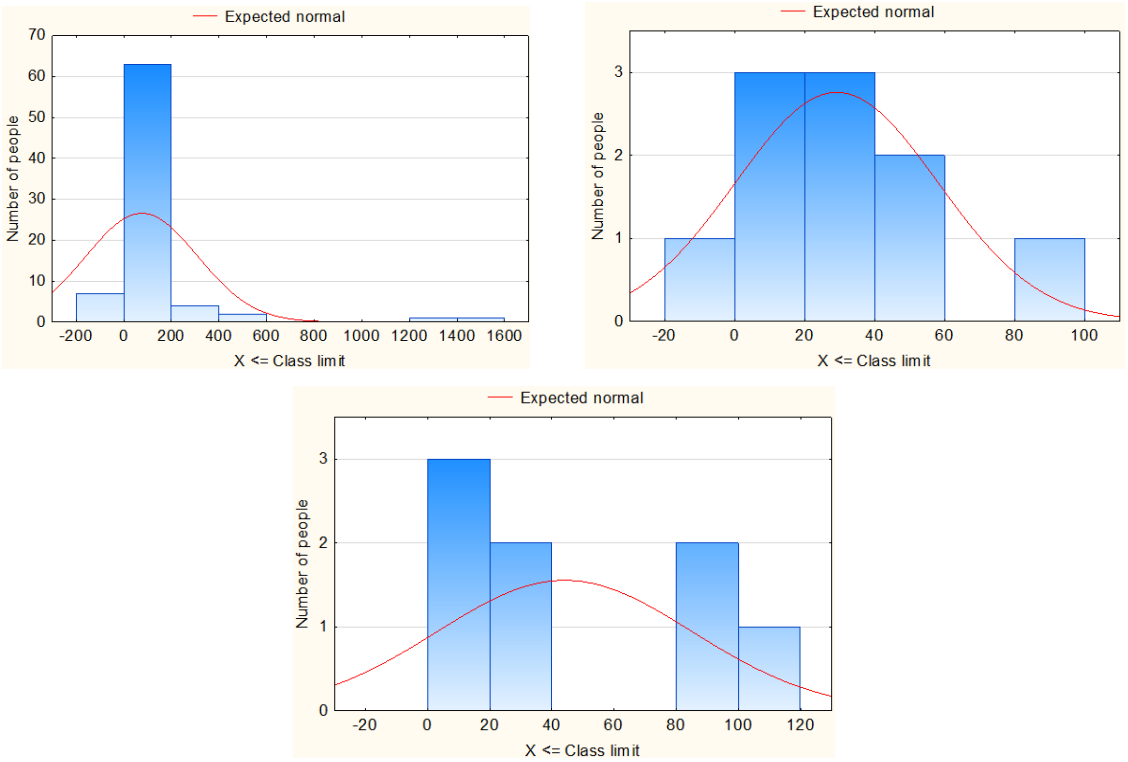

Figure 3: Admins' activity from Poland, Slovenia and Bulgaria (from left to right) in the period of the last 12 months (III 2023 – III 2024)

It turns out that in the countries with smaller numbers of admins, the work and responsibility are distributed more evenly than in the countries with relatively higher number of admins.

The descriptive statistics concerning admins' activity in the period of the last 12 months– all seven countries in sum and individually were prepared, while the mean, median and quartiles of the number of created articles were also determined.

Table 3: Descriptive statistics describing admins' activity in the period of the last 12 months– all seven countries in sum and individually

	Language version of Wikipedia	Mean	Median	Minimum	Maximum	Lower quartile	Upper quartile	SD
1.	Admins' activity in the last 12 months period (from all 7 studied versions)	81.49	16.50	1	1482	3	74	185.53
2.	Poland	91.33	14	1	1482	4	52	242.27
3.	Slovenia	38	35.50	1	101	2	68	36.89
4.	Hungary	81.83	13.50	1	456	5	142	130.37
5.	Czech Republic	55.36	16	1	310	4	82.50	77.88
6.	Romania	79	17	1	732	4	64	190.23
7.	Bulgaria	74.50	63.50	7	162	28.50	121.50	56.79
8.	Ukraine	93.02	16.50	1	858	2	114	174.74

N=259, $p<0,05$

As indicated in the calculations, some countries are characterized with increased levels of average admins' activity (Poland, Ukraine), while some are placed below the average (the Czech Republic, Slovenia). The highest median of activity was in turn displayed by Bulgaria. The complete data are presented in Table 3.

There were no statistically significant correlations observed between cultural dimensions and content-oriented activity. Power distance correlated with deletionism, social activities no., and the proportion of social activities

no. to article editing. Long-term orientation correlated with three variables: deletionism, expression of thanks, and social activities no. Uncertainty avoidance correlated only with the proportion of social activities no. to article editing, and masculinity with the proportion of social activities no. to article editing, deletionism, and social activities no. The more individualized and long-term oriented culture was, the more thanks were expressed per edition. The lower power distance, individuality, and femininity characterised a culture, the more deletionism was in its version of Wikipedia. All correlations are presented in Table 4.

Table 4: Correlations of Spearman's rho between cultural dimensions of Hofstede and social and content-oriented activity of admins

Hofstede cultural dimensions		Social activities no./ Sum of articles' editions	Deletionism (average percentage of deleted editions)	Expression of thanks (thanks/sum of all editions)	Editions in the space: article (content-oriented)	Social activities no.
1.	PD	-0.56727	-0.48102	-0.12165	-0.02418	-0.16130
2.	Indiv	-0.28559	-0.74024	0.14343	-0.08670	-0.09231
3.	Masc	0.42138	0.79939	0.01982	0.08244	0.23033
4.	UA	-0.47857	0.05437	0.00430	0.03774	-0.03732
5.	LO	0.10714	-0.54779	0.24931	-0.06864	-0.20248
6.	Indulg	0.01468	0.18698	-0.18057	-0.01672	0.04608

N=259, p<0,05

Pfeil et al. (2006) indicates that culture influences numerous web behaviours of Wikipedia users, e.g. high power distance decreases deleting activity, while individualism facilitates adding and corrective actions. High uncertainty avoidance would have a negative impact on the total contributions of all these three types of activities. In this study, only masculinity correlation confirmed the expectation. Orientation towards success and effects, typical of more masculine cultures facilitates making more deletions. Contrary to the Pfeil study, in terms of administrators, both levels of PD and individualism decreased the level of deletions made to the admins' editions. This may be explained by potential intimidation before correcting someone who has got some "power" in the community. Social activities were positively correlated with masculinity and negatively correlated with power distance and long-term orientation. The third hypothesis was only partly confirmed.

Teng et al. (2022)in their study of Bahamut community administrators concluded that taking on a social role of an administrator helps to initiate the role-appropriate behaviour of opinion leadership and public space contribution rather than private space contribution. As results from the conducted study in the space of Wikipedia, the administrators in South Eastern European versions of Wikipedia take public responsibility for the community and their proportion of social activity editions to all editions is high (with the exception of one version). However, they do not abandon the content contribution and continue to create articles. Their content-oriented activity does not seem to be culturally dependent, thus it may be oriented towards the common ethos of work to the benefit of Wikipedia. The fourth hypothesis was rejected.

Taking up an administrator's role may be connected with expecting peers' recognition, whereas in Wikipedia this role is respected by the users, which is a socio-psychological form of reward for the efforts for the community (Kuznetsov 2006, p.5). The longer the tenure of an admin, the higher the level of social engagement observed. Likewise, the longer the tenure, the higher the contribution to the content of Wikipedia. Moreover, in more masculine cultures the tenure tends to be longer. The first hypothesis was confirmed and the latter was partly confirmed (only uncertainty avoidance was not correlated with tenure). More experienced editors see Wikipedia not only as a set of articles, but also as a community of editors, so are more likely to admit to social and community factors as important motivators to contribute (Baytiyeh and Pfaffman 2009). Wikipedia administrators place great value on social motivations and the creation of Wikipedia articles as public artefacts comparing to other aspects of their activity.

Research by Picot-Clémente, Bothorel, and Jullien (2015) emphasizes the significance of contribution quality and peer recognition in the admin selection process. In the space of Wikipedia, 80% of contributions are made by only 2.4% of users (Crowston, Fagnot, 2018, p. 90). Similarly in the results of this study, the highest number of

editions are performed by the minority of admins. However, it turned out that in the countries with smaller numbers of admins, both the work and responsibility are distributed more evenly than in the countries with relatively higher numbers of admins, where the responsibility may be dispersed.

5. Conclusion

This study focused on determining how different types of admins' contributions are influenced by particular cultural factors and what kinds of contributions are shaped by cultural context. Based on the data that the author collected, it appears that the tenure of an admin is correlated with his/her social activity and content activity. The more experienced the admin is, the more active he/she is in both spheres. When analyzing how contributions are shaped by cultural context, there are a few aspects that we determined. Firstly, the tenure of admins is correlated with all cultural dimensions, except uncertainty avoidance. While social activity, including expressing thanks for contributions and making deletions are at least partly culturally dependent, the content-oriented activity did not correlate with any of Hofstede cultural dimensions. While analyzing the data, the author found unexpected results, particularly relating to the fact that in Wikipedia versions with fewer administrators, there is a trend towards a more equitable distribution of work and responsibilities compared to countries with a larger administrative group. This results in a potentially more balanced dispersion of responsibilities across administrators.

The conclusions from the study may be of interest to the administrators of volunteer virtual communities, where the engagement and contributions of participants may be unstable and varied, while also not remunerated. Organization of this type of communities of practice is specific and different from typical virtual teams. It is also varied in terms of cultures engaged in knowledge creation. The administrators or managers could adapt to different conditions in terms of their quality-oriented activity (such as deleting/correcting participant contribution) or motivating activity (such as thanks offered for the contribution). The community could also put forward a subject of discussion regarding the length of administrators' rights and number of administrators, as it may have an influence on the activity and division of responsibilities between admins. Additionally, future analysis of a wider group of language versions of Wikipedia would help in understanding the cultural conditioning of management and organization of work better in virtual communities of practice.

Abstract: Knowledge sharing in organizations is a focal process leading to organizational adaptability and sustainable growth. Dynamic capabilities development is critical for this. Diversity, inclusive culture, and gender balance are seen as factors that also support organizations' development. The question of the role of gender in sharing and using knowledge to initiate change in organizations remains open. This study aims to fill this gap. Based on a survey targeted to Polish knowledge workers (495 cases), our data was analyzed using OLS regression (SPSS PROCESS software ver. 3.4). Our research shows that for a manager position, gender matters for the reconfiguring dynamic capability (DCR) building in the organization, thanks to tacit knowledge sharing (TKS). The results show that female managers support DCR in the organization even if TKS does not support their efforts. If supported, their positive influence on DCR grows but not as fast as observed for men with lower starting skills. So, when holding managerial positions, women lose motivation to support changes. The question that arises is "why"? There are some hypothetical assumptions: it might be that since women worked so hard to earn their managerial positions, they want to secure them and avoid any risks connected to changes. In the particular case presented, women managers' lower willingness to support changes may be also caused by their lower level of self-confidence. However, it might be that the reasons are quite different, thus solving this issue requires further studies. The critical value of the presented research is that it delivers one more proof, this time from the knowledge management (TKS) and change implementation (DCR) perspective, that gender inequality in workplaces has negative consequences for organizations.

Keywords: Gender, Tacit Knowledge Sharing, Explicit Knowledge Sharing, Dynamic Capabilities, Reconfiguring Dynamic Capability (DCR)

1. Introduction

Organizations operate in unpredictable environments and face various internal and external conditions that often force them to change, and the best of them can reshape quickly. Challenging conditions act as stimuli, making an unexpectedly good environment for companies to gain or maintain an advantage over competitors through constant learning and innovativeness (Kucharska and Rebelo, 2022). That is possible due to the agility and reconfiguring aspect of dynamic capabilities. Both agility and dynamic capabilities are supported by knowledge management, especially while selecting the best approaches, suitable to particular circumstances (Zięba et al., 2022).

Teece et al. (1997) defined dynamic capabilities as “the firm’s ability to integrate, build, and reconfigure internal and external competencies to address rapidly changing environments.” (Teece, et al., 1997, p. 516). In other words, dynamic capabilities are the organizations‘ abilities to sense and shape external factors, seize opportunities, and improve, merge, protect, and reconfigure assets when necessary to sustain competitiveness. To do so, unique processes of learning about market conditions and customer's needs are applied (Teece, 2014). Reconfiguring dynamic capability (DRC) directly impacts innovation and organizational development. The capabilities of acquiring and creating knowledge contribute to the reconfiguring capability; therefore, they contribute to innovation indirectly (Zheng et al., 2011). It is evident in the incorporation of existing knowledge to create new frameworks. Those processes are especially the implementation of open innovation, cooperation, application of market needs (Ince and Hahn, 2020), development of technology, rearrangement of the workplace (Khan et al., 2020) decentralization of power (Bhardwaj et al., 2021), flexible connecting structures, and cost-cutting (Vallaster et al., 2021), to name a few. Knowledge management systematically implements techniques and tools to identify, analyze, and respond to any knowledge-related issues in an organization (Durst et al., 2016), and this way support dynamic capabilities.

Knowledge may be labeled as explicit or tacit (Nonaka and Takeuchi, 1995) and those categories significantly differ. The more formalizable, manageable, and transferable knowledge pieces belong to the category of explicit ones (Nonaka and Takeuchi, 1995; Faccin et al., 2019). On the contrary, tacit knowledge is often stored in people's minds as experiences, personal beliefs, values, and ways of looking at things (Saint-Onge, 1996). Both types are crucial for innovation (Henri, 2016) and change adaptability (Park and Kim, 2015) when distributed across structures and systems. However, tacit knowledge awareness and sharing through ‘learning by doing’ or ‘social interactions’ are widely acknowledged to be an important component of organizational innovations in

particular (Kucharska and Erickson, 2023). So, knowledge sharing is a focal process for the constant transformation of the tacit kind to explicit and the creation of new tacit thanks to grounded explicit.

Wang and Noe (2010) defined knowledge sharing as a set of behaviors regarding information exchange or assistance. It goes beyond passing the information since the information must be internalized and integrated into the knowledge base of the individual first (Heisig and Kannan, 2020). When knowledge is well distributed and used in processes like task completion, decision-making, and problem-solving it has an impact on organizational innovation and performance (Heisig and Kannan, 2020). Reportedly, knowledge sharing increases team effectiveness (Yoo et al., 2022), making it critical for achieving, sustaining, and improving team effectiveness in environments characterized by unpredictability (Edmondson et al., 2007; Mesmer-Magnus and Dechurch, 2009). Also, it is linked to employee satisfaction (Wang and Noe, 2010; Zheng et al., 2010). The better knowledge-sharing practices among the team members, the more learning opportunities, and individual sense of achievement (Yoo et al., 2022). The learning climate, psychological safety, trust, collaboration (Kucharska and Kowalczyk, 2016; Andersson et al., 2020), social interactions (Ryan and O'Connor, 2013), mentoring (Olaisen and Revang, 2018) and stakeholder engagement (Easterby-Smith and Prieto, 2008) facilitate knowledge sharing, in its both explicit and tacit forms. Thus, knowledge sharing in organizations is a focal process leading to organizational adaptability and sustainable growth. Dynamic capabilities development is critical for this. Diversity, inclusive culture, and gender balance are perceived as factors that also support organizations' development. The question of the role of gender in sharing and using knowledge to initiate change in organizations remains open. This study aims to fill this gap.

2. Conceptual Framework

Recently, some researchers have argued that gender must be included in knowledge-sharing research since it influences organizational structure and behavior (Paoloni and Lombardi, 2018; Scuotto et al., 2022). At the same time, others note that this issue has not been properly investigated, and there are still too few studies analyzing the link between knowledge sharing and gender (Heisig and Kannan, 2020; Yoo et al., 2022). Existing studies show that this research area is an interesting topic to take a closer look at (Paoloni et al., 2022). For instance, it has been shown that women are more prone to knowledge-sharing than men in certain circumstances (Nguyen et al., 2019). They generally spend more time on socialization which fosters knowledge sharing (Denise and Byosiere, 2007). It indicates that gender diversity positively influences knowledge-sharing (Jayasingam et al., 2016), possibly because diversity makes internal communication more open (Lee et al., 2020). So, gender factor studied in the context of knowledge sharing can bring interesting implications. This study focuses then on the role of gender in sharing and using knowledge to initiate change in organizations.

Analyzing the 'state of the art', in many research papers on knowledge management, gender is being used as a moderating factor to analyze the relationships between practices, culture, and engagement. Some of them prove that gender moderates the influence of knowledge-sharing (along with unfair promotion) on affective commitment (Jayasingam et al., 2016), and the relationship between knowledge-sharing intention and knowledge-sharing behavior is stronger for females (Amin et al., 2011; Grubic–Nesic et al., 2015). Contrary to the above statements, some other works prove a lack of a significant relationship between gender and knowledge sharing (Killingsworth et al., 2016; Makela et al., 2012; Al Muzaffar and Alshare, 2015). Instead, Marouf (2015) showed that the combination of gender with other factors had a significant effect on knowledge sharing, precisely sector factor (public vs private), and Heisig and Kannan (2020) noticed gender differences when different levels of education were considered. Among aspects impacting knowledge sharing among individuals, may be gender, personality, role, KM activity, behavior, and cognition (Heisig and Kannan, 2020). It shows that gender does not impact the system individually, but rather in coexistence with other factors.

One such factors is the role (or position) in an organizational structure. There is interesting evidence on how women managers are more motivated to share knowledge among internal and external stakeholders (Sheerin et al., 2020), and how their stronger (than men's) social connections impact their engagement in external knowledge management (Tonnessen et al., 2021). Paoloni and Lombardi (2022) state that greater diversity on the board of directors could improve the knowledge-sharing system. For this reason, we are especially interested in researching the moderating effect of gender and position on knowledge-sharing and reconfiguring dynamic capability (fig. 1). Recently, Kucharska and Karwowska (2024) proved that explicit and tacit knowledge-sharing impacts the 'reconfiguring' component of dynamic capability (Jantunen et al., 2018; Teece, 2007). Kucharska (2024) and Kucharska and Kopytko (2024) showed that gender factors that influence power are often related to position. Therefore, taking into consideration all the above, the following hypotheses were developed:

H1: Gender moderated by position does moderate the relationship between explicit knowledge sharing and reconfiguring dynamic capability (moderated moderation is expected).

H2: Gender moderated by position does moderate the relationship between tacit knowledge sharing and reconfiguring dynamic capability (moderated moderation is expected).

Figure 1 below visualizes the explored relations.

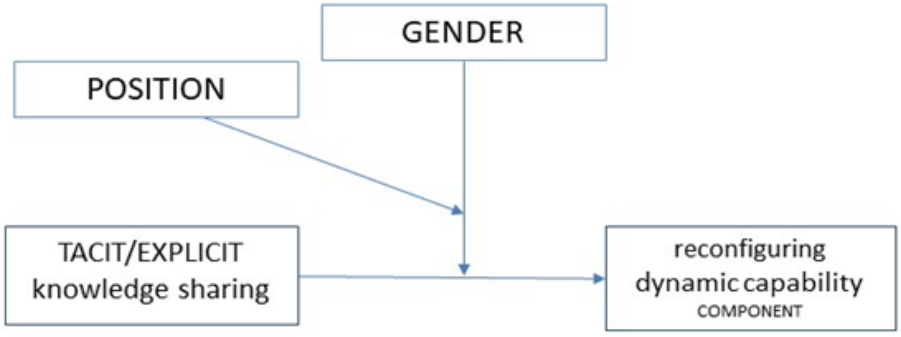

Figure 1: The moderating effect of gender and position on knowledge sharing and reconfiguring dynamic capability

3. Method

This study is based on a survey targeted at Polish knowledge workers (495 cases). Data collection took place in March 2023 using the computer-assisted web interviewing method. Classified respondents declared their 'knowledge worker' status as persons whose work input and output is knowledge. Next, they referred to statements measuring constructs of the interest using a 7-point Likert scale, which was transformed to composite variables for this particular study and method of data analysis purpose. Collected data were next analyzed using OLS regression (SPSS PROCESS software ver. 3.4; Hayes, 2018). Scales measuring particular constructs were adapted from the following sources: tacit and explicit knowledge sharing (Kucharska and Erickson) and dynamic capability 'reconfiguration' component (Jantunen et al., 2018, after Teece, 2007).

The sample structure included 247 specialists and 249 managers, 251 women and 249 men working mostly in private (77%) companies in different sectors. Micro (14%), small (28%), medium (31%), and large companies (26%) were almost equally represented. Measures quality was conducted based on implemented construct measurement consistency tests: the average of variance extracted (AVE), composite reliability (CR), and Cronbach's alpha. AVE exceeded 0.57 for all constructs, which was acceptable (Hair et al., 2017). Cronbach's alpha test was used to confirm the consistency of the construct measurement model. The alpha coefficient was greater than 0.89 for all constructs, which was adequate (Hair et al., 2017, p.112). The CR was greater than 0.80 for all loadings, which was more than the required minimum of 0.7 (Hair et al., 2017).

4. Results

Explicit knowledge sharing and reconfiguring dynamic capability analyzed per gender and position based on this sample did not expose a significant result (H1). The tacit knowledge sharing and reconfiguring dynamic capability analyzed per gender and position based on this sample – opposite (H2). Figure 2 and 'model summary' expose the details of the results obtained.

The results showed that gender does not moderate the relationship between tacit knowledge sharing and dynamic capability – reconfiguring as long as the 'position' factor is not included in the analysis. After the 'position' factor inclusion (moderated moderation analysis), it is visible that for specialist women and men, the explored relation is equally insignificant. But, for a manager position, gender matters for the reconfiguring dynamic capability (DCR) building in the organization, thanks to tacit knowledge sharing (TKS). The results show that female managers support DCR in the organization even if TKS does not support their efforts. If supported, their positive influence on DCR grows but not as fast as observed for men with lower starting skills. In other words, male managers better support organizational DCR if others support them.

5. Discussion

Our research findings indicate that women who are supported better support others regarding knowledge sharing. Those results enrich previous research findings as an important voice in the discussion on the role of gender and position in KS and DCR processes.

Till today, some researchers have not found a link between gender diversity and knowledge sharing, rather indicating the moderating effect of age or regional diversity (Li et al., 2022). Others show that the biological sex of employees moderates the impact of managers' inclusive leadership on knowledge-sharing behavior (Morinaga et al., 2023). Inclusive leadership impacts knowledge-donating practices in groups with higher biological-sex diversity and does not affect groups with lower biological-sex diversity (Morinaga et al. 2023). Our findings support the latter part.

Still, one may ask a question: how do organizations support women so they can support others and facilitate the KS and DCR practices? Taking into consideration our research findings, inclusive leadership is one of the key concepts to apply in organizations. Nembhard and Edmondson (2006) characterized inclusive leaders as those who demonstrate openness, accessibility, and willingness to interact with subordinates (Carmeli et al., 2010). This idea was conceptualized by Randel et al. (2018) as a combination of leadership behaviors that make the team members feel they belong to their team and foster their creativity (Mansoor et al., 2021; Ye et al., 2019). Those behaviors include providing support, ensuring justice and equal opportunities, encouraging diverse contributions and participation in decision-making (Al-Atwi and Al-Hassani, 2021; Randel et al., 2018), while promoting team members' uniqueness without changing their key identities (Randel et al., 2018; Nguyen et al., 2022). It suggests that welcoming and supporting women on higher organizational levels and celebrating their uniqueness is beneficial for the companies.

Randel et al. (2018) argued that inclusive leadership trickles down: the supervisor's behavior encourages similar behavior among team members, so they support and include their colleagues. Similarly, other researchers observed that "when a leader shows inclusiveness, team members who feel psychologically attached to a team are more likely to exchange their knowledge with each other, which further influences team performance" (Yoo et al., 2022). It is also evident in our research findings.

6. Limitation, Implications and Further Studies Suggestions

The key limitation of this research is that it is based on data collected in only one country. Still, more studies is needed to understand the role of gender and position in KS and DCR. Experts gather that the gender aspect is a relevant topic of study in the future (Heisig, 2015). Our findings as well as other recent works in the majority show that gender does matter regarding knowledge sharing but more research is needed to contribute more substantial evidence to these first initial results and avoid "the risk of replicating or overemphasizing the influence of gender" (Heisig and Kannan, 2020). One of the interesting research directions inspired by the results of this study is why women lose the motivation to support changes when become managers. There are some hypothetical assumptions: it might be that since women worked so hard to earn their managerial positions, they want to secure them and avoid any risks connected to changes. Women managers' lower willingness to support changes may be also caused by their lower level of self-confidence. However, the reasons may be quite different thus solving this issue requires further studies. In this study we also have not considered how stereotypes and expectations related to gender affect the knowledge-sharing experiences in organizations, which may be another interesting research focus (Miralles–Vazquez and McGaughey, 2015). Researchers warn that expertise is often regarded as gendered (Azocar and Marx Ferree, 2015), meaning that stereotypes and gendered expectations about role behavior affect how knowledge is created and distributed across the organization (Heisig and Kannan, 2020). Consequently, managers, leaders, and all employees should be aware that gender stereotypes are deeply rooted in society till these times (Haines et al., 2016) so they can self-reflect on their performance. While supporting women leaders in the workplace, organizations may then support their uniqueness and cease the prejudices, rather than nourishing general roles assigned to their gender. It will benefit both organizations and their women employees.

7. Conclusion

The results showed that gender does not moderate the relationship between tacit knowledge sharing and dynamic capability – reconfiguring as long as the 'position' factor is not included in the analysis. After the 'position' factor inclusion (moderated moderation analysis), it is visible that for a manager position, gender

matters for reconfiguring dynamic capability (DCR) building in the organization, thanks to tacit knowledge sharing (TKS). Results showed that the more intensive tacit knowledge sharing in the organization, the more intensively managers support organizational changes. However, this relationship is more robust for male managers than females. This relationship is as strong as that of male managers for male and female specialists. So, when holding managerial positions, women lose motivation to support changes. The question that arises is "why"? There are some hypothetical assumptions: it might be that since women worked so hard to earn their managerial positions, they want to secure them and avoid any risks connected to changes. Women managers' lower willingness to support changes may be also caused by their lower level of self-confidence. However, the reasons may be quite different thus and solving this issue requires further studies.

Abstract: When unexpected incidents occur, such as fire outbreaks or floods, individuals who lack knowledge on how to handle such events are often shocked and unable to act efficiently. Virtual Reality (VR) technology promises to compensate for the lack of traditional teaching environments by immersing users in virtual learning environments with real-life relevance for many emergency scenarios. The primary objective of this paper is to provide a better understanding of how to raise awareness of emergencies and learn to manage unforeseen situations using VR games. Based on a theoretical background examining available literature on Knowledge Transfer (KT), VR and learning theories, we illustrate a case depicting how to handle a fire emergency at a school building. The case describes a VR game to inform students about the necessary steps for preparedness and discuss its utilization as an educational module in a course. Based on this, an Inclusive VR for KT (IVR-KT) framework is proposed that contributes to increasing the understanding of planning and assessing emergency preparedness training in education. The games included in IVR-KT will be developed using retrieved real-time and historical data with a special emphasis on inclusivity aspects by addressing a wide range of users regardless of their personal limitations and constraints. By presenting the framework and providing examples of its key components, the paper introduces new ways of considering KT for emergency preparedness training in education for handling unforeseen incidents.

Keywords: Emergency Preparedness, Evaluation, Knowledge Transfer, Virtual Reality, Serious Games, Education.

1. Introduction

With an increasing demand for practice-based learning and Knowledge Transfer (KT), new innovative ways of learning are crucial. Virtual reality (VR) based Serious Games (SG) are games designed for educational purposes rather than just entertainment. They offer a unique opportunity to simulate various scenarios where the participant can interact in a computer-generated environment while experience the consequences of their actions simultaneously. These actions are critical in emergency services, and therefore, hands-on training plays a crucial role in building skills, maintaining expertise, and strengthening readiness for unforeseen circumstances. Besides natural disasters, there are many man-made unexpected situations, such as fire, terrorist attacks, and transport accidents that may occur in our daily lives. These events can also cause injuries and damage, extensive and lasting physical and mental harm (Valcik and Tracy, 2017), as well as economic losses (Shaluf, 2007). According to the European Fire Safety Alliance, cautious estimates suggest that every year, over 5,000 people die from residential fires in Europe (European Fire Safety Alliance, 2024). Economic losses from natural disasters affected 50 million people in the EU between 1980-2020, and caused an economic loss of €12 billion per year (Majdik et al, 2023). Losses at such a large scale may cause unexpected ripple effects, for example, delaying Eurozone membership and enabling democratic backsliding (Arató, Koller and Pelle, 2021).

Emergency preparedness training is essential in conveying the importance of self-help and mutual assistance. Historically, various methods have been used, including videos, posters, and physical disaster exercises. Nowadays, the integration of cutting-edge technologies such as VR and SG presents promising new avenues for effectively training citizens (Hsu et al., 2013, Heldal, 2016). VR technology, widely recognized for its immersive capabilities, offers a versatile tool applicable across various educational contexts (Collins et al., 2021, Goedicke et al., 2018), and it is already gaining presence in training and decision support for first responders and civil defense (Székely, 2015).

Handling an emergency can be difficult for citizens involved, who must act in an organized way under time pressure. People are also more prone to commit errors in stressful conditions. By integrating VR via module into

a training program that teaches how to cope with life-threatening incidents, learners can repeatedly practice mastering the required knowledge and skills without the risk of incurring costs or triggering accidents that often may occur in real-life situations (Hammar Wijkmark et al., 2019, Song et al., 2021). This module is part of a European Union-funded project, B-prepared (see B-prepared, 2024), and the knowledge assessments are tracked via a back-to-back LMS (Learning Management System) solution between the B-prepared LMS and the LMS of the educational institution. This can allow tracking both individual knowledge progression as well as organizational level KT, for example the KT Metrics developed by the European Commission Expert Group (2009, 2022) for public research organizations. In this context, we further investigate the possibilities of VR interaction mediums (voice command, gesture recognition) and dynamic scenario design (e.g. wheelchair users' evacuation process), allowing to consider escape opportunities for people with, e.g., visual and motor impairment.

In such context, this paper presents the Inclusive VR for KT (IVR-KT) framework for achieving the KT within an educational institution of self-help in emergencies. The structure of the article is as follows: Based on existing projects in the field of VR-supported training, we first describe the fundamentals of KT in VR. We then explain how inclusive immersive training may help KT in disaster preparedness and engage students and teachers to learn by using new technologies. A case presenting a pilot VR prototype for a school fire evacuation scenario is sketched. We conclude this paper by discussing the opportunities of utilizing VR for KT and presenting the potential of the framework to teach life-threatening situations in a more engaging way by introducing an elective course module.

2. Background

2.1 Knowledge Transfer and Virtual Reality for Training Emergency Preparedness

Numerous publications have addressed issues related to Knowledge Management (KM), emphasizing the pursuit of efficient KM by seeking optimal methods and approaches (Wiig, 1997). A pivotal aspect of KM involves the dissemination and accessibility of knowledge within and across selected organizations. Schwartz (2006) asserts that knowledge transfer (KT) is a foundational societal process crucial for learning, which, in turn, drives development. While knowledge sharing (KS) and knowledge transfer (KT) are sometimes used interchangeably, the literature suggests that KS is predominantly utilized when focusing on individuals, whereas KT is more commonly employed when examining groups, departments, organizations, or businesses (Argote and Ingram, 2000; Choo and de Alvarenga Neto, 2010).

But how does anyone know whether the knowledge acquired in a VR environment is effectively transferred to the real world, and which basic characteristics will ensure KT from VR training to real world practices? While VR training has many already identified benefits (Xie et al., 2021), virtual simulations offer a significant advantage in terms of cost-effectiveness compared to traditional training methods for, e.g., firefighters on training grounds or in classrooms (Heldal and Hammar, 2017; Lamb et al., 2020; Hammar Wijkmark et al., 2021) or relevance, confidence (Ooi et al., 2019; Pedram et al., 2021).

In the last decades, many research studies have addressed the potential of VR for KT. For instance, Khanal et al. (2022), Grassini and Laumann (2020) report in their literature review that VR training can help prepare individuals for real-life emergency scenarios. VR has also changed how we engage with the type of VR we using, which, in turn, influences experiences and performance (Heldal, 2004). While there are VR technologies running on everyday computers, these are called non-immersive technologies, and others immerse the users in the simulated 3D technologies, e.g., head-mounted displays (HMDs); and these are called immersive technologies (Slater et al., 2018). VR is also useful for training in scenarios that are difficult to simulate in the real world, e.g., large forest fires, incidents in large buildings, or large public places (Williams-Bell et al., 2015; Heldal, 2016; Reis and Neves, 2019).

According to the learning pyramid (The Learning Pyramid, 2024), students remember only 10% of what they read, 20% of what they hear, and 75% when they simulate, model, or experience the material. Since allowing high experiences is one of the main benefits of VR, our proposed (IVR-KT) allows students to experience life-threatening situations in advance, thus VR games can help learners learn more effectively since they allow users to experience the intended scenarios firsthand and respond accordingly.

From the literature, it has been seen that VR continues to serve as a valuable tool for educating individuals on essential knowledge and skills. However, challenges related to the operational aspects of VR seem to introduce unnecessary obstacles, thereby diminishing learning outcomes (Song et al., 2021) and reducing gameplay self-

efficacy (Hong et al., 2023). This disparity is largely attributed to the inadequate and reflexive utilization of VR technology, failing to account for its full spectrum of capabilities, such as permitting errors for learning purposes. Hence, the development of VR applications should adhere to sound educational theories to ensure optimal learning outcomes. It is important to determine how guidance can negatively affect the acceptance of new learning ways (Fomin et al., 2024) or how leaders contribute to the outcome (Danielsson and Sjöstedt-Landén, 2020). If the user does not know how to make progress in the training, frustration can arise, and their willingness to learn may be reduced. Simplified representation of work steps as well as the lack of multimodal stimuli during VR training, can negatively influence the learning effect. In these contexts, human-computer interaction (HCI) guidelines play a significant role in the design of VR applications (Luo et al., 2021).

3. Methods

We propose the IVR KT framework based on literature from Knowledge Management (KT and KS), VR-based learning, e.g., investigating learning theories and cognitive learning models. It is inspired by the Trifecta model suggested by de Vaujany and his colleagues (De Vaujany et al., 2018), further developed for identifying patterns for VR for training for emergency professionals (Heldal et al., 2018).

The framework identifies aspects of how to teach emergency preparedness in a course module utilizing VR game via B-prepared created LMS API (Application Programming Interface) integration to educational institutions' own LMS, and the knowledge assessments are tracked via a back-to-back LMS solution between those two LMSs. B-prepared LMS has developed in such a way that it can automatically detect knowledge transfer metrics where players can see their individual progress (Majdik et al., 2023). Students can also learn relevant disaster-related knowledge by getting access to 'Disastropedia', a knowledge-sharing platform (see Disastropedia, 2024). In a course module, students receive all the available resources that fit this concept. To allow VR training to be handled via a solution between two LMS systems in a course module, the B-prepared LMS has a built-in player knowledge assessment tracking feature, and the educational institution provides all other resources, IT tools, and rules.

The defined IVR KT framework (see Figure 1) has five layers: a) the technology and other resources utilized, e.g. databases, repositories, resources for games (as the "IT technology" from Trifecta) together with b) influencing rules from the organization (as the "Rules" from Trifecta), c) information on managing VR training (this is a new layer, but necessary to be designed separately), d) involving practices for utilizing VR game based learning (as the "Practices" from Trifecta) and e) for the participants (this is a new layer, for teachers and students). Considering a new training module (a layer a) may influence some or each other layers since they have different mechanisms. Accordingly, we can use the same framework for different training situations. For example, if students want to learn how to handle a school fire systematically, the specific steps they need to take will depend highly on the scenario. The scenario depends on many circumstances, such as accessible buildings, people around, or the exact place of the incidents. This framework can potentially be used for various courses and students, but it is essential to consider issues that may vary. This should possibly be used for various courses and students, one needs to consider issues that may vary. For example, a and b) the technical resources, the current rules needed to be considered (how emergency training needs to be planned at a school) c) considering an existing scenario that needs to be used and further developed for a specific training situation, d) providing examples of applied practices, e.g. who needs to do what for finding escape routes, helping others, or reporting to emergency professionals, and e) considering the participants and their abilities (e.g. with or without functional problems). Through this, we intend to provide a better understanding of important parts of a situation necessary for KT for trainees.

4. Emergency Training

4.1 The Proposed Framework

For VR training in an educational institution as part of the course curriculum, teachers and students will have access to current VR resources and can also update the framework with information continuously. The aim is that teachers could get support for setting up VR training, and students will form teams and thoroughly brainstorm in order to learn about various emergency preparedness in immersive environment. They can experience VR games with the aid of API integration to existing game code repositories as well as design their own scenarios or new design ideas. Accordingly, new features and scenarios may be developed, which will make

learning more interesting and rewarding. For the architecture of the IVR KT framework, inspired by the Trifecta model) see Figure 1.

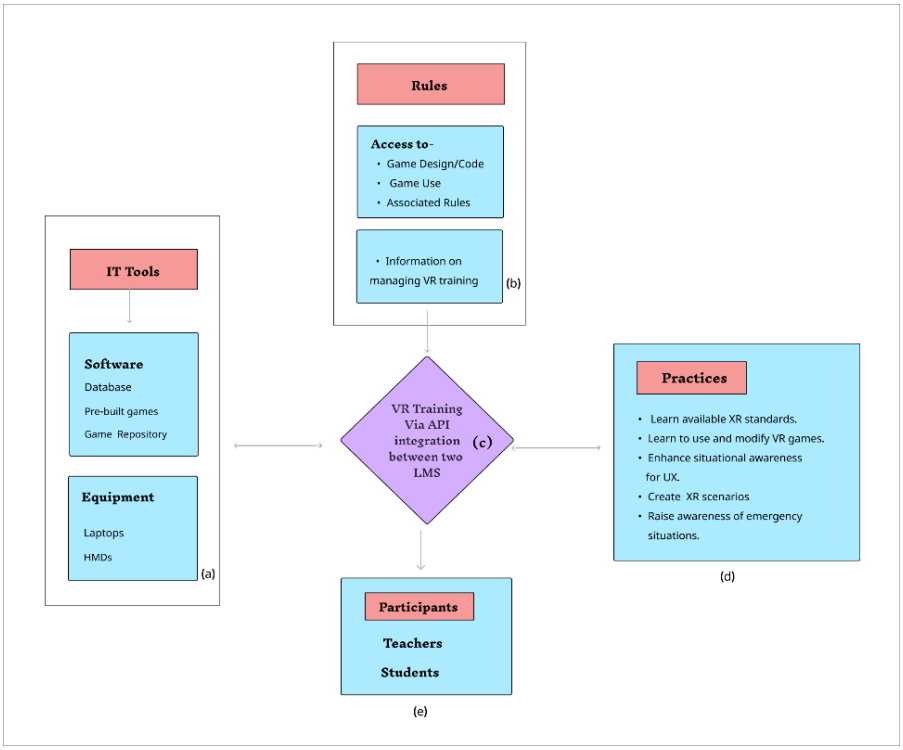

Figure 1: IVR-KT Framework. It has a total of five layers where layers a and b may vary depending on necessity. Layer c is the VR training that will be done via B-prepared LMS API integration into the educational institution's LMS.

We are using the terminology introduced by De Vaujany et al. (2018) for considering digital technologies in organizations. This terminology focused separately on IT technology (a), Rules (b) and Practices (c), but additionally accentuates the main participants due to their different roles and enhances the necessary integration between the two LMS for the actual training (c). Every module can be modified, e.g., the software extended by new games, equipment with new technologies, or the used game with new storylines for different educational modules.

4.2 The Proposed Architecture for VR Games Framework

Since existing games play a central role in the framework, we discuss here some basics that can be included in most of the VR training situations. The proposed VR application is a 3D game environment designed to familiarize students with emergency situations as well as teaching about new technology and XR standards. The design aims to produce an engaging game to increase public awareness and support decision-making in emergencies. The main parts of the architecture (Figure 2) include a data layer, VR game models, and user interface (UI). The game utilizes gamification techniques based on historical data to trigger engagement and learning. The design follows specific learning goals related to situational emergency incidents and general safety knowledge on that field (e.g. fire, flood) and consists of various learning elements. Time-constrained tasks require players to make prompt decisions under stress and provide a unique opportunity to study user behavior. Players will be able to choose from existing locations for scenarios (e.g., Norway school fire incidents) or create a custom scene by setting various parameters. Voice input and gesture recognition are also planned to be used to analyze players' reactions to game-related incidents and detect emotional and psychological states.

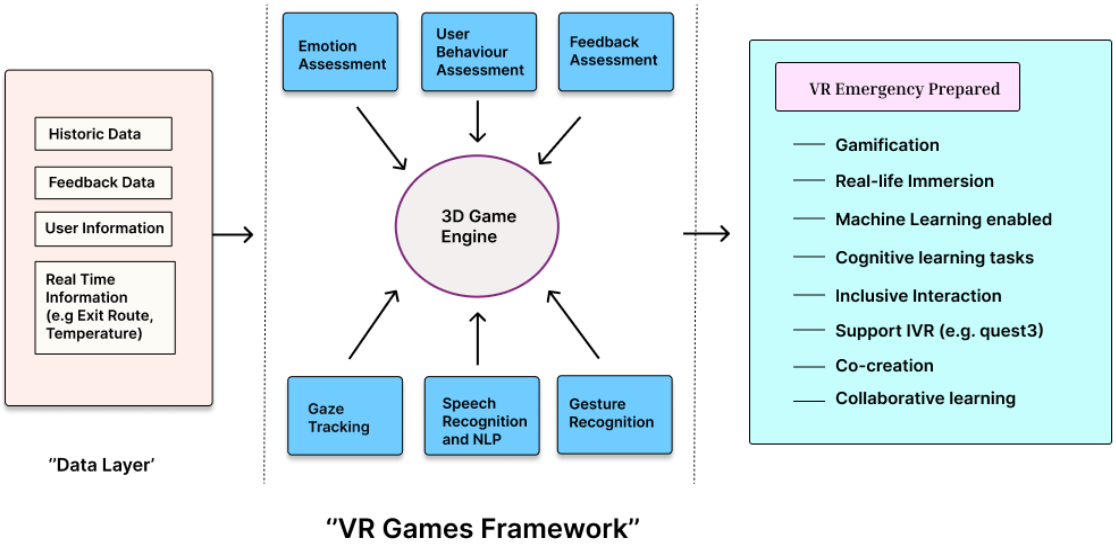

Figure 2: Main architecture for supporting KT via VR games for training. The game architecture includes a 3D game engine with different interaction mediums. Data Layer consists of different types of data which plays a significant role in the VR game framework.

The increasing interest students have in technology and VR provides an opportunity to improve the effectiveness of teaching environmental sciences and social responsibility by implementing this framework. The application incorporates retrieved real-time drill data to generate the environmental conditions necessary for simulating scenarios accurately. The temperature, visibility, smoke detection, length, and intensity of the precipitation, as well as the observation location and time, are all included in the retrieved real-time and historical drill data. Players will be able to wear a haptic suit to feel the temperature of specific scenarios (e.g. feeling warm when fire breaks) to increase the presence of the application as well as user experience and realism. Users will be able to select places and interact with accessible scenarios if data is stored in those specific locations. Different drill data from various locations are stored following the FLAIM framework to protect individual privacy while facilitating collaborative data exchange (Slagell et al., 2006). The game requires players to complete a variety of activities in a timed round to keep it interesting and effective. One of the important aspects of the framework is that users themselves can create scenarios in the game engine and provide feedback for improvement. Those feedback and user behavioural analysis data will work as a base for continuous improvements. From user behaviour patterns, it is possible to detect the most common patterns, e.g., mistakes, navigation, orientation, manipulation, data can help to design more user-centric tasks.

Under the United Nations' social inclusion principle, the Convention on the Rights of Persons with Disabilities (CRPD) requires all UN member countries to ensure that disaster awareness, preparedness, and response efforts are inclusive and accessible to individuals with disabilities (Inclusion Made Easy, 2012). Therefore, emergency preparedness training should follow Universal Design Principles (European Disability Forum, 2010). Our suggested system provides gaze tracking, gesture recognition, and voice interaction with natural language commands. These features increase accessibility and create an inclusive learning environment for everyone, regardless of their personal limitations. Additionally, Machine Learning algorithms will be used to evaluate behavioral analysis, feedback, and student learning patterns to adjust VR content in real-time scenarios. This will support the creation of more user-centric tasks design to ensure learning outcomes, which are necessary for KT. VR interaction can be difficult for untrained and disabled users, therefore our framework offers a variety of interaction methods, including voice command, gesture detection, controllers, and touchpads, in addition to language change possibilities, to provide an inclusive learning environment for diverse users. This ensures that a wide range of users, irrespective of their requirements and constraints, will be able to access our systems.

4.3 A Case: Considerations for a VR Game for Classroom Training

Under the guidance of our IVR KT framework, this experiment uses VR technology to build a Fire safety learning application for school scenarios. We split the fire safety education content into two categories: fire safety knowledge and practical application. The knowledge segment covers topics such as fire alarms, fire protection,

and fire hazards. First students are taught the safety information of the domain, and then they are exposed to the second category where players navigate through different fire safety scenarios. They receive interactive feedback to rectify mistakes and enhance their understanding. Essential guidelines and quizzes are pre-established to ensure students grasp the fundamental concepts. For example: What should you do if you encounter smoke while evacuating during a fire?

A. Keep running to exit quickly

B. Hold your breath and continue evacuating

C. Go back and find an alternate route

D. Stay low and crawl to the nearest exit

The game play part includes simple fire evacuation scenarios based on situational learning theory (see Figure 3). Situational learning theory ensures that learning should be placed in meaningful and complex situations so that users can take the initiative to learn and improve their ability to solve problems while making stories or, based on the available models, build up new stories within the VR app. In a game scene, a flame suddenly erupts from a cabinet in a classroom, causing the students to flee. The scenario unfolds with detailed descriptions, and users must select the correct actions. Currently there are two scenarios: the fire starts in a classroom (first floor) with all emergency exits available (Scenario 1), and the fire starts in a classroom (first floor) and only the right emergency exit is available (Scenario 2). Incorrect responses result in a potential "death," accompanied by alerts highlighting mistakes. For example, if the user is running towards the left emergency exit for scenario 2, an alert will pop up showing that the left emergency exit is closed. The simulations also feature students with disabilities to increase awareness. In one scenario, a wheelchair-using student tries to use the lift when smoke bursts. A pop-up alert shows 'wrong' choice, and help is coming within the scenarios. When the player will click "continue," it will show that help with evacuation chairs is on the way to ensure the student's safe and prompt evacuation. This situation not only teaches wheelchair users to wait for assistance and not panic, but it also raises awareness that special equipment is essential to kept in every fire safety department. The fire rescue department is not responsible for such a scenario. Thus, the organization's general evacuation plan and personal evacuation plan should include those special needs.

(a) (b)

Figure 3: Interface of the IVR KT, showing (a) the start screen, and (b) the entrance of two modules for our case.

4.4 Connection to Actual, Real Incidents and Real-life Implications

Around the world, occurrences involving school fires or residential fires are not uncommon. There's a good probability that the newspaper that contains details on a residential fire. There were twice-weekly arson attacks at schools in the small Norwegian village of 'Nordkjosbotn.' Luckily no injuries were recorded from this incident, but the damage was significant. What if the same incidents happened during school hours? Are the students ready for unforeseen circumstances? And how can we implement prevention measures? For this case VR can work as a great medium for KT on how to be prepared by themselves and increase awareness in emergency situations (Luo et al., 2021), we can implement alike situations and use the questions for discussions.

(a) (b)

Figure 4: Before the Arson Attack at Nordkjosbotn school and town hall (a) and after the attack (b).

An additional example from the beginning of the year, a deadly fire incident at a primary school in China took 13 students' lives (BBC (2024)). VR training can play a great role in preparing individuals for emergency situations not only at the physical level but also at the psychological level. To provide students with a close-to-real-life experience, our framework supports haptic devices. The scenarios are built using real-life incidents, so trainees can feel the heat, smell the smoke, and have a limited time to choose the correct exit route whenever a fire breaks out (Eilaki et al., 2022). If they go through the training multiple times, they will gain more self-assurance and be more mentally and physically equipped to deal with these situations when they arise.

4.5 The Possibilities of IVR KT Framework

As previously stated, the proposed games in the framework are based on actual events that have occurred. The tasks and scenarios are developed using detailed information from the local rescue agency. For example, the arson attack that occurred in Norway is still being investigated, and it was a pre-planned attack. Although the school has a fire alarm and the incident happened in the middle of the night, such an attack cannot be prevented by just placing a fire alarm because it takes the firefighters approximately fifteen minutes to arrive. In addition, the fire alarms identify when a fire has already started, but intruder alarms identify when someone has entered without authorization. This way, if someone is planning to create a fire from within the school building, they can be caught in the act before they even try. CCTV and automatic security lighting outside the school building can lower the likelihood of these events. By utilizing contemporary technologies, educational institutions can improve fire safety plans. VR game framework consists of two parts: 1) Educational content 2) Gameplay. The educational contents are created with a wide range of safety information, including how to prevent them, how to evacuate, and what to do if an incident occurs. This content can raise awareness among educators, students, and other authorities to take more action. Even a tiny error could potentially lead to an accident. Educational institutions may be reluctant to spend enough money on fire safety and installing all the needed equipment for night safety.

Thus, in that regard, the game scenario could look into whether all the windows and doors are properly locked at night so that no one can enter, how by installing an intruder alarm, the suspect can be caught, how not wanting to invest in fire safety led to an arson attack and what happened to recover from it, as well as presenting financial loss to give a real-life example. Everyone related to educational institutes can get all those resources, which can inspire them to be more be-prepared, in addition, for task design and improve user experience, they can also come up with new ideas to improve games design. By working together, IVR KT can contribute to a more conscious society within educational institutions, with implications for other areas.

5. Challenges for Utilizing VR for KT for Emergency Preparedness

Emergency training can be complex and challenging. While having individuals read procedures and ensuring their understanding is a good initial step, it is often insufficient. Based on the literature, we can infer that VR holds significant promise for emergency training due to its risk-free immersive experiences. Despite the great potential of VR, implementing successful VR applications can be challenging due to various social and technical factors, including task design, realism, hardware and software requirements. Since it can be challenging to evaluate and enhance the impact and value of VR training, this paper made a first approach by suggested IVR KT framework. It is based on already-existing resources e.g., data, source code, and considering existing hardware (e.g. HMDs),

but also on enabling students to gain familiarity with common XR applications and critical emergency knowledge (e.g., fire safety information). VR training should be also accessible, inclusive, and respectful of the users' preferences, needs, and rights. For example, the proposed framework can be supported by voice & gesture recognition and gaze tracking to make the system inclusive for everyone, including people with disabilities. Having a simulation that is as realistic as feasible is a desirable quality. However, users may experience psychological distress from an intensely realistic disaster simulation, and certainly, they would not like to be burned in a simulation. In VR and safety science research, there may be a trade-off between mental safety and realism in a disaster-related simulation where more research, new design ideas, and technological advancement in emergency preparedness through virtual reality training is necessary. Therefore, we think the IVR KT framework may play a significant role in imparting relevant knowledge to students and teachers so they can create new, practical ideas through a collaborative approach and the provision of already-existing materials. Since public awareness plays an important role in the effective mitigation of a disaster by arousing community interest and educating society to reduce risk from potential threats (Davis, 1989). In that regard, IVR KT can monitor and assess the learners' performance, progress, and feedback and also provides them with timely and constructive support and guidance.

6. Conclusions

This paper argues for the possibility of offering an immersive and interactive setting for training and teaching emergency planning in education. To this end, it proposes the IVR-KT framework, with the goal of addressing the challenges of making learning more engaging and increasing effectiveness by helping students create collaborative strategies for resolving real-world, life-threatening problems using VR games.

The framework uses historical data as a basis to support the creation of an inclusive VR learning environment where users have various interaction options and can collaborate in a realistic and immersive experience. We extended the Trifecta model to fit emergency training at schools and provide a seamless solution between two LMS for tracking KT. We have illustrated the basic elements of a framework that can be used for developing inclusive immersive games with a focus on accessibility, scalability, and adaptation to use cases, to enhance students' understanding of critical issues in handling emergencies. Future work includes using the IVR-KT framework and adding examples of VR games we recently developed based on the presented principles, utilizing it as a data hub for future students to achieve our goal of KT in emergencies using VR games within an educational institution.

How Enterprises Engage Generation Z in Crowdsourcing: Differences Between Poland and Great Britain

Anna Korombel and Olga Ławińska
Czestochowa University of Technology, Czestochowa, Poland

anna.korombel@pcz.pl
olga.lawinska@pcz.pl

Abstract: Companies are increasingly using crowdsourcing to gain the knowledge, experience and creativity of a given community, commonly referred to as 'crowd wisdom'. The use of crowdsourcing on a large scale is possible thanks to the space created by the Internet and social media. This space is also an environment in which the digital Generation Z, an important partner for businesses, now comprising more than a third of the world's population, is eager to spend time. Already recognized as revolutionizing for economies and markets, this generation is the most technologically advanced of all cohorts. Previously, older generations have passed on knowledge and experience to younger generations, but now we are faced with the opposite: for the first time, the youngest generation is an authority and has a wealth of knowledge that other generations do not have. The aim of the article is to identify and assess the factors that determine the involvement of Generation Z representatives in solving enterprise problems in the form of crowdsourcing and to indicate the impact of gender and place of residence of Generation Z representatives on their involvement in this activity. Empirical studies conducted in Poland and Great Britain in 2023 using the CAWI technique and a questionnaire helped to achieve the objective of this study. The results of the survey allow to indicate the most important motives for engagement of Generation Z in crowdsourcing in both countries. Relationships between the above-mentioned motives and gender and the place of residence of members of Generation Z were also identified. The conclusions of the study are only an extension of theoretical knowledge, but also implications for managers that want to encourage members of Generation Z to cooperate on the basis of crowdsourcing.

Keywords: Crowdsourcing, Generation Z, Social Media, Enterprise, Management, Gender and Place of Residence Differences

1. Introduction

Howe defined the concept of crowdsourcing as "the act of a company or institution taking a function once performed by employees and outsourcing it to an undefined (and generally large) network of people in the form of an open call. This can take the form of peer production (when the job is performed collaboratively), but is also often undertaken by sole individuals. The crucial prerequisite is the use of the open call format and the large network of potential laborers" (Howe, 2006b). Enterprises wanting to develop are increasingly using crowdsourcing to draw on the knowledge, experience and creativity of the crowd (Benoit et al., 2022; Gu et al., 2022), expecting customers to be simultaneously involved in the relationship with the brand and strengthening the brand-client relationship (Brunneder et al., 2020; Mo et al., 2021; Fazli-Salehi et al., 2022). Today's level of digitization means that an invitation to participate in crowdsourcing can be addressed to virtually residents of any geographic location. This means that companies are eager to use this tool to solve their problems by creating innovative solutions.

The generation that is becoming an important market partner for modern enterprises is Generation Z. The role this generation plays in the market game, being an important consumer who expects products and services that strictly meet their expectations, is proven by numbers – according to a trend study conducted on markets in Australia, France, Germany, the Netherlands, Great Britain and the United States (Oxford Economics, 2021), Generation Z will become driving force of economic growth in the next 10 years. This means that Generation Z will become a very important independent source of consumer spending – Generation Z spending will support spending in the six markets mentioned above by USD 30 trillion in 2030, which means a six-fold increase compared to 2019 (Oxford Economics, 2021). Encouraging representatives of Generation Z to participate in this form of communication and cooperation with the company, on the one hand, seems to be simple - the Internet space is, for Generation Z, the environment in which it operates best of all generations, but on the other hand, it requires knowledge from the company, how to motivate representatives of Generation Z to participate in this form of activity.

The aim of the article is to identify and assess the factors that determine the involvement of Generation Z representatives in solving enterprise problems in the form of crowdsourcing. Achieving the goal will deepen knowledge and fill the research gap by identifying the factors that most determine the involvement of Generation Z representatives in solving enterprise problems in the form of crowdsourcing, as well as by

indicating the impact of gender and place of residence of Generation Z representatives on their involvement in this activity.

2. Literature Review

Building and sustaining trust-based partnerships is key to fostering growth, innovation and organizational resilience, particularly in an ever-changing business environment characterized by uncertainty and liquidity (Otola, Grabowska, Krupka, 2023). On the Internet, brand communities are formed around a given brand. The aim of these communities is not only to exchange information and views between its members, but also to interact and build relationships with a given brand (Woisetschläger, Hartleb, Blut, 2008). What features should a brand have to attract consumers and keep them in brand communities? It should have a clear, strong image, a long tradition and the ability to build bonds and relationships, which requires knowledge about the expectations, preferences and value system of members of a given community (Cova, 1997). The generation that knows and uses technology and the Internet very well to carry out everyday activities is Generation Z (Priporas, Stylos, Fotiadis, 2017). These are creative and innovative people open to new experiences. Learning, acquiring knowledge and development take place in accordance with the just-in-time principle, they want to know and have everything immediately, preferably online" (Wiktorowicz et al., 2016). Representatives of this generation are ruthless towards those companies that have failed their trust – most of them, in order to warn their friends, will very gladly pass on negative information about the company's activities or their products to them (Witek, Hall, 2016). The authors assumed 1995 (and later years) as the year of birth of people representing Generation Z (Priporas, Stylos, Fotiadis, 2017; Francis, Hoefel, 2018; Kamenidou et al., 2019), while they accepted 2009 as the last year of birth. Crowdsourcing can be an effective tool for brands to engage with their customers to solve a variety of problems, but it is not suitable for every brand. Crowdsourcing used incorrectly can harm the brand (Heidenreich et al., 2015). Crowdsourcing should be used by brands whose communities are characterized by strong bonds. Brands whose communities do not have strong ties should use crowdsourcing with great caution, considering that in this situation it may cause the crowd to turn against the brand, generating more negative than positive actions. Brands with weaker communities should focus primarily on implementing activities that will strengthen the customer's bond with the brand and/or contribute to the creation of a stronger community (Bal et al., 2017).

The concept of crowdsourcing is created by combining two words: crowd and outsourcing. This concept was first used in 2006 by Howe, which appeared in Wired Magazine (Howe, 2006a), but the idea of crowdsourcing, as Howe himself notes, can be found in the publications of Mackay (Mackay, 1841) and Surowiecki (2005). Howe's (2006a; 2006b) ideas were continued by Brabham (2008) defines crowdsourcing as "It is a model capable of aggregating talent, leveraging ingenuity while reducing the costs and time formerly needed to solve problems. Finally, crowdsourcing is enabled only through the technology of the web, which is a creative mode of user interaction, not merely a medium between messages and people". Brabham (2008), using the term "online community" in his publications, pointed to the close relationship between crowdsourcing and the Internet. Brabham and Guth (2008) found that the effectiveness of ideas presented on crowdsourcing platforms by the "online community" is influenced not only by their quality, but also by communication between the participants of this community. In cases where people creating a given community communicate with each other and discuss the ideas presented, the quality of these solutions is higher than in a situation where participants of the online community communicate only with the online platform. There are many different classifications of crowdsourcing in the literature, e.g. Howe (2008) distinguishes collective intelligence/crowd wisdom, crowd creation, crowd voting and crowdfunding.

The motives determining the involvement of Generation Z representatives in solving enterprise problems in the form of crowdsourcing, which are the subject of the authors' research, are classified in the literature in a very diverse way (Zhao, Zhu, 2014; Wijnhoven, Ehrenhard, Kuhn, 2015). The most frequently mentioned division is the division into external motives and internal motives (Ghezzi et al., 2018): (1) External motives: monetary rewards, reputation, company recognition, increase in professional status, benefits from having a job, reciprocity, responsibility and social capital, self-marketing, social motives, learning; and (2) Internal motives: entrepreneurial mindset, opportunity to express individual creativity; attachment to the group, sense of belonging, ideology; pleasure; fun and entertainment; psychological compensation and self-efficacy; social influence and social identity, information exchange; sense of cooperation; opportunity to establish new contacts; self-esteem; learning.

Zhang et al. (2022), based on the literature review, identified the 8 most significant motives for individuals engaging in crowdsourcing: 1. Cash prizes, 2. Learning or developing competences, 3. Access to a new job, 4.

Gaining reputation and recognition, 5. Taking on challenges and having fun, 6. Self-esteem, 7. Altruism, 8. Sense of belonging to a community.

The motive with the greatest impact on people's involvement in crowdsourcing is the possibility of receiving a monetary reward for presenting the best solution. Prizes and their amounts may increase the likelihood of people participating in crowdsourcing, but at the same time they will not guarantee their appropriate contribution or winning the competition (Patel et al., 2023). Some researchers advise against using monetary rewards to stimulate creativity (Hennessey, Amabile, 2010), while others argue that monetary rewards increase creativity as long as they are linked to a creativity goal (Eisenberger, Rhoades, 2001). This controversial relationship between rewards and creativity has been called the "reward paradox" in the literature (Zhou, Shalley, 2003).

The types and effects of undertaken motivating actions are not independent of each other – some motives strengthen each other, while others reduce the effect of the others. Research has shown that intrinsic and prosocial motives (e.g. motives related to having fun and helping) mutually strengthen their influence on crowd involvement in crowdsourcing problem solving, while monetary rewards combined with prosocial motivation reduce this influence (Acar, 2014). The content of the instructions explaining how to perform a given task also influences the involvement of people in solving enterprise problems in the form of crowdsourcing. Empirical results support a U-shaped relationship between the use of restrictive words and the number of participants, as well as an inverted U-shaped relationship between the use of terminology and participation (Yin et al., 2022). The literature review allows to conclude that there are no studies on the relationship between the gender and place of residence of Generation Z and the motives for this generation's participation in crowdsourcing. The authors formulated the following research questions:

Q1. Which factors most determine the engagement of Generation Z in solving enterprise problems by crowdsourcing?

Q2. Does the gender of a Generation Z representative influence his or her engagement in crowdsourcing? If so, how?

Q3. Does the place of residence of a representative of Generation Z influence his engagement in crowdsourcing? If so, how?

Q4. Is this engagement the same among the representatives of Generation Z in Poland and the Great Britain?

3. Methodology

The research on Gen Zers' attitudes towards brands on social media is a part of a broader study conducted by the authors among students in Poland and Great Britain in 2023. The research employed a combination of qualitative and quantitative approaches, utilizing survey research as an indirect measurement method. It employed survey as the research technique and survey questionnaire as the research tool. The selection of variables used in the study was based on a critical analysis of relevant literature (Gummerus et al., 2012; Gregor, Kubiak, 2014).

Regarding the birth year of Generation Z representatives, there is no consensus in the literature. The most frequently cited date is the year 1995, which the authors of the paper adopted as the cutoff year for their study. The authors also assumed that the independent variable in their study is the specific group of respondents being tested, rather than the entire population of Generation Z. Due to the challenge of definitively determining the age range of Generation Z, it becomes problematic to treat this variable as independent. However, the authors found that utilizing Generation Z as a heuristic is valuable, as generational profiling is now prevalent in popular media and popular culture, providing a descriptive framework.

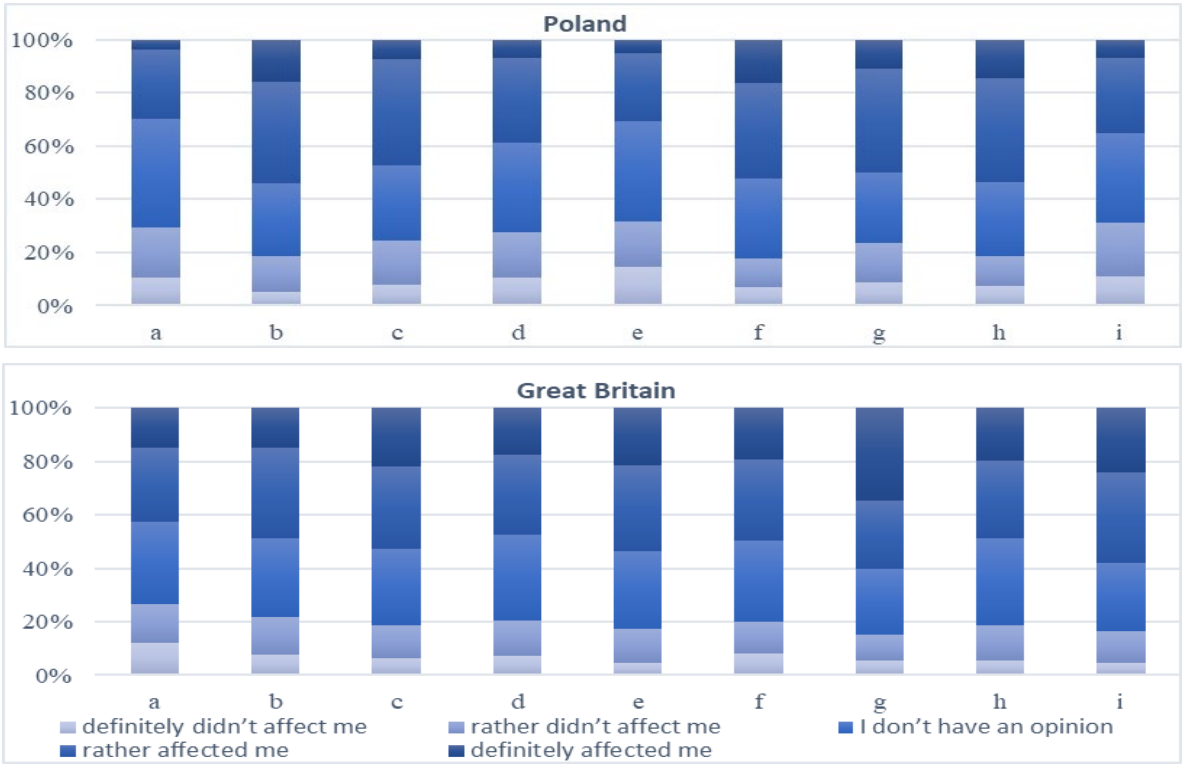
Prior to commencing the main research, the authors conducted a pilot study in 2018, enabling them to identify and rectify any errors in the survey questionnaire before proceeding with the main study. In Poland, a total of 322 students participated (166 females and 156 males), while in Great Britain, a total of 318 students participated (199 females and 119 males). The research employed the CAWI (Computer-Assisted Web Interviewing) technique. In Poland, an online survey questionnaire was administered through the Webankieta.pl platform, while data collection in Great Britain was outsourced to an external institution specializing in survey administration. It is important to note that the sampling method used in both studies was non-probabilistic. While utilizing non-probabilistic sampling, the authors employed statistical inference as an opportunity to identify relationships within the studied groups, as descriptive statistics alone would not allow for such analysis.

Based on the research results, the authors calculated the number and frequency of respondents' responses to each question in the survey. The authors are aware that the sampling technique employed does not allow for the estimation of errors that may arise when generalizing the observed patterns in the sample to the entire population. To identify potential relationships within the studied groups, the authors utilized statistical inference, for which they adopted a certain level of significance, as descriptive statistics alone cannot provide such analysis. Statistical inference was conducted with a predetermined significance level set at $\alpha = 0.05$, and a p-value was calculated for each test. Non-parametric tests were used to examine the relationship between variables: the Mann Whitney U test and Spearman's rank correlation coefficient. The authors compared the p-value with the level of statistical significance to determine whether there was sufficient evidence to reject the null hypothesis (H_0) in favor of the alternative hypothesis (H_1) ($p < \alpha$), or not ($p \geq \alpha$). All analyses were performed using Statistica software, version 13.3.

The authors acknowledge that survey research has certain limitations, such as providing only a surface-level understanding of the phenomena under study and the possibility of respondents providing inaccurate answers. One potential criticism of the presented research results is that the study was conducted on a small group of participants. While small sample sizes can raise methodological concerns, such as limitations in generalization, they can still provide valuable insights when proper statistical tests are applied for inference (Yates, 1934; Nachar, 2008).

4. Results

The presented results are a fragment of research conducted by the authors in Poland and Great Britain at the beginning of 2023. Respondents were asked the following question: "Which of the following factors will make you respond to the company's invitation addressed to a wide group of people (crowdsourcing) and solve a specific problem, e.g. come up with an improvement for a good/service, design a new function for a good/service, design a new good/service, you will come up with a new flavor or name for a good/service?. Evaluate each factor." The obtained numbers (in %) of responses in Poland and Great Britain in 2023 are presented in Figure 1.



a. Desire to interact with a favourite brand, b. Desire to receive a material prize or money, c. Desire to test your skills and knowledge in practice, d. Possibility of participating in a big project without being hired in the organisation, e. Recognition among social media users, f. Developing your own career by building a portfolio and reputation through proving participation in various projects, g. Networking, h. Sharing experiences, possibility of learning from the experience of others, i. Desire to belong to a specific group

Figure 1: Assessment of factors determining the participation of a Generation Z respondent in crowdsourcing - number of responses (in %) in Poland and Great Britain in 2023

Factors rated highest by respondents in Poland: (1) Desire to receive a material prize or money, (2) Developing your own career by building a portfolio and reputation through proving participation in various projects, (3) Networking, (4) Sharing experiences, possibility of learning from the experience of others.

Factors rated highest by respondents in Great Britain: (1) Desire to test your skills and knowledge in practice, (2) Recognition among social media users, (3) Networking, (4) Desire to belong to a specific group.

The next step was to examine whether there is a relationship between individual assessments of factors determining participation in crowdsourcing and the respondent's gender. For this purpose, non-parametric tests were used for two independent groups. These tests verify the hypothesis that the two analyzed samples come from different general populations (statistical communities). The Mann Whitney U test was used (Tables 1 and 2) because the data are measurable, but their distribution is not normal and the data are ordinal (Nachar, 2008; Walters, 2021). In the case of ordinal data, the null hypothesis (H_0) assumes that the types of distributions of the analyzed groups do not differ significantly from each other.

Table 1: Results of the Mann-Whitney U test (with continuity correction) regarding the relationship between the assessment of factors determining participation in crowdsourcing and the gender of the Generation Z respondent in Poland in 2023

Variables	Sum of ranks Male	Sum of ranks Female	U	Z	p
Desire to interact with a favourite brand & Gender	23750.5	28252.5	11504.5	-1.82	0.0692
Desire to receive a material prize or money & Gender	23775.0	28228.0	11529.0	-1.77	0.0761
Desire to test your skills and knowledge in practice & Gender	23989.5	28013.5	11743.5	-1.52	0.1303
Possibility of participating in a big project without being hired in the organisation & Gender	25083.5	26919.5	12837.5	-0.14	0.8909
Recognition among social media users & Gender	23883.5	28119.5	11637.5	-1.63	0.1023
Developing your own career by building a portfolio and reputation through proving participation in various projects & Gender	25621.5	26381.5	12520.5	0.53	0.5939
Networking & Gender	23143.5	28859.5	10897.5	**-2.56**	**0.0104**
Sharing experiences, possibility of learning from the experience of others & Gender	24245.0	27758.0	11999.0	-1.19	0.2347
Desire to belong to a specific group & Gender	24925.5	27077.5	12679.5	-0.33	0.7392

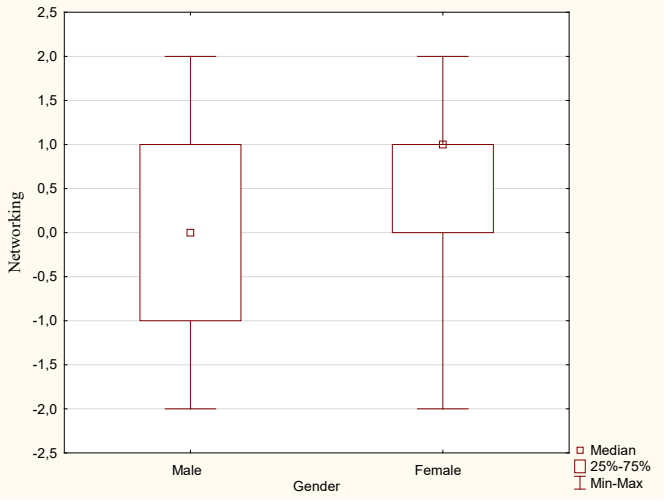


Figure 2: Assessment of the "networking" factor determining participation in crowdsourcing by Generation Z respondents by gender in Poland in 2023

The results of the Mann-Whitney U test for data from the study in Poland (Table 1) provide grounds for rejecting the assumed null hypothesis ($p > 0.05$) only in the case of assessing one factor: "networking".

Based on the adopted level of $\alpha = 0.05$, the Z statistics of the Mann Whitney U test with continuity correction, as well as on the basis of the exact U statistics, it can be assumed that there are statistically significant differences between female and male respondents of Generation Z in Poland in terms of the assessment of only one factor determining the participation in crowdsourcing. These differences consist in the fact that women rated the described factor higher than men. They can be described based on the median, quartiles and the largest and smallest values, which are also visible on the box plot chart (Figure 2).

In the case of the remaining factors mentioned, the types of distributions of the analyzed groups do not differ significantly from each other. Therefore, there is no relationship between individual assessments of factors determining participation in crowdsourcing and the gender of the Generation Z respondent in Poland in 2023.

Table 2: Results of the Mann-Whitney U test (with continuity correction) regarding the relationship between the assessment of factors determining participation in crowdsourcing and the gender of the Generation Z respondent in Great Britain in 2023

Variables	Sum of ranks Female	Sum of ranks Male	U	Z	p
Desire to interact with a favourite brand & Gender	32275.5	18445.5	11305.5	0.70	0.4857
Desire to receive a material prize or money & Gender	33241.5	17479.5	10339.5	**1.97**	**0.0486**
Desire to test your skills and knowledge in practice & Gender	31960.5	18760.5	11620.5	0.29	0.7722
Possibility of participating in a big project without being hired in the organisation & Gender	32624.0	18097.0	10957.0	1.15	0.2500
Recognition among social media users & Gender	30986.0	19735.0	11086,0	-0.98	0.3250
Developing your own career by building a portfolio and reputation through proving participation in various projects & Gender	32271.0	18450.0	11310,0	0.69	0.4890
Networking & Gender	32448.0	17955.0	10934,0	1.06	0.2889
Sharing experiences, possibility of learning from the experience of others & Gender	32928.0	17793.0	10653,0	1.56	0.1193
Desire to belong to a specific group & Gender	30824.5	19896.5	10924,5	-1.19	0.2323

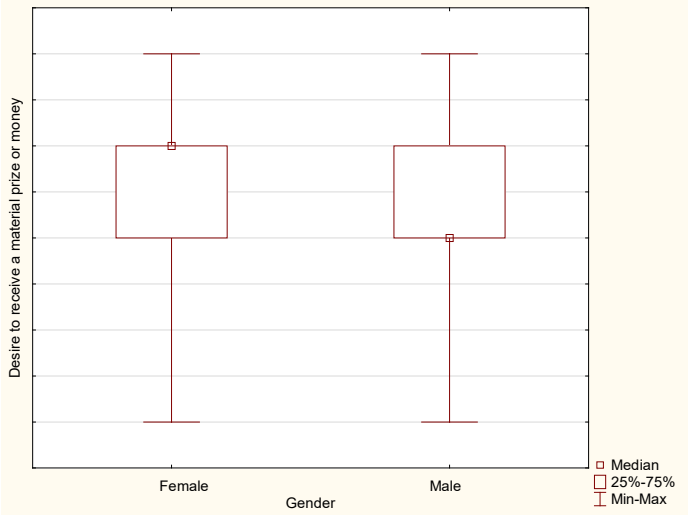

Figure 3: Assessment of the "desire to receive a material prize or money" factor determining participation in crowdsourcing by Generation Z respondents by gender in Great Britain in 2023

Based on the adopted level of $\alpha = 0.05$, the Z statistics of the Mann Whitney U test with continuity correction, as well as on the basis of the exact U statistics, it can be assumed that there are statistically significant differences

between female and male respondents of Generation Z in Great Britain in terms of the assessment of only one factor determining the participation in crowdsourcing. These differences consist in the fact that women rated "Desire to receive a material prize" higher than men. These differences can be described based on the median, quartiles and the largest and smallest values, which are also visible on the box plot chart (Figure 3).

In the case of the remaining factors mentioned, the types of distributions of the analyzed groups do not differ significantly from each other. Therefore, there is no relationship between individual assessments of factors determining participation in crowdsourcing and the gender of the Generation Z respondent in Great Britain in 2023.

The next stage of the analysis was to verify whether there is a relationship between the variables: the assessment of factors determining participation in crowdsourcing (variable X) and the respondent's place of residence (variable Y). To assess the correlation between two qualitative characteristics, the non-parametric correlation coefficient was calculated – Spearman's rank correlation coefficient (Tables 3 and 4). The Rxy coefficient calculated from the sample is an estimate of the correlation coefficient ρ in the general population, and its numerical value is a point assessment of the strength of the connection in the entire population (Akoglu, 2018; Wiśnienwski, 2014). The following set of hypotheses was verified:

$$H_0: \rho = 0$$

towards the alternative hypothesis:

$$H_1: \rho \neq 0$$

Verification of the null hypothesis helped in assessing whether the existing relationship between the studied variables (X and Y) in the sample is only accidental or may also be a regularity in the studied population.

Table 3: Spearman's rank order correlation regarding the relationship between the assessment of factors determining participation in crowdsourcing and the place of residence of the Generation Z respondent in Poland in 2023

Variables	N of valid ones	Spearman's rank R	t (N-2)	p
Desire to interact with a favourite brand & Place of residence	322	-0.0308	-0.55	0.5824
Desire to receive a material prize or money & Place of residence	322	-0.0349	-0.63	0.5323
Desire to test your skills and knowledge in practice & Place of residence	322	0.0206	0.37	0.7122
Possibility of participating in a big project without being hired in the organisation & Place of residence	322	0.0928	1.67	0.0965
Recognition among social media users & Place of residence	322	-0.0138	-0.25	0.8055
Developing your own career by building a portfolio and reputation through proving participation in various projects & Place of residence	322	0.0889	1.60	0.1114
Networking & Place of residence	322	-0.0723	-1.30	0.1954
Sharing experiences, possibility of learning from the experience of others & Place of residence	322	0.0183	0.33	0.7430
Desire to belong to a specific group & Place of residence	322	-0.0652	-1.17	0.2435

The obtained Spearman's R coefficients are not statistically significant. The analysis did not provide grounds for finding statistically significant correlations between the studied variables: the assessment of individual factors determining participation in crowdsourcing and the respondents' place of residence in Poland in 2023.

Table 4: Spearman's rank order correlation regarding the relationship between the assessment of factors determining participation in crowdsourcing and the place of residence of the Generation Z respondent in Great Britain in 2023

Variables	N of valid ones	Spearman's rank R	t (N-2)	p
Desire to interact with a favourite brand & Place of residence	318	-0.0016	-0.03	0.9773
Desire to receive a material prize or money & Place of residence	318	0.0412	0.73	0.4638
Desire to test your skills and knowledge in practice & Place of residence	318	0.0482	0.86	0.3921
Possibility of participating in a big project without being hired in the organisation & Place of residence	318	-0.0582	-1.04	0.3004
Recognition among social media users & Place of residence	318	0.0404	0.72	0.4727
Developing your own career by building a portfolio and reputation through proving participation in various projects & Place of residence	318	0.0846	1.51	0.1322
Networking & Place of residence	318	0.0662	1.18	0.2393
Sharing experiences, possibility of learning from the experience of others & Place of residence	318	0.0024	0.04	0.9665
Desire to belong to a specific group & Place of residence	318	-0.0371	-0.66	0.5103

Similarly to the coefficients calculated for data collected in Poland in 2023, the obtained Spearman's R coefficients for data obtained in Great Britain are not statistically significant ($p > 0.05$). The analysis did not provide any basis for finding statistically significant correlations between the studied variables: the assessment of individual factors determining participation in crowdsourcing and the respondents' place of residence.

5. Conclusion

The results of the conducted research allow us to conclude that representatives of Generation Z living in different countries are guided by different motives when actively participating in crowdsourcing, and that different motives are important for women and different for men. The obtained research results should also draw managers' attention to the use of non-monetary incentives towards representatives of Generation Z. Incentives in the form of rewards (material and/or monetary) turned out to be the most important motivating factor only in the group of Polish respondents.

For both representatives of Generation Z from Poland and Great Britain, non-monetary internal benefits are of great importance. The expectation of receiving a monetary reward turned out to be the most important motivating factor only in the case of representatives of Generation Z from Poland. The obtained results are identical to those of Zhang et al. (2022). For representatives of Generation Z from Great Britain, the most important motivating factor was the desire to test your skills and knowledge in practice. The positive impact of internal factors on the involvement of Generation Z representatives in crowdsourcing is identical to the research results presented in the literature on the subject, which were conducted on other groups of respondents (Brabham, 2010; Zheng et al., 2011). Women representing Generation Z in Poland rated the impact of networking on their involvement in crowdsourcing higher than men, while women representing Generation Z in Great Britain rated the desire to receive a material reward or money higher than men. The obtained results are not consistent with the research results presented in the literature on other groups of respondents (Krishnamurthy, 2006; Zheng et al., 2011; Yin et al., 2022; Patel et al., 2023).

The knowledge obtained as a result of the research will allow managers to plan and carry out activities using crowdsourcing in a way that takes into account the motives that guide representatives of Generation Z when deciding to participate in crowdsourcing. This increases the chance of engaging Generation Z representatives in solving enterprise problems.

Managers, wanting to encourage representatives of Generation Z to cooperate on the basis of crowdsourcing, should not only guarantee Polish authors of winning solutions material prizes or earnings, but at the same time create an environment enabling representatives of Generation Z to feel recognized among social media participants, as well as develop their own career path by building a portfolio and reputation as a result of

demonstrating participation in various projects. Using crowdsourcing, managers do not have to take into account the place of residence of representatives of Generation Z by city/town village if it is not the subject of cooperation.

The conducted survey research is characterized by limitations, which include, among others: the possibility of superficial knowledge of the studied phenomena, or respondents giving false answers. However, the relatively small number of respondents does not allow the obtained research results to be treated as representative. Although small samples may be methodologically questionable (e.g., generalization is difficult), they can be useful for making inferences if appropriate statistical tests are used (Nachar, 2008).

Undoubtedly, future research should be conducted on a larger sample, and quantitative research should be supplemented with qualitative research, including an explanation of the reasons for the variation in motives of Generation Z's involvement in crowdsourcing. Undertaking research in other countries would make it possible to compare crowdsourcing motives among Generation Z representatives of different nationalities and determine which of them occur regardless of geographical location.

Corporate Social Responsibility: Understanding the Concept

Patrycja Krawczyk and Justyna Łukomska-Szarek
Czestochowa University of Technology (CUT), Częstochowa, Poland

patrycja.krawczyk@pcz.pl
j.lukomska-szarek@pcz.pl

Abstract: The concept that organisations consider social and environmental interests and relationships at the strategy-building stage has been around for many years. The first definition of CSR dates back to the 1970s. It was created by the American economist Archie Carroll. His theory was presented as a pyramid of CSR, with economic responsibility as the base and legal, ethical and philanthropic responsibility as the next tiers. The foundations of modern CSR are the principles formalised in 2010 as the ISO 26000 standard. The dynamic development of the concept has gone beyond the level of good practice and has become an obligation for many businesses as reflected in mandatory non-financial reports. In order for the CSR strategy to benefit companies and society, knowledge about it should be widely known The purpose of the article is to show what is the level of understanding of corporate social responsibility (CSR) in society. Corporate social responsibility is a management strategy designed for society. It is a concept analyzed in many academic centers around the world. The assumptions of this strategy are also familiar to most managers of organizations. The word society is repeated many times in its definition. The basis of this concept is concern for people. Many organizations take on the challenge of making profits while respecting human resources and the environment, for social and economic sustainability. The strategy is aimed at employees, local communities and the environment in which people live. Therefore, it is necessary to ask how the state of knowledge about CSR among the main addressees of the strategy. The article will present the results of the research of the first stage of testing the understanding of the concept. Understanding of the concept of CSR in society will be carried out using a survey conducted among a group of students at Częstochowa University of Technology. In the next stages, it is planned to extend the survey to larger social groups. People as the starting points of the entire CSR concept should be aware of what this rapidly growing economic trend is. But, are they? What is their knowledge in this area? Without an understanding of the concept in society, it will remain only an element of the scientific community's discourses or an element of companies' PR.

Keywords: Knowledge, CSR Corporate Social Responsibility

1. Introduction

Global economic development based on sustainability is only possible through broadly understood knowledge (Krawczyk, 2024). The term sustainability is the result of understanding the three aspects: social, environmental, and economic, taking into account the costs of current decisions for future generations. Sustainability is a contemporary and current issue recognized by researchers (Al-Ali Mubarak, Gorgenyi-Hegyes and Fekete-Farkas, 2020) and is the main derivative of this concept for business. Corporate Social Responsibility (CSR), as an issue at the intersection of management, economics and ethics, is an extremely capacious category that can be considered in many dimensions: from social, to environmental, to political (public), to market (Otola and Tylec, 2016). The communication of an organisation's performance in its economic, social, and environmental dimensions to the concerned parties is the principal function of the CSR reporting process. In this way, an enterprise demonstrates the effectiveness of its actions in the area of social responsibility management. Thus, the CSR reporting should be part of the process of creating an organisation's strategy, implementation of its action plans (Krištofik, Lament and Musa, 2016). Entrepreneurs should invest in CSR and seek to improve the quality of their relationships with their funders(Mastrangelo, Cruz-Ros and Miquel-Romero, 2019). Sustainable development should be a core principle of long-term development, both for countries or organisations and for companies. In the private sector, the concept of corporate social responsibility (CSR) is an important, if not the most important, pillar in the process of implementing sustainable development. Knowledge is increasingly important in the management process in today's economy. It serves as a strategic resource of the organization (Piersiala, 2014). CSR has been shown to be an effective means of doing well for the environment and society (Rupp and Mallory, 2015).

According to the Global Reporting Initiative, a CSR report can be defined as: “A sustainability report is a report published by a company or organization about the economic, environmental and social impacts caused by its everyday activities. A sustainability report also presents the organization’s values and governance model, and demonstrates the link between its strategy and its commitment to a sustainable global economy.”

A whole group of related issues can be identified, such as sustainable development, regenerative value creation, greenwashing, European Green Deal, ESG (Environmental, Social and Governance). And although the issues listed here do not exhaust the group of related issues, this study will test the understanding of the concepts

listed. Sustainable development (Liu *et al.*, 2013; Yadavl *et al.*, 2023) is one of hot issue under the current background of resources and environmental crises. Other well knowne – ESG (Environmental, social, and governance), is a set of aspects, including environmental issues, social issues and corporate governance that can be considered in investing (Sabbaghi, 2024). Regenerative Value Creation (or regenerative business models) is the new logic for the urgently needed regenerative economy. It integrates economic success with regenerative impact for people and planet, and equitably benefits all stakeholders, including shareholders and Nature (Konietzko, Das and Bocken, 2023). Implementing Regenerative Value Creation is both a challenge and a tremendous opportunity, as demonstrated by the following corporate examples. It requires fundamental transformation as well as pragmatic transition as companies need to stay profitable while fundamentally reinventing their business models. Greenwashing (Sundarasen, Zyznarska-Dworczak and Goel, 2024; Todaro and Torelli, 2024) is the process of conveying a false impression or misleading information about how a company's products are environmentally sound. Greenwashing involves making an unsubstantiated claim to deceive consumers into believing that a company's products are environmentally friendly or have a greater positive environmental impact than they actually do.

2. Literature Review

Corporate social responsibility is a trend in the economic space that have been developing some time now. Recent years have given rise to the academic discourse of this issue. This shows literature review (Sofian, Mohd-Sabrun and Muhamad, 2022; Bhargava and Ligade, 2023; Effah *et al.*, 2023). To see how widespread CSR considerations are, type the term in the Web of Science search. This brings up more than 40,000 publications from a wide range of scientific disciplines. The oldest date back to 1975 (Clark, 1975; Denham, 1975; Gavin and Maynard, 1975; Mason and Maxwell, 1975). Since the 2000s, the subject has become increasingly popular. Today, more than 4,000 new publications are added to the WoS database every year. These are mainly academic articles. The dominant WoS categories include economics, management and environmental studies. Primarily, the general analysis of the research shows exponential growth in the interest of the scientific community, derived from the continuous growth of articles, authors, and citations (Fernandez-Gago, Cabeza-Garcia and Godos-Diez, 2020).

However, there are not many publications that describe the perception of the concept among the strategy's addressees. Publications can be found on the importance of CSR for employees (Jia *et al.*, 2016; Lemon, 2019; Lee, 2022; Jing, Keasey and Xu, 2023), investors (Cohen, Holder-Webb and Zamora, 2015; Glossner, 2019; Naughton, Wang and Yeung, 2019), local community (Barrio Fraile and Enrique Jimenez, 2018; Crowther and Vilke, 2018; Bojanic and Vucemilovic, 2020), consumers (Vitell, 2015; Quazi, Amran and Nejati, 2016; Deng and Xu, 2017; Nugroho *et al.*, 2024).

Z. Antczak presents the concept of Corporate Social Responsibility (CSR) from a consumer perspective. She analyses the significance of consumer behavior and also presents CSR in the light of the latest research on consumer attitudes (Antczak, 2010).

Enterprises that see the importance of CSR values have quickly noticed that the fact of being socially responsible should be presented. CSR should be an element of knowledge management within an enterprise (Krawczyk, 2022). These conclusions are correct. But this raises another question: can CSR knowledge stay within the organisation? Maybe we should move one step further and communicate the importance of this strategy to the broader public.

The analysis of the literature and the initially prepared research material allows the formulation main task - What is the general public's knowledge of CSR? Problems can be solved by asking a series of specific questions:

RQ1. Whether the concept of CSR is known in general?

RQ2. Whether related concepts are?

RQ3. What is the state of knowledge about the tools used in a CSR strategy?

RQ4. What are the benefits of implementing a CSR strategy?

All considerations have been made from the point of view of those targeted by the CSR strategy, rather than those managing. For such a widely discussed topic, this is a new and unique perspective.

3. Research Methodology

The social sciences have at their disposal a range of methods, techniques and tools for collecting empirical material (Szyjewski, 2018; Skuza, 2019). A survey questionnaire was used as part of this study. The survey questionnaire is one of the most popular and frequently used measurement instruments in practice (Kieżel and Sobczyk-Kolbuch, 2002; Piersiala, 2023). Such studies provide the most economical way of gathering information from representations giving data that apply to general populations (Bihu, 2021). The article will present the figures from the survey that was carried out.

Table 1: Reserch agenda

Link	https://docs.google.com/forms/d/e/1FAIpQLSdBxhC5OBph-nFpw4xvIr3X8lbxccderFbYUm90Rkr8faHA_g/viewform?usp=sf_link
Time	14.03.24. – 09.04.24.
Number of responses	149
Language	Polish / English
Number of question	10 core questions plus a questionnaire
Type of quistion	Single-choice, multiple-choice, with a single-choice grid
The research group	Students of Częstochowa University of Technology (CUT), Faculty of Management
Scale values	1 - low, 2 low medium, 3 - medium, 4 - medium high, 5 - high

Source: own elaboration.

The survey was conducted using Google Form tools. The form is available at the link in Table 1. The research group consisted of students of Częstochowa University of Technology, Faculty of Management, from various fields of study. With the help of an online form, they answered 10 questions related to the topic of the research. The questions were:

- Are you familiar with the term CSR (Corporate Social Responsibility)?
- Which of the terms are familiar to you (1 or more answers)?
- Which term do you think is synonymous with CSR (1 or more answers)?
- Do you know of any tools used in CSR strategy?
- What do you think is a CSR tool?
- What benefits do you see from implementing a CSR strategy in company?
- Implementation of CSR can have an impact on increasing economic benefits (scal: small - 1, large - 5).
- Implementation of CSR can have an impact on the social environment (scal: small -1, large - 5).
- Implementation of CSR may have an impact on the environment (scal: small -1, large - 5).
- CSR implementation can affect employees (scal: small -1, large - 5).

The next section of the article presents the results of the survey.

4. Research Results

The group of respondents who were interviewed gave answers on the basis of which it is possible to formulate the following conclusions.

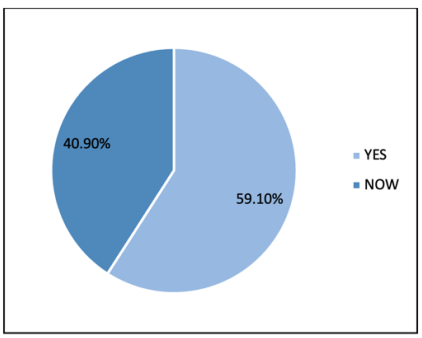

Figure 1: Knowledge of the Corporate Social Responsibility (CSR) concept

Source: owne elaborartion.

The results of the survey showed that more than 40 per cent of the respondents were not familiar with the concept of CSR. Such a result would be satisfactory for the general public (figure 1.). However, it should be noted that the survey was conducted among management students, people who should understand the subject well. There is no correlation between which students from which faculties, which type of study or which age group are unfamiliar with the concept.

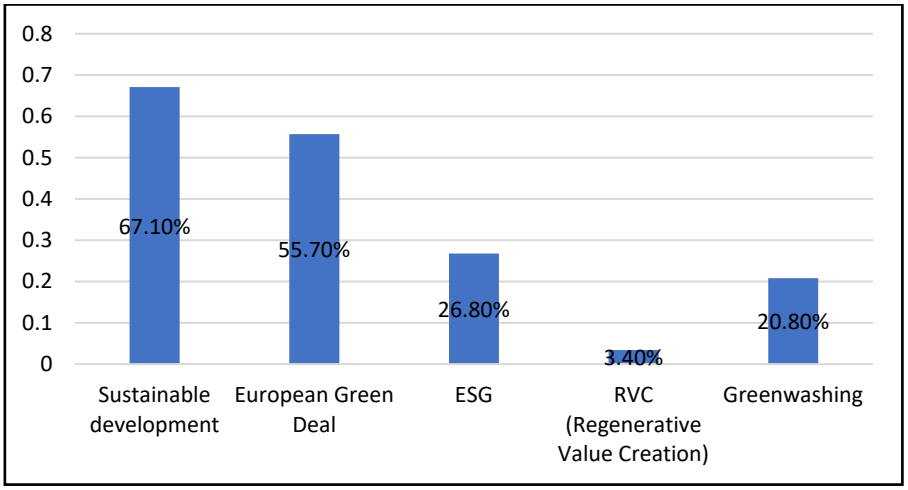

Figure 2: Knowledge of other concepts associated with CSR

Source: owne elaborartion.

Awareness of other related concepts was examined as well, see figure 2. Most people, 67%, are familiar with the term 'sustainable development'. Fewer people, only 3.4%, are familiar with the term 'Regenerative Value Creation' (RCV).

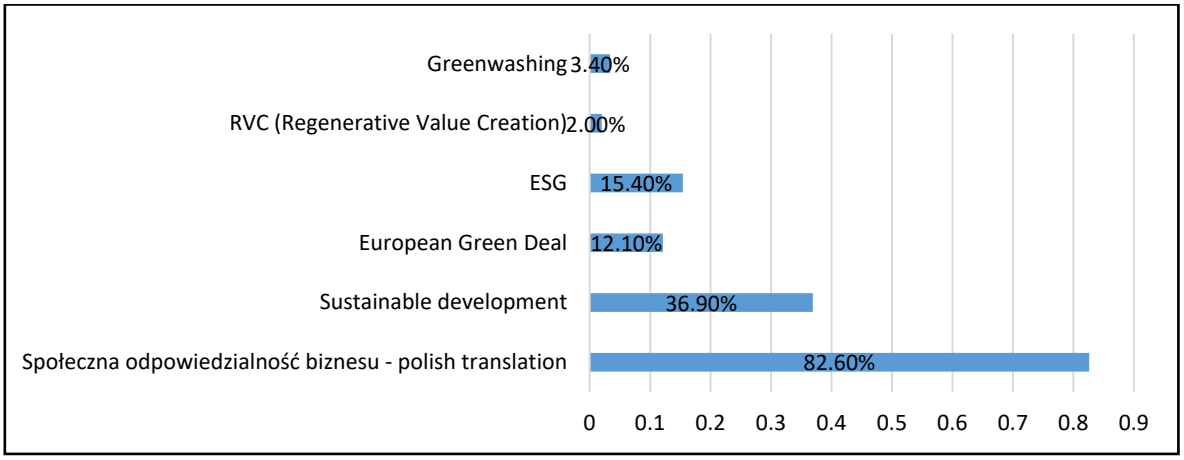

Figure 3: Synonyms for the term CSR

Source: owne elaborartion.

Respondents were also asked which words are synonyms for CSR (figure 3.). In response to this question, more than 82 per cent of respondents were very accurate in pointing out the Polish translation of the term. A synonym for almost 37% was Sustain Develeopment, for 12% European Green Deal and around 15% ESG.

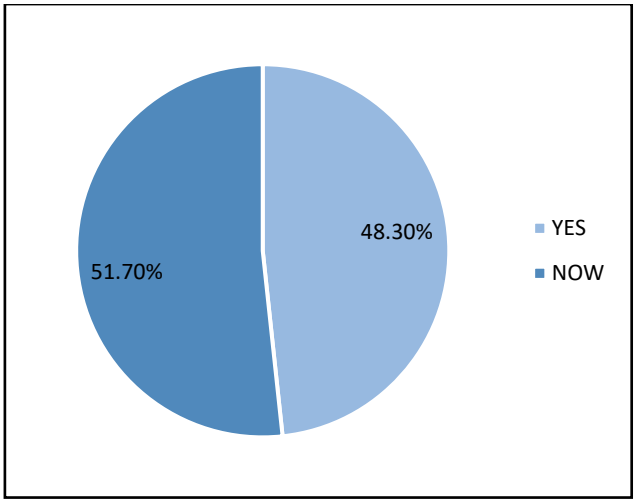

Figure 4: Knowledge of the tools used in CSR strategy

Source: owne elaborartion.

Slightly more than half of the respondents have no idea what tools are being used in CSR strategies. This is a surprising result for the group surveyed - management students. Participants also indicated which tools they were familiar with. Most respondents (68%) knew about community activities. About half said environmental activities - 50.5% - and social campaigns - 49.5%. Slightly less familiar were employee programmes (43.7%) and social reports (39.8%). Management systems (e.g. ISO) and employee volunteering reached similar levels (see Figure 4). The lowest awareness levels were for supply chain management (13.6 per cent) and product labelling (14.6 per cent).

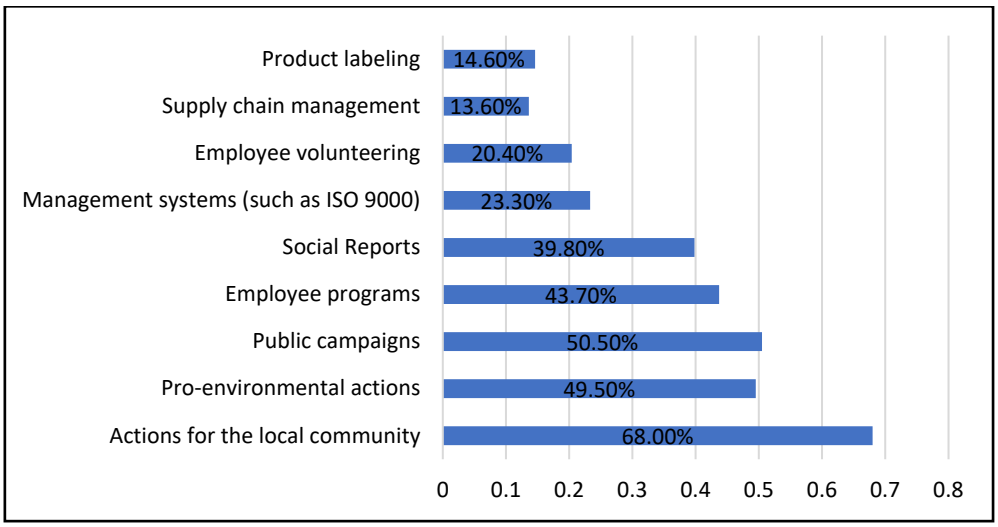

Figure 5: Knowledge of the tools used in CSR strategy

Source: owne elaborartion.

Students were also asked to identify the benefits they see from implementing CSR strategies. They began by identifying specific groups of benefits: economic benefits, social benefits, environmental benefits and image enhancement. Social benefits were seen as the most important by more than 73% of respondents. 58% pointed to economic benefits, almost 50% to environmental benefits and 42.3% to image improvement. The question was deepened. Participants were asked to rate the level of impact in each area on a scale of importance from 1 to 5. Due to the formal requirements of publication (quantitative limitations), the data are not presented graphically in this study.

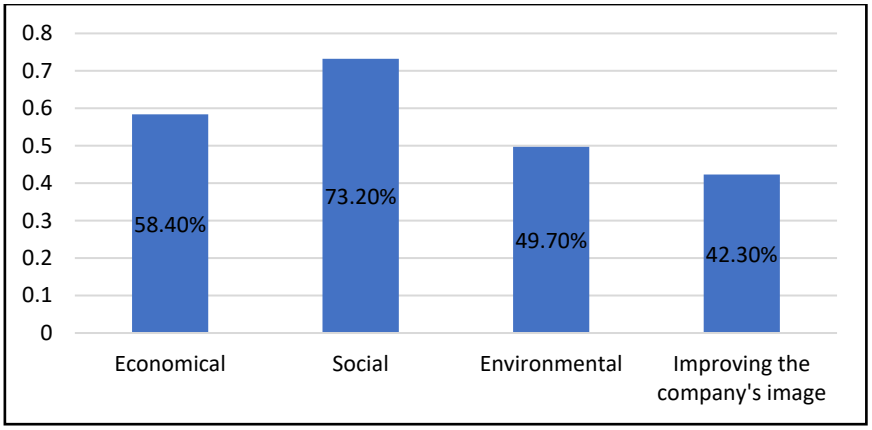

Figure 6: The benefits of implementing CSR strategy

Source: owne elaborartion.

As far as the economic benefits are concerned, they were divided into 4 specific categories: increased profitability of sales, increased investments, better use of fixed assets for human capital, increased liquidity. For the most part, they indicated a medium or medium-high level of impact.

Regarding the impact on the social environment, the following were mentioned: improving the level of culture and safety at work, achieving social goals that would not be possible without business support, reducing the negative impact of business on the environment. In this area, respondents mostly indicated a high, medium or high level. A very small number (up to 4%) reported a low level of commitment.

The third group, the environment, was divided into: Following best practices, managing natural resources and waste rationally, involving business partners in the chain of environmental responsibility and initiating joint pro-environmental activities, popularising pro-environmental ideas. In this area, the survey results show that the level is medium or medium-high. Only a small number of respondents reported a low level.

5. Conclusion And Future Work

Knowledge is an asset in all areas of activity, both for the individual and for the organisation. Managers are under great pressure to demonstrate their social responsibility. This covers issues like the environment, relations with the community and internal relations with staff. The implementation of CSR (Corporate Social Responsibility) strategies can be a response to these needs on the part of companies. Business leaders, scientists and government agencies have spent years studying this issue. It is a very popular topic. However, it is not a widely known topic in society. The results of the survey show that almost 41% of management students are not familiar with the concept. They are not familiar with the tools used in this strategy (more than 50%). They do not fully understand related issues such as sustainable development, regenerative value creation, greenwashing, European Green Deal, ESG (Environmental, Social and Governance). Reliable, substantive, but at the same time simple and accessible knowledge about this strategy should reach the public so that they can expect concrete benefits from the implementation of CSR strategies.

The study has several limitations. Firstly, students from one university and one department were surveyed. The study should be extended to include a wider research group. It would be interesting to survey students from different universities in management and related fields. The average citizen's level of knowledge about this strategy should also be checked. The survey can be conducted at the level of one country, but comparative results from different countries can be very interesting. The present results are therefore the first, preliminary stage of a broader study.

It is obvious that knowledge of the CSR strategy should be spred within the organisation. Knowledge that builds the image of a socially responsible company ensuring its long-term development. Transparency of company knowledge promotes sustainable development. Nowadays, this means going one step further and explain what the CSR strategy is to the general public.

Abstract: Changes in the business context create the need to adjust organizational knowledge to new contexts to enable the organizational agile responses to secure competitiveness. Tacit knowledge is strongly contextual. This study is based on the assumption that business context determines tacit knowledge creation and acquisition, and thanks to this, the tacit knowledge-sharing processes support agility. Therefore, this study aims to expose that there is a strong link between the tacit knowledge flow across the organization and its ability to respond agilely (timely, accurately, and creatively) to contextual changes. Based on the sample composed of 640 Polish knowledge workers and data analyzed with the structural equation modeling method (SEM), this study delivers empirical evidence that tacit knowledge flow is vital for organizational agility. The obtained results confirmed that tacit knowledge sharing mediates between the mistakes acceptance component of learning culture and agility. It means agility, understood as the ability to respond agilely to contextual changes, requires being charged by new, contextual, tacit knowledge obtained thanks to trial-error actions (learning by doing) achievable thanks to breaking conventions and experimentation. Moreover, risk management skills have been proven to be one of the critical characteristics of agile organizations today.

Keywords: Mistakes Acceptance, Learning Culture, Tacit Knowledge Sharing, Organizational Agility, Risk Management

1. Introduction

Although there is no single definition of agility that is universally followed, all definitions commonly share the basic concepts of speed and flexibility for responding to changes in dynamic market environments (Kettunen and Laanti, 2008). It is because agility secures competitiveness (Zastempowski and Cyfert, 2023). In a Finnish survey study of agility in organizations, the most common aims why organizations wanted to become more agile included: productivity and quality, responsiveness to customer/market changes, job satisfaction, fast/continuous learning in rapidly changing operating environments, and competitive and desirable products (Kettunen et al., 2019). So, agile response to the market requires constant acquisition of up-to-date, relevant knowledge about the market and the entire business context to secure business continuity. Since learning culture supports tacit knowledge awareness and sharing and next change adaptability (Kucharska and Rebelo, 2022), then this relation matters also for agility building. This is because change adaptability and agility are related (Park and Park, 2021).

Therefore, this study explores the link between tacit knowledge and organizational agility. It specifically seeks the answer to the question: *Does the relationship between the mistakes acceptance component of learning culture and tacit knowledge-sharing drive organizational agility?*

1.1 Research Gap

This study is framed by Organizational Knowledge Creation Theory, understood as a continuous process of tacit knowledge acquisition and its transformation into explicit form thanks to social interactions (Nonaka and Takeuchi, 1995). Tacit knowledge in contrast to explicit is enormously personal. Tacit knowledge is difficult to express directly in words, and often the only ways of presenting it are through drawings, metaphors, analogies, and different methods of expression that do not require a formal use of language (Koskinen et al., 2003). Thanks to experimentation and learning through interactions and collaborations, its acquisition enables its awareness and, as a result, also sharing, which in more and more remote-work-dominated business environments is often supported by technology and IT competency of the workforce (Kucharska and Erickson, 2023a-b). Technology development forces business conditions change that next provoke changes in working methods. So, technology then forces agility (Lu, and Ramamurthy, 2011; Orłowski et al., 2017) and facilitates agility. Moreover, agility is developed thanks to learning (Dries et al., 2012). Experimentation, that supports trial-error learning (Ambituuni et al., 2021). Trial-error learning (Hull, 1930; Young, 2009) enables individuals and organizations to grow. Therefore, organizational learning is one of the crucial collective skills enabling organizational ability to respond

timely and accurately, and to creatively adapt to changes. Learning culture development is then required to support agility implementation in organizations. Kucharska and Bedford (2020) proved that organizational learning culture is composed of two dimensions: the motivational climate factor and the factor of acceptance of mistakes as a potential source of learning. Moreover, Kucharska (2021a-b) also proved that the mistakes acceptance component of learning culture supports tacit knowledge sharing. Therefore, this study aims to explore whether there is a strong link between the tacit knowledge flow across the organization and its ability to respond agilely (timely, accurately, and creatively) to contextual changes driven by the mistakes acceptance component of a learning culture. Moreover, this study aims to explore how a positive risk-taking attitude is related to organizational agility. Such formulated study aims are important because tacit knowledge's impact on agility has not yet been considered a significant force supporting agility. Altarawneh and Al-Adaileh (2023) proved that agility mediates between knowledge management and organizational transformation ability, but their study generally concerned knowledge management without analyzing in detail how tacit and explicit knowledge supports these processes. Kucharska and Bedford (2020) and Kucharska and Rebelo (2022a) proved that, indeed, the mistakes acceptance component of learning culture supports tacit knowledge sharing and next adaptability, but the risk-taking attitude as related to organizational agility has not been examined in this context yet. So, examining these relations matters to understand better factors influencing the successful agility implementation in knowledge-driven organizations. This study aims to do so.

2. Theoretical Framework

The mistakes acceptance component of learning culture is defined as the organizational acceptance of the case that somebody can be wrong, and reflects the readiness to correct the way of action (Kucharska and Bedford, 2020). This acceptance component opens employees to critical thinking about their own actions without "blame and shame" but with motivation to gain new knowledge sharing instead of hiding (Kucharska and Rebelo, 2022b) and with motivation to make positive change. Maes and Van Hootegem's (2019) model of organizational change assumes that the reflection from a mistake (understood as input to the organizational system) can trigger change. Moreover, Kucharska and Kucharski (2023) exposed that the mistakes acceptance component of learning culture supports change adaptability of employees characterized by technological and non-technological mindsets. Based on this, the hypothesis was developed as below:

H1: Mistake acceptance component of learning culture impact positively on organizational agility

Based on studies of Love et al. (2013, 2016, 2018) or Gelfand et al. (2011), we can assume that learning culture can transform erroneous events into experiences, leading to tacit knowledge creation. Moreover, Kucharska and Bedford (2020) and Kucharska and Rebelo (2022a) proved that, indeed, the mistakes acceptance component of learning culture supports tacit knowledge sharing and organizational adaptability to changes. Based on this, the hypothesis was developed as below:

H2: Mistake acceptance component of learning culture impact positively on tacit knowledge sharing

The tacit knowledge creation and alignment processes are vital for the successful response to uncertainty and must be facilitated by the company culture to support organizational learning. Organizational tacit knowledge creation is an effect of sharing knowledge across departments and teams (social interactions) but also through experimentation and simulation - learning by doing (Kucharska and Erickson, 2023a-b). Al-Omoush et al. (2020), Baran and Woznyj (2020), Cegarra-Navarro and Martelo-Landroguez (2020), and Cegarra-Navarro et al. (2016), Pitafi et al. (2023) claimed that efficient knowledge management matters for successfully implementing agility. Tacit knowledge sharing is one of the key processes that knowledge management focuses on. So, based on this, the hypothesis was proposed as below:

H3: Tacit knowledge sharing impact positively on organizational agility

Control variable – A control variable (CV) represents an additional factor (third variable) that may influence the relationship between an independent and dependent variable in the model tested. A CV may act as a confound, a moderator, or a suppressor (Spector and Brannick, 2011). The CV's imputation methodology enables extraneous variables to be included in a model–control variables are not the focal point of the study yet remain theoretically important (Becker et al., 2016). For this study, such a theoretically important variable is risk-taking attitude. A risk-taking attitude is needed to cross boundaries and comfort zones, which matters for new learning. "(...) learning as one of the organization's core values, a focus on people, concern for all stakeholders, stimulation of experimentation, encouraging an attitude of responsible risk, readiness to recognize errors and learn from them, and promotion of open and intense communication, as well as the promotion of cooperation,

interdependence, and share of knowledge" (Rebelo and Gomes, 2011, p.174). Moreover, works by Funston and Wagner (2010), Galli and Lopez (2018), Moran and Moran (2014), and Rael (2017) enable us to expect that risk management is significantly tied to organizational agility competency building. Based on all the above, we see a risk-taking attitude as a factor that can affect the relation between the mistakes acceptance component of learning culture and tacit knowledge sharing on organizational agility. Therefore, the hypothesis was formulated as below:

$H_{cv}1$: Risk-taking attitude affects organizational agility

Mediation – An intermediate variable that brings a deeper understanding of the relation between two variables is considered to be a mediator. For this research, tacit knowledge sharing is considered to be a mediating variable between the mistakes acceptance component of learning culture and agility, assumed as influenced by this component. Figure 1 visualizes the theoretical framework elaborated above.

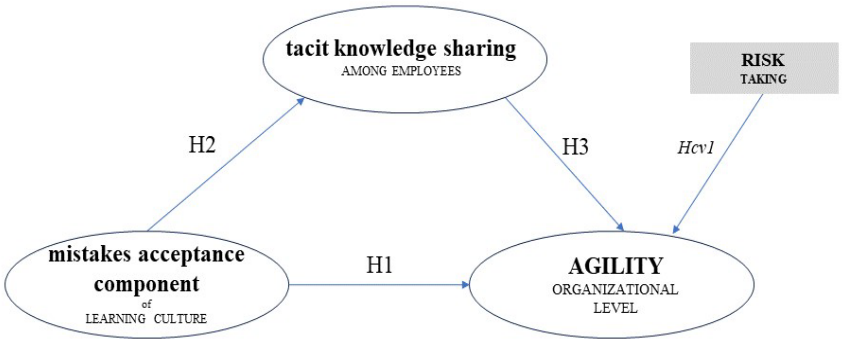

Figure 1: Theoretical model

3. Methodology

Sampling procedure: this study targeted Polish knowledge workers; therefore, qualified respondents declared that their work's first input and output is knowledge. Moreover, to secure the respondents' familiarity with their organizations' issues, we qualified only those who worked a minimum of one year for their current employer. Data were collected in March 2023 by applying the CAWI method.

Sample characteristics: The sample is composed of 640 Polish knowledge workers: 306 specialists and 334 managers; 329 women and 311 men representing mostly private (77%) companies from different sectors to illustrate the general view on Poland (dominating sectors: production and knowledge services 19% each). Measures: respondents referred to most questions using a 7-point Likert scale. Control variables were inputted as composites. Table 1 presents measured constructs scales and their sources. Obtained reliabilities are given in Table 2.

Table 1: Scales and their sources

Mistakes acceptance component **Learning culture** (Kucharska and Bedford, 2020)	• People know that mistakes are a learning consequence and tolerate it up to a certain limit. • Most people freely declare mistakes. • We discuss problems openly without blaming others. • Mistakes are tolerated and treated as learning opportunities.
Tacit knowledge sharing (Kucharska and Erickson, 2023a)	• I share knowledge learned from my own experience. • I have the opportunity to learn from the experiences of others. • Colleagues share new ideas with me. • Colleagues include me in discussions about the best practices.
Organizational agility proxy bases on the Change adaptability scale (Kucharska and Bedford, 2020)	• We are flexible to changes. • We can adjust ourselves to changes. • We adapt to changes easily. • We used changes.
RISK-TAKING ATTITUDE (Kucharska, 2021a based on Zinn, 2020)	• I have a risk-taking attitude. • My boss exposes a risk-taking attitude. • My workmates have a risk-taking attitude.

Method of analysis: structural equation modeling (SEM) using SPSS Amos 26 software (Byrne, 2016).

Sample quality: Kaiser–Meyer–Olkin (KMO) test: .909, the total variance extracted: 70%, and Common method bias: 46% justify the acceptable quality of the sample.

Table 2: Basic statistics obtained AVE root square and correlations between constructs

	Mean	SD	AVE	CR	Cronbach alpha	$_{cv}$**R**	**TKS**	**LCm**	**A**
$_{cv}$**R**	-	-	-	-	-				
LCm	3.16	1.80	0,81	0,93	.93	-0,063	**0,902**		
TKS	3.62	1.20	0,50	0,86	.86	-0,032	0,503	**0,927**	
A	3.64	1.15	0,59	0,85	.85	-0,124	0,6	0,779	**0,922**

Note: n=640, TKS-Tacit knowledge sharing, LCm-Learning culture mistakes acceptance component, A-organizational agility; control variable: $_{cv}$R– Risk-taking attitude; squared root of AVE is bolded, ML- maximum likelihood

4. Results

Control variables imputation requires first running and comparing empirical models with and without control variables (CV), and if the model with CVs is better fitted to the data, then the CVs imputation is justified, and the model results can be analyzed (Becker et al., 2016). The results (Table 3) showed that the model with CVs fits the data better (Model A) than the model without them (Model B). So, this paper further discusses and analyzes the Model A with CVs.

Table 3: Hypotheses verification

Model A with CVs; RMSEA=.058(.046-.069) χ2=125.13(40) Cmin/df=3.12 CFI=.980 TLI=.972					Model B without CVs; RMSEA=.065(.052-.078) χ2=117.84(32) Cmin/df=3.68 CFI=.979 TLI=.971				
Hypothesis	**Significance**		**Verification**		**Hypothesis**	**Significance**		**Verification**	
H1	.27***		*sustained*		**H1**	.28***		*sustained*	
H2	.50***		*sustained*		**H2**	.50***		*sustained*	
H3	.64***		*sustained*		**H3**	.64***		*sustained*	
H_{cv}1	-.09**		*rejected*						
Mediation	direct	indirect	*total*	*Mediation type*	Mediation	direct	indirect	*total*	*Mediation type*
LCm->TKS->A	.27***	.32***	*.59***	*complementary mediation*	LCm->TKS->A	.28***	.32***	.60***	complementary mediation

Note: n=640, ML- maximum likelihood; p<.05 **p<.01 ***p<.001 ns-not significant result

Generally, all hypotheses except the H_{cv}1 were sustained (Table 3; Figure 2). H_{cv}1 assumed the positive impact of the risk-taking attitude on organizational agility. Surprisingly, this impact is observed as negative (β=-.09**). This means that the stronger the positive attitude toward risk for employees, the less successful the organizational agility achievement. Moreover, regarding the expected tacit knowledge-sharing moderation between the mistakes acceptance component of learning culture and agility, this relation is confirmed as complementary mediation (Table 3).

The entire model R^2 =.67 enables us to summarize other factors that are not included in this model (33%), which must be considered to fully understand the influence of the mistakes acceptance component of learning culture on organizational agility, which requires further studies. Figure 2 below visualizes the obtained effects.

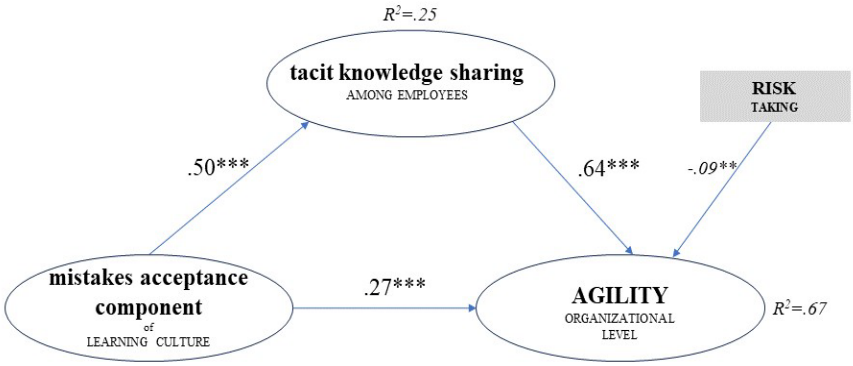

Figure 2: Empirical model

Note: n=640, ML- maximum likelihood; χ2=125.13(40) Cmin/df=3.12 CFI=.980 TLI=.972 RMSEA=.058(.046-.069); p<.05 **p<.01 ***p<.001 ns-not significant result

5. Discussion

The obtained results confirmed that the tacit knowledge sharing mediates between the mistakes acceptance component of learning culture and agility. It means that agility, understood as the ability to respond agilely (timely, accurately, and creatively) to contextual changes, requires being charged by new, contextual, tacit knowledge obtained thanks to trial-error actions (learning by doing) achievable thanks to breaking conventions and experimentation. This revelation expands earlier suggestions by Ambituuni et al. (2021) and Kucharska and Erickson (2023a) that a risk-taking attitude is necessary to break conventions, experiment, learn new things, and share newly gained (not verified yet) tacit knowledge. Also, Denning (2016, 2018) identified next to such vital agile CEO qualities as a customer-first mindset, a company vision for the future, and the ability to continuously create new business models that match employees' skills and create multiple paths to the same aim (scenarios creation), also the readiness to take risks and acquire new institutional skills to develop new paths – as a base for leaders agility, vital for organizational agility.

This study revealed that a positive attitude toward risk blocks agility. And it is the most surprising finding of this research. Instead of the positive influence of the risk-taking attitude of organization members on organizational agility, the negative effect was noted (Hcv1=-.09**). However, this result sheds light on Zanjirchi et al.'s (2017) study, which claimed that supply chain risk factors could be considered drivers of organizational agility. This is because agility, understood as smooth adaptability, is often seen as the effect of efficient risk management. It is because risk is a constant factor in a dynamic business environment. So, on the one hand, the positive attitude towards risk-taking facilitates tacit knowledge sharing (Kucharska 2021a), but at the same time, only efficient risk management leads to organizational agility seen as a smooth collective action toward changing market needs adaptability – as our study results suggest.

Taking a particular innovative action is risky, and non-taking it is risky as well. So, the essence is to select the risk that an organization can afford in the particular business context. Thanks to efficient risk management, the negative impact of inaction can often be seen as higher than the risks of very innovative actions taken, or in other words, very innovative actions are worth risk-taking to avoid risks caused if these innovative actions remain untaken. Summing up, the essence of agility can be, in the light of the given results, seen as the ability to smoothly select the acceptable risk, as suggested by Kucharska et al. (2024). Therefore, risk management skills should be included in the list of key characteristics of agile leaders and agile organizations today.

Moreover, this study targeted Polish knowledge workers. It is because the majority of previous studies concerning learning culture components, precisely the mistakes acceptance component as a source of learning, influence tacit knowledge sharing and change adaptability (Kucharska and Bedford, 2020, 2023; Kucharska and Rebelo, 2022; Kucharska 2021a,b) based on Poland. So, this study gave us a picture of risk-taking attitudes and organizational agility in the same national context previously studied. Thanks to this, we can recognize the difference between the risk-taking attitude meaning, for the tacit knowledge sharing and, the risk-taking attitude meaning, for the agility building. However, the more interesting the findings are, the more critical further studies will be based on countries other than Poland. Such studies are needed to understand the risk-management phenomena for agility in more in-depth. Precisely, for tacit knowledge sharing, the positive attitude of risk-taking is beneficial, whereas for agility building – the opposite – a negative attitude works better.

6. Practical Implications

From the practical perspective, the given results enhance the implementation of a learning culture in knowledge-driven organizations with special attention to the mistake acceptance component. This component is vital for the development of a positive attitude towards the fact that somebody can be wrong and, thanks to this, reflects on one's own actions. Such reflection leads to revealing the contextual tacit knowledge that can be shared among workmates. So, such a shared positive attitude towards the fact that people can be wrong also brings the shared readiness to correct wrong ways of action at work without "blame and shame." The reflection from a mistake can act as a trigger to positive change, enabling better adaptability and competitiveness. Without it, in light of the given results, agility achievement seems to be impossible. The second, very important practical implication concerns risk management. As our study results suggest, only efficient risk management leads to organizational agility, which is seen as a smooth collective action toward changing market needs and adaptability. Therefore, risk management skills should be included in the list of key characteristics of agile leaders and agile organizations today.

7. Limitation and Further Research

The key limitation of this research is that it is based on data collected in only one country. The other critical limitation of this research is that the organizational adaptability scale was adapted here as a proxy for organizational agility. Precisely, the adapted scale omits the factor of organizational ability to respond timely, accurately, and creatively to changes. So, further studies with developed scales for organizational agility are needed to confirm the given findings and conclusions. Furthermore, the analyzed model (Figure 2) explains the phenomenon studied in 67%, while the other 33% remains unrevealed. This means that other factors influencing the relationship between the mistakes acceptance component of learning culture and organizational agility are omitted in the analyzed model and should be identified and studied in more depth in further studies.

8. Conclusion

Answering the question: *Does the relationship between the mistakes acceptance component of learning culture and tacit knowledge-sharing drive organizational agility?* The answer is yes, it does. The results confirmed that the acceptance component of learning culture supports tacit knowledge sharing that fosters agility. Precisely, tacit knowledge sharing mediates between the mistakes acceptance component of learning culture and agility. It means that agility, understood as the ability to respond agilely (timely, accurately, and creatively) to contextual changes, requires being charged by new, contextual, tacit knowledge obtained thanks to trial-error actions (learning by doing) achievable thanks to breaking conventions and experimentation.

Moreover, risk management skills have been proven to be one of the critical characteristics of agile organizations today.

Abstract: Organizational agility is visible in organizational change adaptability, and it is based on the development of dynamic capabilities, strategic sensitivity of leaders, accuracy and timing of decision-making, learning aptitude, flexibility in thinking and acting, and smooth resource flow across organizations, including the knowledge resource. In such a context, this study aimed to expose how the knowledge, learning, and collaboration cultures approach (KLC) supports organizational agility when this relation is moderated by mutual trust among employees, risk-taking attitude, and critical thinking abilities. Based on the sample composed of 640 Polish knowledge workers and data analyzed with the structural equation modeling method (SEM), this study's results proved that the KLC culture synergy supports organizational agility building and that the mistakes acceptance component of learning culture is critical. Moreover, trust among workmates, risk-taking readiness, and critical thinking skills are significant mediators. The key novelty was exposed through the negative influence of a risk-taking attitude (uncertainty acceptance) on agility. Precisely, the lack of risk acceptance or, reversely, the risk-avoidance attitude supports agility. This is because agility, understood as smooth adaptability, is the effect of efficient risk management. Thanks to risk management and critical thinking, the negative impact of inaction risks can often be seen as higher than the risks of very innovative actions. The KLC approach, critical thinking, and trust among workmates support the smooth selection of risks that must be taken in today's dynamic business. Risk is inevitable. So, from this point, the essence of agility is the ability to smoothly and wisely select among risks that should be taken or avoided. In summary, agility can be considered to be the smooth selection of acceptable risks.

Keywords: Knowledge Culture, Learning Culture, Collaborative Culture, Knowledge-Driven Organization, Agility, Risk Management, Critical Thinking, Trust, The KLC Approach

1. Introduction

Business turbulences recently pushed organizations to increase attention to agility as a skill that supports organizational competitiveness and survival (Cegarra-Navarro et al., 2016; Cyfert et al., 2023; Franco et al., 2023; Zastempowski and Cyfert, 2022). Liu (2021) claims that organizational agility is an organizational capacity to achieve high responsiveness and deal effectively and efficiently with market changes to reduce operational uncertainty. Company culture is vital for any organizational capacity building. So, the question arises: how can we describe the culture that supports organizational agility?

Recently, Kucharska and Bedford (2023a-b) introduced the KLC approach and proved that regarding knowledge-driven organizations, knowledge, learning, and collaboration cultures synergy (the KLC approach) supports organizations in their adaptability to changing business conditions. So, the KLC approach seems to be a theoretically very promising supporter for organizations interested in agility building. Since the KLC approach has not yet been studied as an agility predictor – this study aims to do this and additionally expand the body of knowledge by examining if trust, critical thinking, and risk-taking attitudes matter for the organizational level of agility if supported by the KLC cultures approach.

2. Conceptual Framework

2.1 KLC Cultures

The focal point to clarify the KLC culture approach to knowledge-driven organizational culture introduced by (Kucharska and Bedford, 2023a) is the clarification of the key characteristics of each of them and the exposition of their relations. A culture of knowledge dominates in knowledge-oriented organizations that focus more on static knowledge exploitation (Kucharska and Bedford, 2023a; Van Wijk et al., 2012), whereas learning culture dominates in organizations that focus more on dynamic, constantly breaking 'the status quo.' Furthermore, knowledge culture is a base for learning culture. The easiest way to expose the differences between these cultures is to compare the effects of such a different organizational focus. It is easy to predict that if any organization is stuck in the knowledge-orientation stage, then it exists in a reality where static exploitation of knowledge and control dominates, and the new knowledge is rejected. In such organizations, old, proven

methods of cultivating acting are more appreciated than new solutions seeking, and any risk is rejected; consequently, mistakes tied to this risk are avoided. Organizations based chiefly on proven knowledge often prefer to "keep things as they are" - and that "safe, well-known routines control-oriented" organizational attitude might block these organizations' development. In contrast, a learning culture leads to constant, dynamic knowledge acquisition provoked by "intelligence in action" (Erickson and Rothberg, 2012). A pervasive and persistent learning culture is essential to the development and growth of learning organizations in the current economic climate of continuous change (Maes and Van Hootegem, 2019; Rass et al., 2023). An organizational learning culture can facilitate the creation and sharing of knowledge (Kucharska and Bedford, 2023a-b). By itself, a knowledge culture does not have this effect, though it is a basis for fostering curiosity and exposing knowledge gaps that lead to learning. This finding is consistent with the research of Webster and Pearce (2008), who highlighted the importance of situational learning, which is essential to active learning. Situational learning is aligned with the current context. It is especially relevant today in a dynamic and rapidly changing business environment. Acting in such a dynamic business environment might naturally cause many mistakes. Moreover, the lack of mistakes acceptance component of a learning culture can block learning from them at the organizational level. Therefore, a learning culture without developed mistakes' acceptance component is an illusion of learning culture (Kucharska and Bedford, 2020). Based on the above, the hypotheses are given below:

H1a: Knowledge culture positively influences the learning climate component of a learning culture.

H1b: Knowledge culture negatively influences the mistakes acceptance component of a learning culture.

A culture of learning is an organization's ability to create, acquire, and exchange knowledge, modify organizational behaviors and choices, and integrate that new knowledge and insights into its organizational level (Garvin, 1993). Moreover, Kucharska and Bedford (2020; 2023a-b) empirically proved that organizational ability to learn collectively depends on two dimensions: learning climate and mistakes acceptance, and that the climate component (motivational) influences the mistakes acceptance component as a potential source of learning (readiness to be mistaken and to correct actions). Therefore, the hypothesis is added as below:

H1c: The learning climate component of learning culture positively influences the mistakes acceptance component

Moreover, suppose an organization is seen as a group of people coordinated to achieve the aim none of them can achieve alone. In that case, collaborative culture is the essence of any organization's existence (Kucharska and Bedford, 2023a-b). Without collaboration among workmates, there is no reason to name the group of people organization. Organizational learning requires collaboration. Without collaboration, learning in an organization is not collective. Individual learning or even the sum of individual learning does not increase collective knowledge. Organizational learning is based on continuing lessons taken by the entire community together. Otherwise, there is no impact on collective intelligence (Kucharska and Bedford, 2020, 2023a-b). Collaboration supports learning as a source of new knowledge (Nugroho, 2018). Collaboration is the core competency that enables organizations to acquire knowledge collectively. So, collaboration supports the culture of learning that is seen as a favorable learning climate (collective motivation) and the acceptance of being ready to be wrong (Senge, 2006). Based on this, the hypotheses are formulated:

H1d: Collaborative culture influences the learning climate component of learning culture positively

H1e: Collaborative culture positively influences the mistakes acceptance component of learning culture

Collaboration culture supports knowledge culture in knowledge-driven organizations because, for such entities, knowledge is a key resource. Simultaneously, knowledge culture in knowledge-driven organizations simplifies a shared mindset of knowledge appreciation, and knowledge culture supports this way collaboration (Alshwayat et al., 2021). The Kucharska and Bedford (2023b) study empirically proved that knowledge and collaborative cultures correlate. This is characteristic of knowledge-driven organizations where knowledge is perceived as a critical value carrier, object of exchange, and base for strong personal brand creation (Kucharska, 2024). Therefore, following them, the hypothesis is added:

H1f: Knowledge culture and collaborative culture are correlated

2.2 Organizational Agility

In the business context, organizational agility was termed in 1982 as the ability to respond promptly to rapidly changing events (Brown and Agnew, 1982, p. 29). Organizational adaptability reflects how an organization responds to change by managing stress and uncertainty, exposing flexibility or resilience, and supporting those who tackle problems to face the change (Reupert, 2020). Kucharska and Kucharski (2023) proved that the mistakes acceptance component of learning culture supports change adaptability. Martin et al. (2013, p. 1) defined adaptability as 'appropriate cognitive, behavioral and/or emotional adjustment in the face of uncertainty and novelty.' This suggests the dependency of agility on a company culture (Goncalves et al., 2019). Enterprises usually achieve varying levels of agility (Orłowski et al., 2017). These levels depend primarily on human resources' abilities to be agile (Conboy et al., 2011; Harsch and Festing, 2020). This is because agility enables the smooth seize advantage of available opportunities and is connected with social capital and collaborative knowledge creation (Al-Omoush et al., 2020). This is why the implemented KLC approach can be assumed to be a potentially strong predictor of organizational agility. Based on this assumption, hypotheses are formulated as below:

H2: Knowledge culture supports organizational agility.

H3: The learning climate component of learning culture supports organizational agility.

H4: The mistakes acceptance component of learning culture supports organizational agility.

H5: Collaborative culture supports organizational agility.

2.3 Control Variables

A control variable (CV) represents an additional factor (third variable) that may influence the relationship between an independent and dependent variable in the model tested. A CV may act as a confound, a moderator, or a suppressor (Spector and Brannick, 2011). The CV's imputation methodology enables extraneous variables to be included in a model–control variables are not the focal point of the study yet remain theoretically important (Becker et al., 2016). For this study, such theoretically important variables are trust, critical thinking, and risk-taking attitude. Trust is seen as a focal factor affecting the activation of organizational intelligence thanks to its support for tacit knowledge sharing focal for collective learning and adaptability (Kucharska and Bedford, 2023b; Kucharska et al., 2017). "Critical thinking (CT) is constructive thinking about the world of ours that questions and evaluates its operations, history, and management" (Oswald and Mascarenhas, 2019, p.151). Critical thinking is then a base for any learning leading to change. Risk-taking implies uncertainty acceptance (Zinn, 2020). A risk-taking attitude is needed to cross boundaries and comfort zones, which matters for new learning. "(...) learning as one of the organization's core values, a focus on people, concern for all stakeholders, stimulation of experimentation, encouraging an attitude of responsible risk, readiness to recognize errors and learn from them, and promotion of open and intense communication, as well as the promotion of cooperation, interdependence, and share of knowledge" (Rebelo and Gomes, 2011, p.174). Moreover works by Funston and Wagner (2010), Galli and Lopez (2018); Moran and Moran (2014) or Rael (2017) enable us to expect that risk management is significantly tied with the organizational agility competency building. Based on all the above, we see trust, critical thinking, and risk-taking attitude as factors that can affect the relation between the KLC cultures and organizational agility. Therefore, the hypotheses were formulated as below:

$H_{cv}1$: Trust affects the organizational agility driven by the KLC-approach.

$H_{cv}2$: Critical thinking affects the organizational agility driven by the KLC-approach.

$H_{cv}3$: Risk-taking attitude affects organizational agility driven by the KLC-approach.

Figure 1 below visualizes the theoretical framework elaborated above.

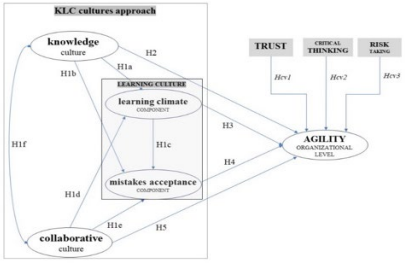

Figure 1: Theoretical model

3. Methodology

Sampling procedure: this study targeted Polish knowledge workers; therefore, qualified respondents declared that their work's first input and output is knowledge. Moreover, to secure the respondents' familiarity with their organizations' issues, we qualified only those who worked a minimum of one year for their current employer. Data were collected in March 2023 by applying the CAWI method.

Sample characteristics: The sample is composed of 640 Polish knowledge workers: 306 specialists and 334 managers; 329 women and 311 men - mainly representing private (77%) companies from different sectors to illustrate the general view on Poland (dominating sectors: production and knowledge services 19% each). Measures: respondents referred to most questions using a 7-point Likert scale. Control variables were inputted as composites. Appendix 1 presents measured constructs scales and their sources. Obtained reliabilities are given in Table 1. Method of analysis: structural equation modeling (SEM) using SPSS Amos 26 software (Byrne, 2016).

Sample quality: Kaiser–Meyer–Olkin (KMO) test: .944, the total variance extracted: 78%, and Common method bias: 37% justify the good quality of the sample.

Table 1: Basic statistics obtained AVE root square and correlations between constructs

	Mean	SD	AVE	CR	Cronbach alpha	$_{cv}$R	$_{cv}$CT	$_{cv}$T	CC	KC	LCc	LCm	A
$_{cv}$R	-	-	-	-	-								
$_{cv}$CT	-	-	-	-	-	-0.09							
$_{cv}$T	-	-	-	-	-	-0.04	0.504						
CC	3.68	1.94	0.57	0.72	.83	-0.04	0.636	0.671	**0.754**				
KC	4.23	1.07	0.71	0.88	.88	0.083	0.425	0.499	0.593	**0.845**			
LCc	3.73	1.04	0.60	0.82	.82	-0.005	0.529	0.571	0.809	0.689	**0.777**		
LCm	3.16	1.80	0.61	0.93	.93	-0.031	0.410	0.430	0.641	0.397	0.593	**0.964**	
A	3.64	1.15	0.59	0.82	.85	-0.129	0.621	0.617	0.750	0.533	0.693	0.592	**0.905**

Note: n=640 KC-knowledge culture, LCc-learning culture climate component, LCm-Learning culture mistakes acceptance component, CC-collaborative culture, A-organizational agility; control variables: $_{cv}$T-Trust, $_{cv}$CT-Critical thinking, $_{cv}$R– Risk-taking attitude; squared root of AVE is bolded

Table 1 shows a high correlation between CC and LCc, which exceeds the squared root of AVE. Since Common method bias exposes an acceptable level, it suggests that CC supercharge LCc.

4. Results

Control variables imputation requires first running and comparing empirical models with and without control variables (CV), and if the model with CVs is better fitted to the data, then the CVs imputation is justified, and the model results can be analyzed (Becker et al., 2016; Carlson and Wu, 2012). The results (Table 2) showed that the model with CVs indeed fits the data better than the model without them. So, the model with CVs is further discussed and analyzed in this paper. Most of the hypotheses formulated were confirmed; the exceptions are H2, H3, and **$H_{cv}3$**. These exceptions are discussed more in-depth in the next section. The general results show that the KLC culture synergy supports organizational agility. The mistakes acceptance component of learning culture and collaborative culture support it directly, whereas knowledge culture and learning climate component of learning culture indirectly. Moreover, all inputted control variables are significant for organizational agility: trust among employees and critical thinking attitude support organizational agility positively, whereas risk-taking attitude – negatively. Figure 2 and Table 2 expose hypotheses verification details.

Table 2: Hypotheses verification

5. Discussion

Results requiring discussion concern those hypotheses that were not confirmed: H2, H3, and $H_{cv}2$. Regarding the lack of sustention of H2, which assumed the positive influence of knowledge culture on organizational agility, it can be clarified by the definitions of knowledge culture and learning culture as well as by previous findings of Kucharska and Bedford's (2023a-b) studies. Knowledge culture itself creates a passive consumption of existing knowledge, but it creates the motivation to learn. Learning culture creates new knowledge absorption and production that leads to dynamic development. It is why H2 is not sustained, whereas H1a, about the positive influence of knowledge culture on the learning culture component – climate (LCc), is significant.

Following knowledge culture - learning culture relations, the H1b about the negative influence of knowledge culture on the mistakes acceptance component of learning culture (LCm) is confirmed. As was expected, knowledge culture itself creates a passive consumption of existing knowledge and, by nature, does not accept mistakes in any form, so it is also a potential source of learning. However, the fact that H3 about the positive influence of LCc on agility was not sustained, whereas H4 about the positive influence of LCm on agility was found to be significant, suggesting that active trial-error learning is fundamental for agility. This conclusion is confirmed critical for active trial-error learning. Without them, LCc is significantly important for agility, but if CVs imputation transforms learning climate into favorable conditions to dynamic trial-error learning through acceptance of mistakes as a potential source of learning that directly supports organizational agility.

Regarding control variables, the hypothesis about the positive influence of the risk-taking attitude of organization members on organizational agility ($H_{cv}3$=-.09**) was not confirmed. Precisely, the opposite - negative influence was observed; the risk-avoidance attitude supports agility. So, it aligns with the findings of Zanjirchi et al. (2017), who claimed that supply chain risk factors could be considered drivers of organizational agility. This is because agility, understood as smooth adaptability, is often the effect of efficient risk management. Thanks to this efficient risk management and critical thinking, the negative impact of inaction risks can often be seen as higher than the risks of very innovative actions, or in other words, very innovative actions are worth risk-taking to avoid risks caused if these innovative actions remain untaken. This is why the impact of critical thinking ($H_{cv}2$=.17***) on organizational agility is so evident. Trust ($H_{cv}1$=.14**), as claimed before by Kucharska and Bedford (2023, a-b) as vital for strengthening the KLC cultural approach benefits. One of the most desired benefits of the KLC approach is organizational agility. So, all the imputed into the model CVs are critical and support agility building.

6. Practical Implications

The key contribution of the presented findings to the practice was exposed through the negative influence of a risk-taking attitude (uncertainty acceptance) on agility. Precisely, the lack of risk acceptance or, reversely, the risk-avoidance attitude supports agility. This is because agility, understood as smooth adaptability, is the effect of efficient risk management. Thanks to risk management and critical thinking, the negative impact of inaction risks can often be seen as higher than the risks of very innovative actions. From a practical perspective, we conclude that sometimes very innovative actions are worth taking to avoid the negative consequences if these innovative and risky actions remain untaken. Risk is inevitable in business. So, from this perspective, the essence of agility is smooth risk management that creates the organizational ability to select risks taken or avoided wisely.

Regarding the KLC approach, as Kucharska and Bedford (2023b) suggested, those leaders who do not expose the KLC approach should not be leaders at any level. This study's findings enable us to add that this rule is particularly significant for those organizations that aim to be agile.

7. Limitations and Scientific Implications

The key limitation of this research is that it is based on data collected in only one country. The second important limitation is the identified strong interdependency between collaborative culture and the learning climate component of learning culture in Poland. This interdependency may cause slight bias, but at the same time, it might expose how focal collaborative culture is for motivation to learn in organizations. Moreover, the results presented reveal direct relations. No mediated or moderated effects are included. So, further studies can explore these relations more in-depth. Furthermore, the analyzed model (Figure 2) explains the studied phenomenon in 68%. It means, that other factors important for understanding the KLC approach's impact on organizational agility that are not included in the analyzed model should be identified and studied more in-depth. The critical limitation of this research is that the organizational adaptability scale was adapted here as a proxy for organizational agility. Precisely, the adapted scale omits the factor of organizational ability to respond timely, accurately, and creatively to changes. So, further studies with developed scales for organizational agility are needed to confirm the given findings and conclusions.

8. Conclusions

Trust, risk-taking attitude, and critical thinking are tremendous for organizational agility building. Moreover, the findings exposed that the KLC culture synergy supports organizational agility mainly through collaboration culture and the mediating power of mistakes acceptance component of a learning culture. Moreover, all the inputted to the model control variables significantly support this relation. The given results proved that the risk-avoidance attitude positively supports agility. This is because agility, understood as smooth adaptability, is the effect of

efficient risk management. Thanks to risk management and critical thinking, the negative impact of inaction risks can often be seen as higher than the risks of very innovative actions, or in other words, very innovative actions are worth risk-taking to avoid risks occurring if these innovative actions remain untaken. So, from this perspective, the essence of agility is smooth risk management that creates the organizational ability to select risks taken or avoided wisely. The KLC approach, critical thinking, and trust among workmates support the smooth selection of risks that must be taken.

Appendix 1: Scales and their sources

Knowledge culture (Kucharska and Bedford, 2020)	• All employees perceive knowledge as a valuable resource. • We have a common language to support knowledge exchange. • We are encouraged to share knowledge, ideas, and thoughts. • We care about the quality of knowledge that we share.
Learning culture (Kucharska and Bedford, 2020)	Learning climate component • All staff demonstrate a high learning disposition. • We are encouraged to engage in personal development. • We are encouraged to implement new ideas every day. • We are encouraged to engage in seeking new solutions. Mistakes acceptance component • People know that mistakes are a learning consequence and tolerate it up to a certain limit. • Most people freely declare mistakes. • We discuss problems openly without blaming others.

	• Mistakes are tolerated and treated as learning opportunities.
Collaborative culture (Kucharska and Bedford, 2020)	• My company supports cooperation between workers. • Cooperation among the different duties, teams, and departments was encouraged. • Co-workers volunteer their support even without being asked • People support each other.
Organizational agility proxy bases on Change adaptability scale (Kucharska and Bedford, 2020)	•We are flexible to changes. • We can adjust ourselves to changes. • We adapt to changes easily. • We used changes.
TRUST (Kucharska and Bedford, 2023b)	• I trust people at work. • People in my team trust one another. • People in my division trust one another. • People in my entire organization trust one another.
CRITICAL THINKING (Kucharska and Erickson, 2023)	• Making sense of things is important to me. • I learn from constructive questioning. • I like to evaluate my work and find out better solutions on my own.
RISK-TAKING ATTITUDE (Kucharska, 2021 based on Zinn, 2020)	•I have a risk-taking attitude. •My boss exposes a risk-taking attitude. •My workmates have a risk-taking attitude.

Cultural Determinants of Sharing High-quality Knowledge: A Case Study of Wikipedia's Featured Articles

Katarzyna Kukowska
Czestochowa University of Technology, Poland

katarzyna.kukowska@pcz.pl

Abstract: Wikipedia is the largest encyclopedia in the world. It works by involving users in sharing knowledge, systematising it and correcting the content of encyclopedia entries. The range of features that involve users in the process of creating the encyclopedia and its derivative projects is much wider. From a research perspective, the socio-cultural foundations of this encyclopedia are the most interesting. The aim of this study was to present the ways in which users are involved in creating articles referred to as featured. Respondents participating in the study were asked this question: does the structure and the way authors and editors of high-quality articles are involved in the project remain dependent on the Hofstede Individualism Index (IDV)? The method used in the study was an analysis of user activity and ways in which users were involved. The author obtained the data using the xTools tool available on Wikipedia. When selecting the language versions for the analysis, criteria were used: 1) their cultural homogeneity, 2) extreme IDV values – individualism versus collectivism, in order to obtain a clear contrast, and 3) a large number of featured articles. For this sample, in cultures with high IDV rates, users were involved in creating and modifying featured articles in significantly greater numbers. However, the smallest share of featured articles concerns the language versions with the highest IDV. Statistically, the study showed significant differences in the form of author and editor engagement in creating high-quality articles. The results obtained do provide grounds for concluding that the quality of content depends on Hofstede's cultural indicators. In continuing the study, it is worth considering making a comparison of the number of featured articles of different language versions in particular fields of knowledge.

Keywords: Activity in Virtual Communities, Cultural Dimensions, Sharing Knowledge, Wikipedia Users

1. Introduction

The prospect of creating a sustainable, evolving and effective organisation based on motivated, active and unpaid activists is very attractive cognitively. The Wikipedia project proves the scale on which the cooperation of a huge number of individuals can be organised. Wikipedia does not rely on traditional forms of governance that require hierarchical leadership. The individual's contribution is fully autonomous, based on intrinsic motivation. The absence of user declarations as to the degree of commitment or tools to coerce a formal agreement has not stopped the organisation from working continuously for over 20 years.

Each language version is an autonomous community under the supervision of the Wikimedia Foundation, with Meta-Wiki coordination. Therefore, the socio-cultural determinants of the activity of Wikipedia editors are of interest to the study. The aim of this study was to present the ways in which users were involved in creating articles referred to as featured. Featured articles are a high-quality body of knowledge, created using a process of collective commitment to knowledge sharing. Wikipedians are guided by the following criteria to qualify an article as featured: a comprehensive description of the topic; a text that covers the main aspects of the topic without going into unnecessary details; neutrality; An exhaustively illustrated topic and an exhaustive overview of sources relevant to the topic is used (https://en.wikipedia.org/wiki/Wikipedia:Compare_criteria...). The high quality of the article is confirmed by the award of a symbolic medal or barnstar. Table 1 presents the symbols used to mark featured articles in the language versions selected for the study.

Table 1: Symbols of Featured Articles of Selected Language Versions in Wikipedia

Indonesian	Dutch Thai	Swedish	Georgian Norwegian Slovenian	Persian Vietnamese	German	Czech	Polish
							

Wikipedia exemplifies new patterns of cooperation and new models of information, revision and distribution that are shaping the modern model of authorship (Alonso and Robinson, 2016). The article is a contribution to a study of the determinants of high-quality knowledge sharing. The main question is: does the structure and the way authors and editors of high-quality articles are involved in the project remain dependent on the Hofstede Individualism Index (IDV)?

The article is of exploratory nature. In order to answer the research question the paper consists of sections and namely: section 2 presents a literature review, pointing out Wikipedia's lack of cultural neutrality, section 3 presents description of the research process, section 4 presents study results (hypotheses are verified in the subsections), section 5 provides a discussion and identifies the limitations of the study. The article ends with conclusions.

2. Wikipedia and Cultural Neutrality

Since the inception of Wikipedia, the issue of the quality of content created by Wikipedians has been raised. This is despite the fact that, after only a few years of Wikipedia, Giles (2005) suggested that scholarly articles on Wikipedia had reached a level of quality similar to that of the Encyclopædia Britannica. Nevertheless, Mesgari et al (2015), when identifying Wikipedia-related scholarly publications, showed that about 80% of research queries focused on quality issues. Konieczny (2021) notes that advanced review processes, particularly "Recommended Article Review", provide good protection and oversight over the quality of content. In the case of featured articles, research is largely focused on processes that monitor the quality of content. One factor influencing the quality of articles is the attributes, roles, and experiences of editors (Ren et al, 2016). Articles edited mainly by "versatile" editors, which occur in various Wikipedia activities, tend to be of high quality. In addition, research has linked the quality of articles to the experience of the main co-author (Kane, 2011), the knowledge of editors, and affiliation with WikiProjects (Kittur et al, 2009). Iba et al (2010) have developed a tool that transforms the flow of edits between contributors into a temporary social network. They analysed 2580 articles from English Wikipedia and identified a key category of coolfarmers, authors who start and create new high-quality articles best suited to enforce behaviours consistent with Wikipedia's culture. The quality of Wikipedia is deteriorated by egoboosters, people who use Wikipedia mainly to present themselves by fuelling discussions on controversial topics. Finding indicators to identify Wikipedia's most valuable contributors can be used for alternative article quality ranking systems based on author quality. Zhang et al (2020) analysed archival data of 6057 articles, examining the evolution of the quality of articles on Wikipedia. Some of the articles will never exceed the low or moderate level. Most articles achieve high quality through years of continuous efforts. In addition, the development of the article is influenced by the time the article was created, its popularity and relevance. Based on the results of the quality assessment of more than 39 million articles in 55 languages, Lewoniewski et al (2019) investigated which topics were best represented in different language versions of Wikipedia. It was confirmed that the popularity of an article could be a factor relevant to assessing quality. Articles on topics popular in a given language are of relatively high quality. One important condition is that a small group of editors contributing a disproportionately high percentage of edits remains in order for the text to achieve the status of featured articles. Lewoniewski et al (2016) proposed models to assess the relative content of the entire article and the quality of the data contained in its structural elements. For each language version of Wikipedia, parameters are selected to enable automatic evaluation. Links between articles in different languages provide opportunities to compare and verify the quality of information in different language versions. On the basis of the various characteristics of featured articles, other articles can be evaluated. Lewoniewski et al (2023) also conducted an analysis of Wikipedia references in 310 languages. Additionally, they classified Wikipedia articles according to different topics. This made it possible to find differences in the range of scholarly sources between the language versions of Wikipedia.

Wikipedia is not culturally neutral. Wikipedia editors reflect their own cultural norms by referring to the process of creating Wikipedia articles and different patterns of collaboration. A high IDV stands for individual identity, dominant over group identity. Self-actualisation and a firm private opinion are valued. Collectivism is concerned with building harmony and consensus within a group, avoiding confrontation (Hofstede et al, 2010, pp 89-134). Cultural differences in Wikipedia language versions based on Hofstede dimensions have been identified by Pfeil et al (2006) etc. The authors found that the likelihood of editors performing different types of actions on Wikipedia was correlated with differences in cultural dimensions. Pfeil et al argued that a greater number of activities would be associated with the linguistic version identified with collectivist cultures. A total of 952 changes to the selected entry of the four versions of Wikipedia were analysed. The higher the IDV of a given country, the more entries members of that Wikipedia page contributed in remedial categories. Stvilia et al (2009) measured the cultural similarity between the three Wikipedias using Hofstede's typology. In the study, the authors analysed quality understanding and value structure by tracking voting and decision-making behaviour on featured articles. In the sample, the number of editors and the number of edits made by registered users were negatively related to quality. The relationship between the degree of similarity of cultural traits and the degree of similarity of quality models in Wikipedias was not conclusive. Nemoto and Gloor (2011) analysed the

process of creating articles and social interactions in five language versions of Wikipedia. The authors found differences in communication behaviour between egalitarian and hierarchical cultures.

Despite extensive research, the debate on the quality of content and the resulting quality of knowledge popularised by Wikipedia will continue. As Jemielniak (2019) notes, Wikipedia will remain in the space of social life, providing free encyclopedic knowledge for the good of the public. Therefore, the motivation to study the behaviour of Wikipedia editors in the light of cultural conditions is justified.

3. Methodology

The article presents the next stage of a cyclical stud y on the socio-cultural determinants of the Wikipedia project, which has been in progress since 2021. So far, the author's study has shown, differences in the cooperation structures of the studied language versions of Wikipedia, in relation to selected cultural indicators by Hofstede (Kukowska, 2023; Kukowska, 2022; Skolik, Kukowska, 2021). The starting point for the current research was the involvement of users of selected language versions of Wikipedia in creating and sharing of high-quality knowledge. Co-authorship in featured articles was taken as an indicator of high quality. The level of involvement of featured article creators in various forms of activity is reflected in the individual namespaces. Namespaces are the types of web pages that make up Wikipedia content, and articles are only part of the namespace. Technically, namespaces are a collection of pages whose names begin with a prefix recognised by MediaWiki software (https://en.wikipedia.org/wiki/Wikipedia:Namespace). The study assumes that there is some correlation between the creation of high-quality knowledge by the most active users in this area and cultural conditions. The Individualism index (IDV) in Hofstede's typology was considered as the basis for differences in the cultural dimension. It was assumed that this differentiation is reflected in the form of activities reported in the statistics of the users represented. The following hypotheses were adopted:

H1 – According to the preferred models of work (collective versus individualistic), the featured articles of language versions with high IDV are created by a small group of people, as opposed to cultures with low IDV.

H2 – The index of individualism in a given culture (reflecting the attitude towards cooperation) translates into a higher or lower share of featured articles in particular language versions.

H3 – The distribution of activity of high-quality content creators in namespaces is clearly different for each language version, in view of the IDV value.

A number of steps were taken to carry out the analysis. First of all, from the https://meta.wikimedia.org/wiki/Wikipedia_featured_articles website, language versions with at least 50 featured entries were selected. The IDV indicator was used to qualify the language versions for data analysis. It was assumed that in the process of creating common content by often very many users, it is this cultural dimension that remains crucial to such a working model. The selection of language versions took into account their cultural homogeneity and extreme IDV values, i.e. above 70 or below 30 on a scale from 0 to 100. The analysis was limited to 12 language versions. The exception was the Polish (IDV47) version, which in the process of data analysis in the files was assigned to the version with low IDV. Some language versions of Wikipedia were not examined - those of the most widely used languages in the world (e.g. English, Spanish, French). They were rejected due to differences in the cultures from which their creators came. This applies especially to English, which is widely recognized as an international language. Using the same language does not always mean cultural closeness, so there was a risk of distorting the study results taking into account the level of IDV.

In the second step, 50 featured articles were randomly selected to analyse their statistics, from each of these versions. Contributors were selected from the history of the articles. Out of 600 featured articles, 2904 authors/editors were selected according to the following measures: 1) the highest percentage contribution to the article, up to the tenth position from the list of editors of a given article, 2) exclusion of bots, and 3) contributors of at least 3 featured articles from the pool drawn. 192 users from language versions with low IDV and 179 users with high IDV were deemed characteristic of user activity. The study analysed user activity by obtaining data from Wikipedia using the xTools tool. Data for the study was collected from January to March 2024.

4. Study Results

4.1 Co-Authorship Structure for Featured Articles – Collectivism Versus Individualism (Verifying H1)

To verify H1, it was necessary to answer the question of what is the structure of co-authorship of high-quality articles. The main axis representing the differences in cultural determinants for creating high-quality content was the division of the language versions of Wikipedia into a set of cultures with a high level of collectivism as opposed to individualistic cultures. After creating two sets of selected language versions overall, the statistics showed a significant difference in the number of total users. Language versions with a low IDV were created by 16,124 active users, and versions with a high IDV had 12,702 more active users (the big difference is due to the very large German version). The total number of editors creating the selected featured articles (before the selection) was adequate to the number of active users. In the language versions of collectivist cultures, 300 articles were produced by 18051 users (median: 2827.5). In individualistic cultures, it was 30,843 users (median: 4,643) per 300 articles. For this sample, in cultures with high IDV rates, users were involved in creating and modifying featured articles in significantly greater numbers. H1 received a negative assessment during verification.

4.2 Contribution of Featured Articles to Encyclopedia Entries (Verifying H2)

The answer to the question of what part of all articles are featured articles in the analyzed language versions of Wikipedia made it possible to verify H2. In the analysed language versions, featured articles account for between 1.7% and 22.1% of all articles in total. Therefore, there is a great discrepancy. The smallest share of featured articles concerns the language versions with the highest IDV: Swedish (IDV87) – 1.4% and Dutch (IDV100) – 1.7%. At the same time, Slovenian (IDV81) has the largest share of featured articles – 22.1%. The set with a lower IDV includes Georgian (IDV15) – 14.4% and Thai (IDV19) – 12.5%. The above discrepancy in the collections accepted leads to the idea that the sheer number of featured articles does not have to be represented in terms of a given cultural dimension. Moreover, the average share of featured articles in total articles for language versions with low IDV is 7.35%, and for language versions with high IDV it is 7.48%. Although this is a small sample, this very small difference in the averages is surprising. In the examples studied, the least numerous language versions of Wikipedia have the largest percentage of featured articles in their encyclopedia entries: Georgian – 284 active users (14.4%), Thai – 1169 (12.5%), Slovenian – 389 (22.1%). H2 has not been confirmed.

4.3 Activities of High-Quality Content Contributors and IDV (verifying H3)

The verification of H3 required an answer to the question of what forms of activity the contributors of high-quality content engage in the most. The Wikipedia statistic describes the characteristics of a Wikipedian's activity by counting the number of edits in a set of MediaWiki pages collectively named namespace (https://en.wikipedia.org/wiki/Wikipedia: Namespace). Namespaces are numerous, and their use varies from language to language. In order to represent user activity, namespaces were grouped according to their functions into the following areas: substantive, technical, interaction (social), content promotion, and working (organisational).

1. Substantive spaces: Main/Article, Category, File and Timedtext are types of namespaces containing content created for readers (recipients). From the encyclopedia's point of view, Mains are the most important. Managing the content of articles (this is the constantly negotiated taxonomy of encyclopedia knowledge) is enabled by Categories. The File namespace contains mainly photos but also other graphic and multimedia forms, and a number of different files that are attachments placed in articles. TimedText, on the other hand, is a multimedia file space that enables the user to add text to video recordings.

2. Technical spaces: Template, Module and MediaWiki contain mainly complex code that enables the user to handle other namespaces. Templates can be more or less complex; they contain rather simple content placed on many pages. One example is the Infobox, which is usually placed in the upper right-hand part of the article; it is technically advanced and can be filled in by entering a small amount of data. A module is a more advanced type of page that some templates use. MediaWiki, on the other hand, is the core software architecture of the Wikimedia projects.

3. Interaction/social spaces: User talk, Wikipedia, Wikipedia talk, Help and Help talk are spaces primarily used for communication between Wikipedians and to inform users about the rules of contributing to an encyclopedia. Originally, this was the purpose of the User talk space. However, such communication was not public, which is why the Wikipedia namespace was created. Common rules were also established in this space, and once

established, the Wikipedia talk space enabled them to be criticised or renegotiated. Help and Help talk have been separated for the benefit of how-to websites.

4. Content promotion spaces: Portal, Book and Story are the types of pages that allow Wikipedians to present content from specific subject areas. Portals are used for internal promotion of certain categories of entries and created according to the model of the main page, introducing the reader to a given topic area. Book and Story, on the other hand, enable individual users to choose content that is interesting to them and promote it outside Wikipedia.

5. Workspaces/Organisational Spaces are any pages where various preparatory work is done, cooperation with other users is undertaken, content is reviewed in detail, and articles are drafted. Dedicated spaces for these purposes are: Wikiproject, Wikiproject talk, Draft and Draft talk. In the case of other spaces, they are also used for the same purpose, although their purpose was different. The User space is used for self-presentation, but often users use it (or rather its subspaces) to create a number of drafts. Talk is a space for evaluating an article, and comments on how to improve an encyclopedia entry are often exchanged here. Talk spaces assigned to other namespaces are treated similarly.

In order to represent the forms of activity in which co-creators of high-quality content engage the most, the Mann-Whitney U test was conducted (Szajt, 2014). The test results are shown in Tables 2-6. Statistically significant differences for the given language versions are marked with an arrow symbol. The direction of the arrow indicates the language version in which users are more active. For the remaining cases, no statistically significant differences were confirmed.

In the case of activity in substantive spaces, the test only showed statistically significant differences in the comparison of language versions with a high IDV index, even in relation to each other. The dominant figures in this system are German and Norwegian, in which only in 3 cases were statistically significant differences not confirmed (for Persian, Thai and Dutch). In substantive areas, it is the co-authors of culturally individualistically conditioned language versions that show dominant activity in relation to collectively conditioned language versions. The only exception is the Czech version, which is inferior to the other versions from its pool (Table 2).

Table 2: Mann-Whitney U test for Author and Editor Activity in Content Spaces

LANGUAGE VERSIONS	IDV	id	ka	th	fa	vi	pl	cs	de	no	sl	sv	nl
id-Indonesian	5												
ka-Georgian	15	-											
th-Thai	19	-	-										
fa-Persian	23	-	-	-									
vi-Vietnamese	30	-	-	-	-								
pl-Polish	47	-	-	-	-	-							
cs-Czech	70	-	-	-	-	-	-						
de-German	79	←	←	-	-	←	←	←					
no-Norwegian	81	←	←	-	-	←	←	←	-				
sl-Slovenian	81	-	-	-	-	-	-	-	-	-			
sv-Swedish	87	←	-	-	-	←	-	-	-	-	-		
nl- Dutch	100	←	←	-	-	←	-	←	-	-	-	-	

In technical areas, all language versions selected for the study showed statistically significant differences in distribution levels in the test in at least 2 cases (e.g. Indonesian with German and Polish). In technical spaces, their users are more active. In this group, the Thai version is predominant in 9 cases, 5 of which refer to individualistic cultures. The trend is offset by the Polish language version, which shows statistically significant differences with all language versions from its set (low IDV) and with half of the language versions with high IDV. At the same time, in every case the Polish language version shows lower user activity in technical spaces. However, this version is an exception that does not show extreme values for the indicator (IDV47) in relation to the others. Cases of language versions with high IDV, in which users are more active (Norwegian, Slovenian and Swedish) are still distributed along with the German language version belonging to their set (Table 3).

Table 3: Mann-Whitney U Test for Author and Editor Activity in Technical Spaces

LANGUAGE VERSIONS	IDV	id	ka	th	fa	vi	pl	cs	de	no	sl	sv	nl
id-Indonesian	5												
ka-Georgian	15	-											
th-Thai	19	←	←										
fa-Persian	23	-	-	-									
vi-Vietnamese	30	-	-	↑	-								
pl-Polish	47	↑	↑	↑	↑	↑							
cs-Czech	70	-	↑	↑	↑	↑	-						
de-German	79	↑	↑	↑	↑	↑	-	-					
no-Norwegian	81	-	-	↑	↑	-	←	-	←				
sl-Slovenian	81	-	-	-	-	-	←	-	←	-			
sv-Swedish	87	-	-	↑	↑	-	←	-	←	-	-		
nl- Dutch	100	-	↑	↑	↑	↑	-	-	-	-	-	-	

User activity in interaction spaces did not show such clear tendencies of dominance of one of the sets as in the case of substantive or technical spaces. In the interaction spaces, no statistically significant differences were confirmed for the Swedish language version. In view of the test results, the Swedish version can be treated as a "typical" version. On one hand, in terms of activity it constitutes the threshold to be reached for collectivist cultures and the lower limit for individualistic cultures. For Norwegian and Vietnamese, one case was shown each. On the other hand both versions give way to the more active Persian version which belongs to a collectivist culture. Compared to users representing different Persian cultures, the language version definitely stood out. For the Persians, 8 advantages were shown: over all versions from their own pool (low IDV) and half of the versions assigned to the individualistic culture (Czech, Norwegian, Slovenian). The Persian version is counterbalanced by the Dutch and German versions with 6 and 5 advantages, respectively, but in their own cultural group (Table 4).

Table 4: Mann-Whitney U Test for Authors and Editor Activity in Interaction Spaces

LANGUAGE VERSIONS	IDV	id	ka	th	fa	vi	pl	cs	de	no	sl	sv	nl
id-Indonesian	5												
ka-Georgian	15	-											
th-Thai	19	-	-										
fa-Persian	23	←	←	←									
vi-Vietnamese	30	-	-	-	↑								
pl-Polish	47	-	-	-	↑	-							
cs-Czech	70	-	←	-	↑	-	-						
de-German	79	←	←	←	-	-	←	-					
no-Norwegian	81	-	-	-	↑	-	-	-	-				
sl-Slovenian	81	-	-	-	↑	-	-	-	↑	-			
sv-Swedish	87	-	-	-	-	-	-	-	-	-	-		
nl- Dutch	100	←	←	←	-	-	←	←	-	-	←	-	

A clear advantage of the activity of authors and editors in the promotion spaces was recorded by the Czech and German versions, defeating in 4 cases representatives of collectivist cultures (Indonesian, Georgian, Vietnamese, Polish) and in 2 cases representatives of their own pool (Norwegian, Slovenian). The versions with the highest IDVs (Swedish and Dutch) dominated the Norwegian and Slovenian versions with slightly lower IDVs. The Polish version of 9 statistically significant differences in no case achieved superiority. Only two versions (Thai and Persian) representing collectivist cultures gained an advantage over the individualist versions: Norwegian and Slovenian (Table 5).

Table 5: Mann-Whitney U Test for Authors' and Editors' Activity in Content Promotion Spaces

LANGUAGE VERSIONS	IDV	id	ka	th	fa	vi	pl	cs	de	no	sl	sv	nl
id-Indonesian	5												
ka-Georgian	15	-											
th-Thai	19	-	-										
fa-Persian	23	-	-	-									
vi-Vietnamese	30	-	-	-	-								
pl-Polish	47	↑	↑	↑	↑	↑							
cs-Czech	70	←	←	-	-	←	←						
de-German	79	←	←	-	-	←	←	-					
no-Norwegian	81	-	-	↑	↑	-	-	↑	↑				
sl-Slovenian	81	-	-	↑	↑	-	-	↑	↑	-			
sv-Swedish	87	-	-	-	-	-	←	-	-	←	←		
nl- Dutch	100	-	-	-	-	-	←	-	-	←	←	-	

The test showed predominant user activity in workspaces for individualistic cultures. Statistically significant differences predicted the favourites of users of two language versions: Dutch and German. Users of the Dutch language version had an advantage over collectivist cultures in 2 cases: Georgian and Indonesian. Other cases of predominance of the Dutch version applied to cultures with high IDV: Czech and Slovenian. The German version had the advantage of greater user activity over 3 versions of its own collection (Slovenian, Norwegian and Czech) and 5 from collectivist cultures (Georgian, Indonesian, Vietnamese, Persian, Thai). As an exception, for the Indonesian version, the test showed a statistically significant difference in distributions compared to all studied language versions except Slovenian. At the same time, the Indonesian version did not gain an advantage in any case (Table 6).

Table 6: Mann-Whitney U Test for Author and Editor Activity in Workspaces

LANGUAGE VERSIONS	IDV	id	ka	th	fa	vi	pl	cs	de	no	sl	sv	nl
id-Indonesian	5												
ka-Georgian	15	←											
th-Thai	19	←	-										
fa-Persian	23	←	-	-									
vi-Vietnamese	30	←	-	-	-								
pl-Polish	47	←	-	-	-	-							
cs-Czech	70	←	-	-	-	-	↑						
de-German	79	←	←	←	←	←	-	←					
no-Norwegian	81	←	-	-	-	-	-	-	↑				
sl-Slovenian	81	-	-	-	-	-	-	-	↑	-			
sv-Swedish	87	←	-	-	-	-	-	-	-	-	-		
nl- Dutch	100	←	←	-	-	-		←	-	-	←	-	

The Mann-Whitney U test confirmed H3, the idea that the distribution of high-quality content creator activity in namespaces was markedly different for each language version in view of the IDV value. In addition, the characteristics of contributors according to categorised forms of activity selected the most and least active among the users of the surveyed language versions of Wikipedia. In the case of the Indonesian version, only once did users gain an advantage, in the technical space (the domain of collectivist cultures) over the German version. The Polish version performed less well against 9 out of 11 language versions, only gaining an advantage over Indonesian and Czech in workspaces. The undeniable favourite in this list is the version of the German Wikipedia, which has only been off the podium podium of the greatest activity in technical spaces. The German version has an overwhelming advantage in the number of active users compared to the other language versions, which suggests that the number of users is a strong indicator. However, in the present study, the characteristics of individual user statistics were used. The overall size of a given version was much less significant. The number of users whose activity was recorded was determined by the frequency of co-authorship in the articles selected.

Therefore, the number of respondents for the 12 language versions varied for each of them, ranging from 23 to 41 users.

5. Discussion and Limitations

It seemed reasonable to assume that high quality was produced primarily by a small group of experts. It did not work for the form of work characteristic of creating the content of Wikipedia articles. The higher number of featured article editors in individualistic cultures may obviously be due to the much higher number of active users overall. However, it should be taken into account that editors of an equal number of articles were compared. Perhaps the reason for such a large difference in the number of editors lies in the greater need to assert one's own individual position in the Wikipedian community, which is attributed to individualistic cultures.

A low or high IDV does not give unambiguous results in relation to the share of featured articles in individual language versions.

The substantive space showed the greatest polarisation of the language versions of Wikipedia in terms of the cultural dimension of individualism vs. collectivism. Activity in substantive spaces is the domain of individualistic cultures. Collections of language versions with high and low IDV in technical spaces, unlike those studied in the case of substantive spaces, are the domain of collectivist cultures. Content promotion spaces remain dominated by individualistic cultures. The results of hypotheses verification are presented in table 7.

Table 7: Results of hypotheses verification

H1 – According to the preferred models of work, the featured articles of language versions with high IDV are created by a small group of people, as opposed to cultures with low IDV.	not confirmed
H2 – The index of individualism in a given culture translates into a higher or lower share of featured articles in particular language versions.	not confirmed
H3 – The distribution of activity of high-quality content creators in namespaces is clearly different for each language version, in view of the IDV value.	confirmed

A characteristic feature of all featured articles, regardless of language version, is the disproportionately large share of individual people in their creation. This study confirms the earlier results of Feldstein (2011), among others. Feldstein pointed out that at the article level, creating a text is more like the traditional creative process of an individual author. Previously, Kittur and Kraut (2008) showed that the quality of an article was positively influenced by the cooperation of a small group of editors, who create an article which is subsequently joined by a larger group. In the present study, the contribution of an outstanding editor for 10 language versions averaged 70-80% of the text. For Indonesian and Norwegian, the figure was over 80%. In the Polish version, on average, 90% of the contribution to the content of the article was made by one user. Therefore, the bottleneck in creating high-quality content in the different language versions of Wikipedia is the involvement of experts. The number of featured articles on a given topic can be a clear indicator of the presence of experts among Wikipedia users.

In the analysis of user activity in individual namespaces, there are individual exceptions to the rule of "superactive" people. Out of nearly 400 cases, 3 "superactive" users were found. If a given user has too many edits (maximum 650,000), the counter is simplified, and there is no preview of activity in individual namespaces.

Creating Wikipedia articles can take a long time. The ability to make changes to articles makes it an ongoing process, although many entries remain unchanged for years. In the case of featured articles, we are dealing with content that can be considered highly comprehensive. The primary difficulty that applies to all people exploring Wikipedia statistics is the collection of data at any given point in time. The data is becoming less relevant day by day. If these are small changes, e.g. in the number of editors of a given article or their contributions, the differences will not be significant. However, when more general data is updated every few months, and in some cases once a year or even at longer intervals, it can have an adverse effect on the reality of the analysis. It is therefore advisable to check the validity of the overall data not only at the beginning but also at the end of the study.

Language versions of Wikipedia sometimes use namespaces in individual ways, for activities that are assigned to other spaces. In addition, each language version can define its own namespaces with no equivalents in other language versions. Of the 12 versions of Wikipedia studied, the Indonesian version is example of this. Indonesian has a Story in its namespaces, which contains catalogues of photos from the phone. Such differences in namespaces require a qualitative study.

6. Conclusions

Statistically, the study showed significant differences in the form of author and editor engagement in creating high-quality articles. One should be cautious about generalising conclusions to cover other versions of Wikipedia. However, the results obtained do provide grounds for concluding that the quality of content depends on Hofstede's cultural indicators. In future research, one may assume that representatives of individualistic cultures are superior to representatives of collectivist cultures in the creating high-quality knowledge.

This paper is an extension of the research on the community involved in the sharing of knowledge on the Internet. The determinants of user activity, resulting in the creation of high-quality content, are presented. It would be advisable to include a qualitative analysis in the quantitative study presented, to highlight the differences in the use of namespaces by individual language versions. Qualitative data would give a more precise definition of the cultural space of representatives of different language versions. This could result in the emergence of a new cultural dimension that would more accurately describe the social reality on the Internet.

Abstract: The current business landscape is characterised by complexity and uncertainty, provoked by rapid technological advancements and interconnected macro trends that pose challenges and opportunities for organisations. In this scenario, spaces for learning and knowledge exchange, enhanced by advanced technologies, emerged as pivotal settings to foster innovation dynamics. Specifically, technology-enhanced learning spaces (TELS) are considered physical, virtual, or hybrid settings that support learning and knowledge processes. However, despite the growing interest, there is still a need for a broader understanding of how to effectively design and manage these spaces to maximise their potential in driving organisational innovation capacity. Accordingly, this study aims to address the aforementioned gap by conducting a comprehensive examination of TELS, focusing on their design, management, and influence on innovation dynamics. To achieve this purpose, the study adopts a multi-case study approach and analyses some TELSs across different organisational settings, such as public institutions, business accelerators and private organisations. Data triangulation of theoretical and empirical investigations are employed to derive key patterns and management phases. The findings reveal that TELS are crucial in promoting innovation and knowledge exchange within organisations. They foster collaboration, experiential learning, and personalized exploration, empowering organisations to generate innovative solutions, driving progress. However, several barriers hinder their optimal utilization, including technological limitations and a lack of effective management strategies. Accordingly, this paper proposes a technology-enhanced learning space management framework that distinguishes key phases for managing those spaces, with the aim of enhancing innovation capacity. Theoretical implications include validating and refining existing conceptual and theoretical frameworks related to TELS, testing them in real life settings. Practically, the study offers a framework and insights for managers to enhance the design and management of these spaces, addressing critical issues and maximizing their impact on organizational innovation and performance.

Keywords: Technology-Enhanced Learning Spaces, Management Framework, Advanced Technologies, Innovation, Multiple Case Study.

1. Introduction

In today's dynamic business landscape, organisations are confronted with a multitude of challenges driven by rapid technological advancements and intertwined macro trends. This has created an environment characterised by complexity and uncertainty. In response, organisations increasingly recognise the need to support and strengthen their learning capacity as a strategic imperative. At the heart of this imperative is the drive to innovate, a vital force that underpins organisational survival, competitiveness, and sustained growth (Hamidi et al., 2019). The ability to innovate, which involves generating and implementing novel ideas, products, or processes, is then intricately linked to learning and knowledge processes (Nonaka & Takeuchi, 2019; Hamidi et al., 2019). Learning and knowledge processes and dynamics form the foundation for cultivating capabilities that are essential for navigating the contemporary business landscape (Yildiz et al., 2021). In this vein, learning spaces, encompassing physical, virtual, social, and cultural dimensions, serve as fertile ground for nurturing innovation and driving organisational success (Morris, 2020; Hamidi et al., 2019). However, the evolution of these spaces has been significantly influenced by various factors, including a shift towards learner-centric approaches and the integration of innovative digital tools (Karam et al., 2021). The COVID-19 pandemic, for instance, has acted as a catalyst, accelerating the transformation of learning spaces into technology-enhanced learning spaces (TELS) to meet new challenges and fully leverage digital technologies for learning and knowledge exchange and dissemination (Lagrutta, 2023; Krishnamurthy, 2020).

This transformation, while challenging, holds the potential to inspire innovation and drive organisational success.

A deep understanding of TELS' diverse applications and contextualisation necessitates delineating the tangible and intangible dimensions that impact learning and knowledge dynamics. As a result, the literature review has generated a working definition of technology-enhanced learning spaces (TELS) and a conceptual framework summarising critical dimensions for design and functionality (Lagrutta et al., 2023). Yet, the management processes deserve deeper analysis to define and distinguish the management phases. While recent contributions have predominantly focused on specific management tools, software, or underlying logic unique to distinct learning spaces, the need persists for generalisable and distinctive phases (Al-Khanjari, 2021; Schobel & Scholey, 2012). Nonetheless, heightened attention towards the topic and its associated issues is evident because modern configurations of TELS, necessitating a comprehensive approach to management that necessitates consideration of all structural and dynamic dimensions, understanding their interplay, and their influence on the inclusion and utilisation of both basic and advanced technologies (Lagrutta et al., 2023).

In line with this research's objectives, it is essential to gain a deep understanding of the managerial phases of TELS that aim to drive innovation dynamics.

This study aims to fill this gap by answering to the following research question: "How can organisations effectively design and manage TELS to foster innovation?" This question holds theoretical and practical implications for organisations seeking to enhance their learning capacity and innovation potential.

To comprehensively address this question, the study aims to enrich insights from the literature and develop a management framework through an empirical approach that can serve as a valuable resource for academics and practitioners in creating and effectively managing such spaces. Given the novelty and the fragmented literature results in the management field, a shift towards empirical research is not only warranted but also crucial (Lagrutta et al., 2023). This approach will facilitate a clearer understanding of the phenomenon within the management context, contributing to the existing body of knowledge (Reyes-Mercado, 2022; Pawlowsky et al., 2020).

To achieve this, the analysis first validates theoretical patterns and insights derived from the literature before adopting an inductive approach to develop a managerial framework.

In this vein, the study adopts a multi-case study approach, focusing on TELS developed across diverse organisational settings in Finland and Italy, all aimed at fostering innovation pathways in alignment with the research. Through a rigorous examination of these cases, the research aims to unearth the dimensions and management phases that differentiate effective TELS in nurturing innovation capacity.

The structure of this paper is as follows: after this introduction, the paper provides a comprehensive theoretical background on the concept of TELS and its evolution, particularly in management literature, derived from an extensive literature review. The methodology section outlines the multiple case study approach employed in this research. Then, the findings of the multiple case study are presented.

Finally, the paper concludes with a discussion of the theoretical and practical implications of the findings, highlighting the unique contribution of this research to the field of TELS management and offering directions for future research.

2. Theoretical Background

Organisations must embrace innovation as a fundamental driver of survival, growth and success to thrive in today's rapidly changing business landscape. However, in this digital Era, innovation takes on a broader perspective, fueled by advanced technologies of Industry 4.0 and 5.0. However, the innovation process goes beyond merely adopting advanced technologies but it encompasses embracing digital transformation and organisational change, fueling mindsets and approaches that foster creativity, adaptability, and dynamic problem-solving. Essentially, it is about continuously seeking new ways to add value to products, services, and processes (Scuotto et al., 2023; Hamidi et al., 2019). In a world where disruptive technologies and market forces constantly reshape industries, organisations that fail to innovate risk falling behind their competitors and becoming obsolete.

This requires agility and adaptability to keep pace with rapid change and emerging trends. Here, knowledge plays a pivotal role. It is not just a byproduct of innovation; it is a catalyst. In fact, effective knowledge management is essential for any organization to adapt to changing market dynamics, drive long-term growth, and maintain a competitive edge in today's digital Era. By implementing systematic efforts to expand personal knowledge and facilitating the creation, dissemination, transfer, and storage of knowledge within and outside

the organization, businesses can foster a culture of innovation and enhance their innovation capacity. This, in turn, promotes an environment that stimulates innovativeness and innovation climate within the organization, ultimately leading to successful innovation (Yildiz et al., 2021; Nonaka & Takeuchi, 2019).

Consequently, to support innovation processes in the digital age, organisations must focus on enhancing knowledge management, fostering a learning culture, and creating spaces that enable innovation and knowledge sharing.

In this scenario, learning spaces have emerged as crucial environments for fostering knowledge dynamics and promoting innovation within organisations, both in the public and private sectors (Csizmadia et al., 2022).

The evolution of learning spaces is a transformative journey influenced by technological advancements, pedagogical theories, and societal needs. Traditionally, learning spaces were confined to physical classrooms with rows of desks facing the teacher, fostering a passive learning environment. However, with the emergence of digital technologies and evolving educational philosophies, the concept of learning spaces has undergone a profound transformation.

Flexible learning spaces (e.g. maker spaces and innovation labs), for example, provide learners with opportunities for hands-on experimentation, creativity, and interdisciplinary collaboration (Lee and Tan, 2022)

Moreover, the proliferation of basic and advanced digital technologies profoundly changes learning spaces' design, functioning and management. In this vein, the technological revolution paved the way for the creation of technology-enhanced learning space (TELS), where learners could engage with content and interact with peers and instructors in virtual or physical spaces, supported by basic and advanced technologies.

It follows that a TELS is *"the physical, virtual and hybrid space, of formal or informal nature, characterised by action and interactions among different actors and their capabilities, which promotes cognitive processes and influences knowledge and learning dynamics, through its tangible and intangible components and with a strong technological component"* (Lagrutta et al., 2023).

Against this backdrop of evolution and transformation TELS have emerged as dynamic and multifaceted environments that integrate physical, virtual, social, and organisational dimensions. By understanding and managing the various dimensions of learning spaces, organisations can create innovative environments that support continuous learning and adaptation. TELS encompasses tangible and intangible dimensions facilitating knowledge creation and learning dynamics (Delgado et al., 2020). A critical analysis of the literature reveals several distinguishing dimensions of learning spaces, including actors, settings, technologies, relationships, and organisational culture (Khandelwal et al., 2022; Illeris, 2004). These dimensions are interrelated and complement each other, contributing to the overall effectiveness of the learning environment (Mulligan, S. 2016). These dimensions are presented in Fig. 1 and discussed in the following. Each dimension offers unique insights into learning spaces' design, implementation, and functioning, reflecting the interconnectedness of diverse dimensions.

2.1 Actors

At the heart of TELS are those who participate in the learning process, including learners, instructors, facilitators, mentors, administrators, and other stakeholders. The diverse roles and perspectives of these actors contribute to the richness and complexity of the learning environment, shaping interactions, collaboration, and knowledge exchange (Lee and Tan, 2023; Lancaster and Milia, 2015).

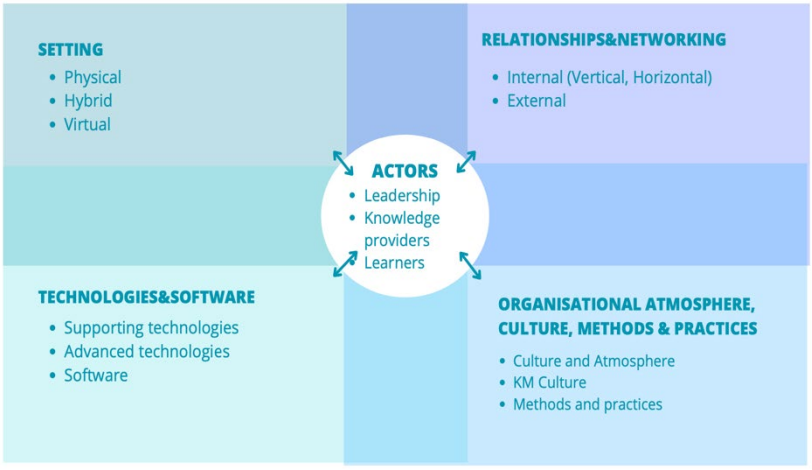

Figure 1: TELS Conceptual framework

2.2 Setting

A TELS's setting encompasses physical and virtual elements that provide the context for learning activities. Physical settings include classrooms, laboratories, workplaces and collaborative spaces designed to facilitate face-to-face interactions and hands-on experiences. Virtual settings encompass online platforms, digital resources, and interactive tools that support remote learning, collaboration, and access to information (Jens and Gregg, 2022).

2.3 Technologies and Software

Technology is central to TELS, enabling access to contents and resources, facilitating communication and collaboration, and enhancing the learning experience. Basic technologies such as computers, tablets, and projectors provide essential content delivery and interaction tools. Advanced technologies, including artificial intelligence, augmented reality, and simulation tools, offer innovative approaches to personalised learning, adaptive feedback, and immersive experiences (Lee and Tan, 2022; Reyes-Mercado et al., 2022)

2.4 Relationships and Networking

Learning is inherently social, and relationships between learners, instructors, and peers play a crucial role in shaping the learning experience. Positive relationships foster collaboration, knowledge sharing, and a sense of community within TELS (Abuhassna et al., 2022). Networking extends beyond immediate interactions to include broader connections and collaborations that enable access to diverse perspectives, expertise, and resources (Ching Lee and Yian Tan, 2022; Müller and Wulf, 2022).

2.5 Organisational Atmosphere, Culture, Methods and Practices

The organisational context significantly influences TELS's design, implementation, and outcomes. Atmosphere refers to the learning space's overall climate and culture which can impact motivation, engagement, and satisfaction. Organisational culture encompasses shared values, beliefs, and norms that shape behaviours and interactions within the organisation. Methods and practices encompass instructional strategies, pedagogical approaches, and assessment methods that guide teaching and learning activities within TELS (Lee and Tan, 2023; Lazzari, 2023)

3. Research Methodology

From a methodological point of view, according to the aim of the study, a multiple case study approach (Yin, 2009) has been rigorously elaborated and developed to provide empirical insights supporting the evidence emerging from the above proposed conceptual model.

Generally, a qualitative management research allows to capture intangible factors that create higher value for the literature. Furthermore, according to Yin (2009; 2013), the conducted case studies aim to gather valuable insights, through literal replication of real-life situations and allow cross-comparisons between different realities

by identifying and defining critical learning points related to the fields of analysis that will result in helpful empirical guidelines for both scholars and practitioners. At its core, the multiple case study approach is a qualitative research methodology aimed at generating and testing theory, particularly in management, when dealing with broad, undefined concepts. It allows for the exploration of complex phenomena within their natural contexts and facilitates the discovery of new variables and insights (Yin, 2009; 2013).

To develop the study, careful consideration was given to ensuring a diverse and representative sample of cases encompassing various geographical locations, organizational settings, and types of TELS.

Then, data collection involved a multifaceted and iterative approach, incorporating both primary and secondary sources to ensure the findings' reliability, validity, and comprehensiveness. Document analysis, participant observation, and in-depth semi-structured interviews with key stakeholders, such as space managers, practitioners, and users, were conducted over an extended research period.

All the interviews were recorded and transcribed. This allowed to have a reliable information base that perfectly reflected the interviewees' thoughts and follows requirements to ensure rigour and validity

The data analysis process was rigorous and systematic, involving the identification of emerging patterns, themes, and relationships within each case. Data were organised, coded, and analysed using qualitative analysis software (e.g., NVivo), allowing for efficient management and synthesis of large volumes of data.

The findings derived from the data analysis were used to validate, refine, and extend existing conceptual framework (figure 1) and develop new insights and conceptual models' specific to the management of TELS for innovation. The study's outcomes aim to contribute to both academic knowledge and practical applications in innovation management, organisational development, and learning.

The selection of nine TELS for innovation, spanning across Finland and Italy, was strategically chosen and each learning space, denoted as Tx, Hx, Dx, Kx, Ax, Cx, Digx, Dihx, and Ox (names changed for confidentiality reasons), was carefully curated to represent diverse perspectives and approaches to fostering innovation dynamics and capacity. The choice of this sample is indeed focused on TELS, which aims to promote innovation dynamics and capacity, providing different perspectives of innovation that are stressed in the following. Moreover, the selection of the cases aims to provide insights into different organisational contexts and approaches to innovation management. This diversity ensures a comprehensive analysis and a nuanced understanding of the processes and dimensions characterising real learning spaces for innovation.

Some of the learning spaces in this multiple case study, in particular, aim to support the development of new ideas and solutions, and thus are involved with startup and entrepreneurial ecosystems; others aim to support individuals and organisations on the path of digital innovation, while others aim to strengthen networking and social innovation. In consequence, these TELS serve various purposes, ranging from digital literacy and social innovation to supporting organisations' digital transformation journey. Despite the diversity in their objectives, these learning spaces share a common goal: to facilitate innovation, knowledge exchange, and collaboration within their respective ecosystems. They act as facilitators, offering a range of initiatives, courses, activities, and consultancy services to guide individuals and companies along their innovation journeys.
Overall, the chosen cases offer a rich and diverse dataset, allowing for cross-comparison and in-depth exploration of the design, functioning, and management aspects of learning spaces for innovation. While existing literature has made some attempts to address this issue, much of it is focused on educational learning environments geared towards facilitating the acquisition of knowledge and skills by students. In contrast, this study seeks to delve into the specific management dynamics of TELS aimed at fostering innovation.

The comparative analysis supports the identification of distinct phases in the management process of TELS for innovation, ultimately leading to the development of a management framework.

4. Findings

The study investigates various TELS for innovation across different contexts, outlining their management strategies, activities, and impacts. Here is a summary of the key findings from each case:

Table 1: Summary of key findings of each case

Tx	It is a community space supported by public financing that aims to connect actors in the startup and innovation ecosystem. It organises events, courses, and networking opportunities. Challenges include assessing long-term impacts and effectiveness, and plans are in place to develop better assessment metrics.
Hx	Situated within a university, Hx fosters entrepreneurial expertise through tailored methodologies like Innovation Challenges and Sprint Innovation Festival. Communication, community development, and continuous feedback are prioritised, alongside integrating technology into the learning process.
Dx	A leading co-creation space focusing on transformative dynamics, Dx brings together professionals, researchers, and facilitators to address high-risk challenges. Their strategy involves understanding diverse motivations, implementing digital technologies, and lean management practices, emphasising co-creation and partnerships.
Kx	This space facilitates collaboration and networking between industries and universities, offering innovative workplaces and co-working labs. It emphasises concrete outcomes, such as new projects and collaborations, and utilises technology to support communication and project organisation.
Ax	Originating from a regional grant, Ax is a diffused learning space for digital innovation, offering courses, seminars, and co-working spaces. Their management approach involves bottom-up and top-down planning, continuous adaptation, and collaboration with associations and local businesses.
Cx	A multi-functional learning space, Cx focuses on sustainable entrepreneurship and offers events, workshops, and creative labs. They sustain their initiatives through a mix of private funding and public calls, engaging learners through tailored events and technology-driven initiatives.
Digx	Dedicated to disseminating digital culture and innovation, Digx operates across small towns, fostering social innovation through activities like hackathons and workshops. Their management approach emphasises joint planning, engagement with young people, and collaboration with local associations.
Dihx	Dihx supports SMEs in digital transformation and offers consultancy, training, and prototyping services. Its management practices involve lean and agile methodologies, community development, and integrating advanced technologies like AI and big data.
Ox	A public-driven space for innovation, Ox focuses on community engagement and developing digital and entrepreneurial skills. It emphasises interaction with the territory, offering diverse activities like training paths, hackathons, and co-creation projects. Ox plans to assess long-term impacts more comprehensively.

Overall, these cases demonstrate diverse approaches to managing TELS for innovation, highlighting the importance of community engagement, strategic planning, continuous feedback, and leveraging technology to drive impactful outcomes.

One pivotal finding of this study emphasises the multifaceted nature of TELS management, which extends far beyond the confines of educational pedagogy. It was revealed that effective TELS management necessitates navigating through a myriad of contextual landscapes, considering legal, institutional, political, economic, and social dimensions, both at local and global scales. This contextual analysis serves as the foundation upon which strategic decision-making is built, empowering TELS leaders to identify and face challenges and barriers while capitalising on emerging opportunities. Moreover, the study revealed a diverse spectrum of financing models employed by TELS, ranging from profit-driven private initiatives to collaborative ventures with public entities and academic institutions. This diversity accentuates the adaptive nature of TELS management, which is finely attuned to each space's unique needs and aspirations.

Community engagement emerged as a pivotal phase in the management of TELS, serving as a conduit for co-creating value propositions intricately aligned with learners' evolving needs and the broader societal landscape. Whether driven by specific demands articulated by learners or broader imperatives identified within the community, TELS leaders engage in co-creation and co-design activities to define strategic intentions and chart a course of action. This bottom-up approach ensures a degree of flexibility and adaptability essential for TELS to evolve in tandem with the dynamic demands of the innovation ecosystem, allowing them to remain relevant and impactful. Consequently, by adapting to local needs and involving community members in the decision-making process, TELS adopt collaborative and inclusive approach to innovation fosters a dynamic environment where continuous learning and adaptation drive sustained development and success. Central to TELS operations and to their continuous connections and interactions with the surrounding territories, lays the concept of open innovation, which emphasizes the integration of manifold perspectives. In this context, the creation and development of communities is critical and necessary. Initial actions, in fact, aim to engage individuals, considering inputs from various stakeholders to shape the definition of the value proposition, through open innovation principles.

The planning phase of TELS management revolves around the formation of strategic partnerships, judicious allocation of resources, and integration of cutting-edge technologies. Despite the transformative potential of

advanced technologies in enriching learning processes, challenges persist in their effective implementation and in assessing their tangible impact. Nevertheless, TELS leaders remain buoyantly optimistic about integrating these technologies into their spaces, particularly in light of the seismic shifts precipitated by the global pandemic, which prompted an accelerated adoption of hybrid learning models.

TELS foster innovation-friendly environments by adopting active methodologies and knowledge-sharing initiatives to nurture a culture of creativity and collaboration. Community development emerges as a transversal activity, facilitating continuous engagement and collaboration among internal stakeholders as well as external partners. Moreover, TELS prioritise the principles of privacy, accessibility, and inclusivity, particularly in the context of leveraging emerging technologies, to ensure a safe, equitable, and empowering learning environment for all participants.

Continuous monitoring and evaluation emerged as the basis of effective TELS management, allowing iterative improvements and data-driven decision-making. response, a proposed management model distilled recurring processes into distinctive phases, offering a comprehensive framework for planning and managing TELS effectively.

5. Discussion: TELS Management Framework

Following the comparative analysis of the case studies, a framework to manage TELS for innovation is presented (figure 2) The management framework for TELS for innovation, presented in figure 2, consists of three sequential phases: Define, Cultivate, and Collect, along with two transversal phases: Analyse and Involve, and include.

5.1 Define Phase

In this phase, the value proposition and objectives are defined based on a shared vision. Planning includes top-down or bottom-up approaches to goal-setting, defining core activities, strategic resources (primarily technological), and budget planning.

5.2 Cultivate Phase

Once optimal conditions and objectives are set, this phase focuses on executing core activities tailored to the goals, target audience, and available resources. Knowledge and learning dynamics are activated through specific methodologies and activities, facilitated by knowledge providers. The space should support innovation dynamics through adaptable settings, stable technology infrastructure, and activities fostering high-quality relationships and innovation.

5.3 Collect Phase

This phase involves gathering reflections and assessing outcomes and impacts achieved. Activity results are compared with initial aims to identify insights for learning and developing innovation activities and strategies. This phase initiates continuous improvement cycles, guiding organisations in ongoing innovation processes to remain competitive in an evolving environment.

Additionally, two transversal phases run through the framework:

5.4 Analyse Phase

This phase addresses social, legal, and political barriers, seeks economic opportunities, and identifies territorial needs through context analysis and continuous monitoring activities.

5.5 Involve & Include Phase

This phase focuses on communication activities and dynamics to facilitate the development of quality relationships and the creation of an innovative community, in line with the principles of open innovation. It emphasises overcoming privacy, accessibility, and inclusivity concerns and building valuable external partnerships with stakeholders.

Figure 2: TELS Management Framework

Overall, this framework provides a structured approach for managing technology-enhanced learning spaces for innovation, guiding organisations through goal-setting, execution, assessment, and continuous improvement processes.

6. Conclusion

Today's business landscape is complex and uncertain due to rapid technological advancements and interconnected macro trends and continuous innovation is the key to organizational survival, competitiveness, and sustained growth (Hamidi et al., 2019). The ability to innovate is intricately linked to learning and knowledge processes (Nonaka & Takeuchi, 2019; Hamidi et al., 2019). Learning and knowledge processes and dynamics form the foundation for cultivating capabilities that are essential for navigating the contemporary business landscape (Yildiz et al., 2021). Therefore, TELS play a crucial role in driving innovation within organisations in the contemporary business landscape. The evolution of learning spaces has been significantly influenced by various factors, including a shift towards learner-centric approaches and the integration of innovative digital tools. The COVID-19 pandemic has also acted as a catalyst, accelerating the transformation of learning spaces into technology-enhanced learning spaces (TELS) to meet new challenges and leverage digital technologies for learning and knowledge exchange and dissemination.

Following these trends, a working definition of TELS and a conceptual framework summarising critical dimensions for design and functionality has been presented. However, the management and assessment processes require deeper analysis to define and distinguish the management phases. In consequence, the RQ driving this study is: "*How can organisations effectively design and manage TELS to foster innovation?*"

To answer this RQ, a management framework for TELS for innovation has been developed through an empirical approach (i.e. multiple case studies).

Overall, the study highlights the importance of effective TELS design and management to foster innovation and enhance an organisation's learning capacity. The multiple case study approach provides insights into the dimensions and features that differentiate effective TELS in nurturing innovation capacity, which can have practical implications for organisations seeking to drive innovation and remain competitive in the contemporary business landscape.

The research provides both theoretical and practical implications. In terms of theoretical implications, the paper provides findings that enrich the existing knowledge concerning TELS in management literature and allows the development of effective and impactful guidelines for management and decision-making and to support the continuous improvement of the specific spaces. Theoretical implications include also validation and refinement of existing conceptual and theoretical frameworks related to TELS, testing them in real life settings.

On the other hand, in terms of managerial and policy implications, the management framework can be helpful to different actors aimed at developing effective TELS to foster the innovation capacity of public and private organizations. Specifically, the analysis empirically investigates the management aspects of TELS designed to promote innovation. The framework may serve as a valuable resource for academics and practitioners in creating and effectively managing TELSs.

The study's main limitation is the lack of a deep analysis of the TELS's impacts on short— and long-run outcomes. Specifically, the analysis highlights the lack of effective assessment methodologies, prompting a need to develop

more robust evaluation frameworks capable of capturing the long-term impacts of innovation.

The limitations represent opportunities for future research in order to reinforce the conceptual framework, the findings' generalizability as well as to collect more pieces of evidence and further rigorous and valid insights to derive guidelines from assessing effective TELS for innovation capacity.

Capturing and Transferring Lessons Learned for Risk Reduction: NASA's Phase 1 Program

David M. Lengyel
The George Washington University Washington, DC, USA

dmlengyel@icloud.com

Abstract: The National Aeronautics and Space Administration (NASA) and the Russian Space Agency (RSA) conducted the Phase 1 (Shuttle-Mir) Program from 1993 through 1998. The joint manifest of this cooperative effort consisted of Russian Soyuz (crew) flights, Progress (cargo) flights, Russian science module flights (Spektr and Priroda), U.S. space shuttle docking missions, and nine long duration missions aboard Russia's Mir space station by U.S. astronauts. The purpose of the program was to establish and create a cooperative technical, operational and managerial experience base between Russia and the United States to reduce risks associated with the assembly, operations, science and logistical support of the International Space Station (ISS). In this paper we take a retrospective look at the extensive capture of lessons learned—gained from Phase 1 and transferred to the ISS program (ISSP)—and how this effort served to mitigate risk.

Key Words: Lessons Learned, Risk Reduction, Knowledge Capture and Transfer

1. The Past is Prologue

The Phase 1Program was rooted in the history of U.S. and Soviet human spaceflight collaboration. While the 1960s were a largely a period of a superpower competition, détente arguably began with the Nuclear Non-Proliferation Treaty (1968) and continued throughout the 1970s. In 1972, discussions began between the two parties on in-space rescue modalities and the docking interfaces required to accomplish such a mission. Uri (2022) notes that the 1972 Agreement Concerning Cooperation in the Exploration and Use of Outer Space for Peaceful Purposes between President Nixon and Premier Kosygin laid the groundwork for what would become the Apollo-Soyuz Test Project (ASTP) in 1975. In the aftermath of ASTP, joint discussions were held regarding "the objectives, feasibility, and means of carrying out a joint experimental program using the Soyuz/Salyut [space station] and Shuttle [still in development] spacecraft" to take place in the 1981 timeframe (OTA, 1985). However, several geopolitical and military events, including the Soviet invasion of Afghanistan in 1979, terminated these plans. It would be almost two decades before the subject would be revisited. Fortunately, the institutional memory as well as the means of organizing joint spaceflight operations between the U.S. and Russia was still available in both countries in the early 1990s.

2. Phase 1 Background

In early 1993, Vice President Al Gore and Russian Prime Minister Viktor Chernomyrdin signed the *Gore-Chernomyrdin Commission* agreement. One of the elements of this agreement envisioned a single long-duration mission aboard Mir by a NASA astronaut, along with a single docking mission by the space shuttle to Mir. Beyond that, NASA, the Russian Space Agency (RSA) and Rocket and Space Corporation Energia (RSC-E) were in early discussions to use the Soyuz-T spacecraft as an assured crew return vehicle (ACRV) for the ISS. The reliable Soyuz had been used as a crew transportation system since 1977 to Russia's six Salyut space stations, as well as the Mir (Portree 1993).

These cooperative activities proceeded with the Clinton administration's Office of Science and Technology Policy (OSTP) in full support. NASA and RSA signed a contract for $400M: $335M for additional NASA astronaut long duration flights to Mir and $65M for early ISS hardware (Phase 2). As Cline (2002) notes, "Russia's motivations to join the program are perhaps the most complex of all the [international] partners...the station could bring Russia into the "free world" and at the same time help the partners with its years of experience in space." This rapprochement was reminiscent of the diplomatic efforts leading to the Apollo-Soyuz Test Project (ASTP) some 23 years earlier at the height of the Cold War. Through Viet Nam, Bosnia-Kosovo, Gulf Wars I and II, and the Ukraine-Russia conflict, cooperation in space seemingly transcends diplomatic relations on Earth.

In June of 1995, space shuttle Atlantis, on mission STS-71 (the 69th shuttle flight), docked with the Mir space station for the first time. Two cosmonauts were ferried to Mir while NASA astronaut Norm Thagard was returned to Earth on the shuttle. At the time, NASA had 14 years of operational space shuttle experience and only 24 weeks of operational space station (Skylab) experience. In 1994-1995, NASA ISS personnel were reflecting on lessons from space station analogs (e.g., nuclear ballistic missile submarines, Antarctic scientific expeditions, etc.) in an effort to glean engineering design, human factors, and operational lessons for application to the ISS.

From 1995 to 1998, NASA had use of the Mir, an actual working laboratory in space, as well as a cadre of Russian managers, engineers, scientists, flight and ground operations personnel, cosmonauts, and physicians to learn from.

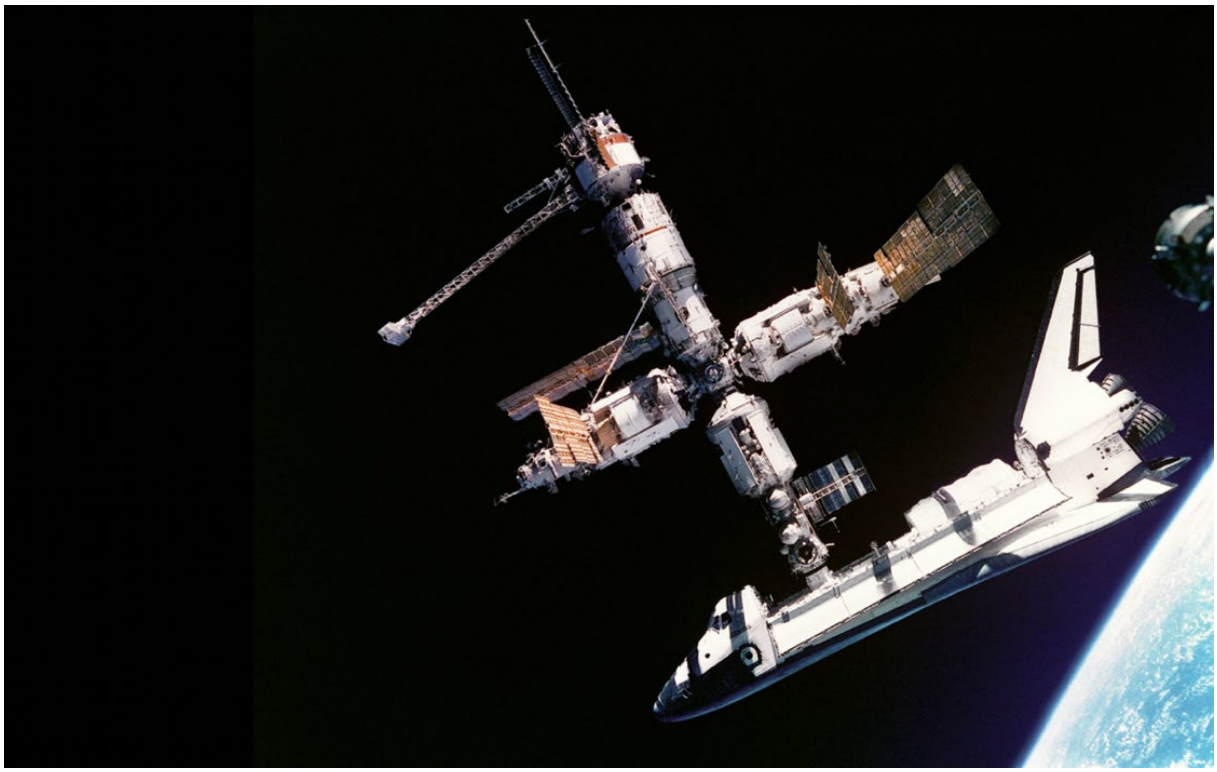

Figure 1: Space Shuttle Atlantis Shuttle Docked to Mir (Credit: NASA)

3. Risk Reduction

As the first phase of the ISS, the Shuttle-Mir Program was a risk reduction effort between NASA and RSA designed to increase the likelihood for safe and reliable operations of the future ISS. Risk reduction generally involves identifying known risks, then developing and executing mitigation plans to reduce the likelihood or consequence of the risks. Learning is generated from the difference between carefully planned activities, expected versus real outcomes, as well as from risk mitigation efforts. Major categories of risks, which may also be referred to as critical knowledge areas, included but were not limited to:

- Developing U.S. and Russian collaborative relationships;
- Refining Space shuttle proximity, rendezvous, and docking operations;
- Developing mission control center integration and joint operations;
- Performing long-duration mission increment planning and execution;
- Integrating crew training (Houston and Star City) and;
- Discovering other knowledge gaps in long-duration spaceflight.

However, not all risks can be effectively identified before flight. In some cases, unforeseen circumstances occur. During Phase 1 an onboard fire caused by a faulty oxygen generator cannister and a collision and depressurization mishap between Mir and a Progress cargo vehicle both occurred. These incidents generated many lessons which were then applied to future ISS emergency procedures (Thieme, 2003). Reflecting on these events, Jim van Laak, Phase 1 Deputy Program Manager stated that, “the relationship we developed with the Russians as a result of these near catastrophes is what enabled ISS to be successful (Van Laak, 2024).”

4. Knowledge Capture / Transfer (KC/T) Modalities

In risk management parlance, the purpose of a mitigation plan is to change the relationship between the existing condition and the potential consequence. Risk statements are therefore carefully written as: Given [condition

X]; there is a possibility that [consequence Y] may occur. Exploration of the relationship between the condition and consequence allows the risk owning organization to develop an effective mitigation plan.

Many ISS risks were unknown and/or undocumented when the Phase 1 Program began due to the ISS nascent risk management processes. As a result, the identification of risks of related to the planning and execution of long duration missions aboard Mir were more a matter of discovery than an intellectual effort of foresight. This was a missed opportunity for the two programs to collaborate and use ISS risk issues to cue KC/T activities in Phase 1, i.e., to capture lessons most useful to buy down risk for the ISS. Despite this, there were several traditional means of KC/T employed during the Shuttle-Mir Program which included:

- Long-Duration Mir Crew Mission Debriefs;
- Space Shuttle Crew Mission Debriefs;
- Mission Operations Directorate Flight Control Team Debriefs and;
- NASA Lessons Learned Capture Activities and Reports (See Para. 4 below).

After the close of the program, knowledge capture involved the following KC/T modalities:

- Technical/Engineering Papers (NASA Technical Reports Server);
- Human Spaceflight Conference Papers;
- Academic Journal Articles;
- Oral History Project Interviews (e.g., Johnson Space Center) and;
- NASA History Office Narrative Reports.

Other sources of lessons learned documented outside of NASA efforts included:

- U.S. Government Accountability Office (U.S. GAO) reports;
- Aerospace Industry Press Articles (e.g., Aviation Week and Space Technology, etc.);
- Non-Fiction Historical Books (e.g., *Dragonfly, Star-Crossed Orbits*) and;
- Congressional Hearing Testimony (Written Submissions and Transcripts).

Had the Shuttle-Mir Program been conducted today, several other means of KC/T activity may have included information technology (IT) aids:

- Collaborative online meetings tools such as MS Teams, Zoom, or MeetingSphere to capture knowledge in real-time and;
- Collaborative team-oriented tools such as wikis, particularly blogs and discussion boards to capture knowledge asynchronously.

One should note that tacit knowledge, the knowledge, skills, and abilities an individual gains through experience, also played an important role in both knowledge capture and transfer. The personnel who worked in NASA functional organizations, such as engineering, space and life sciences, mission operations, flight crew, payload integration and operations, ground systems and operations, all built a knowledge base which was directly applied to the ISS Program. This also includes NASA contractors such as Boeing, United Space Alliance, and Lockheed-Martin. Some senior managers were transferred into leadership positions in the ISS Program, where their management experience and relationships with their Russian colleagues was highly beneficial.

5. The Lessons Learned Architecture

Abiding by the dictum that a little structure goes a long way, particularly when it comes to KC/T activities, two significant and complementary efforts occurred at the end of Phase 1 which merit a more detailed discussion. The first involved the documenting of over 500 individual lessons from each of the Phase 1 working groups, followed by peer-to-peer exchanges with ISS personnel to ensure that each lesson found a home in the Station Program Integration Plans (SPIPs). SPIPS were the backbone of the document/information architecture to guide NASA management of ISS activities. The goal of this approach was to ensure that the ISSP accommodated both positive and negative lessons; the latter included risk issues including the previously mentioned experiences of the onboard fire and depressurization. In addition to SPIPS, there was also transfer of Shuttle-Mir lessons to the ISS vehicle engineering documents, the medical operations requirements document, and standard operating procedures for public affairs activities. Oberg (1998) observed that the lesson insights “dealt less with hardware design than with operational philosophies and that ninety percent of these lessons were process oriented." Many lessons dealt with cross-cultural issues in addition to operational processes.

Table 1 below outlines both the Phase 1 management structure versus the ISS SPIPs:

Table 1: Phase 1 Working Groups and ISSP Integration Plans

Phase 1 **Management Structure:**	**Station Program Integration Plans (SPIPs)**
Team 0 Senior Management	Program Management (SPIP Vol. 1)
WG-1 Public Relations	Manifesting and Schedules (SPIP Vol. 2)
WG-2 Safety and Mission Assurance	Cargo Integration (SPIP Vol. 3)
WG-3 Flight Operations and Systems Integration	Payload Integration (SPIP Vol. 4)
WG-4 Mission Science	Logistics and Maintenance (SPIP Vol. 5)
WG-5 Crew Training and Exchange	Launch Site Processing (SPIP Vol. 6)
WG-6 Mir Operations and Integration	Training (SPIP Vol. 7)
WG-7 Extravehicular Activity	Increment Execution Preparation (SPIP Vol. 8)
WG-8 Medical Operations	Real-Time Operations (SPIP Vol. 9)
WG-9 Institutional Communications	Sustaining Engineering (SPIP Vol. 10)

Another lessons learned effort involved the joint NASA-Russian technical teams producing the Phase 1 Program Joint Report. For this heavily researched narrative report, "the Working Groups were tasked to describe the organizational structure and work processes that they used during the program, joint accomplishments, lessons learned, and applications to the International Space Station Program (Nield and Vorobiev, Eds. 1999)." As a joint report, it helped define a path forward for working with the Russians and was a critical part of the KC/T effort.

6. How to Operate a Space Station

Although transferring Phase 1 knowledge to the ISS Program was a collegial exercise, there were a number of issues raised by Phase 1 personnel early on which were ignored or shrugged off as being artifacts of NASA's "customer" role onboard a Russian space station. For example, ISSP operations managers pushed back on the Phase 1 conclusion that ISS operations would most likely be dual-language (Russian and English) and not English-only. Over time that risk was realized by the ISSP and a great deal of resources had to be spent on interpreter and translator services, flight crew language training, dual-language procedures development, as well as a requirement for NASA and Russian support group flight controllers and planners to be stationed in Houston and Korolev.

The language issue was likely due to a cognitive bias exhibited by many ISS Program personnel. Hence, the belief early on that Phase 1 lessons were not necessarily applicable to the multi-international partnership that defined the ISSP. In Russia however, many of the personnel involved in Phase 1 believed that the ISS was simply an extension of the Mir operational philosophy. Unlike NASA personnel, the assumption on the Russian side was that most management, engineering, systems integration, crew training, medical support, etc., would remain the same or very similar. To some extent that was true during early ISS operations but there is no argument that the risks associated with rendezvous and docking, planning and execution, and, perhaps most importantly, crew training and bridging the cultural gaps, had been mitigated to very low risks levels by the Phase 1 Program.

Aside from three missions to NASA's Skylab in 1973 and 1974 for a total of eight months, NASA philosophy was focused on turning space shuttles around for six-to-sixteen-day flights. Reflecting on the Phase 1 program, NASA Flight Director Paul Dye noted that; "I think everybody knew all along that flying a Space Station is different than flying a Shuttle, and we probably would have come to the answers that they [Russians] have, sooner or later, too, but by sitting and watching how they do business, and looking at it, I think we probably shortcut some of the mistakes that we might have made (Dye, 1998)."

7. Conclusions

Measuring the value of the knowledge gained from Phase 1 in terms of the risks mitigated in the early operational years of the ISSP in an economic sense is a difficult endeavor. However, it could be inferred that the success of ISS assembly missions, on-orbit flight crew operations, ground operations, and increment and real-

time planning operations can be attributed in part to what both space agencies and their contractors learned in Phase 1. As astronaut and Phase 1 Program Manager Frank Culbertson explained; "the expense of flying the Shuttle is there, whatever the mission happens to be. I think that flying to Mir is one of the most productive ways to fly the Shuttle in terms of what we learned and what we accomplished...the cost of the contract with the Russians is about the same, rough order of magnitude, as one shuttle flight. And for the cost of one shuttle flight, we've flown to the Mir ten times and brought back innumerable lessons learned and probably saved unsuccessful shuttle flights in the future because of knowing something that we now know from Phase1. I believe it has been a very cost-effective insurance policy for the future (Oberg, 1998)."

In capturing and transferring knowledge, it is beneficial to consider a combination of techniques to ensure a comprehensive and accessible knowledge base, both tacit and written. Some of the positive aspects of the Phase 1 KC/T were that it was well documented, well communicated, and contextual. Having said that, the process was sub-optimal and could have been improved with a more disciplined planning process upfront. I offer the following KC/T planning checklist for those looking to reduce future risks through KC/T activities:

> Start with a **Systems Analysis** to ensure that problem definition, requirements, goals, and objectives are clearly defined. The analysis should ensure that all "systems" associated with the program (organizations, hardware, software, infrastructure, etc.) are properly incorporated, as well as interfaces between systems, to include international partners.
>
> Identify **Critical Knowledge** needed using a risk-based approach. The risk register, problem reporting systems, system safety analyses, mishap and close call systems, etc. can provide a valuable cueing system pointing to value-added information.
>
> A **Knowledge Architecture or Taxonomy,** whether it be an organizational breakdown, work breakdown, or engineering and science disciplines, is useful in organizing the information for later discovery and reuse. Within the architecture, key word **Tagging** of all products will aid in online search discovery.
>
> Clearly defined **KC/T Management Roles and Responsibilities** are required to ensure accountability, **Appropriate Resource Allocation,** and decision-making authority. In many cases, a KC/T effort is task organized and will therefore require coordination across multiple operational and institutional organizations (e.g., IT department, history office, public affairs and media), making an **Integrated Product Team Charter** a useful coordinating tool.
>
> Development of a **KC/T Schedule** allows more efficient resource allocation, progress tracking, alignment, and coordination among the stakeholders in the KC/T effort. Obviously, sufficient time should be allocated to the KC/T effort so as not to shortchange the quality of the knowledge products or formal transfer processes.
>
> Development of a **KC/T Communications Plan** will ensure the objectives of the capture and transfer effort are clearly defined, both internally and externally. When combined with the KC/T schedule, the communications plan should inform stakeholders of the key activities, milestones, and flow of information between all parties. The plan should identify opportunities to engage the public in the output of KC/T products via social media channels.
>
> Lessons learned are often best learned when they are codified in **Programmatic, Design, Operational and Training Documentation.** They become the standard for future efforts by identifying the documentation as targets for key **Validated Practices.**
>
> Execution of **Knowledge Capture / Transfer Activities** can include interviews, videography, writing assignments, creation of a **Narrative Report**, media preparation, training products development**,** population of a **Knowledge Portal** (if required), conduct of **Lessons Learned Forums,** establishment of **Mentoring Programs,** development of an **Expertise Locator,** and so on.
>
> **Encourage and Reward Personnel** participating in the KC/T process. This includes encouraging the writing of academic journal and conference papers. Obvious benefits include improving the morale, motivation, and retention of employees. As new programs ultimately replace programs that are completed or cancelled, the problem of **Knowledge Retention** may become acute if personnel are not transferred to the new program(s). To the extent possible, consideration should be given to retaining experienced personnel in their functional areas on new programs.

8. Epilogue

Established in 1996, the goal of the NASA Johnson Space Center Oral History Project (JSC OHP) is to capture history from the individuals who first provided the country and the world with an avenue to space and the moon. Participants include managers, engineers, technicians, doctors, astronauts, and other employees of NASA and aerospace contractors who served in key roles during the Mercury, Gemini, Apollo, Skylab, and Shuttle programs.

These oral histories ensure that the words of these space pioneers live on to tell future generations about the excitement and lessons of space exploration (JSC OHP, 2024). The following two interview segments provide a good synopsis of the knowledge gained from the Phase 1 Program which ultimately benefitted the ISS Program.

Andy Thomas, NASA Astronaut: "Throughout the course of the Phase 1 Program we've learned the mechanics of how you service and operate a space station; how you arrange and load a vehicle, launch it, rendezvous and dock to the space station, transfer goods, transfer crews, which we wouldn't have otherwise. It shouldn't be underestimated how to work collaboratively with the Russians because we have different cultures, different languages and that itself is a big accomplishment…it's inconceivable to do the International Space Station without first taking these steps in the Phase 1 Program (Thomas, 1998)."

General Yuri Nikolayevich Glazkov, Deputy Director of the Gagarin Cosmonaut Training Center: "I think the main result of Phase 1, which is coming to an end, is our successful transition to the International Space Station. Of course, everything that is ending now is not really an end; it is flowing into the building, assembling of the future Space Station and its future operation. I heard President Bill Clinton a few times calling the future International Space Station "the bridge into the future," and I do believe that it is the transfer of our achievements of the twentieth century into the twenty-first century, especially for our kids. That's why I'm preparing my daughter to become a cosmonaut (Glazkov,1998)."

Abstract: In recent years, we have witnessed a growing increase in applications involving some form of Artificial Intelligence (AI). Conversational AI has gained considerable prominence among the various types of AI applications. Classified as a type of generative AI, chatbot applications such asOpenAI's ChatGPT or Google's Bard are now utilized by multiple authors as tools. Despite its many advantages, the indiscriminate use of this type of generative AI in texts can raise ethical questions about who owns authorship of a particular work, as a human author may have contributed very little to the production of certain content. The concern about authorship is paramount in producing scientific publications, such as articles, dissertations, or theses. To avoid such questioning, some authors may develop strategies to conceal the use of generative AI in their productions. This work aims to introduce the concept of Text Laundering (TL), which we name as such due to its similarity to the practice of money laundering — applying various consecutive alterations to AI-generated text to make its origin indeterminate. This work will also develop the concept by examining examples of similar practices in the literature employing an ad hoc search. A method for applying TL to mask the origin of a text will be proposed, and the results obtained in a simple test will be presented to determine the success of our strategy. We hope this work can contribute to discussions on preventing the fraudulent use of generative AI. Discussing TL methods does not imply endorsing them but rather exploring potential mechanisms that can be maliciously utilized to gain advantages through generative AI, identifying them, and preventing their use. AI-generated texts can harm knowledge management systems, and we highlight the need to include AI-verification tools in such systems. Such tools can enhance the trustworthiness of information in knowledge management systems, improving knowledge externalization and sharing processes. Finally, we expect to promote future research on TL techniques and the proposition of new strategies to combat fraudulent practices in scientific research.

Keywords: Text Laundering, Artificial Intelligence, Generative AI, Conversational AI, AI-generated Text

1. Introduction

Artificial intelligence (AI) has brought forth the capability to generate texts that mimic the style and content of those produced by humans (Kreps, McCain and Brundage, 2022; Barbosa, 2023). Conversational AI has gained considerable prominence in the last few years among the various types of AI applications developed. Chatbot applications such as OpenAI's ChatGPT (Generative Pre-trained Transformer) or Google's Bard focus on creating human-like interactions and responses in a conversation and are now utilized as tools by many authors as they can help facilitate natural and engaging text-based interactions, providing assistance, generating creative content, and supporting various language-related tasks.

While the use of chatbots can be beneficial in empowering humans to develop new products, exploring a wide range of problems and solutions, and consequently increasing innovation performance (Bouschery, Blazevic and Piller, 2023), it is necessary to consider the ethical implications when it comes to their employment even when classified as potential transformative agents in different domains that require textual production (Stokel-Walker and Van Noorden, 2023). In particular, ethical concerns associated with preventing the reproduction of plagiarized texts or the dissemination of erroneous information must be addressed (Pavlik, 2023). An important question regarding the creation of texts through generative AI systems, i.e., systems capable of generating new content, such as text, images, or music, based on patterns learned from large datasets, is to recognize whether a particular text is or is not the result of AI. A possible benefit of concealing generative AI would be that using more humanized AI-generated texts can enhance user interaction, promoting a better understanding and acceptance of conveyed information, as it resembles natural writing (Bozkurt *et al.*, 2021). Nevertheless, the use of this type of technology is not always beneficial.

In the context of higher education, the integration of generative AI within Higher Education Institutions (HEIs) introduces some ethical considerations. While these tools hold promise in enhancing research processes and knowledge dissemination within academia, their implementation raises concerns regarding academic integrity and undergraduates' skills building and evaluation (Chan and Hu, 2023; Michel-Villarreal *et al.*, 2023; Wang, 2023).

Generative AI technologies offer unprecedented capabilities in content creation, aiding researchers and educators in generating diverse materials for study and publication. In an era where the labour market evolves rapidly, HEIs face the imperative to adapt their curricula to meet industry demands (Dos Santos *et al.*, 2023). This pressure often leads to the integration of cutting-edge technologies like generative AI into educational practices. However, their introduction forces HEIs to reassess their educational curricula (Dai, Liu and Lim, 2023), as generative models could potentially overshadow critical thinking and originality in students and researchers work (Spector and Ma, 2019).

The rapid adoption of such tools underscores the importance of fostering skills in prompt engineering among undergraduate students (Dai, Liu and Lim, 2023). As generative AI systems may produce erroneous or misleading outputs (Fui-Hoon Nah *et al.*, 2023), individuals must possess the theoretical knowledge to identify and correct these inaccuracies effectively. Moreover, the rapid advance of generative AI adoption forces a shift in educational focus towards equipping learners with the competencies to engage with AI technologies critically (Dai, Liu and Lim, 2023).

In this rapidly evolving landscape of generative AI adoption, this work aims to introduce the concept of Text Laundering (TL), which we define as such due to its similarity to the practice of money laundering — applying various consecutive alterations to AI-generated text to make its origin indeterminate. This concept not only sheds light on the potential vulnerabilities of AI-generated content detection tools but also underscores the inadequacy of relying solely on such tools to deter the fraudulent use of generative AI by undergraduate students or researchers. We hope to present some preliminary thoughts on this novel concept, develop it, and discuss how to determine whether a text was produced by humans or by AI and subsequently laundered to create ways for discovering AI-generated laundered texts. We expect this work can serve as a foundation for future discussions on preventing the fraudulent use of generative AI in HEIs context, raising the discussion whether identifying fraudulent use of AI should focus on identifying AI-generated texts or on discerning whether the guiding intelligence behind the AI-generated text is human or artificial. Discussing TL methods doesn't mean supporting them. Instead, we explore how the utilization of text laundering methods demonstrates the inefficacy of current AI-generated text identification techniques in detecting the malicious use of the tool for undergraduates and researchers to gaining unfair advantages in their work.

The text laundering of an AI-generated text employs techniques – often automated – to make it more challenging to identify the text's AI origin. How to generate texts more similar to those produced by a human author is already a highly debated and intriguing topic in natural language processing (Camacho-Collados and Pilehvar, 2020). Therefore, there is a need to develop literature for a practice that has been taking place and to assist in improving the detection of the artificial origin as AI systems improve and texts generated by humans and AI tend to look more alike.

Including AI-generated laundered texts in corporate knowledge management systems can have detrimental consequences. For example, it may lead to challenges in accurately externalizing tacit knowledge and documenting lessons learned. Therefore, AI-generated data could result in the loss of nuance or context, leading to less effective knowledge-sharing and decision-making within the organization. Additionally, reliance on AI may introduce biases or errors into the knowledge management system, compromising its effectiveness and reliability.

This work shows how to develop a concealment method for the artificial origin of a text produced by generative AI tools against AI detection tools. We will then discuss ethical questions regarding this process, particularly concerning fraudulent scientific research practices. This topic is of significant educational, academic, and social relevance, as these tools and their growing interest are essential in all these areas. We also hope this work can encourage future research on TL techniques and that researchers can propose new strategies to combat fraudulent practices in scientific research.

2. Theoretical Background

This section explores the theoretical foundations necessary to understand generative AI methodologies used to generate text and Stylometry, which analyze linguistic patterns and determine authorship. Next, we discuss the ethical concerns associated with AI applications, particularly plagiarism and the proliferation of false or misleading information. Finally, we present applications for detecting AI-generated content.

2.1 Generative AI

Generative AI refers to a class of artificial intelligence systems designed to create or generate new content, such as images, text, audio, or even video, that is convincingly similar to the data it has been trained on. Unlike traditional AI models for classification or prediction tasks, generative AI models focus on creating new content. These models typically utilize techniques like deep learning, particularly Generative Adversarial Networks (Creswell *et al.*, 2018) and Variational Autoencoders (Doersch, 2021), to produce output that exhibits characteristics similar to the training data. Generative AI has applications in various fields, including art, design, entertainment, and even scientific research, where it can be used to generate synthetic data for experimentation or to assist in creative endeavors. These systems can also employ techniques such as natural language processing when dealing with text generation (Mou, 2022). The impact of AI on copyright and related rights is also a topic of discussion, particularly regarding the recognition of authorship and responsibility for copyright infringement (Bysaga, Byelov and Zaborovskyi, 2023).

In the academic field, researchers can use generative AI for the automated production of academic texts, such as abstracts, essays, and even dissertations and theses. Additionally, these systems can deliver adaptive learning content by interacting with students through text and voice (Barbosa, 2023). However, generative AI tools are most commonly employed to produce and modify texts. Their ability to generate original and contextually relevant content from a given dataset has significantly advanced natural language processing. Generative text AI tools become widely used as they can produce fluent and contextually relevant texts in just a few seconds, allowing users to generate new content or make their writing process more efficient and agile.

To give some examples of tools, we here will focus on OpenAI's. One of the various generative AI models used to create or edit texts is the GPT-3.5, a transformer-based language model capable of generating coherent and context-relevant texts. GPT-3.5 is trained using a large amount of textual data for translation, text summarization, and dialog generation, among other applications. ChatGPT is a specific implementation of the GPT-3.5 model focused on conversation. It can answer questions, provide information, assist with problem-solving, and engage in natural language dialogues. Another example is OpenAI Codex (OpenAI, 2024). The Codex is a language model trained on programming code and can generate code from natural language descriptions. It can assist developers in writing code by providing suggestions and auto-completing code snippets. Yet another example is TextGPT, a variation of GPT-3.5 specifically designed to work with natural language text that can generate stories, essays, articles, and poems, among others. All these tools can create and modify texts, exemplifying how AI can assist in text creation and editing across various domains.

2.2 Stylometry

A possible method to detect AI-generated content is Stylometry. Stylometry is the field of study that analyzes text's linguistic and stylistic characteristics. Stylometry gained strength by developing computational tools designed explicitly for this purpose (Boto Bravo, 2018), and the possible applications are many: plagiarism detection, countering identity deception, email impersonation detection, authorship detection in SMS messages, identifying speech writers, multi-modal authentication on mobile devices, among others (Neal *et al.*, 2018). Tools such as Stylo R have been used to analyze and classify literary works based on their typological and stylistic characteristics (Boto Bravo, 2018).

Furthermore, computational statistical tools such as ContaWords have also been used to identify stylistic elements in literary texts (Ferreira Barrocal, 2021). Machine learning techniques can also be used for authorship attribution and characterization (Deutsch, 2020). In addition, critical editions of literary works have been produced to examine their plot, attribution, and historical context (Ferreira Barrocal, 2022). In digital humanities, data mining techniques can visualize concepts, author constellations, and indexed citations of digital collections (Rota, 2022). Recurrent neural networks generate obfuscated texts, preserving their original semantics (Franco and Oliveira, 2019). Finally, the automatic detection of fake news was explored (Santos, 2022). These studies

demonstrated applying computational and statistical methods to analyze and comprehend texts. Researchers can use stylometric analysis methods to investigate the possible artificial origin of a text.

There are still challenges in authorship analysis using stylometry techniques, such as a lack of sufficient data or inconsistencies in text samples (Neal *et al.*, 2018). Achieving high accuracy in stylometric analysis, especially with large and diverse datasets, remains a significant challenge. Still, some studies report accuracy rates ranging from 53.8% to 98.312% for tasks like authorship attribution and verification (Neal *et al.*, 2018). The accuracy of stylometric analysis can vary depending on various factors such as the specific task being performed (e.g., authorship attribution, verification, profiling), the size and quality of the dataset, the features and algorithms used, and the complexity of the writing style being analyzed (Neal *et al.*, 2018).

2.3 Ethical Issues

Among the many issues concerning generative AI applications is the issue of plagiarism. If an AI system generates a text that is similar or identical to a pre-existing text, will it be considered a misappropriation of someone else's work? Chatbots frequently do not mention who published it or even from what source (website, book, magazine, etc.) the information came. Still, the model training may use data from specific sources without acknowledging the original authors.

Generative AI also presents ethical challenges regarding its dual modes of operation: autonomously generating content and synthesizing user input. In the former, the AI may inadvertently produce text resembling existing works, raising concerns of plagiarism. In the latter, the AI acts as a facilitator, crafting text based on user input, blurring lines of authorship and authenticity. As such technologies become more widespread, addressing these dilemmas and establishing guidelines for responsible use and content attribution becomes increasingly urgent.

Another issue is the authenticity and authorship of a text. AI-generated texts often present themselves as though a human wrote them, potentially resulting in a lack of authenticity. The authorship of the texts generated by the AI must be appropriately attributed and disclosed to avoid deception or manipulation (Rossetti and Angeluci, 2021).

Regarding the manipulation of information, AI has the potential to create texts similar to authentic and reliable texts. However, they can also increase the proliferation of false or misleading information. This AI capability can lead to the spread of misinformation and undermine public trust in AI-produced texts.

Another important point is responsibility and supervision, as the production of texts by AI also raises questions about who will be responsible for the generated content. Who would be responsible for ensuring the accuracy, integrity, and ethics of texts produced by AI? Careful monitoring and oversight are required to ensure that the texts generated meet ethical and quality standards.

Finally, there is still the possibility of ideological or discriminatory biases in the text. Even today, AIs are trained on large datasets, which may contain built-in biases and biases. These biases can be reflected in texts generated by AI, reproducing or expanding inequalities, discrimination, or societal stereotypes.

2.4 AI-Generated Content Detection

An AI detection tool is software capable of identifying, recognizing, or classifying specific objects, patterns, behaviors, or information in data or images. Some of these tools may use AI to perform stylometric text analysis.

As generative AI tools become more accessible to the public, AI-generated content becomes more common. To be able to determine if AI produced an article or content is something fundamental to content marketers. Fortunately, some methods exist to assess and determine if the content is AI-generated.

One way to identify this AI-generated content is to look for repetitive or unusual patterns in the text. AI text generation is imperfect, i.e., it may not look human in a human or automated analysis. Sometimes, texts tend to repeat sentences or structures. This repetition may indicate that the content was generated by AI rather than a human author. AI content detection tools may also use machine learning and natural language processing techniques to determine whether the content was created by a human or not in an AI versus AI clash. Machine learning techniques can make computer systems more efficient with every text analyzed. AI applications designed to detect the use of AI in texts can also analyze large amounts of information available on the web about a specific content topic in seconds. This analysis can potentially make the detection of AI-generated content more precise. Several free AI content detection tools are available to help identify whether certain content was generated by AI or by a human author; one example is GPTZero.

GPTZero (GPTZero, 2024) is a tool designed to identify text generated by artificial intelligence, specifically by large language models like ChatGPT. It is helpful when understanding the source of a piece of writing is important, such as academic integrity and content authenticity. GPTZero analyzes the statistical properties of text and its Stylometry, such as how random or predictable it is. Based on this analysis, it can tell with some accuracy whether the text was written by a human or generated by a large language model. It's important to note that GPTZero detection is not perfect. As AI language models continue to develop, GPTZero's ability to detect them might require updates.

AI Detector (Corrector App, 2024) is an application designed to scan and analyze texts to identify the use of AI technology. The tool analyzes words like *the*, *it*, and *is,* which tend to be often used by AI text generators. They claim to search for unnatural transitions and errors in the text and the lack of the author's personal opinions since AI-generated texts often present heavy facts in their contents.

3. Methodology

The proposed methodology aims to create techniques that modify an AI-generated text to hide its origin as artificial text. The approach combines four main stages: the setup stage, the text generation stage, the text laundering stage, and the AI-detection & analysis stage.

In the setup stage, we define the tools used in the process. We need to select three types of tools: the generative AI used to produce the text, the tools responsible for altering the generated text, and finally, the tools used to validate if the modified text is detectable as human-made or AI-generated.

In the text generation stage, we use the generative AI (selected in the setup stage) to create a Corpus of text. The AI employed in this stage is supposed to generate coherent and relevant content, but it is also expected to be detected by AI-generated text detection tools.

In the text laundering stage, the text is processed through single or multiple tools (also selected in the setup stage) to resemble a human writing style. We denominate the tools used to alter the AI-generated text to achieve this goal as *text laundering tools*. The idea behind this stage is that sequential laundering processes like translation and paraphrasing will introduce nuances and subtleties often found in human-written texts while removing evidence from known biases derived from AI-generated text. Therefore, we expect to trick the detection tool and statistical analysis.

In the AI-detection & analysis stage, we use the altered text as an input to AI-generated text detection tools (also selected in the setup stage) to assess the success of the laundering. At the end of this stage, we analyze if the results show consistent difficulty in identifying the text as AI-generated. If the results are unsatisfying, we can return to the setup step to modify the tools used in the text laundering process to improve the results. We summarize the described process in Figure 1.

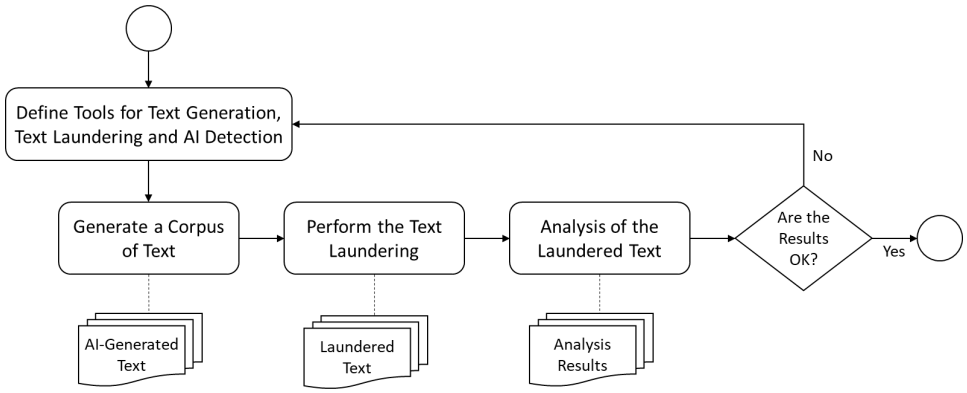

Figure 1: The proposed methodology for the development of Text Laundering techniques.

4. Experiment

In this section, we conduct an experiment on text laundering using the proposed methodology. In the setup stage, we chose ChatGPT as generative AI used to produce the text, Google Translate and Scite as text laundering tools, and GPTZero and AI Detector to validate if the altered text is detectable as human-made or AI-generated. We selected ChatGPT for its popularity and ability to generate quality content in its free version. Google Translate

and Scite were chosen to show that several types of applications can be used for text laundering. Finally, we selected GPTZero and AI Detector because they can detect ChatGPT-produced text.

In the text generation stage, we give ChatGPT the following prompt: "I need you to generate ten topics from different Knowledge Areas and, for each Knowledge Area, a famous and complex topic. I just want the topics; I don't need to generate any text about them." The response was (1) Quantum Physics -Schrödinger's Cat Paradox, (2) Philosophy - JohnRawls's theory of justice, (3) Biology - CharlesDarwin's Theory of Evolution, (4) Mathematics -Fermat's Last Theorem, (5) History - The Cold War and the nuclear arms race, (6) Psychology - SigmundFreud's theory of personality, (7) Sociology - The concept of consumer society, (8) Law - The ethical dilemma of using torture to obtain information, (9) Medicine - The discovery and development of vaccines, and (10) Computer science - The P versus NP hypothesis in computational complexity theory. We then asked ChatGPT to generate a text of approximately 300 words about each topic, one at a time. These texts served as the corpus of text for this experiment.

In the text laundering stage, we use the Google Translate and Scite tools to modify the original text to make it more human-like. In this process, we used Google Translate to perform a double translation (change the text to another language and then back to English). We use Scite to paraphrase and rewrite the text. We end up with three versions of each text: the original version (before the laundering process), the Google Translation laundered text, and the Scite laundered text. We highlight that we can use any tool to create any post-processing workflow to disguise the text, including AI-generating tools (such as ChatGPT) to perform the laundering. We also highlight that we can achieve better results using multiple laundering tools in sequence.

In the AI-detection & analysis stage, we sent each text to the GPTZero and AI Detector to analyze their performance. These tools analyze and identify language patterns generated by AI models, allowing us to confirm the authorship of the texts. The results of the detection experiment are shown in Table 1. We now decide if the results are good *enough* to achieve our goals. If we find the results unsatisfactory, we can revisit the setup stage to adjust the tools utilized in the process or the workflow of laundering tools employed.

Table 1: Results of the experiment.

Text ID	Original Text		Laundered (Google Translate)		Laundered (Scite)	
	GPTZero [AI/Human]	AI Detector [% fake]	GPTZero [AI/Human]	AI Detector [% fake]	GPTZero [AI/Human]	AI Detector [% fake]
Text 1	AI	18.82%	Human	19.94%	AI	8.82%
Text 2	AI	49.97%	AI	57.23%	AI	9.97%
Text 3	AI	49.97%	AI	37.37%	AI	9.97%
Text 4	Human	0.08%	Human	7.38%	Human	0.08%
Text 5	AI	34.67%	AI	65.36%	AI	4.67%
Text 6	AI	1.55%	AI	9.97%	AI	0.55%
Text 7	AI	0%	Human	9.97%	AI	0%
Text 8	AI	0.02%	AI	0.02%	Human	0.02%
Text 9	Human	0.41%	Human	0.03%	Human	0.41%
Text 10	Human	46.70%	Human	41.52%	AI	6.70%

Analyzing the results, we observe that the original AI-generated texts vary in human-likelihood. The original ChatGPT text passes as human in 3 of 10 texts in GPTZero without changes. Similarly, the original text is below *10% fake* in 5 of 10 texts. Regarding the text laundered with Google Translate, we see improvement in the GPTZero assessment, with 5 of 10 texts labeled as human-generated. Meanwhile, in most cases, the AI Detector considered the Google Translate results worse than the original text. Regarding the text laundered with Scite, we see a significant improvement in the AI Detector assessment, with all texts below *10% fake*. However, in the GPTZero results, the Scite laundering kept the 3 of 10 texts labeled as human-generated.

5. Discussion

Our results showed that text laundering can help make texts less artificial and more authentic in the eyes of AI detection systems like the AI Detector. However, we highlight that the effectiveness of this laundering can vary depending on the chosen tool. Our experiment involving the analysis of 10 texts found that four were considered less artificial by the AI Detector after undergoing text laundering. This result indicates that the appropriate choice of laundering tool impacts text detection, making them more genuine and less susceptible to being labeled as artificial.

However, we highlight that the detection methods used by AI Detector systems can vary. Some may be more sensitive to specific laundering techniques, while others may have different rules and algorithms. Therefore, no universally effective method of text laundering works equally well for all cases. Each text and context requires careful analysis to determine the appropriate choice of laundering. We should consider factors such as the type of text, the target audience, the communication objective, and the specificities of the detection system used. For example, in some cases, removing specific language patterns or adding contextual elements may be necessary to decrease the text's authenticity.

We recognize that there is no universally effective approach. Each case requires an individualized analysis, considering specific detection methods and the characteristics of the text in question. The discussion about the ethical implications related to the choice of text laundering tool and its influence on text detection is of utmost importance. Several ethical issues in this context deserve consideration (Bysaga, Byelov and Zaborovskyi, 2023).

One key point is using text laundering to deceive or manipulate artificial intelligence detection systems. Using a text laundering tool to circumvent these systems and provide misleading or false information can produce severe ethical consequences. For example, the spread of misinformation undermines the reliability of information and compromises informed decision-making. Furthermore, the choice of text laundering tool can also raise ethical concerns about privacy and consent. If text laundering involves manipulating or altering other people's texts without their knowledge or consent, it can violate privacy and copyright rights. It is essential to respect individual rights and ensure that any text laundering process is carried out ethically and transparently (Rossetti and Angeluci, 2021). Another important ethical implication is the possibility of bias and discrimination. If specific text laundering tools are more effective in reducing the detection of artificial texts produced by specific groups or communities, it can lead to unfair discrimination. It is crucial to ensure that the choice of laundering tool is unbiased and does not perpetuate or amplify existing prejudices (Temsah *et al.*, 2023). Additionally, we highlight ethical implications related to the reliability and transparency of artificial intelligence detection systems. If the systems cannot identify laundered texts effectively, it can undermine trust in AI technologies and create an environment conducive to spreading false information (Rossetti and Angeluci, 2021).

Although, concerns regarding the detection and prevention of AI-generated content emerge. While these measures can preserve academic integrity, they may inadvertently suppress the creative potential of Generative AI within educational contexts. Rather than solely relying on detecting AI-generated content, HEIs should prioritize educating students on responsible AI usage and encourage the ethical application of Generative AI as a supplemental tool in their learning journey. Therefore, the use of text laundering techniques and tools can serve to demonstrate that alternative methods of detecting fraudulent use of Generative AI should be employed, focusing more on evaluating the ability of undergraduate students to be the guiding minds behind AI-generated texts rather than whether the texts were generated by AI.

Finally, we highlight the necessity of carefully examining the ethical implications of using a text laundering tool. It is necessary to consider the impact on information reliability, privacy, consent, discrimination, and transparency of AI systems. Ensuring that text laundering is conducted ethically and responsibly is essential to promote integrity and trust in AI technologies. The discussion between assistance and complete substitution in the context of AI technologies raises essential questions about acceptable limits and the ethical implications involved. On one hand, AI assistance can bring significant benefits in various areas, such as healthcare, education, and work. The ability of AI technologies to assist humans in complex tasks, provide valuable insights, and enhance efficiency is undeniable. Assistance can involve automating repetitive tasks, analyzing large datasets, and even assisting in decision-making.

6. Conclusions

AI can create texts that closely mimic human writing. However, there's ongoing debate regarding the credibility and impact of AI-generated texts in foreign policy. Platforms like ChatGPT are being investigated for their

potential to produce written content across various fields. However, identifying AI-generated texts and dealing with the ethical considerations they raise pose significant challenges.

This work proposes a methodological approach to develop methods to mask the artificial origin of AI-generated texts, contribute to the development of more effective verification tools, present text laundering techniques, and address associated ethical issues, particularly within the context of HEIs.

Based on the results obtained, we can conclude that the choice of text laundering tool significantly impacts the detection of texts generated by artificial intelligence. Of the ten texts analyzed, we found that four were considered less artificial by the AI Detector after the laundering process. This result indicates that adequate laundering can positively affect detection.

This work contributes significantly to Knowledge Management by developing methods to mask the artificial origin of AI-generated texts, and the approach shows an open issue that must be solved with the development of more effective AI-verification tools, prioritizing the evaluation of the intelligence behind the generated text over the evaluation of AI-generated text. We expect such verification to enhance the trustworthiness and authenticity of information within Knowledge Management Systems and improve the knowledge externalization and sharing processes.

However, we highlight that detection methods vary and require a case-by-case analysis to determine the most appropriate wash. No universally effective method works in all situations. Therefore, it is critical to carefully consider the different laundering methods available and adapt them according to the study's specific needs.

This study has limitations worthy of mentioning. First, we use only a single text-laundering step, which can limit the effectiveness of the process. Furthermore, we analyzed only ten texts, which may not represent all possible variations and results. We also considered only one text generation tool, two laundering tools, and two detection tools, which may restrict the scope of the results.

Future research can explore multiple laundering steps, increase the number of analyzed texts, and include various generation, laundering, and detection tools. This research will help to gain a more complete and accurate understanding of the effects of these processes on detecting AI-generated text. Furthermore, conducting tests on several detection tools would be important to assess their effectiveness in detecting false or misleading information. Automating the laundering process would be crucial to increase efficiency and scalability. Finally, knowledge management systems can integrate AI-detection tools to improve their knowledge externalization and sharing processes.

Community-Led Innovation: Lessons from VEB2023, European Capital of Culture Programme

Katalin Lőrincz[1] and Judit Hargitai[2]
[1]University of Pannonia, Department of Tourism, Veszprém, Hungary
[2]Public Foundation for the Culture of the Veszprém-Balaton Region, Veszprém, Hungary

lorincz.katalin@gtk.uni-pannon.hu
judit.t.hargitai@gmail.com

Abstract: The "Microgrant" funding scheme launched under the Veszprém-Balaton2023 aimed to ignite creativity and innovation within local communities, businesses, and organizations in Veszprém and the Balaton region, as part of the European Capital of Culture initiative. Facilitated by the Veszprém-Balaton Region Public Foundation for Culture 2022-2023, this initiative utilized a unique four-round framework wherein community-driven projects ranging from community gardens to cultural exhibitions were presented and evaluated through a community decision-making process. Utilizing a cooperative board game format, the community decision-making process ensured diverse perspectives were considered, fostering consensus among jury members. The Microgrant project, with a funding pool of HUF 350,000 (approx. EUR 915), sought to empower local communities by supporting small-scaled projects all year round. These projects not only enriched the local cultural landscape but also fostered community cohesion and engagement. The research methodology approached the issue of social innovation from several angles. Structured interviews were conducted with VEB2023 staff (7 people) to map the application process and the community decision-making process, a questionnaire survey measured the opinions of jury members involved in community decision-making (64 people), and spatial and thematic characteristics were used to examine the 241 winning mini-proposals. The paper delves into the practical implementation of community decision-making process, focusing on innovation, sustainability and adaptability. Beyond economic considerations, these initiatives have indirectly contributed to enhancing the subjective quality of life, diversifying the cultural offerings of the Lake Balaton region, and shaping the attitudes of residents towards community involvement and cultural preservation. Based on the outcomes, new inquiries arise: How can we leverage community decision-making, a methodology closely intertwined with the social dimension of sustainability, in forthcoming initiatives? How might this approach be flexibly adapted to various settlement and spatial development blueprints? And what are the key attributes that describe the potential of small-scaled communities?

Keywords: Microgrants, VEB2023, Spatial and Thematic Characteristics, Community Decision-Making, Social Innovation

1. Introduction

Community decisions are often based on the assumption that groups usually make better decisions than individuals. In other words, more eyes see more of the important information; open discussion helps to consider aspects correctly; members of the group feel the decisions made together more their own, and those in charge are also more motivated to implement them (Waldmüller, 2010). At the same time, several authors (Arrow, 1951; Weber, 1978; Czibor, 2014) emphasize that (average) persons, as members of the community, use the information available to them in distinct ways, and in decision-making situations their rational behaviour is also different. Many varying points of view can be discovered regarding the nature of community decisions. According to Arrow's (1951) "Impossibility Theorem" community decisions are never coherent and they are inconsistent. Community decisions are not made in a vacuum: they are influenced by the previous decisions, the practical issues of the given moment, the abundance or lack of information, as well as the credibility, reliability of information, and the low level of time investment and "attention" (Johnson, 1999; Szántó, 1999).

What does community involvement, or in a narrower sense community decision-making mean in practice and how can this be applied in projects that strengthen cultural and social sustainability? What experiences can be drawn from the endeavours of European Capital of Culture (hereafter ECOC) projects in this direction, and how can the methodology of community decision-making be further developed? In this study, after a brief summary of the theoretical background of the concept, the authors present specific ECOC solutions (Wroclaw, Rijeka).

In 2023, in the Veszprém-Balaton region of Hungary, the microgrants served as a functional and applicable good practice. During the primary research, structured interviews were conducted with the grant experts, while the local actors, involved in the jury evaluating the applications, took part in an online satisfaction survey. The study presents the spatial and thematic characteristics of the implemented microgrants, as well as the opinions of the applicants, based on the microgrant reports and a questionnaire survey.

2. Theoretical Background

2.1 The Scientific Background of Community Decision-Making

Community decision-making goes back thousands of years, since it has always been typical in small communities to decide together on matters affecting everyone. With the development of modern societies and the population growth, this form of decision-making has been pushed into the background in most places (Barr-Hashagen, 2000). We had to wait until the end of the 20th century for the big political and economic institutions to rediscover the power inherent in community decision-making – of course, this also required that it has become easier than before to reach and organize people with the development of information and communication technology.

The theory of community decisions (public choice theory) is basically a scientific field at the border between political science and economics. The subject of its interest is similar to that of political science, but its methodology differs from that: it uses the well-known and proven tools of economics concerning the study of human behaviour (Szabó et al., 2020). Its fundamental finding is that actors in the government sector behave similarly to market actors and pursue their own individual goals in their actions and decisions, striving for individual profit maximization.

The theory and practice of community involvement (the following terms are also used: participatory decision-making; participatory budgeting; social participation in planning, design; public support for participation in local development) are among today's prominent social issues. In a broader sense, community decision-making is part of the so-called community development, which can also be interpreted as an activity open to interdisciplinarity (Vercseg, 2020). This process can apply to changes in any area of life, and its basic purpose is to involve those concerned in community action, in becoming more active citizens. According to Henderson (2005, 2006), the concept of community development is increasingly being replaced by the terminology of community involvement (community engagement), which assumes social justice, participation, equality, learning and cooperation in the selection of values.

Community decision-making (citizen decision, participatory decision-making) can also be understood as a kind of social participation, where local actors are informed and consulted, but at the same time a more active participation and involvement (cooperation, empowerment, transfer of power, delegated decision-making) is realized from the community's side. In relation to local governments social participation is an active learning process that "provides the opportunity to express various points of view and ideas. Another advantage is that information that was previously not known to everyone is often published, points of view generally converge, and solutions can be outlined that serve to satisfy more and more actors" (Pallai, 2010:11).

The participatory (or participation) decision-making process, which is closely related to the topic, primarily means a freely chosen decision-making method that the manager chooses for the tasks to be solved in a given project. This choice applies to a specific project, so the leader's freedom is not impaired, but strengthened by this option, and the leader's solution toolkit is expanded, which can be used for the benefit of the given community. In his study, Németh (2021) presents the applicability of the method in connection with case studies in Esztergom and Nagymányok.

Dobay-Tzadok (2006) examine the dilemmas of community decision-making in practice in the case of a settlement (Modi'in, Israel) where, as a result of modernization, a difference of interests is formed within the community. In connection with the specific international case study and research results the authors state that human rationality is limited, the expertise and receptiveness of the participants in community decisions is finite, so the experts supporting the decision-making processes must adapt to this.

Examining new forms of cooperation and studying urban development based on social innovation (URBACT programme) experts emphasize active, participatory initiatives (Veresné Somosi – Sikos, 2023). According to their opinion, in a new local government model – in relation to the factors of operation – the acting and cooperating task of local government, the function supporting citizen decision should be emphasized (URBACT II Capitalisation, 2015).

2.2 The Role of ECOC Programs in Community Building and Community Decision-Making (International Examples)

The European Capital of Culture project can be considered one of the most successful initiatives of the European Union: in recent decades it has been proven that, in addition to stimulating cultural life, moreover economic, community and urban development, the event can also play a significant role in tourism in the participating cities (Lőrincz, 2017). Based on experience winning the title improves the international visibility of the cities and a significant tourism activity starts in the towns, moreover the local communities also benefit from the renewed cultural offer, thus the image of their place of residence improves in their eyes as well (Richards, 2020). Since the mid-1990s, and especially in the last decade, many ECOC programs have placed special emphasis on audience development and cultural engagement, which affect both the balance of their cultural programs and the design of specific projects and events aimed at involving local communities (Tommarchi et al., 2018; Demartini et al,. 2020).

Recently several ECOC programs have successfully implemented the microgrants scheme, among which the good practices of Wroclaw and Rijeka inspired the staff of VEB2023:

- Thanks to the "microGRANTS ECoC 2016" program in the European Capital of Culture Wroclaw 2016 project, city dwellers and local communities were able to realize their ideas related to community, cultural and educational initiatives (https://www.wroclaw.pl/rozmawia/mikrogranty). In Poland, the slogan "Spaces for beauty" of the microgrant program was the same as the title of the successful ECOC application. In this scheme each winning project could receive financial support of up to 5,000 zlotys (approx. 457,000 forints or 1,170 euros in April 2024). In the ECOC program of Wroclaw the range of applicants was extremely wide: private individuals (adults), informal groups with adult representatives, non-governmental organizations, home owners' associations, social cooperatives, church institutions and religious organizations could apply. Applications submitted online were evaluated by an external, independent jury based on a predetermined point system. The microGrants program is successful and continues to this day: from 1 to 15 May 2024 individuals, civil communities and young people can apply with initiatives related to animation, recreation, education or art.
- The Rijeka2020 European Capital of Culture programme also encouraged community participation. The aim of the project running under the slogan "Port of Diversity" was to create the city of culture and creativity for Europe and the future. On the one hand the organizers invited the Rijeka population and civil organizations to propose minor greening projects and to organize cultural and artistic events in the city districts. The invitations also included applications for the "Civil Council", in which members of the local population evaluated the quality of the submitted applications and selected the best ideas deemed worthy of funding. In the framework of the ECOC programme many individuals and civil groups responded to the call, submitting a total of 141 projects. 155 local residents applied to participate in the "Civil Council" (Partner project • Rijeka 2020). The initiative is still alive today under the name of "active citizenship" (Active citizenship – City of Rijeka), leading to the participation of the local population in budget planning and adoption of the budget. "Proračun(ajme)" is a budget education game in which the citizens of Rijeka, in addition to learning about the actual budget items, can choose the projects they want to implement that are not included in the existing budget.

3. Case Study of the Veszprém-Balaton 2023 Ecoc Project: Microgrants Programme

3.1 Good Practice of Microgrants in the VEB2023 ECOC Project

The spirit of the Microgrants Program, the objective of supporting communities, was already included in the first application document of the VEB2023 project, the Veszprém2023 Bidbook, under the working title "White Spots Program" (Veszprém2023 BidBook, second round application material, 2018). During the preparatory years (2019-2022) the VEB2023 management consulted several times with representatives of European Capital of Culture programmes and experts, as a result of which the idea of a smaller grant (microgrant) scheme and the decision-making methodology involving local population were further strengthened.

At the end of 2022 the "Small-Scale Community Grants Program" (hereinafter referred to as microgrants) initiative was launched within the VEB2023 program. The microgrants scheme set three priority goals, namely education, simplified support system and practical application of community decision-making.

- Education meant that anyone who had not applied before – be it a non-governmental organization, municipality or economic operator – could try themselves in a simple scheme and achieve a sense of success. This helped these actors to apply for larger sums later and to confidently participate in more complicated procedures.
- The simplified procedure and the standard subsidy (HUF 350,000, approx. EUR 915) made it possible to apply for events and tools that were not possible to get from other sources – due to the scale –, therefore the organizers of the program considered this type of scheme as filling a gap.
- For the sake of more transparent, more diverse and more effective evaluation VEB2023 experts developed and tested the community decision-making process. The practical utilisation of the method, the eight application rounds proved its effectiveness.

The city of Veszprém won in December 2018, together with the Balaton-Bakony region, the title of European Capital of Culture of 2023. The settlements of the region could join from three counties (Somogy, Veszprém, Zala). The intention was confirmed by signing a cooperation agreement, which involved the payment of membership fees. The Microgrants Program was opened exclusively for settlements having ECOC cooperation agreements. In connection with this, the staff of the Public Foundation for the Culture of the Veszprém-Balaton Region, in close cooperation with the ECOC program, held application briefings at nine locations, preparing and informing potential applicants from the local communities. The goal was to support community events and activities with artistic-cultural or local historical values, which responded to real, local needs with a fresh approach in the fields of theatre, music, fine arts, applied arts, movement arts, dance, architecture, cultural history, local history, folk art, landscape culture and ecology.

The preparation and implementation of community decision-making, the operation of the grant scheme, and the realisation of applications mobilized enormous forces. In numbers this meant that in the four application rounds a total of 600 bids were received, and these were evaluated by a total of 64 jury members in four community decision-making rounds for the city of Veszprém and four additional rounds for the region. Taking into account the judging criteria and the application fund of HUF 84 million (approx. EUR 220,000) the jury members supported 240 winning applications. In 2023, in the Veszprém-Balaton area the programs featuring diverse themes (the most popular being music, knowledge dissemination and folk art/tradition) had an impact on the lives of more than 100,000 people, one third of whom were local residents, and 61% of whom were visitors to the settlement or tourists.

3.2 Practical Implementation of Community Decision-Making

Decisions regarding the microgrants were made based on a new kind of methodology, involving the local population. Although community decision-making (citizen decision, participatory decision-making) is not a complete peculiarity in domestic settlement development, as far as we know, no one has used it yet for application judging. Lukácsházi Gergely sociologist and Bogáti Réka lawyer from the PartLab team helped the program owners in developing this innovative form (helloveb.hu, 2023).

The volunteering jury members involved in community decision-making were selected according to demographic factors (age, gender, place of residence) and interests. The decision process itself was assisted by a moderator, furthermore a game table and tokens represented the applications. In the first step the jury members got to know the applications with the help of the presentation put together by the moderator. For each application the jurors received a short summary, a voting aid and a paper notebook, where they could write their thoughts as they proceeded. During the judging they had opportunity to ask questions about the applications and discuss them. The main task of the moderator was managing time and ensuring a tight session.

Jury members representing the population of Veszprém and the region made supportive decisions based on their own value judgments, with the help of tokens, jointly. In this process they had to convince each other, argue, and clash different points of view. At the same time the organizers of the grant scheme asked the public representatives also to rank the applications according to the four parameters of involvement, creativity, community impact and quality project planning, as well as to take into account the objective aspects included in the call for applications. With objectivity in mind jurors had to try to support programs that

- are unfeasible or difficult to implement on a business basis;
- speak to local people about passing on local traditions;
- are created with a lasting community-building intention;
- can possibly have a lasting, tangible end result;

- do not finance daily operating expenses, but use the funds for the benefit of a community.

3.3 The Process of Community Decision-Making – Experts' Point of View

Regarding the community decision-making process itself structured interviews were conducted with several VEB203 employees and experts involved in the application process, as well as with Lukácsházi Gergely (PartLab), the developer of the methodology based on playful elements. The expert discussions (involving 7 persons) touched on

- the main principles of conducting the Microgrants Program;
- the innovative elements and novelty value of community decision-making;
- application criteria (amount, location, purpose);
- the methodology of community decision-making (selection of jury members, location, moderator, playful elements), its advantages and disadvantages;
- proposals and future plans for community decision-making.

The sociologist expert emphasized that during each round of decision-making people unknown to each other sat together, and at the end of the process they achieved the final result by choosing values and in the framework of cooperation. "Judging is a great experience... we didn't know what the actual result of the decision-making would be, it was decided there on the spot." Lukácsházi Gergely emphasized. During the community decision-making techniques used in coaching and board games were used, i.e. the civilian jury members had to choose values, cooperate and then decide next to a game table, with the help of tokens. Conversation, debate, persuasion and argument appeared as key elements, and group decisions were made at the end.

Figure 1: The picture of the board game table used in the jury sessions

Source: VEB2023

The experts working in the framework of the Veszprém-Balaton 2023 programme and conducting the microgrants highlighted both the advantages and disadvantages of the community decision-making methodology (Table 1).

Table 1: Experts' perception of conducting the microgrants and the community decision-making method

Advantage	Disadvantage
close to people, humane way of working	there is not necessarily an insight into the (application) interests when selecting the jury members
impartiality, independence	registration process for jurors: the sample could not always be taken from the region
makes decision-making transparent	jurors' sensitivity to social problems – this often diverted the decision in a different direction
diversity prevails	in terms of jury members there were 1-2 repetitions, i.e.: some jury members were called for evaluation more than once.
strong community-building role	question of professionalism and competence – civilians decide
people unknown to each other sit to a table	the decision-makers do not know the applicants / the background of previously awarded amounts, they decide based on the title and content of the micro-application
jury members feel the program their own	time- and resource-demanding process
the active jury member is usually an "influencer", opinion-leader in his or her own environment	
togetherness	
the opinion must be assumed	
local patriotic spirit	
small communities see that it makes sense to get started – we pay attention to the MATTER	
the application procedure is simple and non-administrative

3.4 Thematic and Spatial Analysis of the Microgrants

The winning microgrants were analysed based on the data of simplified application accounting (data received by the Public Foundation: implementers of winning applications, locations, themes, timing, type of program, target group's size, age and locality). In this study, we present the thematic and spatial pattern.

During the year 2023 – in quarterly cycles – 240 winning applications were implemented in the settlements of VEB2023. The impact of winning applications is diverse, but focused basically on the smaller communities operating in the given municipality. Based on the professional reports received it was confirmed that the microgrant applications conveyed meaningful recreation, positive experiences and new knowledge, while the sense of identity and the local community strengthened within the settlement, the relationship among generations and between new settlers and deep-rooted residents developed in a positive direction; the passing on of traditions, the revival of forgotten habits was realized. The awareness-raising programs were characterized by joint design-creative work, and they were implemented in good, familial-friendly atmosphere. Several participants reported that they were planning to continue.

The microgrant winners (N=43 persons) named the three most characteristic terms related to the application scheme. Based on the answers, a visual word cloud can be drawn, where the expressions "simple, fast, community, creative, useful" are the most typical ones (Figure 1).

Figure 2: "What comes to mind when you think of the term 'microgrant'?" – the most typical answers of the winners (N=43)

Source: Public Foundation for the Culture of the Veszprém-Balaton Region, 2023

About the spatial distribution of microgrants it can be said that most of the programs (58) were implemented in Veszprém, followed by Balatonfüred (17) and Várpalota (10). In terms of population-application ratio we can highlight Vászoly (283 people) with 7, Balatonudvari (350 people) with 6 and Balatoncsicsó (261 people) with 5 winning applications (Figure 2). Out of the 116 settlements (approx. 300,000 residents altogether) that joined the programme, 63, i.e. 54% of the municipalities, received support from the microgrants scheme.

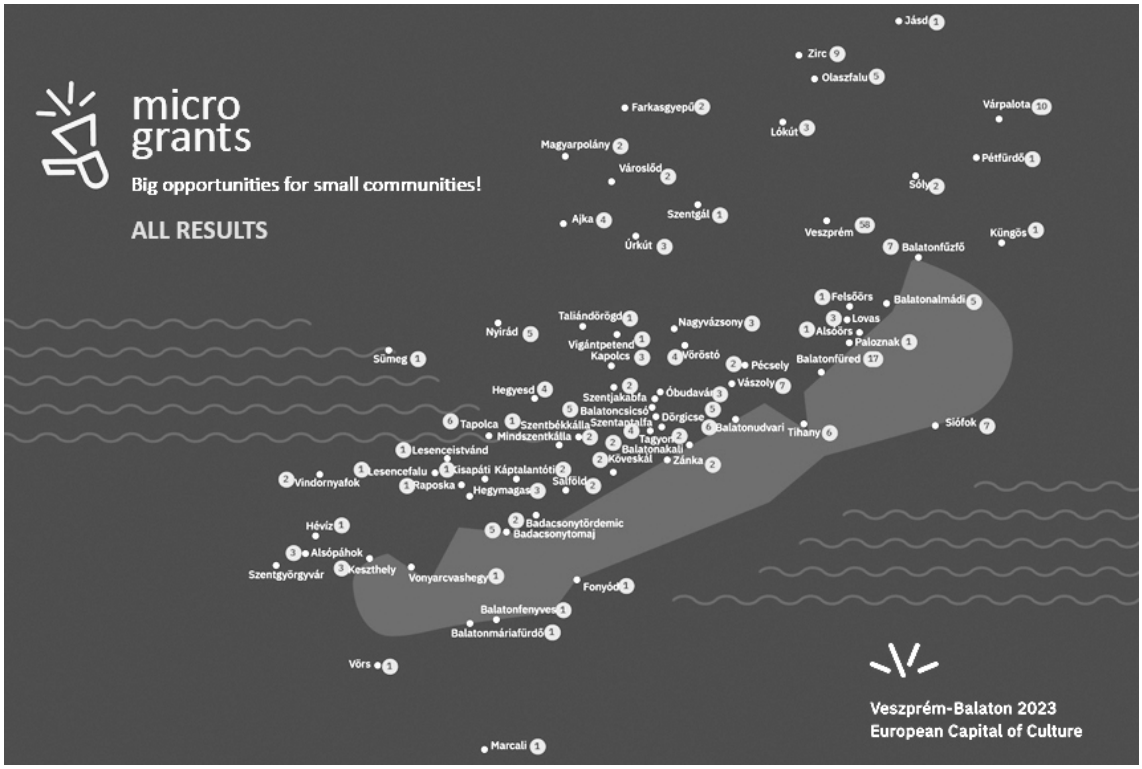

Figure 3: Spatial distribution of the microgrants

3.5 The Opinion of Jury Members Involved in Community Decision-Making

Based on the sent invitations and contact information, each jury member was given the opportunity to evaluate the process of community decision-making and to express his or her opinion anonymously. After the judging the questionnaire sent out by the moderator concerned mainly the assessment process (fun, exciting; easy to understand, to follow; transparent; efficient and smooth), the final result of the judging work (satisfaction with the selected applications), as well as the evaluation of their own role and of the community participation experience (team spirit; moderator's work; organization; proposals for the future). Respondents rated each statement on a scale of 1 to 5, and sent their suggestions and criticism replying to open questions.

Based on 64 responses the jury members rated the jury day a total of 4.91 points on a scale of 1 to 5, which clearly shows the positive assessment. Those participating in decision-making were most satisfied with the quality of preparation, organization and execution, and least satisfied with the selection of location, the services provided on site and the "tiring" aspect of the judging process. In general it can be said that the respondents from Veszprém spoke more critically than the residents of the regional settlements (Figure 3). From another point of view, 67 jurors would gladly participate in a similar event in the future as well or recommend it to a friend or acquaintance.

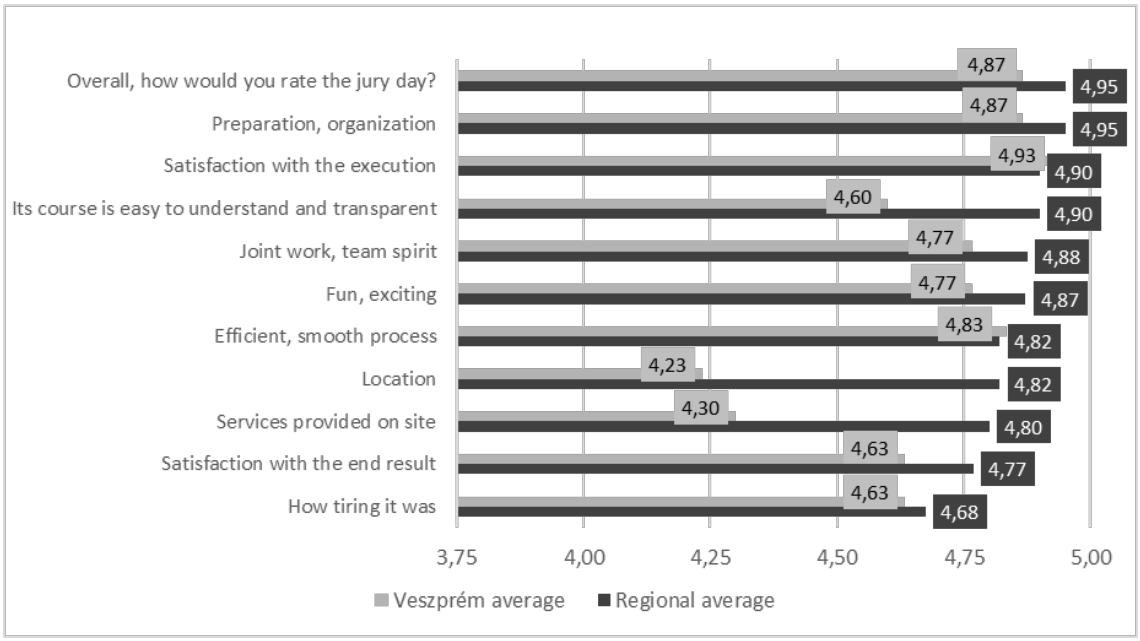

Figure 4: Judges' satisfaction with different features of the jury day, by area (N=64)

4. Summary, Conclusions

Based on the results it can be said that the implemented Microgrants Program contributed to the expansion of event offerings of the European Capital of Culture thematic year, to the involvement of people living in the area of Lake Balaton, as well as to community building and awareness raising. Despite the fact that the HUF 350,000 (approx. EUR 915) standard subsidy can be considered low, 15% of the winning applicants were businesses. Starting with the second round of applications identical programs implemented in several settlements appeared, with the cooperation of municipalities. The target groups were coloured by the disadvantaged, by those who "newly settled in", as well as by the different generations. Some of the programs dealt specifically with environmental awareness (planting trees, building bird feeders, manufacturing briquette bricks, etc.), but sustainability elements (recyclable cups, plates, selective waste collection) were also often emphasized during implementation. The continuation of the realized events and making them a tradition were expressed many times as a demand.

The opinion of experts participating in the process of community decision-making and in the execution of the microgrants is unanimous regarding the continuation. In their view the methodology and approach tested also in practice can be extended and adapted to the community development activities of Hungarian settlements. In relation to the application conditions specific proposals were formulated, affecting the following criteria:

- Grant amount: a minor (inflation-adjusted) increase of the eligible grant amount, namely to HUF 500,000 (approx. EUR 1,275) for 2024.
- Time schedule: quarterly periods, a schedule adapted to seasons and special holidays as well is recommended.
- Regional distribution of the application framework, mitigation of regional disparities: if the program continues in the VEB2023 region, the proportion of the application fund between Veszprém and the settlements in the region should be one-third to two-thirds. Encouraging application activity and increasing initiative is specifically recommended for the settlements of Bakony hills and of the southern shores of Balaton.
- Application topic: the current goal – community building, development of creativity – can be extended to other areas, for example to support civil associations. The priority task of the future is to separate the goal and the means (what result the community expects and through which type of activity or program it is effectively achieved) during the presentation and development of the application idea.

- The jury involved in community decision-making: the composition of the jury, which should consist of persons selected from the community given on the basis of socio-demographic aspects, is still a determining factor for success. It is worth giving priority to diversity and the different interests of jury members, therefore a larger campaign and effective communication are recommended in connection with the recruitment of jury members.

The closing of the VEB2023 program provides an opportunity for a kind of knowledge sharing, the transfer of experiences and good practices. The experts of the microgrants plan to publish the entire methodology of participatory community decision-making (from the call to the end of applications) in a detailed guide. According to the plans the eBook format document will be delivered to as many municipalities, non-governmental organizations and grant scheme decision-makers as possible, with the intention that they will also benefit from the advantages of community decision-making. The primary academic and practical contribution of this endeavor will be the decision-making guide upon its release.

Examining the Impact of Local Developments and Effective Governance to Foster Social Innovation Practices

Tivadar Máhr and Eszter Júlia Németh
University of Pannonia, Faculty of Business and Economics, Innovation-management Department, Veszprém, Hungary

mahr.tivadar@gtk.uni-pannon.hu
nemeth.eszter.julia@gtk.uni-pannon.hu

Abstract: Social innovation grassroots initiatives play a pivotal role in addressing locally occurring problems - such as aging population, high unemployment, and inequality of disadvantaged groups - by recognizing them and responding with adequate answers that are in harmony with the needs of the local community. Therefore, focusing on the even more urgent difficulties of sustainable, bottom-up initiatives of social innovation, the balance of effective governance and locals has an enormous role in fostering real solutions. However, the process to solve these challenges is multifaceted, based on the renewal capacity of the local community that is rooted in the volume of involvement, effort and willingness to adapt and learn, including on the one hand the local inhabitants, and on the other hand the decision-makers, politicians and administrations. By examining the impacts of local developments and effective governance in the context of social innovation the authors seek answers how local developments and effective governance can contribute to enhance social innovation and what are the biggest challenges of local communities they are facing? What kind of instruments can contribute to create a positive change? With respect to the research question, the methodology contains qualitative focus group discussions, where professionals from business, academia, government, and civil organizations were asked. In conclusion, the results and novelty of the research show that local developments supporting the partnerships between the stakeholders, have a massive goal to jointly support the progress of public goods and life-quality, sustain and increase local wealth, knowledge transfer, strengthen the cohesion among locals, and support prosperity in a determined local territory. By drawing attention into real cases the authors introduce how to support social innovation in diverse areas of life through effective governance and local developments. The research emphasizes the importance of modern forms of local governance to establish an ecosystem that supports the processes of social innovation with appropriate instruments, including the capability, attitude, talent, and commitment of local governance leaders, role of cooperation culture among quadruple helix members and the necessity of knowledge transfer and adaptation between stakeholders.

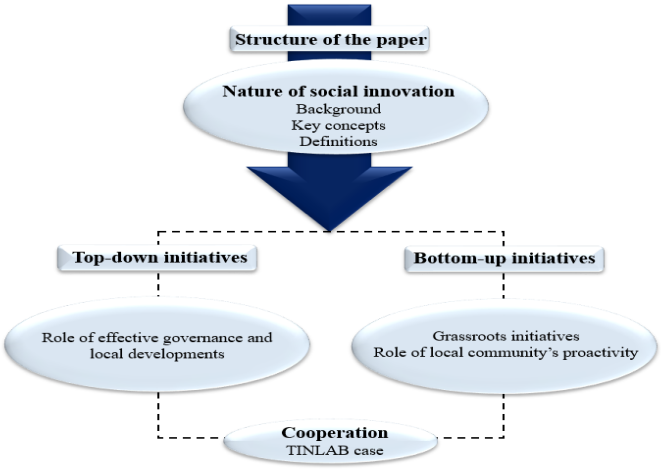
Keywords: Social Innovation, Local Developments, Grassroots Innovation, Effective Governance, Public Good, Knowledge Transfer

1. Introduction

Examining the entire nature of innovation, more specifically focusing on ***social innovation*** is a challenging, but an increasingly urgent task, due the widespread societal issues, such as aging society, gender inequality, climate change, self-evaluation problems, youths' life starting crisis or new labor necessities due digitalization (Rodek, Bogdány, Máhr, & Rentz, 2024). Of course, the list of social problems is much longer and dynamically expanding. First and foremost, approaching the term of social innovation, there is no universal consensus in its definition (Varga, 2017), however it composes many building blocks. The concept was used already by Joseph Schumpeter that serves as a worth by facilitating structural transformation in society. However it came to the mainstream in the 1990s and has been a popular topic ever since (Baker, & Mehmood, 2013). According to the Oslo manual, social innovation is a kind of innovation, characterized by "*social objectives*" aiming to increase the well-being of people or collective groups (Oslo manual, 2018, p. 252). Social innovation can arise everywhere, however areas with frequent social and environmental challenges boost its appearance (Bogdány, Varga, & Veresné Somosi, 2021). The rise of new societal needs such as modern labour perspectives, different approaches among generations, changing social relations are driving the evolution of social innovation practices and implementation of new ideas (Rodek, Bogdány, Máhr, & Rentz, 2024). Just as the basic definition of innovation implies, social innovation is characterized also as a non-linear process, wherein diverse actors come together and take joint actions, mutually put their efforts into the processes and share their knowledge to call advantageous results for life (OECD, 2021, p.12).

The necessity of social innovation practices is significant, which can emerge from ***top-down initiatives***, such as through the activities of the local governing authority or institutions, by introducing modern policies or new strategies, or from a ***bottom-up approach*** based on the proactivity of a local community. However, it is significant to understand, social innovation is a complex phenomenon, which requires comprehensive

management to understand the cause-effect relationships and to deliver proper answers for the arising necessities.



Source 1: Visual introduction

Source: own edition

Therefore the authors are focusing on how ***local developments*** and ***effective governance*** can contribute to enhancing social innovation and what are the biggest challenges of local communities they are facing? What kind of instruments can contribute to creating a positive change? With respect to the research question, the methodology contains qualitative focus group discussions in order to gain deep understanding of the topic. Among the objectives of the qualitative methodology were to gain information about aspirations and driving factors of social innovation, grassroots practices and connections of local government. The focus group discussions involved professionals from diverse areas such as from the sphere of business, academia, government, as well as locals and civil organizations were asked.

The paper has several contributions. Firstly, the research provides a comprehensive analysis about the nature of social innovation and role of grassroots initiatives, highlighting the connection to effective governance practices. Secondly, the paper identifies the significance of modern governance practices that can serve as a driving force in social innovation practices and supporting the social collaborations. By analysing the qualitative insights of the diverse stakeholders, the findings have practical implications and suggest the importance of implementing modern governance perspectives into the daily life of local governments. Overall, these contributions provide a starting point for supporting a transformation in the establishment of modern government approaches, which are beneficial for strengthening the role and impact of social innovation's grassroots initiatives.

The study is structured as follows; in the following section the article summarizes the findings of a literature review by showcasing the entire definition framework and nature of social innovation, the next section introduces the role of grassroots initiatives and role of local governments and finally the study introduces the qualitative focus group discussion results with conclusions.

1.1 Taking a Look at Social Innovation

Social innovation is not merely a by-product, it is a significant type of innovation viable on its own, and created by organization of social associations, knowledge unions to solve locally occurring societal needs, however previously it was often mentioned next to technological innovations as an integral part (Rodek, Bogdány, Máhr, & Rentz, 2024). Furthermore, the white paper of social innovation states, social innovation can strongly connect to the innovation in technology, encompasses those technological renewals that are accepted by the community (Bogdány, Varga, & Veresné Somosi, 2021). Due to the Covid-19 pandemic, the importance of social innovations has been amplified to generate adequate solutions to the diverse societal and environmental issues (OECD, 2021, p.1). However, taking a look to an earlier period, already the 2008 financial crisis contributed to recognizing the role and potency of social innovation in the level of policy generation (OECD, 2021, p.4). As Rodek, Bogdány, Máhr, and Rentz mentioned in their work, social innovation is generated to satisfy the human

needs, bring a change, broaden the capacities and allocation of resources, as well as to support the creation of new practices and ideas (2024). Therefore it is clearly visible that social innovation is multifaceted and means a process from the ideation till the realization of solutions to the locally occurring challenges. It can focus on the enhancement of social objectives, can provide new processes, methods, models or integrate diverse competencies. According to the OECD "*social innovation is generally a product of collaboration between several actors, either directly or through a trusted intermediary, which results in collective knowledge building*" (2021, p.11). The authors agree with this formulation, as well as with those who mention both collaboration and its effect on knowledge creation. Collaboration fosters knowledge transfer, the birth of new ideas, at the same time it can deliver new perspectives to the members through interaction, and finally it leads to new, creative solutions. In conclusion, the process of collective knowledge building can contribute to develop and share new practices that can ultimately support the evolution of social innovation. By taking another definition about social innovation, Mulgan's perspective states "*it refers to innovative activities and services that are motivated by the goal of meeting a social need and that are predominantly diffused through organizations whose primary purposes are social*" (2006). In this statement, it is important to highlight the dual focus of social innovation, that is on the one hand seeks to realize innovative outcomes and on the other hand aims to implement social impacts. Moreover, referring to the views of Varga, there are diverse factors that foster social innovation practices. Among these, it is useful to note the aim to identify new, effective and sustainable solutions to locally occurring barriers and needs, while also fostering cooperation and interaction among locals (Varga, 2022). By examining the complex nature of social innovation, multifaceted components and intricate interplay can be seen between the actors. This is clearly visible in the work of who mentions the differences between the basic type of innovation and social innovation. In the social type, the action goes beyond the individual level, and demands interaction that has a societal impact. "*The reconfiguring of social practices, in response to societal challenges, which seeks to enhance outcomes on societal well-being and necessarily includes the engagement of civil society actors*'' (Polman, Slee, Kluvánková, Dijkshoorn, Nijnik, Gezik, & Soma, 2017, p.4). Phills and colleagues' mentioned the financial aspects of the innovation process that is used to gain social value and benefits so in line with the statements social innovation can be defined as a "*novel solution to a social problem that is more effective, efficient, sustainable, or just than existing solutions and for which the value created accrues primarily to society as a whole rather than private individuals*" (Phills Deiglmeier, & Miller, 2008). Taking conclusions about the definitions, existing studies concentrate on the diverse background of social innovation, whereas it is clearly visible that the driving force of social innovation is the increase of social well-being, to foster social change and positive development by taking into consideration the local circumstances. In addition, these definitions deliver broader connotations, in which the role of collaboration is meaningful, due to knowledge transfer and creation activities that can support the progress of social innovation.

Many elements encompass the initiation or hindrance of the movement of social innovation. As in a basic form of innovation, so in social innovation creativity plays a huge role to find renewed practices to local problems. Additionally, worth remembering, it is a demand driven procedure, which requires specialized solutions to the local circumstances, needs and obstacles (Bogdány, Varga, Veresné, 2021). These currently occurring local challenges make it necessary to establish new ways of collaborations among locals, different institutions like the government, industry or academia, to identify and realize the stakeholders and create a live cooperation by calling them (Varga, 2022). Therefore, joint cooperation of the heterogeneous stakeholders supports the evolution of the processes. At the same time, by involving and engaging the heterogeneous actors an open knowledge flow is characterizing the complex framework of social innovation. Consequently, the holistic approach of social innovation demands expertise, willingness, trust and involvement of locals into the decision making (Varga, 2022). Taking an example, many times there is a lack of knowledge on local levels therefore the benefits of social innovation cannot be fully exploited (OECD, 2021, p.4).

In conclusion, as the definition of social innovation suggests, the concept is multifaceted, encompassing several fundamental elements. Focusing on the origin of social innovation, it is driven by collective actions of the heterogeneous stakeholders aiming to address locally occurring societal challenges. The interacting community, the engaged people serves as a supporting source of its progress. Based on the statements, there is a prevailing consensus that social collaboration plays a major role in order to effectively contribute to a positive change in the well-being of a local community. To explore the broad context of social innovation, the next section seeks to explore the role and possibilities of grassroots initiatives in social innovation practices.

1.2 Grassroots Innovation

There is a prevailing consensus, that social innovation has a growing importance and a significant task for the future to minimize the current locally occurring problems (Rodek, Bogdány, Máhr, & Rentz, 2024). A considerable amount of literature has been published, initiating social innovation practices can come from two main directions. On the one hand, it can begin as a "*top-down*" action -originating from the local government - or on the other hand it can emerge as a "*bottom-up*" or "*grassroots*" proposal – driven by the local proactive community (OECD, 2021, p.12). Other voices concern three different social innovation sources, the grassroots innovations of civils, responses to local needs and thirdly as a renewal and transformation process (Nemes, & Varga, 2021 as cited in Rodek, Bogdány, Máhr, & Rentz, 2024).

Notably, bottom-up initiatives have a major role in the development of social structures and community competencies. These initiatives arise locally, seeking to find answers for the urgent, uncomfortable local problems or needs. This requires the local stakeholders to discuss all approaches as well as to support the initiatives (OECD, 2021, p.12). By accepting the statement, grassroots activists can generate sustainable solutions for local situations by approaching the local interests, framework and value system. According to the research of Bogdány et al., grassroots innovation can deliver several advantages for a community. First of all, there is a community level advantage, which means new work possibilities or community services. On the other hand, the change of ideology can be mentioned among the advantages that can be gained by grassroots innovations (2021). Many studies have concerned the impact of grassroots innovation and naming as a community innovation. Recent evidence suggests it is a great source of renewal within the local community. Moreover, going beyond the source and output of grassroots innovation, education and community learning are inseparably connected to it. Approaching beyond the process, among the stakeholders there is a knowledge sharing, therefore an open innovation is characterizing the process (Rodek, Bogdány, Máhr, & Rentz, 2024).

Throughout the examination of the non-linear social innovation bottom up initiatives, diverse actors - including the members of the public-, private- organizations, NGOs, the civil society, governmental actors, or academia - are cooperating (OECD, 2021, p.14). Therefore social innovations are characterized by even bigger complexity, which requires a strong collaboration, proactive engagement from the heterogeneous actors and agility (OECD, 2021, p.17). Additionally, the supporting environment is a powerful factor in the process and contributes to the successful end result. So, managing and mentoring the entire process is a significant task (Katonáné Kovács, Varga, & Nemes, 2017) and not just the locals should understand its importance, but the local government should realize the power of it.

1.3 Effective Governance and Local Developments

According to the white book of Social Innovation National Laboratory (TINLAB), social innovation requires both top-down, government driven and bottom-up, citizen led engagements in which territorial networking has a great role to be effectively coordinated by the actual social needs (Bogdány et al., 2021). TINLAB came to life in 2020 in a partnership of four consortium members, namely with three universities and one foundation. The consortium is led by the Eötvös Lóránd University, joint partners are the University of Pannonia, University of Miskolc and Hárfa Foundation. The objective of the consortium is to support social innovation initiatives and practices and to create a knowledge pool due the diverse network of the Quadruple helix members. Therefore TINLAB identified significant focus areas like digitalization, future of labor, climate protection and determined clear activities to support social innovation practices such as through thematic forums, social innovation trainings for mentors and managers or by the support of pilot projects in social innovation initiatives. Recognizing these social dynamics, political structures should adapt to better address the local needs. Modern perspectives in effective government are vital in order to provide adequate answers for the locally emerging social needs. In line with the above mentioned, collective actions and co-production with the locals are essential in this regard. Networks among heterogeneous actors are playing pivotal roles. Strong social ties are connected to effective networks and can help to overcome cultural obstacles. This can also promote synergy, as well as foster inclusiveness especially in vulnerable communities. Furthermore a socio-political transformation is essential, necessitating new perspectives in governance which emphasize the role of grassroots initiatives, prioritize the importance of involvement of locals in the decision-making processes and at the same time to hear the voices of the citizens (Galego, Moulaert, Brans, & Santinha, 2022).

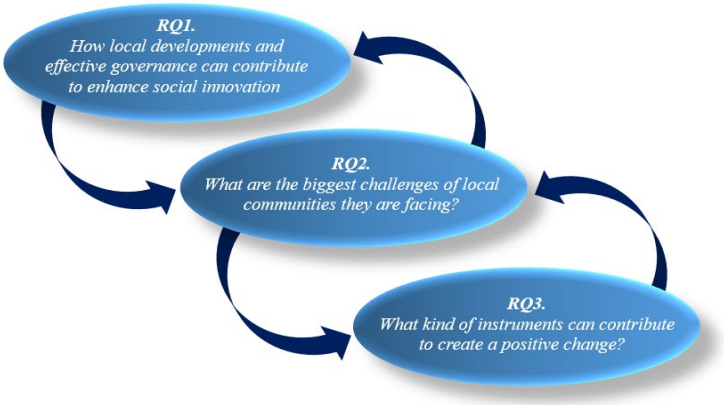
Effective local governance relies on good management practices and proper skills. In the case of social innovation, urgent local problems should be effectively realized, evaluated and on the long run properly solved in line with the local value of the community. Therefore, knowing the local circumstances serves as a baseline in the decision making processes (TINLAB, 2021, p.5). According to the work of Pálné Kovács, a good local governance is characterized by the capability to provide locally good solutions. Furthermore, good governance is democratic, efficiently manages the duties, transparent for everyone, legal, thinks and acts in a future oriented manner, behaves ethically and as a service provider. Also important to be open and supportive for the initiatives. An effective local governance based on local knowledge, that is a great resource for effective developments. Last but not least, it is important to mention the leader, who has a vital role therefore a great leadership and adequate style is necessary. In conclusion, city mayors should connect to both local and global knowledge, should build networks and mobilize them (Pálné Kovács, 2015) to foster developments. As an example of the URBAN program's town level social innovation, the role of effective governance is visible. In line with the previous authors, local areas have a vast duty to realize their characteristics and values. By knowing them, they can exploit their collaboration in which social innovation is a tool to support the processes. As a task for the local government, to work together with the locals, involve and empower them, while they cannot act as isolated actors. In conclusion, a holistic perspective is needed from the local government to be able to act effectively (Varga, 2017).

Social innovation is a great catalyst of sustainable development. Effective governance can foster sustainable social and environmental interactions. The governance has the power to create a bridge among the actors and with the tool of social innovation traditional rules can be challenged and exchange mechanisms can be established among the diverse actors, by at the same time responsively creating modern governance structures (Baker, & Mehmood, 2013). Moreover, social innovation impacts the development of a region, however as noted by Katonáné Kovács, Varga, and Nemes, the contribution cannot come to life without a supporting environment, engaged and empowered mentors (2017). Therefore, within the process of social innovation, highlighting the role of grassroots initiatives is vital, that can address locally occurring necessities to find proper solutions in balance with the needs of the local community (Katonáné Kovács, Varga, & Nemes, 2017). Bottom up initiatives are increasingly valuable, local governments should realize their power, and promote them. To properly foster social innovation practices new governing approaches are needed. Local governments should understand its entire nature, empower and involve locals into the real decision making processes by listening to their voices (Varga, 2017).

Local governments have a great responsibility in social innovation practices and play crucial role in fostering local developments in the horizontally and vertically wide area of social innovation. The relevance of the topic is based on the growing demand for effective solutions, due the local demands (Rodek, Bogdány, Máhr, & Rentz, 2024), therefore collaboration of local governments with social innovators is vital. This requires an open working manner to establish development plans and ideas based on local needs, and support the engagement of heterogeneous members, namely the Quadruple helix members. This joint engagement and strong participation serves as a significant basis to reach common goals in local developments by improving the quality of life, leveraging local assets, and strengthening social cohesion. In conclusion, local developments encompass a wide range of activities with the objective to support social and economic progress through joint participation (Bogdány et al., 2021).

2. Methodology

By examining the impacts of local developments and effective governance in the context of social innovation the authors seek answers for the following research questions:



Source 2: Research questions

Source own edition

To shed light on the above concerns, qualitative focus group discussion was used to analyze the situation deeply. According to the research objectives, a qualitative focus group methodology is a great tool to capture diverse viewpoints and gain insights about real life experiences (O. Nyumba, Wilson Derrick, & Mukherjee, 2018). However this methodology is only one small part of the TINLAB project in which all of the pre-defined research areas of social innovation were examined and asked through focus group discussions (FGD).

The methodology enables to collect attitudes and aspirations on the topic of local developments, effective governance in line with social innovation practices. The focus group interviews were conducted with participants from the academia-government (local)-enterprise-civil networks. They represent the large urban and rural areas, but also the developed capital and West-Hungarian region and the less developed East-Hungarian region. Participants have at least 10 years of experience in their field and an extensive personal network of contacts, giving them a broad perspective on local development and governance. Participants were selected based on personal approaches, with the main criteria being their role in the four-helix model, their professional experience and their network of contacts. The expertise of the interviewees invited was the primary factor in the selection process, while their other (e.g. political) views and motivations were not explored and thus not taken into account. A further criteria was that participants should be territorially representative of both metropolitan and rural areas, and geographically representative of both developed and less developed rural areas.

The FGD were conducted online. Based on the guideline of a pre-defined focus group guide, in approximately 110 minutes, 4 blocks were asked. These sections contained the challenges, innovative solutions, sources of involvement of the local community and networking platforms. The trained moderator guided the discussion. The article synthesizes the results of 2 focus groups, altogether the answers of 9 participants.

3. Results

By summarizing the main findings of the DGD in the topic of effective governance and local developments, several meaningful challenges have been identified. First of all, **attitude and abilities towards social innovation practices and local developments.** Questions are arising often whether the local government is capable of supporting social innovation practices and capable of creating a supporting environment, while very often the abilities are lacking. Also a problem can arise when the leadership cannot demonstrate that it has power in its hand and cannot effectively manage the local challenges. Therefore talent and attitude are important factors especially in smaller communities in case of the developments. Local governments do not always realize its role in the local developments, especially in the case of the establishment of economic development strategies, however that would be useful.

"...I think one of the most important factors, whether your leadership can demonstrate to the local community that you have some tools in your hands to solve problems effectively."

Secondly, **resources and cooperation can challenge the effectiveness of local governance.** Very often, local resources like human, expert, economical ones are underutilized due strict rules and tight perspectives of the local governance.The local government suffers from the lack of resources, especially human resources which limit the openness towards social and economical innovations. There is a low level of cooperation among the local actors that serves as a barrier. On the contrary, a competing behavior is characterizing the interaction of the governmental, civil and industrial sectors. Even in the age of globalization, digitalization, and industry 4.0. there is a low level of interaction in the local governmental sector. Communication with the diverse stakeholders is also on an improper level and the local leadership has not followed the speed of the expected development.

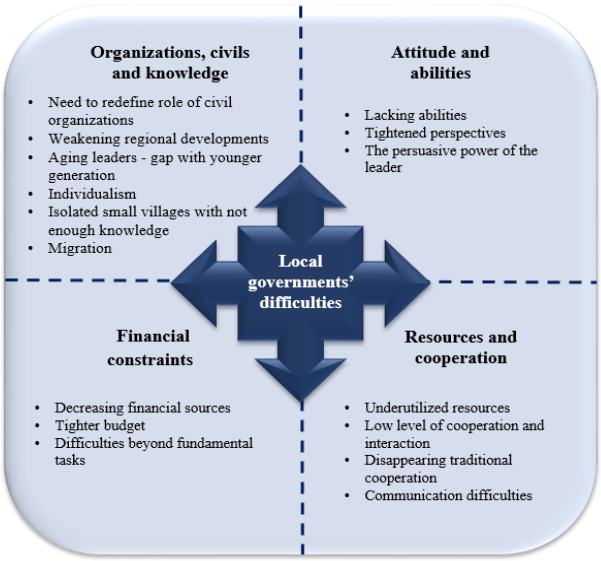
"...The existing attitude system is a challenge. For example, when two local markets organise, they immediately see themselves as competitors to each other, rather than saying that they align their calendars and one operates on Wednesday and the other on Saturday, in effect living better together, working together. Without coordination at the municipal level, it doesn't work. In a good case, it's done by a mayor or someone who is a pretty strong public figure in the city. In the absence of such people, there is no central coordinating force to drive good will towards cooperation. They cancel each other out as competitors…"

Thirdly, **different organizations, civils and knowledge impact evolution.** There would be a need to redefine the role of civil organizations, while they can support the social innovation practices. The Middle level of regional development has been weakened. The aging leaders of these organizations could not provide a renewal and there is a gap with the younger generation, who live in their online environment. An increasing individualism describes the current environment in the local communities. Traditional cooperation disappeared and was replaced by new online ones. There are several difficulties in isolated small villages where there is not enough knowledge, however at the same time there is a great need for innovations and solutions. Furthermore, migration is a significant issue. Visible the fact that big cities from smaller towns and foreign possibilities from big cities absorb the people with more education and work possibilities.

"The issue of emigration and how to deal with it is a significant one. Large cities absorb the adult population, thanks to educational institutions and job opportunities."

Finally, financial constraints characterize the situation. The **financing sources are decreasing**. Local governments are facing difficulties. Beyond the fundamental task there is a lack of financial sources.

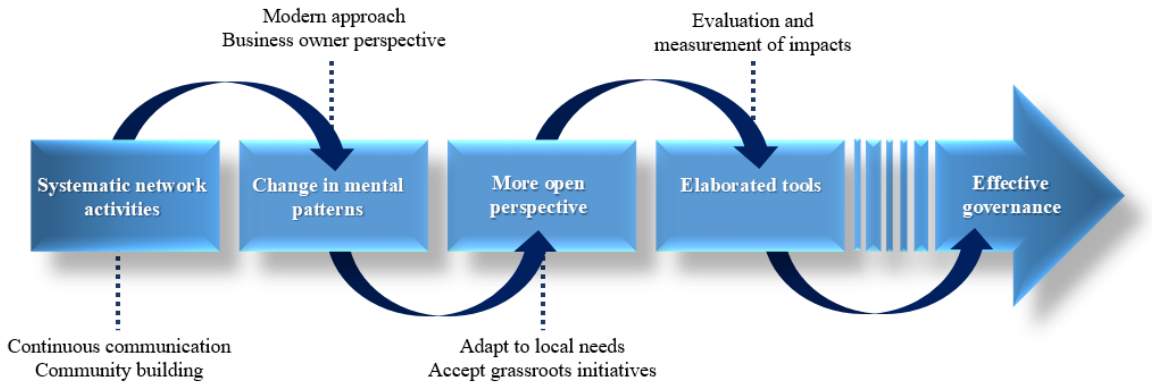
"There is no social innovation without the economy - it will finance it later. The two cannot be separated, social innovation itself has to figure out how it fits into the economy."



Source 4: Difficulties of local governments

Source own edition

In order to solve the challenges there is a need for the establishment of a local ecosystem in which the heterogeneous actors can collaborate and act for a common social goal to increase the well-being of the local community. According to Rodek, Bogdány, Máhr, and Rentz's work, the ecosystem is a network of actors whose both individually and collectively contribute to the knowledge creation, development of new solutions in a loose or tight cooperation form. Innovation ecosystem is a dynamically changing collaboration of the heterogeneous actors, who has a common specific objective that is carried out within the framework of innovation ecosystem (2024).



Source 5: Building components of effective governance

Source own edition

Based on the opinion of the FGDs' participants, not just cooperation but the process should be supported by a **more systematic networking activity**, which serves as a tool for supporting communication and community building, contributes to creativity, knowledge exchange and idea generation for local problems. This can support the evolution of the local ecosystem that serves as a framework for the local developments. As for the **local government, a change in the existing mental patterns** are needed. The old working manners should be replaced by a new, business owner perspective, in which they realize their power to facilitate real solutions and to support the other helix actors. There is a need for the **open perspective** from the centralized governance to adapt to the local needs and to accept the community innovations. Finally, **elaborated tools** should be generated for evaluation and measurements of the impacts. These can serve as a useful guide in the process of effective governance and can support the grassroots initiatives.

4. Discussion

Summarizing the literature, social innovation gains vast importance nowadays, due to the dynamically changing circumstances that are challenging local communities (Rodek, Bogdány, Máhr, & Rentz, 2024). As the definition itself suggested, social innovation provides a solution for locally occurring necessities, trying to raise living conditions (Oslo manual, 2018, p. 252) by actively involving and engaging heterogeneous actors. At the same time, the concept draws the attention to the importance of collaboration whereby difficulties could be effectively solved (OECD, 2021, p.11). Therefore the mutual participation of both top down approaches from the governing authorities' side and local communities' grassroots initiatives are equally important for the long term success (Bogdány et al., 2021). Exploring deeper into the research topic vertically, local governments have significant importance and contribute to the local developments. This requires a modern, adaptive and open perspective and a supportive yet powerful leadership (Varga, 2017). Through qualitative research, the authors examined the topic and found answers regarding RQ1, how local developments and effective governance can contribute to enhance social innovation. By looking for answers, the participants highlighted the importance of major areas. Proper attitude and abilities are necessary for effective governance. These can significantly encourage social innovation practices, foster cooperation and diverse partnership due to an open and flexible attitude. At the same time the establishment of a supportive environment is vital to assist grassroots initiatives, to understand the local needs yet to know the local possibilities and circumstances. However this requires adequate skills, to be able to create a collaboration with the Quadruple helix members, involve and engage the civil society as well as to mobilize human and financial resources. Furthermore, the RQ2 focused on challenges faced by local communities and suggested that there are often issues with the outlook of local governments. It highlighted the necessity that local governments need to adapt to the current local demands by presenting a modern perspective in order to properly arrange social innovation initiatives and support the flow of local developments. Local communities often feel the lack of a supportive environment due to the old mental patterns, budget constraints, low level of cooperation, aging local governmental leaders, tight perspectives, changing cooperation forms, isolation among groups and low level of communication. The listed barriers require adaptive, flexible and open behaviour from all of the Quadruple helix members to find solutions and eliminate the challenges faced by local communities.

In search of solutions the study draws attention to the instruments that can contribute to positive change. As it was mentioned previously, collaboration among the diverse actors, involvement of the local communities, openness from the side of local governance to the grassroots initiatives are building components of the solution. So this requires a well-defined concept or in other words an itinerary that supports the local governments. Therefore, as a suggestion of the authors, local governments should establish a systematic network activity in which proper and continuous internal and communication as well as networking have a necessary role to strengthen the local ecosystem. Secondly, there is an urgent need to transform the existing mental patterns by replacing modern, collaborative, involving, encouraging and business owner perspectives. Thirdly, mentality should be changed. Local governments should be open and curious to the local challenges, needs and possibilities to support the grassroots initiatives by understanding the local environment. That is a challenge however a must in the long run. Last but not least, as in all project, the evaluation of the processes and measurement of the impacts should be part of the local governments' transformation to evolve continuously with the local needs. Consequently, these results provide an important insight into the importance of modern governance perspectives that should be realized by the local governments in order to exploit the possibilities of local circumstances and be able to manage the complexity of social innovation practices to the locally occurring urgent challenges.

5. Limitations

To enhance the rigor and transparency of the study, it is necessary to address the limitations of the study comprehensively. The objective of the small number of focus group discussions was to start a vast research by gaining insight about the both horizontally and vertically broad topic and to monitor the significant elements by important members of the social innovation. However, the current research contains limitations and bias concerning the qualitative methodology due to the reached target groups and the small sample size. First and foremost, the methodology of the research relies only on a focus group discussion conducted online in Veszprém, Hungary. The way supported the communication, made it possible for the researchers to depict the topic with the help of analysing verbal communication elements, however as for the potential bias, the focus

group discussion's online form and the role of the moderator may influenced the perspectives and the interaction of the participants. The online form restricted to analyse nonverbal communication elements. While the research addressed at least one of the representatives of the quadruple helix based on the 3-pillar selection criteria that was necessary to find diverse perspectives from actors, on the other hand the size of focus group discussion was limited. Only 2 rounds of focus group discussions were implemented with a total of 9 people, who may not fully capture all of the perspectives. Therefore the reliance of the focus group discussion is not relevant and only a snapshot can be seen. However, in line with the previously highlighted limitations, further elaboration of both quantitative questionnaire and qualitative structured expert interview research is needed to gain a more specific and detailed insight about the nature of social innovation, impacts of local developments and effective governance from the bottom and top sides of the actors. The authors acknowledge the importance of the topic and recognize the necessity for comprehensive research methodologies, therefore with the help of mixed methodology, the research will be continued. This future direction support on the one hand the quantification of the data, by reaching the quadruple helix members and on the other hand a deeper understanding of the current results.

The Role of Stakeholders in Crowdfunding Success: Insights From a Systematic Literature Review

Maurizio Maraglino Misciagna
Dipartimento Jonico in Diritti Economie e culture del Mediterraneo, Università degli studi di Bari Aldo Moro, Taranto I Italia

maurizio.maraglino@uniba.it

Abstract: In the last decade, crowdfunding has emerged as a pivotal innovation in financial and entrepreneurial ecosystems, reshaping how projects are funded and how investors interact with emerging ventures. This paper conducts a systematic review of crowdfunding literature from 2010 to 2020 using the PRISMA method, focusing on the roles and interactions of diverse stakeholders within the crowdfunding framework. By integrating stakeholder theory, the study examines how alignment of stakeholders' interests—ranging from founders and backers to crowdfunding platforms and regulatory bodies—contributes to the success of crowdfunding initiatives. The review highlights the evolution of crowdfunding, not only as a funding tool but also as a community-building platform that leverages Web 2.0 technologies to foster interactive engagement. Findings suggest that successful crowdfunding requires more than financial transactions; it necessitates a robust ecosystem where stakeholders' expectations and contributions are clearly understood and managed. The study contributes to academic and practical understandings of crowdfunding by delineating the dynamics between various stakeholders and providing insights into how these relationships influence the outcomes of crowdfunding campaigns. Future research directions are suggested, including deeper exploration of the regulatory impacts and the long-term sustainability of crowdfunding as a finance model.

Keywords: Crowdfunding Models, Stakeholders Theory, Literature Review, Web 2.0 Technologies, Financial Innovation, Entrepreneurial Ecosystems

1. Introduction

Over recent decades, technological innovations have dramatically transformed the realms of communication and finance, fundamentally altering how individuals interact and conduct business. Among the most notable shifts is the rise of crowdfunding, which has quickly ascended to prominence as a modern financial innovation. This funding model democratizes investment, enabling thousands to participate interactively via the Web 2.0 network, thereby becoming an essential tool for SMEs and startups (Belleflamme et al., 2010). Crowdfunding allows these entities to source capital directly from the "crowd," with each contributor offering small amounts that collectively support various projects (Belleflamme et al., 2013). This method not only facilitates job creation and economic growth but also empowers ordinary individuals to influence the market by opening up new funding avenues (Sigar, 2012). As crowdfunding continues to surpass expectations, its strategic importance escalates, especially for startups that leverage innovative technologies to obtain significant financial resources. This study aims to dissect the structure of crowdfunding, focusing on the contributions and interactions of various stakeholders within this ecosystem. Employing stakeholder theory, the research seeks to elucidate the roles and impacts of the different parties involved, evaluating why crowdfunding campaigns succeed when the interests of all stakeholders align (Harrison et al., 2013; Burtch et al., 2013).

2. Theoretical Framework: The Crowdfunding

Research on crowdfunding has undergone substantial growth over the last decade. Before 2006, the literature on this subject was relatively scarce, with interest beginning to surge particularly in the United States around this time, marking it as a novel solution to the funding challenges faced by new ventures (Röthler et al., 2011). In contrast to traditional funding sources such as venture capitalists and banks—which typically invest at later, more mature stages of business development—crowdfunding provides early-stage funding directly from a diverse pool of individual backers, including friends and family (Robb et al., 2014). Initially discussed under various terms such as "social lending" and "peer-to-peer lending," crowdfunding has since emerged as a distinct and widely adopted method of financing (Hulme et al., 2006; Klafft, 2008). Belleflamme et al. (2013) identify several key motivations for choosing crowdfunding, including financial support, increased public exposure, and valuable feedback on products or services. Subsequent studies have demonstrated that successful crowdfunding campaigns not only establish market legitimacy but also significantly enhance the customer base and visibility of products (Martin, 2012; Burtch et al., 2013). Moreover, theoretical models have shown that reward-based crowdfunding can facilitate price discrimination, enabling companies to identify and target customers willing to pay premiums for early access to products (Belleflamme et al., 2010; Hu et al., 2014). This section of the literature illustrates how

crowdfunding has evolved from niche financing options into a critical tool for market access and business growth, reflecting its increasing adoption and sophistication in the global financial landscape.

2.1 The Evolution of Crowdfunding in a Digital Era

Crowdfunding epitomizes the contemporary challenge of steering global progress towards a more digital and interconnected society. Over the past decade, the evolution of Web 2.0 technologies has catalyzed the emergence of innovative business models that place the digital user at the center of consumption and production processes (Brenner et al., 2014). This paradigm shift has transformed users from mere endpoints in the value chain into integral participants and co-decision makers, compelling industries to reconfigure and embrace digital business models. Among the various forms of crowdsourcing—such as crowdvoting, crowdcreation, and crowdfunding—crowdfunding distinctively operates as an open call, primarily online, soliciting financial contributions from individuals rather than professionals. These contributions come in various forms including donations, exchanges for future products, or rewards (Howe, 2006; Belleflamme et al., 2014). While not a new concept, with historical precedents such as the funding of the Statue of Liberty's pedestal in 1885 through small donations orchestrated by Joseph Pulitzer (Harris, 1986), crowdfunding has gained substantial prominence in recent times. Notable examples include Barack Obama's 2008 election campaign, which raised $800 million, with a significant portion coming from small donors (Kappel, 2009), and its surge during the 2008-2009 financial crises as a vital funding avenue for startups facing credit access challenges. Today, crowdfunding is not only celebrated as a financial innovation but also hailed as a democratizing force in finance and knowledge dissemination, albeit not without risks of misuse, necessitating continuous vigilance (Shiller, 2013). The essence of crowdfunding lies in leveraging technology, capital financing, and the power of the crowd, which collectively enable the accumulation of significant financial resources through small individual contributions (Beaulieu et al., 2015). Its participatory nature, which enhances its effectiveness through group involvement, contrasts sharply with venture capital's selective focus. Analysis of data from successful Kickstarter campaigns and venture capital investments in the US between 2009 and 2015 illustrates how crowdfunding has served as an alternative funding channel during periods of venture capital scarcity, overcoming the geographical limitations inherent in traditional venture financing (Sorenson et al., 2016). Unlike venture capital, crowdfunding's democratic nature allows for broad participation with minimal capital, though it typically affords backers less control over funded enterprises (Mollick, 2013). As a result, crowdfunding has emerged as a versatile and influential term that encompasses various digital fundraising strategies, fundamentally reshaping the landscape of entrepreneurial finance (De Crescenzo et al., 2020).

3. The Ecosystem of Crowdfunding Stakeholders

Crowdfunding is distinguished by a diverse array of actors, each crucial to its success. For newcomers, crowdfunding might appear as an expansive network of individuals, often referred to as the "crowd" or "community," where anyone can financially support an idea or a startup. However, the reality reveals a more sophisticated stakeholder approach, where aligning the interests of all parties is essential to enhance the overall well-being of those involved in the crowdfunding process (Peda, 2012; Sen, 2012). This modern phenomenon's success is predicated on the effective alignment of stakeholder interests as posited by stakeholder theory. An initial step in analyzing crowdfunding from this perspective involves identifying the needs it fulfills and how various parties contribute to and benefit from the process (Valančienė et al, 2014). The crowdfunding operation varies significantly based on how intermediaries perceive and organize campaigns (Belleflamme et al, 2013). Rather than allocating all R&D resources to internal teams, a company might invest in emerging ventures, thereby controlling their development of new solutions without direct acquisition. This arrangement allows for a broader range of minority investments and gives small entrepreneurs the freedom to innovate under the guidance of a larger firm's management, with the potential for the firm to acquire a majority stake under favorable terms as the startup matures. Intermediaries play a crucial role as they influence numerous aspects of a campaign's execution. Crowdfunding excels in mobilizing people and generating innovative ideas, surpassing other funding mechanisms. The involvement of intermediaries is pivotal, encompassing various agents such as the crowd, campaign initiators, platforms, consultancies, and regulators. The "crowd" typically includes the founder's family and friends, who are key supporters or "crowd investors," especially in equity crowdfunding projects (Agrawal et al., 2010). Freeman (1984) provides a seminal definition of a stakeholder as "any group or individual who can affect or is affected by the achievement of the organization's objectives." This study aims to elucidate how entities interact within the crowdfunding ecosystem using stakeholder theory and emphasizes the importance of aligning towards shared objectives for value creation. Beyond profit, key participants in crowdfunding are

driven by motives including communication, branding, networking, and technology. The literature review has identified major stakeholder groups and outlined their roles and influence within the crowdfunding framework. Crowdfunding has evolved significantly over the past five years, gaining wider recognition and utilization. The technology underpinning it has also advanced, leading to the evolution of stakeholder roles during this period. The subsequent sections will delve deeper into the major players in crowdfunding and their development. Belleflamme et al. (2012) categorize crowdfunding into two primary types based on the involved actors: one where the goal is to gather sufficient funds with crowdfunding acting as a pre-sale mechanism, and another motivated by potential financial returns, with actors assuming the roles of investors. Ordiani et al. (2011) identify three categories of crowdfunding actors: those proposing ideas or projects for funding, the "crowd" that backs selected projects expecting a profit, and crowdfunding platforms that facilitate connections between those seeking and providing funding for new ventures. Emerging prominently yet underrepresented in scholarly discussions are crowdfunding associations. These associations have gained significant relevance by facilitating the exchange of knowledge and experiences, investing in the value creation process for the benefit of all involved parties (Quero, 2018). With increasing interest in crowdfunding, governments have begun to implement new regulations to govern the process, enhancing the importance of crowdfunding associations in their advocacy role to preserve and enhance the benefits of crowdfunding for all participants. Table 1 below outlines the recognized actors in the crowdfunding context, detailing their actions and intentions as depicted in existing literature.

Table 1: Actors in the Crowdfunding Context

3.1 The Role of Founders in Crowdfunding

The founder, whether an individual or a legal entity such as a company, foundation, or association, plays a pivotal role in initiating a crowdfunding campaign to support their idea or project. Literature has referred to these individuals with various terms such as "creator," "borrower," "entrepreneur," "company," "founder," "owner," and "startup." Beaulieu et al. (2015) note that while these labels are diverse, many are too narrow and fail to capture the broader scope of involvement within crowdfunding contexts. For example, on a rewards-based crowdfunding platform, the person launching a campaign might not necessarily be an entrepreneur in the traditional sense, thus not required to establish a startup. Founders are central to the crowdfunding ecosystem; their primary role is to conceptualize a product or project and articulate their ideas compellingly and clearly to potential backers through a crowdfunding website. However, their involvement extends beyond merely seeking financial support. According to Dingman (2014), founders also engage in crowdfunding to gain visibility for future funding opportunities, test market receptivity to an idea (Helmer, 2014), and foster relationships by promoting open communication and collaboration with backers (Gerber, 2012). Launching a crowdfunding campaign involves significant responsibility and requires meticulous preparation and strategic planning. Without these, the risk of project failure increases substantially. Founders must understand that initiating a crowdfunding campaign without a well-thought-out strategy can lead to inadequate funding, thus jeopardizing the project's success. This

aspect underscores the substantial responsibility that founders bear, as underestimating the importance of a strategic approach can have dire consequences for their projects.

3.2 The Central Role of Technology in Crowdfunding

Technology is an indispensable element in the structure of crowdfunding. It facilitates the aggregation of funds, interaction within support communities, presentation of projects by founders, and connections with institutional investors like venture capital, banks, and business angels. Crowdfunding platforms, therefore, act as a crucial hub for all stakeholders within the ecosystem. The technology underpinning these platforms has advanced significantly in recent years, enhancing their capacity to serve as effective intermediaries between founders and the financial community.These web platforms bridge the gap between founders, investors, and supporters, allowing founders to showcase their ideas and projects to a broad audience. This facilitates the submission of funding applications and creates investment opportunities for backers or professional investors who might not otherwise have access to such ventures through traditional financing channels (Beugré et al., 2013; Valančienė et al., 2014). Furthermore, the integration with social media platforms like Facebook and Twitter boosts the visibility of projects, enabling backers and founders to promote their initiatives effortlessly within their social networks, thereby attracting a larger pool of potential supporters (Beaulieu, 2015). The critical role of these platforms is highlighted by their function as intermediaries, with the success of the crowdfunding process heavily reliant on their effective perception and organization (Valančienė et al., 2014). Ramos (2014) identifies four distinct types of crowdfunding platforms based on the nature of the financial transaction involved:

- **Equity-based platforms**, which focus on projects offering investors tangible returns in the form of equity.
- **Lending-based platforms**, aimed at providing loans in exchange for interest payments, thereby appealing to those seeking financial returns.
- **Rewards-based platforms**, which offer non-monetary rewards such as DVDs or T-shirts as incentives for financial contributions, appealing to supporters interested in personal or creative rewards.
- **Donation-based platforms**, designed to gather donations for socially driven projects, where the rewards are intangible, such as a sense of solidarity or contribution to a cause.

These platforms are instrumental in shaping how crowdfunding campaigns are perceived and operated, thus playing a pivotal role in the development and success of various crowdfunding endeavors.

3.3 The Role of Backers in Crowdfunding

In the crowdfunding ecosystem, backers play a crucial role in enabling projects to reach their funding goals. Through web platforms, these individuals—ranging from small donors to major investors—provide the capital necessary for founders to transform their ideas into viable projects or to address specific needs. The contribution of backers is vital not only for financial support but also for validating the market potential and assessing the investment worthiness of the projects (Beaulieu, 2015). To describe the role of an individual who supports a crowdfunding campaign both financially and communicatively, the term "supporter" is used consistently. However, the nomenclature may vary, including terms such as 'supporters', 'suppliers', or 'lenders', depending on the platform and the specific model of crowdfunding employed (Gerber and Hui, 2014). Supporters' involvement extends beyond mere financial contributions; they often actively participate in market testing and provide feedback that is crucial for the iterative development of the project. The motivations driving individuals to become backers are diverse. One significant category includes altruists, often friends and relatives of the founder, who contribute without any expectation of tangible returns. Their support is driven by personal connections and a desire to help someone they care about succeed (Gerber et al., 2012). Another group consists of motivated supporters, those who engage because they want to be part of the project's journey and its potential impact. This includes enthusiasts passionate about a project’s theme or mission, and investors looking for early opportunities in promising ventures. Each backer's contribution, whether small or significant, combines to form a collective effort that supports the crowdfunding campaign's success. This communal support not only provides the necessary funding but also creates a network of advocates who share and promote the project, further enhancing its visibility and likelihood of success.

3.4 The Role of Consultants in Crowdfunding

The consultancy segment within the crowdfunding ecosystem has seen notable growth in recent years, emerging as a crucial category of stakeholders. This group consists of advisors who guide founders through the

crowdfunding campaign, often in return for compensation. These professionals provide essential expertise that helps founders craft and launch effective online campaigns. Consultants in the crowdfunding context can be categorized into two distinct groups: traditional and modern. Traditional consultants generally align with professions such as lawyers, accountants, and notaries, offering services that ensure compliance with legal standards and financial scrutiny. On the other hand, modern consultants specialize in the digital and web marketing sphere, focusing primarily on managing communication and enhancing the visibility of online crowdfunding campaigns. Their role is increasingly vital as the complexity of digital interaction grows. Research by Ralcheva and Roosenboom (2016) highlights the critical role of these advisors in providing consultancy services that are prominently featured on campaign pages of crowdfunding platforms. The involvement of professional advisors not only lends credibility to the projects but also boosts investor confidence by validating the project's potential and the team's commitment to success (Mejia et al., 2019). This nuanced differentiation between types of consultants underscores the evolving landscape of crowdfunding, where the integration of digital expertise is increasingly recognized as pivotal. The ability of modern consultants to navigate the complexities of online fundraising is crucial for the success of campaigns, especially in an era where digital presence significantly influences public perception and funding outcomes.

3.5 The Role of Professional Investors in Crowdfunding

Professional investors, encompassing entities like banks, venture capital firms, and business angels, play a traditional and foundational role in the financial landscape (Beaulieu et al., 2015). They differ from typical backers in crowdfunding due to their structured investment approaches and their focus on substantial financial returns. However, the emergence of equity crowdfunding—where supporters directly invest into a company's equity—has positioned crowdfunding as a viable alternative to these conventional financial channels, attracting a broader and more varied base of supporters. According to Beaulieu (2015), traditional financing sources view crowdfunding as a complementary phase that aids in market validation for a product or service. This perspective is particularly evident in how venture capital firms approach companies that have successfully undertaken crowdfunding campaigns. For instance, a venture capital firm may be more inclined to invest in a company post-crowdfunding, seeing the successful campaign as evidence of market demand and reduced risk (Burns, 2014). This approach benefits from the crowdfunding process, which not only tests the market's receptiveness to the product but also demonstrates the entrepreneur's capability to attract funding from a broad audience. Business angels and venture capitalists often prefer observing an entrepreneur’s ability to secure crowd-based funding before committing their investments. This strategy is predicated on the notion that success in crowdfunding can significantly mitigate the risks associated with new ventures, as it proves the concept's validity and market appeal (Valančienė et al., 2014). This evolving dynamic between traditional investors and crowdfunding platforms highlights a shift in how projects are funded and ventures are evaluated. Professional investors are increasingly recognizing the value of crowdfunding not just as a funding mechanism, but as a critical tool for gauging market interest and potential success.

3.6 The Role of Regulatory Bodies in Crowdfunding

This category encompasses entities that, in accordance with the laws of each country, oversee particular sectors. Specifically for crowdfunding, Italy entrusts oversight to Consob (National Commission for Companies and the Stock Exchange) and the Banca d'Italia (Bank of Italy). Conversely, in the United States, the SEC (Securities and Exchange Commission) assumes regulatory responsibility. These institutions play a crucial role in drafting and implementing regulations governing crowdfunding to ensure a secure and equitable environment for all involved parties (Beaulieu et al., 2015). In addition to federal legislation, crowdfunding activities may also be subject to state-specific laws and licensing requirements, further shaping the regulatory landscape (Gelfond et al., 2012).

4. Value Creation through Stakeholder Interaction in Crowdfunding

This document delves into the actors involved in the crowdfunding process through the lens of stakeholder theory, aiming to understand how interactions within the crowdfunding phenomenon can create substantial value.

As illustrated in Figure 1, the interconnectedness of all actors is crucial; the satisfaction of the objectives of all actors in the process is essential for the creation of value and the success of crowdfunding initiatives.

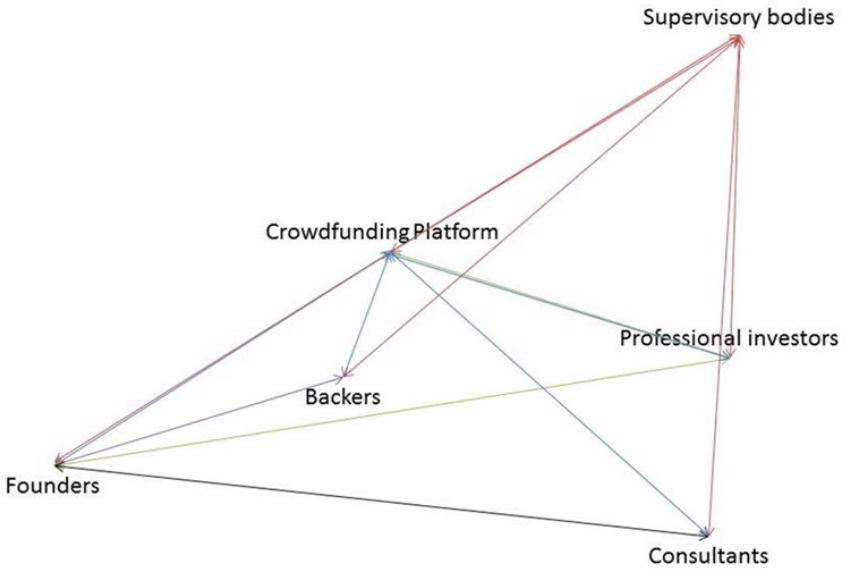

Figure 1

The scientific literature extensively recognizes the importance of the relationship between stakeholders and companies, a bond characterized not only by a convergence of interests but also by increasingly active stakeholder participation in decision-making processes. Despite its relative novelty, the crowdfunding phenomenon is highly dynamic and continually evolving, influenced by both internal and external management that generates value within the crowdfunding process. Success in crowdfunding is contingent upon meeting the common goals of all stakeholders. This analysis delineates various stakeholder classes within the crowdfunding process, considering the presence of one, two, or all three of the following attributes:

- The stakeholder's power to influence the crowdfunding process;
- The legitimacy of the stakeholder's relationship with crowdfunding;
- The urgency of the stakeholder's expectations regarding entrepreneurial projects.

For example, founders possess all three attributes, having the power to shape the process, legitimacy through relationships, and a direct link to the urgency of expectations: without the support of backers, a campaign cannot succeed. However, customers and suppliers must also be integrated and transformed into users, encompassing both investors and startups. Crowdfunding platforms are legitimized by their relationships between founders and supporters or professional investors and have the power to influence fundraising. The varying technological networks and media visibility of web platforms can influence a founder's choice of platform. Backers also embody the three attributes of legitimacy, power, and urgency, acting alongside professional investors as intermediaries between web platforms and founders. Consultants possess two attributes: the urgency of expectations in bridging the founder's project with the crowd, and legitimacy through their relationships with the web platform and project founder. Both founder and consultant share the goal of achieving crowdfunding success, albeit for different reasons: the founder needs funding and visibility for their product or service, whereas the consultant seeks to validate their strategic contribution to the campaign's success. Moreover, supervisory bodies hold the power to regulate and legitimize relations among the various actors, especially within the equity crowdfunding market, through adherence to regulations. Understanding these dynamics is crucial, as value creation is only possible when the interests of all stakeholders are satisfied, leading to a deeper comprehension of the actors' interests, needs, and expectations. Analyzing the crowdfunding process as an effective means allows companies to build trust with their stakeholders, enhance their reputation, contribute to equitable and sustainable social development, and improve processes and products. Hence, stakeholder involvement is essential for enhancing actions that impact society and companies alike. While the crowdfunding process might initially seem to hinge solely on backers or investors and founders, it actually encompasses a broader range of stakeholders whose interests must be considered. Crowdfunding stakeholders constitute a global community, with some governments recognizing its potential to create jobs and foster economic recovery, thereby investing significant efforts in regulating the discipline, particularly in the equity-based model (Valančienė, 2014). This research lays the groundwork for future studies to more deeply explore the types of value created in crowdfunding, the practices of value creation, and the growing interconnectivity among stakeholders that supports the development and sustenance of crowdfunding ecosystems. Future research could also delve into the

demographic analysis of stakeholders across different countries engaging with web platforms, shedding light on how demographic culture influences the crowdfunding value creation process. Future studies might consider an international comparative analysis to understand how crowdfunding varies across cultural and regulatory contexts. Long-term impacts of crowdfunding on business success, including the survivability and growth of startups, warrant deeper investigation. The advent of emerging technologies, such as artificial intelligence and blockchain, offers new avenues for enhancing crowdfunding campaigns and their security and efficiency.

nuno.matos@icaa.pt

Abstract: The permanent search for organizational competitiveness in a context marked by sustainability objectives and digital transformation leads companies to develop management tools and models that guarantee them a high level of competition. Understanding intellectual capital management (ICM) processes in the different areas of business activity is, therefore, a priority for creating value. This research aims to analyse ICM through an audit of its main dimensions and try to understand its relationship with knowledge management processes, namely the retention and transfer of knowledge in an area that still needs to be explored: the performing arts industry. The performing arts, also known as 'creative experience providers', are professional areas based on arts and culture, which are based on selling cultural shows (e.g., theatres, ballet companies, orchestras) and whose professional activity is acting for audiences. The research methodology is based on a case study carried out in a Portuguese performing arts organization. The theoretical support model was an intellectual capital management model previously tested in companies with a different profile than these organizations. The main findings point out that intellectual capital management in the performing arts industry can be audited. However, adjustments must be made to these industries' working realities. It was also concluded that intellectual capital management is a critical factor in the success and survival of these industries, so the management of this asset and its valorization is strategic. The uniqueness of this study is its contribution to stimulating data-driven discussions regarding the necessity of improving intellectual capital management practices in organizations, with particular emphasis on organizations such as those in the performing arts sector, where the most significant value is centred on the intangible assets of each worker.

Keywords: Intellectual Capital Management; Knowledge Management; Performing Arts

1. Introduction

Among the scientific and business community, it seems clear that the creation of value in a company is related to its ability to manage its intellectual capital, making retention, sharing, and transfer of core knowledge of its activity. The management of these intangible assets is even more strategic in business entities that are highly dependent on the individual knowledge of each worker and their ability to share this asset, as is the case in the Performing Arts (PA) sector.

These organizations, belonging to the creative industries sector, have a particular profile, as they cannot financially support themselves. The need to explore the way they organize themselves internally to promote shows that create a connection with their audiences and, thus, their continued sustainability through the financial assistance of their Patrons raises several questions that arise within the scope of intellectual capital management.

In many cases, these organizations are managed using State funds and can remain in business, even when there are management deficiencies, given their contribution to a country's culture.

A well-known example of this organization in Portugal is OPART, E.P.E (OPART), which is designated as a public business entity. OPART manages some of the best-known artistic houses in the country, the São Carlos National Theater (SCNT), the National Ballet Company (NBC), and also Victor Córdon Studios (VCS). As a company in the Performing Arts sector, it demonstrates its importance by managing the only opera house in Portugal.

This research chose the case study of OPART. Since it is a convenience sample, it will focus on the Teatro Nacional São Carlos and Victor Córdon Studios.

The São Carlos National Theater is an ancient house in the performing arts sector in Portugal. Opened in 1793, this theater is considered the only theater in Portugal that presents a production based on opera, choral, and symphonic music shows.

The Victor Córdon Studios correspond to an OPART project that simultaneously works in dance and music, promoting sharing activities within the artistic areas. The VCS aims to create interconnected programs between the NBC and the SCNT, allowing a more direct connection with audiences by allowing this experience and direct contact between artists (who teach) and audiences (who intend to learn).

This research aims to verify whether it is possible to audit the management of intellectual capital in Performing Arts organizations and to evaluate the performance of organizations in the Performing Arts sector by managing their intellectual capital.

2. Theoretical Considerations

Goods are mainly derived from knowledge and cannot be touched because they lack a physical form and are known as intangible assets. Sectors that utilize intellectual property rights more frequently in connection with their human capital activity tend to benefit more from these assets (EPO and EUIPO, 2016).

Intellectual capital is acknowledged as an organization's primary intangible asset. It is essential to its success and profitability since it is the foundation of all knowledge that exists and can be used to create value.

Several definitions of intellectual capital exist, and comprehensive research confirms that scientists do not universally acknowledge a single definition.

While Galbraith's 1969 publication is credited with coining the term "intellectual capital," the concept of intellectual capital management emerged from three different sources: the research conducted by Hiroyuki Itami (1980) on the impact of intangible assets on Japanese corporate management, a study conducted by a group of economists (including Penrose, Rumelt, Wemerfelt, and others) in search of a fresh perspective on business; and, lastly, the writings of Karl-Erik Sveiby in Sweden. Intellectual capital would only have become prominent with this author's contributions. His work introduced a novel perspective by emphasizing intangible assets as the primary strategic concern for enterprises.
